EduKBr’s greatest commitment is to create an online community involved and prepared to collaborate in an innovative way in order to make this educational environment useful and adequate to our reality, aiming to (a) democratize access to information, (b) disseminate the Internet as an object of common use and of wide-range application in Education, (c) develop the technological/scientific aspects of Computer in Education.

The EduKBr Portal idealized for this project is an specialized environment whose principal preoccupation is quality of information and it is structured to develop: (a) teaching-learning process, (b) implementation of human resources, (c) planning of distant-learning courses, (d) educational technology resources, and (e) Web-based Dynamic Communities for Learning.

The environment is divided in web sites that present projects, activities and services based on thematic content directed to: (a) the everyday life of youngsters and adults, (b) multicultural aspects and (c) disciplines or study areas prone to have or to suggest interesting topics and content associated to the Brazilian Web. Because EduKBr is a thematic portal, consequently, considerations and pedagogical content are specific for each of the web sites of the environment. All the actions of the portal aim the formation and integration of citizen that are capable of exchanging experiences and realizing activities for personal and/or communitarian growth, within the new Information Society context.
Is this sense, the pedagogical content is directed to the assistance of some problem resolutions of our socio-economic-cultural reality and of our educational system (e.g. late school computerization, lack of motivation for participation in classes), that has been identified through ethnographic researches.

In a long term, the EduKBr Portal will be capable of (a) offering Brazilian schools a space with variety in possibilities and educational activities of quality, (b) simplifying the use of technological resources in order to facilitate interaction, integration and access to tools (e.g. search engines, videoconference, GroupWare tools, production of images, sounds, etc.) within an only environment, (c) providing a democratic way of accessing documents and multimedia content, (d) facilitating query, inclusion and actualization of data/information in a distributed application activity, (e) combining curricular and extra-curricular items, meeting the interests of the users community, and (f) keeping an attracting, ludic, secure and stimulating place on the Brazilian Web.

Considering the opportunities and problems identified above, these objectives indicate the strategic relevance of the project and point to the social application and the economic potential for Education on the Internet.

The Educational Portal idealized for this project intends to be a "point of reference for the Brazilian Education" and an "Open and Virtual school on the Internet", according to the respective philosophical directives that characterize all of the works developed by EduWeb with collaboration of KBr Project.

Every website and project developed by the pedagogical team of KBr Project and graphically and technically implemented with partnership of EduWeb on the Brazilian Internet are serious products, result of educational field researches and of a qualitative evaluation process realized together with its users. Only after going through these stages the product will be available without any cost for the user.

In addition, security associated with quality were more than a criteria for being considered an important condition for those who intend to access selected information, far from the amount of random content presented on the Internet. Once in the portal, the user should not have any possibility of diversion.

When we think of security, we do not refer only to pornography or improper communication the Internet provides. There is, also, preoccupation regarding the quality of information presented, may it be produced by our pedagogical team or by suggested links.

It is important to point out that nor are we naive, or pretentious, but we know that not always we are going to reach our objectives—knowing the challenging characteristics of our users age (up-to-18-years youngsters). However, our obligation is to be at the head, offering places and indicating pages that offer relative security to schools. Surely our care does not invalidates the responsibility and attention teachers must have and pass to their students in classroom or in computer laboratories when they are using the Internet. This recommendation is valid to parents who do not watch the time their children spend online or what use their children make of the navigation on the Internet.

The differential, pioneering and another strategic relevance of the EduKBr Portal Project that guarantee and make its implementation technically possible are: (a) its interface verticality, (b) its commitment with Information Technologies applied to the creation of Dynamic Communities for Learning on the Web, and (c) the use of resources of Educational Technologies (e.g. Interactive Multimedia) for a quality Education/Distant-learning.

However, for the project to be successful, are still need we financial resources to: (a) guarantee the management autonomy of the environment, (b) pay the regular professionals and specialists that act in each of the thematic web sites, (c) study carefully the pedagogical content, (d) create an attracting graphical interface that is, at the same time, coherent with the new form of language and communication established on the Internet, and (d) offer a quality product committed with the formation of citizens that participate in the Information Society.

The proposition of this new education, supported by the use of mechanisms of science and of technology, should not cause the abandonment of human values. It should, instead, involve an specific knowledge directed to a social organization of the production and an opening of the specialized work market.

One of the roles of school is to form citizens apt to face the challenge of the society. The current model of society needs, unquestionably, of computer systems allied to a process of multieducation.

It is, therefore, vital that the use of the Internet in classrooms be clear. It is important to develop interest in, train and form teachers so that they participate in this development and be capable of transmitting their experiences and knowledge to their students. It is necessary to form a critical mass in debates on implications (specially those of social nature), methods and tools of computers applicable to Education in order to avoid the arising of a purely instrumental perspective of the use of computers in school.

It is for—and in—this scenario that the thematic web sites to the EduKBr Portal Project are structured.
QuS-Support of Digital Video Broadcast (DVB) in the Next-Generation-Internet

Artur Lugmayr, DMI/TTKK, Finland; Heikki Lamminen, DMI/TTKK, Finland

This presentation provides an overview of possible protocol suites for encapsulating a high bandwidth demanding Digital Video Broadcast (DVB) stream in IP overlaying protocols, namely RTP, RTCP, RTSP and RSVP over fixed technology as physical transmission media. The presenters introduced a DVB Protocol Layers for transmitting DVB Service Information (DVB-SI). This layer-model will be extended and generalized for generic DVB stream transmissions by using a Multi-Protocol Architecture approach, that allows achieving inter-operability in multi-protocol architectures. This approach allows co-existence of different protocol architectures as a set of mixed protocol families, and seems to be quite suitable for transmitting DVB streams over IP by using different protocol types. Furthermore this presentation emphasizes quality-of-service, bandwidth requirements, resource-reservation and real-time boundaries for this very high demanding networking application.
Quiz collaboration — cheating or a learning opportunity?

Robert Lundquist
Division of Quality Technology & Statistics
Luleå University of Technology, Sweden
robert_l@ies.luth.se

Abstract: In a statistics course for engineers, we have designed a system for assessment where web-based quizzes is one of the key elements. The basic ambition has been to find a way to make students more active during the course, and to provide learning situations where discussion and collaboration are key elements. The need to achieve this in a cost-effective way has also been addressed. The new course design is a structure where students along the course have to answer sets of randomly selected questions that often are based on random data sets. The course design has made it possible to encourage student collaboration, both in other parts of the course and in quiz answering.

Introduction

The quality of learning is to a great extent dependent on reflection. However, even though a reflective behaviour usually is regarded as something desirable, it does not seem to be one of the most apparent characteristics of many students within higher education today. One underlying claim in this paper is that one of the most influential elements determining student behaviour is the assessment system, an element found in most higher education courses. The purpose is often to get a basis for the assignment of grades, but the process is seldom or never neutral: the assessment procedure is usually something students adapt to. The assessments are usually perceived as an integral part of the educational system and often also as legitimate, but there are several drawbacks with the most common assessment designs. Some of these that will be discussed in this context are the following:

- In many courses based on ordinary lectures, students tend to be rather passive during lectures even if teachers might regard activity as a way to get the opportunities to reflect upon.
- In a course with a final exam, students often tend to spend a great deal of their efforts rather late in the course preparing for this exam. When sorting out new concepts depend on time and reflection, which clearly is the case in our statistics course, it would be better if students were more active earlier in the course.
- The assessment procedures are often resource demanding, as well in construction, review, grading as in the administration of grades.

Furthermore, there often seems to be a heavy emphasis on getting the right answer rather on learning from mistakes which from a constructivist viewpoint seems more desirable (see Lundquist, 1999). This emphasis is an obvious effect from relying on exams and grading, because in such systems, it is the final answer that is counted and not the processes that have lead to this end. This emphasis is however presumably part of a more general culture, so this might appear just as clearly in systems based on other assessment approaches.

The new course design – background

In a statistics course for engineers, we have tried to find ways to cope with the drawbacks that were previously mentioned. It is one of our largest courses (6.0 ECTS credits), running four times a year with between three to six groups with about thirty-two students in each group. The grading system is based on two parts, the assignment part and an exam part. Both are compulsory, and depending on results in the exam part, students are assigned one of 4 grades: not satisfactory, 3, 4 or 5. After a gradual development drawing on experiences from changes in several courses, we have now got a course based on the following elements:
• Depending on teacher preferences, class sessions could be organized as either a) a mixture of lectures and problem solving, or b) no or very few lectures but where students work together in groups of about four with solving suggested problems, and where the teacher role is more of a facilitator (see Dunkels, 1996).
• Laboratory assignments where students work with statistical software to solve larger sets of problems. In the course there are now 4 such assignments, out of which 2 are subjected to a procedure of peer review: students review other student lab reports under the guidance of a teacher. No grades are assigned, but having completed these assignments is one of two compulsory elements in the course.
• During the course the students are required to answer a set of 4 web based quizzes.
• The final exam consists of two parts, the first with questions similar to the ones in the previous quizzes and a second where students submit full solutions. A student is assigned a grade of 3 when both the quizzes and the first part of the exam are completed. If a student wants to try for a higher grade (4 or 5) then the second part of the exam must be completed.

As a side effect, previous students who for some reason have not completed the final exam with satisfactory results have been allowed to go through this quiz system. Several of these have left their studies and are now working, even though they have had at least this actual course unfinished. For several individuals in this group, this design has made it possible to complete the exam part of the course without having to go to Luleå, something that has been perceived as favourable.

Overall effects

The course has been running with the present design for a year, and most important is that we have no indications that the new design has lead to any noticeable loss in student understanding. Instead we believe that it has been an overall improvement, mostly because of the following:

• Students are more active during the running course than they used to be.
• The quiz construction with random selection of questions and differences in questions in repeated attempts makes repetition meaningful: it leads to variation rather than rote learning.
• Many students collaborate, both in general and in quiz answering. They often seem to respond the way we want them to: rather than trying to find an efficient way of ‘feeding the system’, the quiz element is perceived as providing support in their learning.
• Students appreciate that the quiz structure (which is described further in a following section) provides immediate feedback.
• It has required some effort to construct quiz questions, but it has still not meant an overwhelming workload due to the fact that many questions have been constructed in previous courses that have been easy to import and, if needed, to rewrite. During the year 00/01, the quiz module has been kept relatively unchanged because of the need to see how it works in a steady state.

The quiz construction

The quizzes are part of the course web designed in WebCT. The course web contains other elements such as handouts, bulletin board, e-mail and management of student results. During the course, quizzes are set up in the following manner:

• Every quiz is made available during about a week with start and end dates following the course.
• In a given quiz, there are about 7 questions.
• A given quiz can be answered 5 times, and the best result is counted as the final one for that quiz.
• The questions are often selected randomly from a larger database, so in two repeated attempts or when two students enter at the same time, the questions are usually not the same.
• One of the different question types is called ‘calculated’ meaning that the system generates a set of numbers defining the particular question, and where students should enter a number as their answer. An example: in a question like “Given that a component’s lifetime could be described by a normal distribution with mean 100 and standard deviation 20 (hours), what is the probability that the component will last longer than 120 hours?” the numbers 100 and 20 are selected from a database of randomly generated data sets.
Issues of concern

We have been concerned by the possibility to ‘cheat’ in this system. All students have to answer their own quizzes, but obviously we cannot definitely say who has answered a particular quiz. We have used different limits on the time a given quiz is available as a means to make cheating harder. There are those who cheat or at least depend heavily on others, even though they seem to be relatively few as far as we can understand from course evaluations. However, it seems as if the most important part in making cheating less likely is the construction with random selection of questions where several of these are based on randomly generated data sets. Since a particular answer set cannot be used directly in two quiz sessions, we have found that students are not so likely to ‘help’ each other by answering questions for someone else. Collaboration has instead of being a way to cheat become a positive element: two students working together get to see more questions than each of them would individually. The entire design is also dependent on relatively low emphasis on assessment as a whole. The course elements are not graded separately as is common in higher education in many countries, but mostly simply compulsory. With grades assigned to quizzes, there would presumably be a greater urge to act rationally, i.e., make the most out of as little input as possible. This usually implies what teachers call ‘cheating’.

Another important issue is whether the series of quizzes really can match the kind of final exam used before. There are obvious differences as to the level of detail that can be measured with the two instruments. Many students say they have learnt more than they would have with an ordinary final exam, both because they are required to complete the quizzes during the course and because of the collaborative element. Such opinions seem to have some validity, especially when expressed by elder students who only wanted to complete the exam part of the course, since they have previous course experiences to compare with. However, we cannot be certain that student results with the quiz system are on a level with the previous situation with the final exam. The issue is not easy to resolve, partly because of inherent difficulties to define what we really want to measure, i.e., understanding of the subject. This problem will hopefully be possible to tackle in future studies.

The issue of changes in workload is also not so easy to deal with. The amount of time spent on designing and review of final exams is naturally greatly diminished. Instead we have had to spend more time responding to students’ e-mail, administration of the course web, sorting out technical questions and such. There has also been a change of when teacher resources have been spent. Instead of putting a lot of efforts in the later stages of the course with review of exams, there have now been more hours spent on for example design and maintenance of the course web. Our impression so far is that there has been a net gain in the sense that we have spent less time on the course as a whole, but there have been no really thorough measurements yet.

It has also been evident that this kind of structure itself can generate stress and frustration. All students are not so experienced with computers, so for some, the general idea of having to work with computers is frustrating. There has also been a tendency by some students to perhaps spend more time than they should have when answering quizzes. Instead of going back to the literature or simply think, some seem to perceive the quiz as some kind of computer game where they make repeated attempts without really trying to come to grips with a particular question. Furthermore, since the quiz system is machine based, the grading of answers is merciless. A simple typing error can make the entire answer graded as incorrect, whereas a written exam is reviewed by a human who is able to make balanced judgments. The overall impression is that most students have perceived the course design as positive. In course evaluations they have noted that there has been a supportive atmosphere both between themselves and with respect to the teachers. Many have also expressed great satisfaction with the quiz system, and then especially the prompt feedback. On the negative side is the frustration and stress experienced by some students. They are not so many, but on the other hand, they seem to be so troubled that their reactions cannot be simply ignored.

Conclusions

With a basically constructivist approach, our ambition has been to make it possible for students to collaborate, discuss and learn from own mistakes in order to make the course elements meaningful to themselves. The idea of using a course web is in itself something we primarily have perceived as a way to facilitate students’ work, but we could mostly do without such support structures. The possibility to use self-correcting web based quizzes on the other hand has been a new element. Assessments usually have a significant influence on student behaviour, and this effect often seems either neglected or regarded as a problem. Our ambition has been to make use of this influence rather than trying to avoid it. The assessment system now consists of quizzes, administered sequentially during the course, and with a quiz design where repetition becomes variation and where collaboration is an advantage rather than the opposite. The experiences so far are positive. Our ambition was to improve our course by constructing an
efficient structure that does not simply decrease teacher-student contact but instead makes use of new ways of interaction. The present use of quizzes has become such a way.

Acknowledgements

Even though this paper has one single author, the entire course design has been the result of close collaboration within a group consisting of me and my colleagues Kerstin Vännman and Fredrik Johansson.

Abstract: Research has shown that faculty plays a key role in successful implementation of online instructional courses. Since faculty hold such an important role in the successful implementation of online courses the purpose of this study is to identify training, support given and needed, hours spent online, type of web course implemented and information that can be used to foster effective distance learning programs in the university setting.

From 1995 – 1998, higher education institutions offering distance education courses increased from 33 percent to 44 percent (Lewis, Snow, Farris & Levin, 1999). Many universities are purchasing online course delivery systems (such as Blackboard and Web CT) to use for their online courses. Faculty will have to be trained and given support, and more staff will be needed to maintain and improve distance education programs for the future. According to Williams (2000) the thirteen identifiable roles that are required to implement and manage distance education programs in higher education include: administrative manager, instructor/facilitator, instructional designer, technology expert, site facilitator/proctor, support staff, librarian, technician, evaluation specialist, graphic design, trainer, media publisher/editor, and leader/change agent.

Studies on online instructional courses in higher education institutions (Betts, 1998; Rockwell, Schauer, Fritz, & Marx, 1999; Willis, 1994; Wilson, 1998) indicate that it is the faculty who play the key role in its successful implementation. It is imperative to determine those factors that affect faculty in their adoption of online instruction such as support and training to improve an online program (McKenzie, Mims, Bennett, Waugh, 2000). In a study done concerning faculty education, assistance and support (Rockwell, Schauer, Gritz, & Marx, 2000) it was found that faculty needed further education about, assistance with, or support for developing interaction, developing instructional materials, and applying selected technologies. Other studies (Clay, 1999; Betts, 1998; Clark, 1993) support the need for training and support for distance educators.

The purpose of this study was to identify: a) training received on Blackboard (online course delivery system), b) tools used on Blackboard with courses, c) the number of hours spent interacting with students on-line each week through the use of Blackboard, d) other uses of Blackboard besides online classes, e) the number of hours students are spending per week using Blackboard for the course, f) if an adequate amount of support for Blackboard implementation was received, g) what kind of support was needed, h) the number of hours or classes that were used to orient students to Blackboard, i) other technology used in classes in past, and j) the type of web course (web-presence, web-enhanced, web-centric, or fully web based) that was offered using Blackboard.

The sample for this study included fifty-nine faculty members at the University of Louisiana at Lafayette who chose to include online technologies in their teaching and research. Respondents spanned seventeen different departments including faculty, staff, and administrators. A survey Blackboard Usage and Technology Integration Questionnaire was
developed. The survey consisted of open-ended and closed-ended questions pertaining to information on Blackboard training, Blackboard support, tools utilized in classes, amount of time involved online with Blackboard, number of hours spent to orient students to Blackboard, other technology used with courses, and type of web course implemented on Blackboard. The study was conducted during the Fall 2000 semester.

Forty-one surveys were returned. Findings indicated one web presence course, twenty-two web-enhanced courses, five web-centric courses, and web based courses were offered. Blackboard was being used for the majority for placement of the syllabus. Additionally Blackboard was implemented for Internet assignments, External links, and Discussion Board. The majority of faculty had not gone through formal Blackboard training. The hours that faculty spent per week on Blackboard for one class ranged from one hour to ten hours. Faculty estimated that their students spend anywhere from fifteen minutes to eight to ten hours per week on Blackboard for one class. The majority of faculty felt like they had enough technical support for their implementation of Blackboard. Additional support that faculty felt was needed included technical assistance in setting up the courses on Blackboard. Most faculties had previously used PowerPoint notes and Internet assignments in their courses.

In conclusion, faculty is using new technology in their teaching. For faculty to be successful with technology integration, training and technological support is a must.

Workload, Advantages, & Disadvantages of a Newly Developed Online Course

Susan Lyman, Univ. of Louisiana at Lafayette, USA; Doug Williams, Univ. of Louisiana at Lafayette, USA; Lucy Begnaud, Univ. of Louisiana at Lafayette, USA

The introduction of computer technology necessitates a change in the approach to education at the university level. Distance education is capable of offering new learning opportunities unrestricted by time, distance, or individual differences among students. The course Health and Sexuality was designed and piloted as a web-based class during the Spring 2000 Semester in the Department of Kinesiology at the University of Louisiana at Lafayette. The purpose of this study was to determine the workload hours pertaining to the design and teaching of an online course, and to ascertain advantages and disadvantages involved in taking and teaching an online course. Some advantages students expressed included the ability to work at their own pace, and not having to attend class. Disadvantages included computer problems, and procrastination. Grading workload and time on the computer increased tremendously for the professor. This information will be used to improve online teaching and learning.
Expanding e-learning effectiveness.
The shift from content orientation to knowledge management utilization.

Abstract: The e-learning industry in recent years faced a tremendous development. The technological
capabilities of modern tool-sets expand from off-line to on-line solutions covering a wide spread of learning
needs (Close et al, 2000), (Ruttenber et al). Nevertheless the requirements of modern business units seem to
diversify from training seminars to corporate learning portals implying a desired reinforcement of capacities
for effective actions. Academic institutes such as universities have to adopt their traditional approaches in the
modern setting. The e-learning initiative both in corporate and academic environment defines new ways of
improving performance. The objective is to reveal the necessity to formulate dynamic learning environments
capable to be customized according to value perceptions. The research effort is concentrated on the definition
of variables that will enhance the value justification of such systems and will realize the modularity of a value
creating e-learning environment through advanced knowledge management systems.

INTRODUCTION
The establishment of e-learning systems within business settings or academic institutions is something like
fashion. Many models, many different types, many markets, many interest groups, different degrees of
satisfaction and many users looking for customized solutions (Urdan & Weggen, 2000). Unfortunately the e-
learning market is not as mature as we would prefer in terms of effective solutions, advanced functionalities and
learning standards.

The analysis of the e-learning market in Europe as well as in USA is not only difficult but it has to be based on
issues closer to effectiveness than to population increase. In most of cases the virtual universities, the e-learning
systems base their functionality on a simple browsing mechanism accompanied with a section of web links and a
few on-line quizzes. In other words which is the value of such a system when in most of cases the employment of
the ICT’s is limited on static learning scenarios. We could state that these systems secure the growth of the so-
called distance-learning marketplace in Europe even though the learner satisfaction from such a system is very
limited. A critical question is can we enhance the learner satisfaction on an e-learning system or his first
impression will be negative. The mass of integrated e-learning platforms seems to be unable to support different
degrees of value delivery. They seem to construct their powerfulness over common characteristics that in general
simulate the traditional way of teaching. So a number of critical questions emerge:

Does e-learning differentiates from the traditional learning? Can we define concrete ways of content enrichment in virtual
environments, which add value in traditional learning content and support dynamic learning settings? Can we justify
theoretical foundations that prove the different value layers of learning efforts? Can we test the ability of learning
environments to support different educational goals through the employment of different learning processes? Can we develop
learning environments capable of supporting the intellectual capital exploitation both in academic and business
environment? Finally but not least, can we formulate a framework that will support the Enterprise Application Integration
in a manner that will take into account the learning needs of business units? In other words can we define an application
layer within business Intranets that will establish knowledge management architecture?

Our experiences from various projects related to e-learning can be summarized in the figure 1. The learning
effectiveness, a concept with various quality factors included, has a direct relation to the technological complexity
of the e-learning environment. The distinction of five relevant learning paradigms is not only a theoretical value hierarchy that formulates a contextual setting for analysis. It rather gives an essential feeling for the inability of many e-learning initiatives to be effective for the trainers and the trainees.

The five learning paradigms that deliver different levels of value are:

<table>
<thead>
<tr>
<th>STAGES OF E-LEARNING EVOLUTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Static Content Delivery</td>
</tr>
<tr>
<td>2. Learning Objects Management</td>
</tr>
<tr>
<td>5. Integrated Learning</td>
</tr>
</tbody>
</table>

Table 1: The technological characteristics of the five e-learning paradigms:

The majority of e-learning initiatives are limited on the application or the customization of learning platforms that facilitate the delivery of learning content on a predefined, static and sequential way. The flexibility of such implementations is rather inadequate to support the dynamic nature of learning, but as it is the easiest form of doing e-learning it is also the common one. The incorporation of knowledge management mechanisms in learning platforms such as learning objects databases supports the effective management of learning content in terms of reusability and utilization of knowledge bases. This functional enhancement of e-learning environments is not enough to utilize the learners' perception for e-learning usefulness.

The inability of the two first e-learning paradigms to provide dynamic features to the learners as well to the trainers set a "wall" that has to be penetrated in order to exploit further the effectiveness concept. This penetration has to be based on more sophisticated technological components that allow the establishment of dynamic e-learning strategies. The orientation of e-learning to the learning processes that define the learning paths for the trainers is very critical. The detailed analysis of different learning processes provides a pool of available learning scenarios. The reveal of learning paradigms that penetrate the "wall" require more advanced technological infrastructures. For example the dynamic combination of learning processes in e-learning environments have to take into account the full support of the embedded learning subtasks. In other words the engineering of such a system will need enormous effort for the well-justified distinction of learning subtasks and subsequent technological required components.

Another consideration for the enhancement of effectiveness should be the profiling capability of an e-learning platform to utilize its components on the direction of creating one to one learning situations. The recognition of learning needs, the diversification of learning styles, the categorization of learners according to their preferences in specific learning processes, their interest in specific learning objects that cover their knowledge deficit are namely parameters that differentiate the e-learning paradigm of customized learning scenes. The profiling procedure for the accomplishment of such a scope has to be based on advanced algorithms and of course extensive parameterization of the e-learning environment. The multifold flexibility seems to be a well-defined effective learning goal but in order to be tested and to be implemented it needs enormous research effort. Finally the need to develop effective knowledge management mechanisms in modern business
units, sets a subsequent goal to integrate e-learning systems with other critical enterprise applications. The orientation of e-
learning to business process knowledge management in modern e-businesses and enterprises of the digital economy formulate a context on which the learning content has to be discovered in all the spread of the daily business operation. The tacit and explicit knowledge that is hidden in people, business processes and services has to be captured and promoted in e-learning systems. The Enterprise Application Integration dimension of e-learning paradigms nowadays is the piece of the puzzle that has to be incorporated in e-learning paradigms. The critical issue from this perspective is to be able to develop a grid on which every business processes could be related with specific learning processes. A first implication of our intention to create a theoretical tool capable to map the relation of a business processes to a mix of different learning processes is a grid that helps the relation of any business process to specific learning processes according to their embodied value. A learning scenario is a combination of learning processes that formulate the educational space for the trainer and the executive trainee. A first approach is presented in figure 2.

![Learning Processes Grid](image)

**Figure 2. The business to learning process grid**

The two dimensional grid defines four separate quadrants capable to describe four different learning situations. We distinguish four learning situations that are supported by different learning processes:

1. Understanding
2. Meaning creation
3. Process understanding
4. Intellectual Capital Exploitation

The conceptual model implies that every business process could be break down into separate business tasks that can be positioned somewhere on the learning grid. Consequently this approach could be analyzed further in order to specify in a more detailed way the parameters of each learning situation. The selection of specific learning processes changes the mode for the executives training. The selection of advanced learning processes with increased information transformation requirements enhances the quality of the achieved learning goals. The value delivery through the e-learning paradigm is organized through the employment of specific learning templates. So, the Author of such a system is going to be navigated through an advanced mechanism on which the main role is to choose the learning situation that best fits the trainee needs. Of course the value dimension of such a system is not implying a concrete measurement system of value satisfaction. The intention is to formulate a method on which the trainer would be responsible for the maintenance of all the content material capable of supporting different value levels of trainee exploitation. The difficulty of this ambitious aspiration is the development of a metadata content classification mechanism that will support the classification of the learning content on the e-learning system knowledge-content base.

**CASE STUDIES**

Our research unit (eLTRUN, www.heltrun.aueb.gr) in the past three years has participated in the design and development of e-learning systems both in European and International level. In parallel the realization of the need to utilize e-learning solutions gaining experiences from knowledge management theory formulate a two-fold approach: The analysis of e-learning from knowledge management perspective. For this scope we understand the necessity to research on the linkage between the efficiency of e-learning systems and the capacity of
knowledge management mechanisms to provide a core component for e-learning. But even though the capacity of modern systems to manage the knowledge effectively in terms of data management mechanisms we concluded that something more was missing on the puzzle of effectiveness. The analysis, the specification and the formulation of a concrete e-learning pedagogy (Lytras 2000) in terms of learning processes, learning styles, learning modes and learning motivation parameter (Lytras 200). The previous work related with our research has to do with various e-learning projects implementation.

The Teletraining Center of Athens University of Economics and Business (www.teleduc.aueb.gr) was implemented in order to provide a pilot e-learning system capable to support the delivery of four seminars all over Greece, covering topics such as electronic commerce, statistics and marketing. The technological infrastructure includes servers, digital cameras and three of the most popular e-learning platforms such as WebCT, Lotus Learning Space and Blackboard. The first analysis of a survey conducted having as a sample the students of the e-commerce seminar provides useful recommendations: First of all it was more than clear evident the need to enhance the functionalities of the system with dynamic ways for the construction of learning content. The limitation of the e-learning platform to support students in different modes than sequential browsing of learning modules was a major disadvantage. More over the inability to provide mechanisms that would facilitate the exploration of knowledge according to specific learning needs was pointed out as a learning obstacle. From teacher's perspective there was a major difficulty at the reconstruction of learning material since there is a limitation in html pages linking. Additionally the content management constraints the creativity and doesn't support flexible learning scenarios [8].

The GEM consortium, Global Master in Electronic Commerce) (www.helrun.aueb.gr/gem/new) is an international network of business schools sharing a common curriculum in e-commerce at the master's degree level. The global character of the program is ensured through the official cooperation of the best business schools and universities in Europe and North America, all experienced in research and education in e-commerce. The program has received the endorsement of the European Commission and G7's Information Technology group.

The development of an e-learning facility was considered from the members of the consortium as a vital process of the whole master program and for this reason there was an extensive research on the capabilities of the integrated platforms to support the whole approach. The Athens University of Economics and Business undertake to develop the e-technology course for e-commerce master program..

The MODEL IST (Multimedia for Open and Dynamic Executives Learning) project is an innovative approach pursuing the development of a dynamic learning environment capable of managing effectively the knowledge in business units. The MODEL approach is trying to define a new market of knowledge management solutions and tools. We could describe it as a niche market that facilitates the development of competencies and the exploitation of the human capital. The core competencies in the modern organizations are constructed through vital business processes that in general provide a web of interconnections among people, knowledge resources, customers, tasks and evaluation standards. The major observed problem in the current situation is the absence of knowledge management systems that increase the re-usability of knowledge for training purposes. The executives training is mainly accomplished using executives' seminars and various workshops with reliance on not clearly defined quality standards. Moreover most of business units suffer from their inability to support new hired employees according to the specific characteristic of core business processes and business environment in general. The cost for training a new employee is superlative and increases if we take into account knowledge oriented and not routine business processes. In other words we have an exponential increase for the cost of training or learning when the subject of the training is more value creating.

In the Leonardo Da Vinchi project called e-LEARN we investigated the capability of WebCT to support English language courses for public sectors executives in collaboration with Linguaphone. Finally the project ESWL (Educational space without limits) set a postgraduate master course available to the students of three master programs in Greek Universities with the use of WebCT. All these projects and extensive research has reinforce our approach for e-learning. The major components of our approach for e-learning effectiveness and evaluation are presented in the following section.

DYNAMIC LEARNING CONCEPTS
The e-learning concept can be really treated as a technological advancement with advantages and disadvantages. The ability of the information and communication technologies to realize its various components formulate a wide range of applied informatics. On this continuum of available technologies we have to incorporate intelligence in order to enhance its performance and efficiency. The common practice to buy an e-learning platform, to adopt content or to buy content and to deliver on 24-hour basis the learning material to various learners has a justification: It provides an easy way to claim your presence on e-learning irrelevant the absence of mechanism that exploit the value diffusion for the learners and the trainers.

Our approach is setting or is currently researching the ability of a three-dimensional model to expand the traditional considerations for e-learning importance. The Multidimensional Dynamic Learning (MDL) Model is based on three complementary dimensions:

- The Knowledge Management dimension
- The e-Learning dimension
- The application integration dimension

![Figure 3: The MDL cube](image)

Each of these describe in synopsis detailed considerations that confront the e-learning platforms such as knowledge management systems with embedded e-learning pedagogy and capacity of dynamic integration with other crucial business applications. To be more specific we will use three explanations for the three dimensions of MDL model.

The Knowledge Management Sophistication summarizes the ability of the e-learning platform to manage learning content in various formats, to re-use learning modules and to support knowledge management processes such as knowledge creation, knowledge codification, knowledge transformation and knowledge diffusion.

The E-Learning Dimension stands for the ability of an e-learning system to construct effective learning mechanisms and learning processes that support the achievement of different educational goals. With no doubt this dimension incorporates issues like learning styles, learning needs, learning templates as well as learning specification settings. The majority of e-learning platforms do not support mechanisms that would enhance the re-usability of learning content. The enormous efforts that have to be paid in order to redesign learning content or to adopt traditional content for e-learning purposes burdens the effectiveness of these tools. Our model, claims that the KM sophistication dimension is exploited enough when there are established knowledge processes that manipulate dynamic content. The re-usability of content and the support of high value learning processes presuppose the presence of an advanced KM subsystem capable to categorize, to enrich and to integrate various learning objects. Consequently the enrichment of learning content with various metadata is necessary for the application of dynamic learning. Very few learning platforms can nowadays provide metadata to the learning content and when this is applicable there is no a mechanism that allows the data mining of relevant learning objects from the learning warehouse system that manages the learning content.
The **Application Integration Dimension** summarizes for the e-learning platforms the capacity of collaboration with other business applications in order to obtain learning content from real business operations. This dimension seems to be the less detected on the common e-learning platforms and this causes a number of gaps for the effective implementation of e-learning systems. The critical issue of insufficient content in many situations is due to the inability of the organizations to establish a knowledge generation mechanism through the operation of information systems that support the most important business processes. Because in general, the e-learning systems in corporate environments can play the role of the most significant intellectual capital exploitation mechanism. (Stewart 1997).

The e-learning marketplace has been face a tremendous orientation to static approaches. Through the combination of the two life cycles, the knowledge management framework and the e-learning life cycle, the knowledge objects are transformed dynamically to learning products through specific consideration. The XML language increases the capability for the inclusion of semantics in knowledge objects and every knowledge stage as well as every stage of the transformation model enriches the initial knowledge objects with specific metadata. This approach has to be based in integrated approaches, which include ontologies (Staab and Maedche 2000), (Staab et al., 2000), knowledge management, semantics and annotations (Perez and Benjamins 1999).
The proposed model that is presented in figure 4 depicts the double loop knowledge management exploitation. With no doubt the full utilization of the proposed model requires further explanations and justification. For example in our approach the transformation framework intends to support a sophisticated e-learning system where the educational scene is constructed dynamically through the deployment of well defined learning processes.

Figure 4. The integrated e-learning knowledge management framework

**PAPER CONCLUSION**

The MDL model approach sets a method for the evaluation of any e-learning platform. Of course the presentation of the method on this paper was limited due to the length limitation. The whole approach of MDL cube MODEL is supported by a number of accompanying frameworks and theoretical concepts, which in collaboration enhance the scientific justification. The development of a system that will realize the upper right layers of the cube is currently our research priority. Of course the required modules need extensive justification and creative work. We believe than in one's year time we will be able to launch international an integrated e-learning knowledge management system with the characteristics that we mentioned on this paper. The refinement of our approach is a continuing process and will be supported by a number of new projects that we are going to propose in Greek and European Commission programs.

**REFERENCES**

Abstract: AESOP (An Electronic Student Observatory Project) is a framework used for recording, and analysing user actions in a Smalltalk programming environment. One of its main aims is to provide an apparatus for identifying and analysing problems beginners have when learning to program. It is targeted on a distance learning course using an environment, LearningWorks, which has been modified to appeal to starting programmers. This paper describes the tools used to analyse the learning of programming concepts, for a large number of students.

Introduction

The AESOP project provides a way of recording students use of Smalltalk (Macgregor et al. 1999). The Smalltalk environment, LearningWorks (Woodman et al. 1999 & Goldberg et al. 1997), is used on the course M206 Computing: An Object-oriented Approach offered by the Open University (OU). AESOP aims to record student use of LearningWorks tools: HTML browsers, simulations, and programming applications. These tools appear in LearningBooks (Woodman et al 1999), and significant events occurring in them are recorded in a format which aims to make analysis of student learning straightforward.

Student use of LearningWorks

Students use the LearningWorks tools to write correct code by following highly structured sets of instructions and by developing novel solutions to set problems. The instructions and problems are introduced in LearningBooks, where each LearningBook has sections, each section has detachable pages, and each page has a tool. The first section always has a HTML-browser page containing instructions for practicals and discussions. An “amphibian” microworld, using instances of classes Frog, Toad and HoverFrog, introduces the basic object concepts of message sending, state, behaviour, inheritance and polymorphism. This microworld, (Fig. 1), shows amphibians whose behaviour and state are affected by messages from action and menu buttons.

The AESOP software

The AESOP software has three main software components. The first component is a Recorder, which records the student’s use of LearningWorks. the second is a Replayer that can be used to replay what was recorded. Finally, various analyses are proposed, and analysis methods are added to the Analyser component. All three components have been developed incrementally from prototypes (Goldberg & Ross 1981).

The Recorder writes time-stamped strings representing “user events” to a text file. Each entry in a recording is a time-stamped event-signature, which represents a student action such as a page turn, button click, hyperlink selection or expression evaluation. The Recorder is launched automatically when a LearningBook is opened, that is, no student intervention is required.

The Replayer plays back a recording to show an investigator the important events that the student precipitated. The replay speed is chosen by the investigator, from “fast-forward” to “single-step”. Replaying is useful to give the investigator an overview of a small selection of recordings, and suggest analyses that can be pursued.
The Analyser searches for patterns of behaviour across sets of recordings. A wide variety of possible analyses have been identified, and several implemented (Thomas & Paine 2000a). For instance, a Time Tool attempts to distinguish the time that a student spends doing various activities (Thomas & Paine 2000b) and a Required Messages tool outputs a trace of significant events.

Analysing the recordings

Around 400 students volunteered to use the recorder software during the 2000 presentation of the M206 course. The students e-mailed their recordings to the AESOP team who replayed a selection of the files and then pursued a variety analyses (Thomas & Paine 2000b). For example, by simply observing a student recording on fast forward, it was found that students were having problems making an object of class HoverFrog hover and change colour at the same time. This occurred when students attempted the practical exercise shown in Figure 2.

Figure 2: A practical exercise
One student's response to this practical is shown in Table 1. The *Required Messages Tool* produced this extract from a complete recording. It shows that the student evaluated the expression series contained in lines 2 to 6 of the extract.

</table>

Table 1: An extract from a recording produced by the Required Messages analysis tool.

The extract shows, in line 6, that the student tried to send two messages, *hover:by: and colour:*, to the object named *hoverFrog3* at the same time. At this stage of the course, the student has not been shown how to use parentheses, as in:

\[(hoverFrog3 hover: Up by: 1) colour: Red,\]

and so received the error message (in a dialog box) shown in line 7 of Table 1. The student's response to the error message is shown in line 8 where they simply tried a rearrangement of the two messages. The result, not unnaturally, was another dialog error message. The result of not being able to solve the problem frustrated the student, who simply stopped trying to resolve the difficulty and jumped to another part of the practical via a hyperlink (step 9).

This behaviour raises a number of questions. For example, do other students have similar problems with this practical? Do students ever complete the practical correctly? To answer such questions a more powerful analysis than *Required Messages* is needed. This is the *Required Tasks* tool, which searches a recording for the sequence of messages that define a specific task. To do this, another tool, known as the *Task Descriptor* was built that is used to define a task. Figure 5 shows the description of the "hover, by" task with *Task Descriptor*.

![Task Descriptor](image)

Figure 3: The Task Descriptor tool.

In this example, the task is defined as being complete if the student evaluates

*hoverFrog3 hover: Up by: 2.*

The precise test for completion of this practical is much stronger than this, but this will suffice for sake of illustration. The input fields on the left-hand side of the window shown in Figure 3 specify the chapter, session and
practical in which the task appears, and assign an identifying number (1) to the task. The text area on the right-hand side of the window is used to define the task. The symbol @ denotes the start of the line, 1 is the score for completing the task, and > means it is an evaluation expression (there is a variety of types of task that a student can be asked to carry out).

Clearly, if a student recording includes the task defined in this way we can be confident that the student (eventually) succeeded in the task and the Required Tasks tool enables us to locate the relevant part of the recording for further investigation. However, we are also interested in those situations where students have tried to accomplish the task but have failed. In such cases, the correct outcome, as defined in the task describer in Figure 3, would not be observed in the recording. Therefore, the specification of tasks in the Task Describer has been extended in a variety of ways.

First, there could be a number of equally valid solutions to a particular task. The Task Describer tool deals with this by allowing its user to specify the different solutions as separate lines. It also allows the use of wild cards to indicate that certain parts of a task description are not significant. This is illustrated in Figure 4.

However, the main focus of attention is the search for incorrect attempts at tasks. To do this, the user must enter descriptions of tasks that are incomplete or which describe partial matches with the expected solution.

The Task Describer tool has a further embellishment. It allows the user to associate a value (in the range 0 to 1) with each task description. This value represents a score that indicates how well, in the investigator's opinion, a description matches a correct solution. This enables us to score each student's attempt at a task and, by looking at all students' recordings, give a score to each task indicating how easy or difficult the students found that task. This latter activity is accomplished by using the Analyse Tasks tool.

### Implementation architecture

The main AESOP classes are:

- **ObservatoryRecorder** – records user events.
- **ObservatoryReplayer** – replays recorded user events.
- **ObservatoryAnalyse** – launches analyses.

A previous publication (Macgregor et al. 1999) described the recording instrumentation in detail. The present paper concentrates on the analysis instrumentation.

An instance of class **ObservatoryAnalyse** has an interface for starting each analysis. Selecting the appropriate item in the Analyse menu launches an analysis. One of the aims in developing the analysis tool was to make it straightforward for new members of the research team to develop new analysis methods for themselves. The first stage in developing a new analysis method is to think up a name for it and add it to the menu. The class **ObservatoryAnalyse** was designed so that all that this would involve would be to add a line to the class method **analysisActionsMenu**. For instance, to add the menu item **required event signatures** simply involved adding the line

![Figure 4: The Task Describer tool with multiple task descriptions and wild cards](image-url)
mb add: 'required event signatures' -> #requiredEventSignatures.
Where mb is the menu builder object, 'required messages' is the string shown in the menu item, and
requiredEventSignatures is the name of the method called when required event signatures is selected.
The required event signatures analysis enables the user to extract designated recorded event-signatures. For
every example, to look at the event-signatures reflecting that the student has (i) opened a LearningBook and (ii) has
selected an anchor, an appropriate line is added to the start of the method:

```smalltalk
requiredEventSignatures := #('openUserVersion*' 'selectAnchor*' ).
```

self analyseForRequiredEventSignatures.

Note that the second line of the method body continues the analysis.
The file to be analysed is loaded into the Analyser in the same way that a file is loaded into a word processor. This
causes the class variable, ObsStream to reference the stream of characters contained in the file. Each analysis
proceeds by going through the file line by line and applying an appropriate sub-analysis to each line. For instance, to
analyse all lines in a file to check if it contains a required event-signature, the following code is used.

```smalltalk
analyseForRequiredEventSignatures
[ObsStream atEnd] whileFalse:

  self analyseExpressionForRequiredEventSignatures
```

Each line in the recording contains an AESOP expression consisting of the event-signature and its timestamp.
Therefore, the method analyseExpressionForRequiredEventSignatures simply adds any required
expression to a variable, then at the end of the analysis the variable shows the found expressions in the analysis tool
window, for example:

- openUserVersion: true 02/19/2000 7:43:29.000
- selectAnchor: c06s2.htm 02/19/2000 7:44:16.000
- selectAnchor: c06s2p4.htm 02/19/2000 7:45:56.000

A user-initiated action can precipitate several messages within the environment, but only one event-signature is
recorded to represent the action. On analysis, the event-signature (with its timestamp) provides the information
needed about the original user-initiated action.

**Future work: analysing masses of data**

The construction of a tool to compare the tasks that a student has been asked to do with what they actually did has
been described. But it is important to remember that students are encouraged to do additional work or simply
experiment. We need to build analysis tools that can analyse experimental approaches taken by the student. The idea
of comparing an actual recording with an "ideal" recording is being pursued. In the ideal recording we flag methods
and code evaluations that require students to use their initiative. These will provide the basis for task descriptions in
the Task Description Tool.

We wish to examine data from a succession of LearningBooks to see how a given concept is used as time
progresses. If, for example, a concept is introduced in one LearningBook, it should be possible to see that concept
being used in later LearningBooks. If that concept is used incorrectly we should observe errors – and perhaps be
able to deduce that the error was made because a concept was not picked up at an earlier stage.

If we see patterns of behaviour that are common to many students, it will be possible to say something useful:
possibly that the teaching of that concept is flawed and should be changed. Whilst this may be useful information to
the course team, it is not answering the central question of how students learn. It could be much more informative to
examine what the student does immediately after being confronted by an error message. At present the only way to
detect student’s understanding of concepts is to look at practicals where they have had to think out answers for
themselves, rather than just following a “monkey-see monkey-do” process. We are actively considering whether to
include more structured self-tests in the LearningBooks.

LearningBooks assume that students will read the accompanying printed texts but the recordings do not show what
the student does or how long the student spends doing it. It may be the case that students continually refer to the
accompanying texts in order to clarify concepts whilst tackling the practical. It may be worthwhile, therefore,
supplying electronic copies of printed texts so that, when performing the practical, the student can refer to the
computer-based text. We could then record when a student accesses particular information and begin to address the
issue of whether a substantial gap between recorded events represents time when the student is interacting with other materials or taking a break.

The notion that all course materials would be available electronically coupled with the fact that a recording can give valuable information about errors that a student makes, has encouraged us to investigate the idea of an on-line coach. That is, a piece of software that uses data about student behaviour in the face of errors to provide (i) help in the form of hints as to solve well-known problems and (ii) access to the relevant course materials for an explanation of the concepts related to the error. At the time of writing, a proof of concept implementation has been built (Thomas et al 2000).

Conclusion

Current work is pursuing research questions about learning and the refinement of unobtrusive instrumentation and analysis software. The project involves automatic recording, replaying and analysis of data from student-programmers using the OU LearningWorks programming environment. This approach allows researchers to investigate concept acquisition and change, factors affecting performance, and the identification of areas of misconception and difficulty.

The questions we are trying to specify and answer concerning how neophytes learn object concepts have been outlined here. The implementation of a selection of the AESOP tools has been described, especially those pertaining to analysis. The recording software is now fairly stable, forming a good basis for further development of replaying and analysis software. Many technical problems remain, but we believe that we have identified the main ones, and that progress will continue to be made.

During 2000 we are concentrating on determining appropriate analyses to be made of the mass of data we have collected. Beyond 2000 we shall extend the instrumentation to analyse the entire course of 5000 students. By then it is hoped that an on-line coach will be providing useful support to all our students.

Electronic Collaboration Tools – Diffusion of an Innovation

Brian Mackie
Northern Illinois University
DeKalb, IL 60115
bmackie@niu.edu

Jack T. Marchewka
Northern Illinois University
DeKalb, IL 60115
jtm@niu.edu

Abstract: In the last few years several types of electronic collaboration software tools (ECST) have come onto the scene. However, organizations have not fully accepted the wide spread use and features of these tools. Therefore, their full potential and opportunity envisioned has not been realized. The purpose of this study is to understand how ECST can be viewed as an innovation and how, as an innovation, ECST can be diffused throughout and accepted by an organization. Applying diffusion of an innovation theory, an empirical study will assess how well a proposed model describes a user’s satisfaction with a tool and their subsequent willingness to adopt it. Moreover, this study will focus on several tools and evaluate the users satisfaction and subsequent willingness to willingly adopt a particular ECST tool.

ECST Adoption Model

(Rogers 83) identified five different attributes of innovations (1) relative advantage, (2) compatibility, (3) complexity, (4) trialability, and (5) observability. Subsequently, these five variables may have a direct influence on an individual’s satisfaction with a particular ECST tool. In turn, an individual’s satisfaction will influence their decision to willing adopt a particular tool. The relationship of these variables is illustrated in (Fig 1).

```
Figure 1: ECST Adoption Model
```

Relative advantage is “the degree to which an innovation is perceived as better than the idea it supersedes” (Rogers, 83). Relative advantage has been generally related positively to adoption (Rogers 83)(Tornatsky & Klein 82). In the context of ECST tools, and individual may find that a particular tool overcomes many of the limitations associated with same-time/same-place meetings. Therefore,

**H1:** An individual’s perceived relative advantage of an ECST tool will be positively related to the individual’s satisfaction with that tool.

Compatibility is “the degree to which an innovation is perceived as consistent with the existing values, past experiences and needs of potential adopters” (Rogers 83). Subsequently, an individual’s satisfaction with an ECST will be influenced by their perception of how well the tool fits or is compatible with the task at hand. It follows, then, that the compatibility of ECST should be positively related to the individual’s satisfaction.

**H2:** An individual’s perceived compatibility of an ECST tool to the task at hand will be positively related to the individual’s satisfaction with that tool.
Complexity, on the other hand, is “the degree to which an innovation is perceived as relatively difficult to understand and use” (Rogers 83). Studies have found complexity to be negatively associated with adoption (Rogers 83)(Tornatzky & Klein 82). Consequently, the perceived complexity of an ECST tool should be negatively related to the individual’s satisfaction with that tool.

**H3:** An individual’s perceived complexity of an ECST tool will be negatively related to the individual’s satisfaction with that tool.

Trialability is “the degree to which an innovation may be experimented with on a limited basis” (Rogers 83). In short, trialability provides a chance to learn and evaluate an innovation so that an individual can eventually make a decision whether to adopt it. Therefore, trialability should be positively associated with an individual’s satisfaction with a particular ECST tool.

**H4:** An individual’s perceived degree of trialability with an ECST tool will be positively related to the individual’s satisfaction with that tool.

Observability is “the degree to which the results of an innovation are visible to others” (Rogers, 1983, p. 240). Therefore, an individual will have a higher degree of satisfaction with a particular ECST tool when they can observe how the tool may provide meaningful benefits by using the tool.

**H5:** An individual’s perceived degree of observability with respect to the benefits associated with an ECST tool will be positively related to the individual’s satisfaction with that tool.

In addition, an individual’s degree of satisfaction will ultimately influence their decision to willingly adopt an innovation.

**H6:** An individual’s perceived satisfaction with an ECST tool will be positively related to the individual’s willingness to adopt that tool.

**Research Design**

This study will survey over 80 students at a large midwestern university who will use a particular ECST tool or toolset as part of their course work. The students will be assigned into small groups of three or four members. Each group will be required to research and write a paper on a selected topic and then present their topic to the class using a presentation software package. As a major part of this assignment, the groups will be required to meet for a minimum of three hours each week online over a period of five weeks. To start the study the students will be introduced to several different types of ECST tools. This will include: remote meeting; file sharing; desktop sharing; text/voice chat; messaging; other miscellaneous ECST tool types;

As part of the assignment, each group will be required to use and evaluate two different collaboration tool sets that will include all of the above ECST types. Each group will have one week to work with the tools and setup a collaboration schedule that will be used for the remaining four weeks of their assignment.

Data for this research project will be collected using online surveys and an online diary. Each student will be asked to complete a survey each week that will focus on the variables identified in the ECST Adoption Model. The results of these surveys will be used to test the model and to determine whether their perceptions changed over the course of the assignment. Each student will also document their experiences with the tools on a Web site set up specifically for this research project. This online diary will provide valuable qualitative data that can be used to supplement the survey data. The results of this study will be available and presented at the conference.

Deconstruction of Socio-technical Information Systems with Virtual Exploration Environments as a Method of Teaching Informatics

Johann S. Magenheim
Department of Computer Science
University of Paderborn, Germany
Fürstenallee 11, 33102 Paderborn
jsm@uni-paderborn.de

Abstract: The working group Didactics of Informatics at the University of Paderborn develops and evaluates a multimedia exploration platform for information systems (MEPIS) to the needs of teaching and learning informatics at secondary schools. The paper describes the basic ideas within a system-oriented approach of didactics of informatics and two of its most relevant ideas: the perception of a socio-technical information system and the concept of deconstruction. The pedagogical and technical requirements of developing multimedia tools and integrating them into teaching and learning processes in informatics will be outlined, and the demands on a multimedia-based exploration environment for the process of deconstruction will be described. Finally, a concept of evaluation of teaching and learning processes in informatics under the perspective of a system-oriented didactical approach and the practical use of an exploration platform at secondary schools will be presented.

Socio-technical information systems in a didactical perspective

By socio-technical information systems (IS) we understand the unity of software including the graphical user interface (GUI), the hardware, embedded systems for control and regulation of peripherally technical processes and for communication with other IS and, last but not least, the associated social action system of persons, who are interacting with the IS and with other people. The technical part of an information system is exceedingly connected with its social part, by human computer interaction (HCI) and further direct or indirect technical functionalities of the information system, affecting the interactions of humans with the system and the interaction between persons. The social interaction in the context of the information system extends this to a socio-technical information system. As an example, for instance, an aeroplane can be mentioned. Information systems, e.g. embedded systems, are closely linked with the surrounding technique of the airplane to a local network of hard and software. The crew acting with this information system via the GUI of the board computer and the software implemented there extend this system to a socio-technical information system. Safety of the plane and the passengers do not only depend on the correctness of the soft- and hardware but also on the ability of the crew to interact capably with this system. The term of the socio-technical information system, in which an action system formed by interacting persons is merged is a subsystem, has its science-theoretical roots not only in computer science but also in the sociology of technique (viz. e.g. Ropohl 1999).

The software of socio-information systems represent fundamental ideas and methods of informatics and also the concept of workflow and patterns of social action within the system. Social action, social roles of people and the workflow in the system's context will be influenced, e.g. by human computer interaction (HCI) with the technical parts of the system moderated by the graphical user interface (GUI). In the process of software development a model of the future system's functionality and its integration into the working and social context has to be generated. Modelling and developing software under this perspective is a highly communicative and interactive activity and needs close cooperation between developers and customers. Therefore, we need cooperative and evolutionary concepts for software development with stepwise refinement of its functionality. The technical implementation of a computer science system can therefore be used to prove the consequences of decisions in the context of the modelling process and co-operative action between developers and customers.

Objectives of a system oriented didactical approach

An important lesson for teaching informatics is that programming - in the sense of coding - is only one part of the construction process of an IS, and that it can no longer stand alone as the centre of a curricular concept.
Techniques of system modelling and of evaluation of existing information systems as well as theoretical aspects of informatics should also be a relevant subject of informatics work in the classroom. Scaffolding curricular concepts of teaching informatics at secondary schools which focus on the modelling aspects of software development and the social dimensions of IS are important issues.

Instruction using a system oriented didactical approach in informatics should include these essential objectives:

- Teaching fundamental concepts of informatics (like algorithms, methods of software technique..)
- Learning about (computer-based) modelling techniques.
- Recognising software development and the construction of IS as a communicative and co-operative process, i.e. construction decisions and group interests should be balanced.
- Learning, that the social impact of an implemented IS has its roots in the phases of requirement definition, specification and design of software.
- Creating technical systems and IS is not only a technical but also an important social process with large influence on society.

Realising this approach fosters not only the knowledge of fundamental concepts of computer science but also important comprehension and orientation in an engineered world and thus substantial aspects of general education are obtained in informatics at school.

Fostering modelling abilities of students by deconstruction of IS

Beyond algorithms, small software development, or the construction of a tiny IS classroom project, informatics also needs computer-based tools for modelling and for the exploration of existing IS. In complement to the method of constructing software, the method of deconstruction of software is a methodical alternative in informatics lessons. In addition, it also gives students the opportunity for discovering styles of learning and focuses in a special way on the modelling and design process as well as on the social implications of information systems.

The term "deconstruction" comes originally from the methodical concept of philosophy and science of literature (viz. e.g. Derrida 1997). It aims to analyse the structure and content of text and to interpret the author's opinion. Also it intends to find out about things, which have not been said by the author, but nevertheless were very important for the author's message. Deconstructivism can also be found in the fields of architecture and arts, where we may discover traditional and new concepts of design, logic, formal and informal structures, implicit messages, and so on. Why not transfer this concept in the area of teaching software techniques?

Deconstruction as a Method of Didactics of Informatics

![Deconstruction as a Method of Didactics of Informatics](image)

**Figure 1**: Deconstruction as a method of Didactics of Informatics
Software has different forms of appearance and allows different views to discover it: We could look at the source code and see classes, methods, algorithms, programming language structures or even informatics concepts such as e.g. the problem solving method 'divide and conquer'. We might look at the GUI and learn about software ergonomics as well as about the functionality of the software. We might learn about the organisation of work within the IS and the abilities people must have to handle this product. UML diagrams (unified modelling language) and documents that have been generated during the phase of design-decision complete the arrangement. It's like a puzzle and pupils might look for the pieces and put them to the whole. The complexity of a multimedia-based exploration environment should be scalable so that it might be adapted to the level of different learning groups. When constructing software by themselves, pupils have to obey the chronology of the process and then, due to the lack of time, the software to be developed cannot be very complex. Deconstruction allows a kind of time travelling and offers a simultaneous look at different stages of the software development process, i.e. the preliminary interaction contexts of an IS before its development, the phases of software development, and the implementation and change of social context of the IS. Software design decisions may become a subject of discussions and alternative concepts of specification could be conceptualised. In addition, supplementing modules of the software could be constructed and systems' functionality could be changed. Thus, the fundamental informatics concept of re-engineering could be realised in the classroom. The main objective of this endeavour in an exploration environment is to strengthen the pupils' sensibility towards the decision-making character of modelling processes and to let them learn about the methods of modelling and software techniques. Thus informatics at school will be able to realise some essential objectives of general education: contribution to the school student's problem solving competencies, fostering social competencies e.g. (ability to work in a team, communication abilities), ability to use cognitive tools not only in informatics but also in other areas, and last but not least the ability to value the social impact of changes in technology, especially in information technology.

Virtual exploration environment MEPIS

To realise this didactical concept it is necessary to develop didactical software with open access to the source code and a multimedia-based exploration environment, which offers the different tools and types of documents such as: Java development kit, object browsing system, examples of CRC-modelling, description of use cases, description of social context of IS (patterns of interaction, types of workflow), video sequences of social action representing the use cases, interviews with future users, interviews with developers and applicants, documents concerning with the history of ST and IS, parts of documentation of the concrete IS, fragments of source code, elements of the GUI of the software, description of methods to develop, modules of software to develop, UML class
and sequence diagrams, GUI prototypes, alternative software design concepts, software development strategies, scalable prototypes of software to develop and so on.

The scalable exploration environment should be used for different learning scenarios in informatics at school. It should also be integrated into the teaching and learning process of the class. In an informatics project, which e.g. is to construct a small piece of software, pupils may use the exploration environment to answer questions that arise during their classroom work. The software represented in the system could be extended by creating new modules. MEPIS also represents the concept of learning by example. Informatics-related problem solving, constructing software, learning about informatics and deconstruction of an IS with MEPIS should be an integrated part of classroom work.

Questions of evaluation in a system oriented didactical approach

Learning and teaching processes are very closely linked and represent different views on the same matter. Therefore, the main subjects of empirical classroom research should be the teacher (teaching process), the students (learning process), to include the classroom interaction between students and the teacher and among the students themselves. Also, the human computer interaction (HCI) of the students with different computer-based tools and with the multimedia exploration environment (MEPIS) should be empirically evaluated.

There are some very interesting empirical studies dealing with different subjects of learning at schools. The international TIMMS-study about teaching-styles and students' conditions of learning mathematics produced especially remarkable results. But there is a lack of such empirical studies in regard with informatics at schools, and there are none regarding the special research interests of a system oriented didactical approach of teaching informatics at secondary school. Due to the perception that it is an important task of computer science to model and create information systems that have a tremendous impact on the associated social interaction system and even on the whole society, modelling and creating a small information system has always been an important classroom activity in informatics. With a system-oriented approach, a small IS, represented in a multimedia exploration environment, could be analysed and deconstructed, its socio-technical elements then bared for further learning and discussion. Empirical analysis of informatics at school under the perspective of an system oriented didactical approach pose some of the following questions:

- Does the method of deconstruction and the use of MEPIS foster the students' abilities of modelling a small IS and do they acknowledge the fact that the functionality of IS depends on design decisions that could be influenced by the interests of applicants, developers, users or given economic circumstances? Does the use of deconstruction and of MEPIS change the objectives and the practice of informatics in school from a programming language course into a course in which fundamental informatics concepts are submitted? Does the method of deconstruction and the use of MEPIS open the pupils' view for the social impact of information systems and help them realise that an IS implicates an associated system of social action? Does deconstruction in terms of general education not only foster formal problem-solving abilities but also social competencies like teamwork and communicative competencies? Will deconstruction contribute to technical and general education by fostering the comprehension of the possibilities of forming a socio-technical information system in different ways? What is the contribution of a multimedia exploration environment of IS to informatics at school? Can it increase the effectiveness of computer-based modelling techniques and create a constructivist learning environment? These are some of the essential questions of the didactical research project.

The observed contradictions between issues and results in educational practice motivates a new strategy for application of didactics of informatics. Therefore, recommendations, materials and multimedia tools have to be designed and tested. The MEPIS-project supports a new kind of relation between research, training and educational innovation. At first, future curriculum of informatics education has to be defined and a desired learning-process to be described. Thus, a number of hypotheses need an empirical evaluation in the context of the research. The courses can be videotaped at different periods to analyse case studies. Analysis focus could be the structure of the lessons, the methods used in problem solving, and the students' skills of thinking. The research group has to decide which parameter of the concept has to be changed to the next step to improve the solution. During a longer period, each step of evaluation can be manifested in a multimedia database. The possibility of storage and retrieval of large quantities of empirical data has a long tradition in didactics. What is new is the access to multimedia data and the ability to use it to analyse and compare complex learning-scenarios. Therefore, the empirical research concept must be acknowledged as a long term study.
Evaluation strategies of teaching and learning processes in informatics

Empirical data can be collected by using and combining qualitative and quantitative empirical research strategies and instruments like interviews, questionnaires, observing and videotaping lessons, assessment of course materials, or group discussions about observed teaching-practice. To obtain more empirically founded information about teaching and learning informatics it will be useful to examine the classroom interaction between pupils and teacher and among the pupils themselves. Further objects of empirical analysis of classroom practice could also be teaching-styles, organisation of classroom work by the teacher, course materials, writings on the blackboard, curriculum concepts of the lessons, source code and documentation of the software developed by the pupils, keystroke-recording of human-computer interaction situations in the classroom, results of running tests of the pupils' designed software, media support and the technical equipment in the classroom, pupil records in their exercise books, opinions of teacher and students about informatics and the objectives, the content and the practice of the attended lessons. An important source of data with didactical relevance will also be the evaluation of navigation patterns with MEPIS. Qualitative data covering the whole classroom interaction process may mainly be collected in a sample of some classes at few schools. Quantitative data will also be collected in control groups to value the influence of teaching-methods, didactical concepts of informatics and the role of multimedia-based exploration environments. For evaluation purposes and recognition of the results of empirical classroom research, it will be useful to compose clusters of students which are homogenous with respect to relevant research variables like cognitive and methodical precognition, abilities and learning types or the influence of gender.

The implicit theoretical concepts of didactics of informatics will also be empirically examined in discussions with heads of faculties or schools and the teachers by interviewing students and by the analysis of video-recording of lessons (Magenheim 1999).

Figure 3: Evaluation Concept

To collect case-study data for empirical evaluation of classroom scenarios it is necessary to record a lot of classroom interactions. Therefore, classroom practice has to be observed and videotaped by two cameras, one for the teacher's and one for the students' perspective. Sometimes, it even might be necessary to use not only fixed but also portable cameras. The operator is allowed to walk around in the classroom to record discussions within groups or to visualise pupils' interaction with the computer. But videotaping classroom interaction for evaluation purposes has to be handled very considerately, trying not to disturb the sensitive communication context between teacher and pupils and to minimise interference from outside.

Special attention must be given to the analysis of MEPIS. We want to find out patterns of use and navigation with MEPIS. What kind of knowledge and methodological competence do the students gain by using the exploration environment and how will they transfer their competences to solve informatics-related problems at school? This
may answer some questions concerning the integration of constructivistic virtual exploration platforms into a concept of traditional methods of teaching in classrooms. We will use well-known empirical instruments of human computer interaction and software ergonomics and combine them with methods of classroom research to find answers.

Conclusions

Evaluating learning- and teaching-processes is an important subject of didactics of informatics at university and has to be integrated in informatics teacher-training at university. Evaluating classroom practice and the use of multimedia exploration platforms in informatics serves different purposes. Methodology and the tools of research, also the results of the empirical study, have to be connected with the practice of teacher education in informatics. It is very important for teacher students to learn about the educational practice of informatics at school. They will come to know about differences between theoretical concepts and practice of informatics lessons. Evaluating learning informatics is necessary not only to produce new findings or get information about current results from other research projects but also to understand empirical research methods. In a process of lifelong-learning future teachers should be able to enlarge their knowledge about teaching by studying further research results on classroom practice in informatics. Founded on a critical judgement of these research results and due to their own experience future teachers may improve their teaching-practice.

Finally, to foster these skills it is important to offer teacher students in seminars at university the opportunity to gain their own experience with classroom situations, discussing and evaluating their own behaviour in the classroom and to strengthen their faculties for self-assessment. Thus, teacher training at university will make a substantial contribution to improve teacher students' abilities for lifelong-learning and, as a result of this, in long term to increase the quality of informatics at school.

We hope that integrating multimedia tools into the their own teaching practices will not only enlarge the teacher students' methodical abilities but will also contribute to the understanding of the concept of modelling and to the pupils' comprehension that socio-information systems are formable in different ways.

As another spin-off of the MEPIS-project, the video-tapes and the variety of lesson-oriented materials may be used to establish a "best practice" data base of lessons in informatics, which may also be used to improve quality of teacher training and thus finally, the quality of informatics at school.

Abstract: A new CD-ROM of Teaching History of Arts is presented in this interactive session. The content of the CD-ROM is Architecture, Painting and Music in Greece, Ireland and Finland. Every country has chosen "a golden period" of history in each art and presents it using multimedia material. There is also possibility to update the information in hard disk through Internet.

1. General Description

The CD-ROM takes the user to three countries in three ways. The first one is a "data mining" which is an interactive engine that helps the user to access information by art, time period, picture, name and context. By exploring the material of CD-ROM the user collects the necessary information of three arts of three countries. The second engine is a slideshow creation and customisation tool for teachers. Thus he/she is able to create appropriate teaching material according to the needs of a certain lesson. The third one is an interactive game engine that has evaluation purpose.

All "software engines" retrieve and process information from common "pools of knowledge" (databases) that are placed on the CD-ROM or exist in the Internet or local discs or servers.

During the presentation the audience will find out versatile use of this CD-ROM and they will have ideas for creating similar products. After the presentation the session participants are able to test the CD-ROM in order to have a personal experience of this learning tool.

2. Key Objectives

This CD-ROM is an on-line educational software that allows end-users to retrieve, discover, set-up and exchange information about the arts and their history in each of the three European countries. It presents new teaching and learning processes that emerge from the on-line use of open-ended educational software, by testing it in everyday school life.

2. The Scenario

The main menu is the starting point of all educational activities available in the CD-ROM. The mentioned software engines include several groups of activities such as: Art presentation, Teachers' desktop, and Game. The host explains these activities to the user and prompts him to choose one of them. By choosing an Art the user proceeds to
the "data mining" section of the application. Teachers may choose the slideshow, in case they use the CD-ROM in the Classroom, or Teachers' desktop if they want to set-up a slideshow or change the application parameters. At last everyone can choose to enter into the gaming section to entertain him/herself and to evaluate his/her knowledge on History of Arts.

Selecting an Art, while being in the main menu, the user proceeds to next stage, where objects of special interest are placed on the screen by chronological order (multiple scrollable timeline graphic screen). In this stage there are available brief descriptions of the socio-economic environment for each period for every art, in the form of text and narration.

After choosing an object the user reaches the main screen that presents essential information by using pictures, text, videos, narration and hyperlinks. Further information can be reached by clicking on each one of the five predefined buttons (Location, History, General Description, Tell me more, Frequently Asked Questions). This information is attached to a series of overlapping windows, so that the user can track the depth of it.

Teachers' desktop or teachers' laboratory provides an interface with wizards that help them to adapt the application to their needs without changing its structure. Thus, the presentation of information becomes more flexible. The pool of contents supplies the slideshow with all available media relevant to the theme, which exist in the CD-Rom, in local discs, or the Internet. We propose to develop at least six slideshows (two for each Art) as examples in order to ease the job for other people.

The presentation of any information is supported by a number of external utilities. These utilities help the user to exploit this information with the CD-Rom software package as well as with other packages. They are Help, Glossary and Notes.

Finally, by choosing the Game, the user enters into the evaluation section of the application, which also is an entertaining one. In this section a series of educational games drive the user through predefined trails to his/her final qualification. The game is scaled up with a set of rounds that lead to different certificates or diplomas. Partial games-quizzes of different types and forms are drawn in random order from a game pool.
Interdisciplinary learning process with ISDN-videoconference: “The production of Wine”

Jukka Maki, The Ziridis Schools, Greece

In this paper I explain thoroughly one example of an innovative project using ISDN-based videoconferencing in teaching of elementary students.
Is It Possible To Teach Music In a Classroom From Distance of 1000 km?
Learning Environment of Music Education Using ISDN-Videoconferencing

Ph.D.-student
Department of Educational Studies and Teacher Training
Faculty of Education
University of Oulu
Finland
jmaki@tkk.oulu.fi

Abstract: ISDN-technology has solved many educational problems in rural areas in Lapland, Northern Finland. This paper presents the results of research conducted in Utsjoki School about music education in classrooms. The instruction has been given using ISDN-videoconferencing from a distance of 1000 km. Also the model for teaching music in VC-environment is presented.

1. ICT in Teacher Training

The University of Oulu (Finland) has a ten-year-experience in distance learning. Located in Northern Finland, Oulu, is a center for small distant villages and towns in Lapland. Distance learning has become an everyday way of instruction and communication. The Department of Educational Sciences and Teacher Education of the University of Oulu is a leading educational institution in the field of DL. The use if ICT in DL (and generally in teaching) is a part of the compulsory studies for students. Students are also able to take optional courses of ICT.

Students complete their practicum studies at the University Experimental School and in village schools. Many schools in scattered areas do not have teachers with different focus areas of instruction. ISDN-videoconferencing has given opportunities for teacher trainees to practice their teaching skills with ICT and pupils in remote schools have had the opportunity to receive instruction in every subject of the school program.
2. The University of Oulu/Music Education

The Department of Educational Sciences and Teacher Education of the University of Oulu has Kindergarten, Elementary Teacher, Music Teacher and Subject Teacher departments. The University of Oulu is one of the three universities in Finland providing subject teacher education in music teachers for comprehensive and secondary schools. The goal of the music education program is to provide the student with skills, information and attitudes required in widely and autonomously taking care of tasks in music education as well as developing the work and scientific aspects. The student is familiarized with the goals, contents and protocols of music education as well as with the application and observation of pedagogic music research. [musicedu.oulu.fi].

Essential points of emphasis in studies are amongst others music and communication technology. All students take part in learning of distance education -methods, lesson planning, using videoconferencing and creating www-material for music lessons.

The Music Department has taken a leading role in developing and integrating the music education in Northern Finland. Cooperation has been done between schools, institutes of music and the Department. Some projects have been done by the members of the staff but mostly in cooperation with the students. Thus all the partners - professors, students, distance teachers and students in institutes and schools - have had important and unique experiences in music education by distance.

During the practical period of the studies at the Music Teacher Department the students taught music to the school of Utsjoki located 800 km from Oulu. The attempt to create a learning environment similar to a normal classroom with face-to-face teaching.

3. Models For Teaching In ISDN-Videoconference Environment

![Diagram of learning environment using ISDN-Videoconference](image)
In the first model a local teacher is alone conducting the lesson with the remote class. There might also be a teacher, but in many cases in scarce villages there are no special teachers for all the subjects of the school curriculum. Even the pupils take care of the facilities and the classroom discipline. More often there is however a teacher as a technical tutor, but he may not have any knowledge of the teaching subject. The local teacher has the main responsibility of teaching.

In the second model a teacher is conducting the lesson with the local class and the remote class together. There may also be a remote teacher or a tutor. If the remote teacher is familiar with the teaching subject, the responsibility of teaching can be divided between the two teachers. The interaction and communication goes on between all the partners. [musicedu.oulu.fi/koti/jmaki.htm].

4. Utsjoki-Project

Utsjoki is a good example of activities that has been done using videoconference in teaching and as part of the practicum of teacher trainees.

Utsjoki is a village with 1500 inhabitants and it is situated in the very North of Finland on the Norwegian border [www.utsjoki.fi]. The municipality has three villages which are located tens of kilometers from each other. Each of them has a school of own but only with few pupils. Without VC-technology
the pupils could not receive all the lessons of the comprehensive school program. The main school in Utsjoki has also upper secondary school. Many students of Lower and Upper Secondary School of Utsjoki are brought with taxi from a distance of 50 kilometers or more and some pupils remain every school week in Utsjoki returning home only for the weekends.

4.1. Background to the Project

In the early 90's there were first experiments of distance learning using Tele-X-satellite and later ISDN-lines. There also existed need for distance medical services and so there was interest in different level of municipality. Other villages in Lapland, technological institutions, universities, state and province became partners in the project, too. Because of the long distances from cultural centers and scarce teacher resources, videoconferencing has given new aspects for education.

The Utsjoki-project started in 1995 as preliminary preparation. Experimenting, research and establishing period was implemented in 1996-1999. It had financial support from the Finnish state, European Social Fund and European regional development Fund-project. Because of the excellent results, the Project-application with videoconference was continued until July 2000. [www.utsjoki.fi/~utspoli].

Most of the activities have taken place in the lower and upper secondary school. The main goal of the Utsjoki-project is to create and develop learning methods and networks that increase educational equality and utilize the decreasing resources of the schools. The networking of schools both inside the Utsjoki municipality and with other municipalities in the Lapland region makes it possible to combine the scarce resources of education providing the schools with further possibilities to exist.

4.2. Teaching music from distance

The Utsjoki School had a music teacher last time 15 years ago and so the pupils had no possibility to have music lessons. The use of ISDN brought a music teacher in the classroom and the pupils were enthusiastic with the instruction. The lessons were instructed from the University of Oulu, the University of Helsinki [www.helsinki.fi], Music University Sibelius Academy in Helsinki [www.siba.fi] and the Institute of Orivesi [www.kvs.fi]. The learning environment was developed to create a similar as a normal classroom face-to-face teaching.

The lessons consisted of teaching
The experiences were very positive. The Utsjoki School last had a music teacher 15 years ago and the pupils had not been exposed to music lessons. Use of ISDN brought a music teacher into the classroom and the pupils were satisfied with instruction. Teaching with two-way videoconferencing has major problems with the limited possibilities of sound and picture as they are of vital importance in teaching music. The University of Oulu has developed this learning environment and tried to minimize these particular problems.

Teaching with two-way videoconferencing has major problems with the limited possibilities of sound and picture which are more emphatically in teaching music. The main role is the quality of sound and picture. Using one ISDN-line (128 kpbs) a delay of 0.5 seconds occurs. It doesn’t sound very much and in normal communication (speaking) it doesn’t bother us at all. But that delay is very big when making music with remote class – it’s even impossible to sing and play simultaneously. When there are in use two ISDN-lines (256 kpbs) or three (384 kpbs) and the lip synchronization is adjusted, the delay is so minimized that human mind doesn’t even notice it.

There are no differences when teaching theory or history of music from a distance or face-to-face. The teacher is able to use all the written and acoustic material plus the internet and application sharing. Also pupils are able to work in groups, present their exercises and teamwork with the same way as in normal classroom situations. Distance lessons give more possibilities for collaborative and self-directed learning and pupils come more responsible for their own learning, because they must be active participants in the learning process.

Learning to play instruments and ensemble playing meet some problems in teaching. When a pupil is learning guitar, the teacher cannot go next to him and show where to put his fingers. He must explain verbally but he can zoom his camera close to his own hands. This is even better than a classroom situation where a pupil tries to see from the distance of several meters the finger placement. So there comes a question: is distance teaching actually “close-teaching”?
The teacher can always show the rhythms with his own guitar. The same happens with teaching the drums: he shows how to play and pupil imitates. In face-to-face situation the teacher is able to take the hands of a pupil and play together with him. This cannot happen in distance lesson. But again one advantage: quite seldom there are two drum-sets in one classroom – during distance lesson the teacher can play together with pupil and the teaching is more practical.

Because music lesson has always quite high amount of decibels, the teacher and the learning group must agree some practical rules: when and how to start and finish, in which way the teacher interrupts the playing etc. Because the sound is delivered with microphone, the distant teacher might not hear all the details. That’s why it’s good to use more than one microphone and place and direct them in a proper way.

The modern videoconferencing technology also gives the teacher also the possibility to zoom the remote camera. So he is able to follow closely the performance. Furthermore he is able to play MIDI-instruments together with the remote group. If the teacher also has a classroom with him, they become really versatile jam-sessions between the local and remote pupils. The distance has no borders: one group in Finland and the other group in Australia – making music together!

The critical point in teaching music with ISDN-videoconference is the excellence of planning of the lesson. The teacher must prepare everything very well: the lesson plan, all the music to be listened, to written examples of partitures, transparencies, instruments, VC-equipment – everything must be physically close to him. And he must always be flexible to change his good lesson plan in case of technical problems. A remote music teacher must be a “super-teacher”. A good music teacher also uses other means like the internet and email which supplements real-time teaching. Often fax, post and even telephones are useful and necessary ways of communication.

The evaluation of the learning is sometimes quite complicated in music lessons. The teacher doesn’t always see or hear all the pupils and that’s why the participation during lessons is not always well recognized e.g. when they’re singing together there might be problems to separate the voices. If there is a tutor or remote teacher, the evaluation is possible to do together. Often the atmosphere during the lessons is not conveyed via ISDN. After every lesson it’s good to have a feedback discussion between teachers and also pupils can tell their thoughts. In the case of the Utsjoki-project it was even more essential, because part of the lessons were instructed by the
remote tutor (teacher of physics). Those lessons were however planned by the music teacher and the pupils in turn reported about the lessons to him.

Comparing the Impact of Two Types of Knowledge Organizers on Learning Complex Conceptual Material in a Second Year Course on German Thought and Culture

Paul M. Malone  
Department of Germanic and Slavic Studies  
University of Waterloo  
Waterloo, Ontario, Canada  
pmalone@uwaterloo.ca

Vivian Rossner-Merrill  
Centre for Learning and Teaching Through Technology  
University of Waterloo  
Waterloo, Ontario, Canada  
vmerrill@uwaterloo.ca

Abstract: The purpose of this study is to provide students in a culture course with a study method that allows them to better conceptualize abstract and complex material. The study will be undertaken through a series of steps. First, students will receive ungraded training sessions in constructing knowledge maps and matrices ("frames and slots"). The instructor is also using knowledge maps and matrices as teaching aids and models. Students will be required to construct their own maps or matrices for two assignments. In these assignments, students will incrementally acquire competence in making knowledge maps and matrices, providing them with the expertise needed to complete the next step: constructing a knowledge map or matrix that acts as a proposal for a research paper. Finally, as part of the final exam, students will complete a concise knowledge map or matrix based on recall of information from the short assignments.

The Study

In this study, two types of strategic learning practices—knowledge maps and matrices—are compared for their impact on learning complex conceptual content. Knowledge maps are visual organizers of key concepts, typically hierarchically arranged and with labeled links between them, designed to represent understanding of the presented material at a given stage in the learning process. Matrices are frequently described as "frames and slots," where categories or themes of content are set out in frames or columns, and more detailed information pertaining to them is arranged in rows or slots to produce a table. Much research has been done documenting the usefulness of knowledge maps at both the K-12 and college level, particularly in the field of the natural sciences (see, for example, Novak, Gowin, & Johansen 1983: Briscoe & LaMaster 1991; Ruiz-Primo & Shavelson 1996; Regis & Albertazzi 1996; Markow & Lonning 1998). Relatively little research, however, seems to have been undertaken on knowledge mapping at the level of higher education outside the scientific field (one exception is Leahy 1989). Matrices are frequently presented (along with other visual organizers) as useful aids for organizing information during the educational process (see, for example, West, Farmer, & Wolff 1991; Jonassen, Beissner & Yacci 1993). These aids, too, are often seen as being most helpful in connection with such traditional "difficult" disciplines as the sciences, but have also found wider application in the humanities (Garrec 1978; Kleg 1988), as well as in non-academic applications for students (Dees et al. 1991; this study involves knowledge maps as well, but applies both these strategies to personal management, i.e., time and stress management). To date we have found no studies that focus on comparing the effectiveness of these two strategies, knowledge maps and matrices, on learning in any discipline. This study takes a first step toward addressing these apparent gaps in the literature.

The tendency to apply these strategies to the scientific fields may reflect the perceived centrality to the sciences of conceptual knowledge based on certain "core concepts" of a discipline (see Romance & Vitale 1974). Non-scientific disciplines, however, are often equally dependent on such conceptual knowledge; the focus of this
study is a course in German intellectual history which demands of the students not only the learning of a broad historical overview involving a great deal of basic information, but a degree of understanding and expertise in certain overarching important philosophical, aesthetic and cultural concepts.

The purpose of this study, currently underway and to be completed in February 2001, is twofold: first, to assess the impact of using knowledge maps compared to matrices as aids to student learning in the context of an undergraduate class on German thought and culture; and second, to instruct students in the value of using these strategies for organizing their knowledge. The strategies act as externalizations of students' understanding of difficult conceptual material they will encounter in the course—a process that will enable them to assess the completeness and accuracy of their work against models provided by the instructor. Knowledge maps have the advantage of providing links between concepts and related information, but they also have a relative disadvantage: namely, the fact that they are cognitively more challenging to learn and to execute. An advantage of matrices, on the other hand, is that they foster the organization and categorization of information and descriptors in a straightforward manner, and are accordingly much easier to construct (perhaps explaining their greater use in the supposedly conceptually simpler non-scientific disciplines); unlike knowledge maps, however, they do not make the links between concepts and descriptors explicit. Consequently, it is not clear which will be more effective for student learning.

Students in the map treatment will use the IHMC Concept Map Software (available for download at http://www.cmap.coginst.uwf.edu/), created at the Institute for Human Machine Cognition at the University of West Florida, for map design—easy to use freeware that is downloadable at no cost (although the size of the file virtually requires a cable modem or network connection). All students will be able to access the software either by using their own computer equipment or through on-campus computer labs, or both should they prefer. Students in the matrix treatment will use Microsoft Word (or any other word processor or program capable of making tables) to design the matrix tables as needed for each required assignment. Both groups will use freehand drawing for the final exam. In both cases, the software involved has a relatively short learning curve for basic proficiency but is capable of producing visually appealing and easily legible results. In addition to obtaining feedback from the students regarding the efficacy of the two learning strategies, the questionnaire will also collect data about their perceptions of the adequacy and usability of these tools.

Our research hypotheses are as follows:

(1) For each student outcome, the two treatment groups are equal. Outcomes are:
   a. Two short assignments
   b. Term paper proposal
   c. One map or matrix question on the final exam based on recall of information from the two short assignments
   d. Final exam score
   e. Course grade

(2) There is a relationship between students' performance and their perception of the usefulness of knowledge maps or matrices as learning aids, as indicated by their responses to a brief questionnaire.

We also expect, although we will not attempt to prove, that relative to previous years' classes that did not use such visual organizers, the use of knowledge maps and matrices as learning aids will enhance students' comprehension and retention of structural historical/cultural knowledge in the three areas represented by the short assignments and term paper proposal. This assumption is grounded in the expectation that the use of knowledge maps and matrices as a feedback tool will facilitate meaningful learning; that is, learning which allows students to capitalize on what they have already learned by placing it more immediately in a structural relationship with new information (Ausubel & Novak 1978; Novak 1998).

The first phase of this study will be undertaken through a series of steps over the progression of the course term. First, students will receive training sessions in planning and constructing knowledge maps and matrices. Further, the instructor will use both matrices and knowledge maps as teaching aids and as models for the students. Students will be required to construct their own maps and matrices for two short assignments. In these assignments, based on the work of (Regis & Albertazzi 1996), students will incrementally acquire competence in making knowledge maps and matrices in the following sequence before working independently of instructor support. These are:

Assignment 1: (Arian Controversy) Known terms – a fixed number of concepts are assigned and each student constructs the map or matrix using only the terms given. The knowledge map students choose the linking relationships and the concept structure she/he considers most suitable.
Assignment 2: (Humanism) **Concept stimulus term** — only one concept label is assigned; each student structures and elaborates her/his own map or matrix using the given label.

Assignment 3: (Term Paper Proposal) **Open** — no concept label is assigned; the number of labels the students can add is open; each student structures and elaborates her/his own map or matrix on the topic of their choice using the given label.

Final exam question: (Choice of either assignment 1 or 2) **Guided choice terms** — students are given a number of terms greater than required to construct the map or matrix, not all of which apply to the question. They are instructed to use only the appropriate concepts to construct their own maps or matrices.

These are developmental steps in map and matrix making designed to guide the student toward greater ability to construct them independently of instructional support. For the two short assignments, each step is designed to provide them with the experience needed to complete the next step in the sequence. These steps are preliminary to constructing on their own the map or matrix proposal for the major research paper. Finally, along with short answer and essay questions on the final exam, students will be required to complete a concise knowledge map or matrix question requiring recall of information learned in the two short assignments.

Maps and matrices will be scored for completeness of conceptual structure and accuracy of related information for both treatments and, for the former, accuracy of links between concepts for the knowledge map. Presentation (visual clarity and coherence, as well as spelling and, where applicable, grammar) will also be evaluated. The knowledge map and matrix response question in the final exam is similarly scored but will not be returned to the students. Data analysis will take place after students have completed the course.

In the second phase, this study will be repeated in the Winter 2001 term, and the data merged for final analysis.

**Implications of the Study and Preliminary Results**

If it makes no difference to learning outcomes whether concepts maps or matrices are used, then the potential conclusion is that the "simpler" and more straightforward matrix strategy is equally effective to the knowledge mapping strategy in the production of meaningful learning, understanding and retention.

Preliminary results for the data analysis undertaken thus far indicate that the strategies contribute equally to learning outcomes when students' averaged grades on assignment 1 and the term paper proposal are taken into account. Table 1 illustrates that for each of these outcomes, the knowledge map and matrix groups' scores were the same. The map and matrix final exam question responses, however, show an advantage for those using knowledge maps.

</table>

Table 1: Averaged grades on assignment 1, term paper proposal, and exam question. *Students were given a choice of using either maps or matrices for this task.

While at this point in the analysis no substantial claims can be made about the relationship between the strategy chosen and learning outcomes, students did exhibit clear preferences across the A and B grade ranges. The total number of map/matrix choices for the students is 44. Overall, they chose maps 53% of the time and matrices 43% of the time. A more informative picture of the potential importance of using maps instead of matrices to enhance learning outcomes is presented in Table 2.
Table 2: Grade range and preferences for using maps or matrices across four tasks.

<table>
<thead>
<tr>
<th>Grade Range</th>

<td>8 (67%)</td>
<td>12</td>
</tr>
<tr>
<td>C</td>
<td>6 (50%)</td>
<td>6 (50%)</td>
<td>12</td>
</tr>
</tbody>
</table>

Those students achieving in the A range preferred using knowledge maps 70% of the time, while those in the B range preferred matrices in almost the same proportion (67%). The C range achievers chose either matrices or maps in equal proportions.

An even clearer picture emerges when comparing map and matrix users responses in Assignment 1 and the term paper proposal as presented in Table 3. To date, these have been coded for identification of the following key information pertaining to the requirements of the assignments: (1) issues identified; (2) supporters and facts about them; (3) related historical actions and events; and (4) overall conclusions generated as a result of the students’ research.

In each case the average assignment grades remain the same.

Although the average grade is the same for the map and matrix groups, the matrix group generated substantially more information, 60% more, to achieve at the same level than did the knowledge map group. (Note that for Assignment one the key concepts were provided by the instructor prior to students completing the assignment. In the Term Paper Proposal, students were given no prior information.) This finding becomes even more marked in the analysis of just one coding category, in this case, “issues,” in Assignment 1. The knowledge map group recorded 36 items and the matrix group recorded 92 items – 28% and 72% respectively from a total of 128 items of information. In this case, the matrix group generated just over two and one-half times the amount of information than did the knowledge map group – again, noting that the average assignment grade for both groups was the same.

We noted that if using either knowledge maps or matrices appears to have the same effect on student learning outcomes, then it is simpler to use matrices. We can conclude that using either one or the other appears to be just as effective when looking at the averaged grades for the work presented above. This is deceptive, however, because while there are no differences in the averaged grades, we found that the amount of work, as recorded by coding information items, was significantly discrepant between the groups. While knowledge maps and matrices are both very useful visual organizers for most students, the knowledge maps appear to provide more than that.

Our data suggests that using knowledge maps assists students to represent and recall their knowledge in a highly condensed manner, thus making the learning effort more salient and much more effective and efficient for these students than it is for those using matrices.

How did the students like using the software? A short 12-item questionnaire distributed at the end of the course shows that all students rated them highly as study aids, as conceptual organizers, and as useful teaching tools that are easy for instructors to learn and apply. Most felt confident in their ability to make maps or matrices and thought they would use them in other courses. Interestingly, most didn’t want to discuss their maps or matrices with the instructor, nor did they want them used as evaluation tools.

Finally, the relatively low learning curve and high ease of use of both software programs, particularly for matrices, leads us to the conclusion that, given modern technology, extremely sophisticated pedagogical strategies with successful outcomes are more than adequately supported by quite simple and readily available technologies.

CoBrowser: Surfing the Web Using A Standard Browser

K. Maly, M. Zubair, and L. Li
Department of Computer Science
Old Dominion University, Norfolk, VA 23529

Abstract: Co-browsing is a synchronous class of collaborative application, which allows a group of users to “surf” the web together. Such an application can be deployed in an education environment in several ways. For example, courses that are project oriented might require students to collectively research or explore information on the Web. In this paper, we describe CoBrowser, a prototype co-browsing system that supports multiple groups, CoPointer, and Chat sessions. In past, co-browsing architecture have been based on either a proxy server or required a specialized plug-in for the web browser. The proxy server based approach is complex and is not scalable. The proposed CoBrowser addresses both these limitations and works on any platform that supports a graphical Web browser with Java capability.

1 INTRODUCTION

Co-browsing is a synchronous class of collaborative application, which allows a group of users to “surf” the web together. Such an application can be deployed in an education environment in several ways. Few examples are: (a) Courses that are project oriented might require students to collectively research or explore information on the Web. A group of students may be working together to write a report on the subject of computer security. For this, students may decide to research the material together to identify papers, which they can use for writing the report. (b) Instructor holds a recitation session with a group of students to explain or elaborate on some concepts discussed earlier in the class. (c) An instructor may find it useful to use different media, such as animation and video available in a digital library, to explain a breadth-first search algorithm.

Recently, many collaborative web applications have been developed (Maly et al. 1997, Mshow 2001, Centra 2001, Helpmeeting 2001, Davis et al. 1998). Most of these approaches either require modification of the browser, are based on the X Window System protocol. However, these approaches do not lend themselves easily to a group of users working on multiple platforms (such as Unix, Windows NT, MacOS, and Windows2000) concurrently and spontaneously. Clearly, it is no technical problem to write a distributed software system that runs on all participants' machines and has the desired functionality of synchronizing their browsing. However, in today's world, people are constantly on the move working from different machines and are unwilling to go through a complex install process to join a group session spontaneously. One should add that it is a technical problem to write such a system to work on all platforms. The second approach is based on the use of proxy server that is responsible for coordinating and delivering content to all the participant browsers. This
requires only minor modifications in a user's browser but the approach has turned out to be fraught with great technical difficulties that nobody we are aware of has completely solved. In (Davis et al. 1998), we describe these and our own initial proxy approach.

This paper describes an approach that works on any platform that supports a graphical Web browser with Java and JavaScript capability and is easy to implement. Most new Web browsers, such as the Netscape and Microsoft Internet Explorer, have this capability. Also, in this approach it is not necessary for every user in the group to be on the same platform. It is feasible for some users in the group to use a browser on a Unix machine, while others use a browser on Microsoft Windows. In past, co-browsing architecture have been based on either a proxy server or required a specialized plug-in for the web browser. The proxy server based approach is complex and is not scalable. The proposed CoBrowser addresses both these limitations and works on any platform that supports a graphical Web browser with Java capability. Another advantage of this approach is that it does not modify the browser. Coordinated browsing can be integrated with audio to enable users to speak while browsing. However, this paper will only discuss the coordinated browsing architecture and its implementation.

The rest of the paper is organized as follows: Section 2 gives an overview of the architecture of the CoBrowser, Section 3 discusses the basic operation, and in Sections 4 and 5 discuss additional features. Conclusions and future work are detailed in Section 6.

2 COBROWSER ARCHITECTURAL OVERVIEW

CoBrowser is a multi-group co-browsing system. That means it allows several co-browsing groups existing simultaneously without interfering with each other. A typical co-browsing group consists of several participants who can surf the web together. CoBrowser provides the following functionality for a co-browsing group:

- When a user in the group loads a document from a site in a co-browsing session, the same documents gets loaded on all the other users' Web browsers.
- When a user resizes his browser window or drag the scroll bars in his browser window, all other users in the same group will get the same changes in their browser windows.
- If one user loads a local file into his browser (either drag and drop a file icon or use file open), all the other users in the same group will see that file in their window as well.
- When a user points to somewhere in his web page, any of other users in the same group can see that pointer.
- When a user wants to talk with other users in the group, he can enter the group's chat room.

The key idea of CoBrowser is to monitor a user's activity such as opening a new URL, resizing his browser, scrolling the browser window, and etc., and then communicate this information to other users' browsers in the group. The other users' browsers on receiving this information perform the same activity such as download the same document or resize it's own window or drag the scroll bars. We use Java and JavaScript technology to implement our system. As seen
in Figure 1 the CoBrowse system consists of software for a Central Service (CS), a collocated Webserver (WS) and a Co-browsing Server (COS). At the client side we have users that have JAVA enabled browsers and that form mutual exclusive (this is only a limitation of the current implementation) groups of surfers that share the same experience.

![Diagram of CoBrowse system](image)

**Figure 1:** Multi-group architecture for co-browsing system.

### 3 COBROWSER BASIC OPERATION

To illustrate the working of the co-browsing architecture, we consider the following scenario where a new user joins an ongoing co-browsing session of two users. In the ensuing explanation we shall use always one group of users. Our system has been implemented to handle a number of simultaneous groups. The code to handle multiple groups is extensive and actual is the main cause of tricky bugs because we need to keep separate data structures for each group's information. However, there is no fundamental architectural design feature that is needed to go from one to two or more groups.

**Registration Process.** The new user downloads a registration document served by the CS-WS, see Figure 1, when the user starts cobrowsing by clicking the appropriate link on the CoBrowser home page. This document has a Java applet embedded in it that has the information about all the existing groups and all the users in each group. The browser downloads a signed applet that requires certain privileges on the user machines and runs it.
The applet registers itself with the Co-browsing server. The applet registration process involves informing the CS that it is active and the port number at which it will be listening. Upon receiving this information, the CS updates its table of active Web browsers in the session. Note, due to security restriction of Java applets, the Co-browsing server (CS) and the Web server (WS) have to be on the same host. The Java applet security environment does not allow applets to communicate to any host other than the host from where it is was downloaded.

**Joining a Session.** A new user, user-3 joins the existing group: cobrowsing-architecture. A new window, CoBrowser Window, is opened. The Java applet gets the URL of the current document being viewed by the group and sends it to the CoBrowser window. User-3 can start co-browse in the CoBrowser window. The Java applet remains active until the user leaves the co-browsing session. Since all new documents are loaded into the new CoBrowser window, the embedded applet remains active in the old window.

**Co-Browsing in a Session.** User-3 clicks on a link that points to the URL http://www.some.site/doc1.html or he resizes or scrolls in the new window. User-3’s applet sends the request to the co-browsing server, which broadcasts the new URL or resize, scroll event to applets running on User-1 and User-2’s Web browsers. The applets, upon receiving the URL information, issue a request to their respective browsers to load the new document in the new window or resize it or scroll the bars.

## 4 COPOINTER SUPPORT

When a group of users use CoBrowser system, one user may want to point to a specific position of the CoBrowser window to draw the attention of other group members. To satisfy this requirement, we implemented a special feature -- CoPointer. When one user moves his CoPointer to one specific position of a Co-Browsing page, all group members’ CoPointers move to the same position. The CoPointer has the following features:

- The CoPointer always floats over CoBrowser Window.
- The CoPointer can be set and released.
- The group member who sets the CoPointer is the owner. Only the owner can lead the moving of the pointer and release it.
- The CoPointer will show the owner’s name.
- There is only one CoPointer in a group, so a member in a group can only set the CoPointer after an existing CoPointer is released.
- The CoPointer points to the same position of the Co-Browsing page of a group when it first appears.
- The CoPointer keeps pointing to the same position of the group members’ CoBrowser windows when the owner moves it.

This is actually quite difficult to achieve within our architecture. We could not without greatly increasing the complexity make the pointer be the typical pointer shape expected in distributed collaboration system. However, by using the browser window methods and properties provided in JavaScript, we implemented the CoPointer through a browser window. To create a CoPointer, we create new browser window that is a a page with the owner’s name and a
e which gives the appearance of CoPointer. "Pointer" is the name of the window title. To make browser window look like a pointer, we open the browser window as small as possible. We do so by opening the CoPointer at 100* 25 at (10, 10) of the screen, which is just big enough to hold the pointer image and owner's name. This browser window has no menubar, toolbar, locationbar, personalbar, and scrollbar, and not resizable. A snapshot of a cobrowsing session along with the CoPointer is shown in Figure 2.

![Figure 2. User 1 and User 2 in a chat session.](image)

Because the CoPointer need to be coordinated with the instances at other users, the relative position of CoPointer to the CoBrowser window instead of the absorption position of the monitor is recorded and compared. When a CoPointer is set, a timer is turned on to check the relative position of the owner's pointer periodically. Once the relative position is changed, the new position is sent to CoBrowser server. Then CoBrowser server broadcasts the information to other group members whose pointers will be moved to the new position accordingly.
When a user joins or leaves a group, we need additional checking for CoPointer system. The group pointer status records whether a CoPointer of this group has been set, and the group pointer position records the current position of the group’s CoPointer. When a CoPointer owner leaves a group, the pointer status is checked. If the CoPointer is still set, an alert pops up to warn the user to release the pointer before leaving the group. When a user joins the group, the group pointer status and position are checked. If a CoPointer has been set, a pointer window is shown on the position of the CoBrowser window indicated by the group pointer position.

5 CHAT SUPPORT

To alleviate the problem of not having audio yet available in our system we added as a short term solution a chat facility. We simply took on of the many free-ware JAVA chatbox classes and integrated it into our CoBrowser. The session management issues for Chat are similar to the CoPointer issues. A snapshot of a chat session along with a cobrowsing session is shown in Figure 2.

6 CONCLUSION

This paper describes a co-browsing architecture that allows a group of users to “surf” the web together. The architecture works with any graphical Web browser that supports Java applets. The users may potentially be geographically separated and working on different platforms. The system has been extensively tested for single and multiple groups and is available for demonstration from a server we run here at Old Dominion University: http://www.cs.odu.edu/cobrowser/. Source code licenses are available from the University (one company is using the software for a 'helpdesk' system) and we will make code available also for non-commercial, academic research teams. We are in the process to test the scalability of our architecture. Support for page annotations will also be included for the pages placed in a tour where a group of users can follow a prescribed tour. Providing a means for such asynchronous use will facilitate the creation of reusable courseware materials. It also allows greater flexibility for large groups of students working together whose respective time constraints (work, parenting, etc.) would otherwise prohibit traditional collaborative methods. Once the complete Java Media APIs are available, audio will also be supported with the co-browsing architecture. This feature will enable co-browsing participants to have simultaneous audio and web browsing explorations.

Acknowledgment. We would like to acknowledge W. Haiyan for implementing the CoPointer support.

Design and Implementation of Java and Flash Programs for
Teaching and Learning Elementary Number Theory

Yiu-Kwong Man
Department of Mathematics, The Hong Kong Institute of Education
10 Lo Ping Road, Tai Po, New Territories, Hong Kong
Email: ykman@ied.edu.hk

Abstract: Mathematics is widely perceived as an abstract subject to learn. However, information technology can be used as a tool for enhancing the students' understanding of the abstract concepts behind and also arousing their interest in learning a variety of topics of mathematics. This paper reports the design and implementation of Java and Flash programs for teaching and learning elementary number theory in the Hong Kong Institute of Education. Illustrative examples with screen dumps for topics such as Greatest Common Divisors, Eratosthenes Sieve, Prime Number Distributions and the Chinese Remainder Theorem will be provided.

Introduction

Mathematics is widely perceived as an abstract subject to learn. However, information technology can be used as a tool for enhancing the students' understanding of the abstract concepts behind and also arousing their interest in learning a variety of topics of mathematics. This paper reports the design and implementation of Java and Flash programs for teaching and learning elementary number theory in the Hong Kong Institute of Education. The programs are aimed at providing an interactive, flexible and user-friendly environment where instructors and pre-service student teachers can use it for teaching and self-learning purposes. Illustrative examples with screen dumps for topics such as Greatest Common Divisors, Eratosthenes Sieve, Prime Number Distributions and the Chinese Remainder Theorem will be provided. We hope our experience could be shared with those who are interested in developing interactive courseware in their own institute.

Design and implementation of our programs

Our attempt to integrate information technology elements into the number theory module is in fact part of a Teaching Development Grants Project being funded by HKIEd. The end product will be a comprehensive mathematics website hyper-linking all useful module materials, resources and self-design programs for easy browsing and use by students and instructors for teaching, self-learning or revision purposes. To cope with these ends, we have chosen Java and Flash as our basic programming tools in consideration of their portability, flexibility and versatility in web design. As a mathematics educator, we do believe that merely drills and practices derived from a text-based format should be prevented (Kennedy and McNaught, 1997). We do not favor a computer program or software, which is simply an electronic book. In our design, we have incorporated some basic features in our computer programs, which reflects well our teaching philosophy and pedagogy of the subject concerned. For instance, we designed an interactive Flash program to illustrate how the Eratosthenes Sieve can be used to find out primes out of the first 100 natural numbers step by step (see Fig. 1). This feature is what we call "dynamic teaching", which means to exploit the computer's ability to help explain abstract ideas or concepts which instructors may otherwise find it difficult to elaborate using transparencies, or chalks and blackboard only.

A criterion for effective teaching and learning is whether we are able to make material to be taught both interesting and stimulating. Another feature of our programs is to incorporate interesting animations to let students realize that the idea of certain important theorems could be originated from our daily life. The famous Sunzi Theorem (also known as the Chinese Remainder Theorem) is in fact a good illustrative and motivating example on this aspect. We designed an animated version of the Sunzi problems by Flash (see Fig. 2) and motivated students to formulate a general method of solution before a formal introduction of the theorem using the modern mathematics symbols.
One of the major uses of computer in education is to perform simulations. For the topic on the Distribution of Primes, we implemented the interesting spiral distribution of primes as discovered by Prof. Ulam in 1963 (see Fig. 3). Students can use the program for exploration purpose by changing the initial value of the spiral and observe the distribution pattern of primes. Another feature incorporated in our design reflects our belief that learning by doing is an important process in learning mathematics. For instance, we implemented a Java program to stimulate the scenario of computing the greatest common divisors of two integers using the Euclidean Algorithm, which would otherwise be done by pencil and paper in the traditional learning mode (Man et al, 1999). A screen dump of such as design is show in Fig. 4.

Figure 1: Eratosthenes Sieve

Figure 2: An animated version of the Sunzi Problem

Figure 3: Ulam’ s Spiral of Primes

Figure 4: An interactive program for computing GCD

Concluding remarks

We believe that the computer technology and the world wide web have a major role in the support of teaching and learning nowadays. Traditional delivery of certain subjects, such as number theory, can be enlivened more by suitable incorporation of computer simulations, animations and interactive computer activities. We hope our discussions in this paper could arouse those who are interested in developing interactive courseware in their own institute and would share their valuable experience with us in the near future.

Acknowledgments

The author would like to thank the Teaching Development Grants Committee for financial support of this project.

Abstract: Pre-service teacher education must prepare the students to effectively integrate technology into their teaching. But how to do that without the aid of teaching method disciplines, with no computer lab and no budget for software? Those challenges are faced in a project for the initiation of computer use in education that is developed in a Science teacher education program. Adopting a project-based learning strategy, students build products as webpage collections and multimedia tutorial, in a cooperative work and using creative ways. A “virtual computer lab” was structured with students’ computers, in their home. Different shareware and freeware are used to develop the products. The tasks are developed in agreement with a schedule that doesn't coincide with the classes. The teacher plays a role of to challenge and to provide pedagogical and technological support to the students. The results of the experience are significant and stimulate the following of the project.

The computers are being used in Brazilian elementary and high schools. By other side, our pre-service teacher education programs still behave as if that resource yet didn't there be while pedagogical. Our colleges and universities, in their majority, do not use computers in teacher education – we have what we call a techno-absence in the teacher education. Our teacher education programs lack a learning technologically rich environment necessary to allow future teachers to develop a critical evaluation about educational applications of information technology (IT) and to discover how to use computer in the schools.

When we decided to incorporate IT - and not to teach computer – into our Science Teacher Education Program we found a first challenge: the teaching methods disciplines couldn’t do the job. The difficulties to infuse IT are of several orders, but certainly the fact that the teacher education faculty still don't feel prepared to effectively use IT in their classrooms is the main one. (Bosch, Cardinale, 1993; U.S. Congress, OTA, 1995; Marinho, 1998).

To face that challenge, since we could have the contribution of teaching methods disciplines, we created PIPeTI (the acronym for Information Technology Pedagogical Initiation Project). The Project is being developed, since 1999, into the Cytology course.
that integrates the specific subject curriculum and is offered to the students in their first semester at the University. The students would be initiated into educational use of IT through projects developed as tasks performed by teams.

But it was not easy to start the Project. We have no time to the tasks, since the discipline has a lot of themes to be developed. That time problem had been overcome when the Project became an outclass activity. Another problem: we lack a computer set to be used by the students. So, students used their own computers - we created what we called the "Project's virtual lab" to overcome that hardware lack. Another problem: we have no budget to software. So we used shareware, freeware or evaluation versions of software, with special attention to intellectual property rights.

The Cytology's professor has the role of providing the pedagogical and technological support for the students.

The cell is the Project's main theme. Some students developed web pages to be used by children; others were challenged to build multimedia tutorials to be used in Biology classes with high school students or at the higher education programs. This way, our students could use try several software: Microsoft FrontPage, HotDog, HotMetal Pro, VisualClass (a Brazilian software for multimedia developing), Neobook for Windows and others.

Our evaluation pointed that the Project shows a feasible and relatively simple option to incorporate IT into pre-service teacher education. Our students, both in interviews and in comments made in class, stated that they felt that they were doing the work of a real teacher, creating with IT something they would be able to use later in their own classrooms. The Project is a valid experimentation of educational use of computer, leading the students to test the potential of that technology as a teaching resource. And, in a very interesting way, our Project used the space of a so-called specific content discipline to carry students to think pedagogical strategies for using computer, associating content and technological procedures into teaching-learning.

The project continues also as a possibility of demonstrating that the pedagogical qualification doesn't need to be restricted to teaching method disciplines.

Abstract: The mission of the NetPro European project is to develop project-based learning through Internet. The NetPro project is creating tools and services to facilitate communication and collaboration between distant students, and to manage access and control of project deliverables. NetPro project teams form cross-institutional learning communities. This new learning environment is a distributed system that facilitates sharing and peer reviewing of project deliverables and interaction in special interest group discussions, regardless of how studies are organised locally. The outcome of the project also includes practical handbooks for students, tutors and trainers to support them in making full and effective use of the learning environment. NetPro methodologies and tools are being developed by running pilot projects: the four streams of pilots are briefly described in the paper. A formal evaluation process is an integral part of the project and its preliminary outcomes are discussed.

Introduction: the NetPro project

NetPro is a European project that develops methodologies and tools for supporting network based project learning within the engineering curriculum. The unique approach applies principles found in collaborative (Johnson & Johnson, 1996), constructivist (Korhonen and Valimaki, 1995) and self-directed learning paradigms (Knowles, 1990). Computer networks are already used for distribution of learning materials, discussion based collaboration, submission of work, etc. However, there are no good tools available to support student-centred project-based learning activities. The NetPro project is creating Internet tools and services to facilitate communication and collaboration between distant students, and to manage access and control of project deliverables as well as electronic publishing. These tools simplify the management of project-based learning activities, saving time for staff and students. In NetPro, the project teams may naturally form cross-institutional learning communities. The outcomes of the NetPro project also include practical handbooks for students, tutors and trainers to support them in making full and effective use of this learning environment.

Project Based Learning and the net

Project based learning is a common form of collaborative pedagogy in engineering education. There are already many initiatives where advantages of new technology are being applied to support project learning (Acuna et al., 1996; Collis, 1997; etc.). In our approach the different project teams form a learning community where learning within and between international project teams is supported. This happens through sharing and peer reviewing of project deliverables, and interaction in special interest group discussions. A "deliverable" is a document submitted for assessment or review, such as an engineering design, a progress report, or a review of another group’s work. The learning environment developed in the NetPro project focuses specifically on supporting project-based learning in international and multi-institutional contexts. It is based on process models with specific learning phases, and participants with precise roles. The custom Internet tools and services facilitate the communication and collaboration between distant students, as well as control of project deliverables, access to documents and electronic publishing.

For tutors the NetPro learning environment provides management tools, e.g. indexing of projects and their required deliverables and setting-up of collaborative learning activities. For learners tools are provided for distribution and sharing of project deliverables, collaborative learning activities, peer assessment and access to project and learning related information sources. Improving the efficient use of tutors' time is achieved through the Project Deliverables Centre database, part of the NetPro learning environment. It provides a structured system for allocating, monitoring and collating assessed work and for communicating with the student groups.
Inter-institutional activities

The benefits of network-based learning can be demonstrated within an institution, but they naturally lend themselves to inter-institutional working. The NetPro system has been designed to support collaboration between students from several universities. Most European universities follow similar curricula in the engineering field so in principle it is possible to have joint activities. However the philosophies and working practices of the various institutions are so diverse and ingrained that it would be futile to aim for a common structure, so the goal is to provide meaningful learning tasks for all participating students regardless of how their studies are organised locally. The first problem is working language: if the students do not share a common language then there is no point in expecting them to work together. The second problem is synchronising course content and phasing: cooperation is only possible if the classes study the same topic at the same time of year. If these two conditions are satisfied then joint working is possible. Experience has shown that cross-institutional co-operation is difficult to implement and the inevitable obstacles can only be removed by a motivated project staff.

Using an intranet to provide notes for students will usually entail some locally specific information, and this must be identified before the resource is shared. The NetPro learning environment takes full advantage of the inherently distributed nature of the world-wide web to allow local information to be embedded in a centralised system, thereby avoiding the difficulties of imposing uniformity. Even when student groups in different institutions are working on the same project, each group can be assessed according to local practice.

The Network Based Learning Environment

The NetPro learning environment is a distributed system where each participating pilot site has its own local learning environments integrated to the collaboration space provided by the project. The collaboration space is a database application with user specific Web interfaces which facilitates sharing and peer reviewing of project deliverables, and interaction in special interest group discussions. The application is used through a standard Web browser. Users do not need any knowledge of Web authoring or special tools to use the application.

Project Deliverables Centre

The Project Deliverables Centre (PDC) is the core of the NetPro learning environment. It has two primary purposes: to support knowledge sharing between students, and to ease the tutor's workload in high level project management. Students deliver their work for assessment or review by depositing it in a file and uploading the file to a Web server using a custom GUI. The main view of the PDC is a graphic which shows which items have been delivered, using a coloured-smiley metaphor (Fig.1).

Features of PDC

The Administrator view of the PDC helps the supervisor to modify data within different projects.
create, modify and delete PDCs
create, edit and delete student groups for a PDC
define deliverables for a PDC
assign groups for peer reviews
view peer assessment results

When a new student-group is created, the system sends a computer-generated email to the student project manager giving the identity and password for access to their record, and other operational details. This student can then update their own group's data:

- view PDC
- edit group details
- deliver work for assessment or peer review
- access other groups' work for reviewing
- assess group members' contributions to the joint effort (peer assessment)

Peer review

Reviewing other groups' work can enhance the learning experience of project students, for both the reviewer and the reviewee. Different groups can design parts of the system using different approaches. After the designs have been completed and documented the groups can do peer reviews about these different approaches and see their benefits and drawbacks, so the all the groups can learn from each others' work.

The PDC allows the tutor to allocate cross-group review tasks, and it displays their status so that each group knows when their reviewee's work is available for review and when their own work has been reviewed. These peer reviews form part of the assessment requirement and are, like all deliverables, delivered by entering their URL into the appropriate field in the GUI. It is thus just as easy to review the work of a group in a remote institution as it is within one's own site.

Peer Assessment

The NetPro learning environment also includes facilities for the students within a group to assess one another's contribution by awarding grades against a given set of criteria. Each student can see whether their colleagues have completed this task, but the values awarded are concealed until everyone has done it. It is of course up to the supervisor to decide how to use these data.

Discussion spaces

The problem of communication among the actors of the learning process is a general issue and goes beyond the boundaries of the Netpro project. A successful exchange of information among students is, of course, very beneficial for learning, but it is not possible to force them to talk to one another constructively. With inter-institutional working, the problem is made worse by the impossibility of using face to face communication that must be replaced by some other tool. In NetPro, each project has available one or more open discussion spaces, called Special Interest Groups (SIGs). They are a sort of bulletin boards where course participants can read and write messages. Messages posted on SIGs are public: every project member can read and reply to them.

The Handbook

NetPro tools are, of course, very helpful to anyone developing network-based project learning. Tools alone, though, are not enough: adequate documentation and help must support the actors of the NBPL process to understand the methodologies and put them into practice. To complement the tools we are preparing a handbook which provides a step-by-step guide through the process, and each step of the process includes a planning/implementation tool. The handbook will include:

- checklists (e.g. process checklists or checklists on copyright etc.)
- templates (e.g. Word documents for course planning)
- case studies of good practices
- curriculum models
- guidelines/models for learning project manuals
- design guidelines for course web sites ("House Style")

The handbook includes extensive case studies that synthesise the experience made by the project partners in the pilot courses.
Pilot courses

The goal of the pilot courses is to test and evaluate the network based project learning methodologies, environment and tools developed in the NetPro project. The pilots' learning environment consist usually of a problem specification and assessment requirements that may be supported with related network based learning material and documentation. Traditional lectures, tutorials and laboratories integrate the NBLE. The students study the provided material and do what the problem requires. The tasks require subject-specific engineering knowledge and project-management skills to be applied. This work of students is defined as the student project, and it forms the context in which the NetPro team is developing the NBLE. The pilot courses are implemented in the real study context of students, i.e. they are fully integrated into the curriculum of their study programme and the students earn credit units by carrying them out.

Because curricula at the partner universities differ considerably and the project makes no attempt to harmonise them, common areas of subject matters in information technology have been identified and the pilot courses have been designed around them. Each pilot site is responsible of organising the project activities locally in the way that fits its curriculum and local teachers and tutors take care of the teaching related to the project.

During the life of the project, four streams of pilot courses have been running and evaluated by the project partners:

- Interactive Web Application (http://pww.evitech.fi/nble/studies/courses/)
- Multimedia Authoring and Applications (http://pww.evitech.fi/nble/studies/programs/e4098/courses)
- Weather Station (http://pww.evitech.fi/netpro/pilots/ws/)
- Electronic System Design (http://www.esng.dibe.unige.it/netpro)

Within each stream, several individual pilot courses have been designed and carried out, in two separate runs of piloting activities. Because of the preliminary nature of the work and the institutional constraints, not all the pilots provide a full implementation of all NetPro features. Instead, each pilot usually stresses one or more aspect of the pedagogical scenario involved.

The goal for the students' projects in the Interactive Web Application pilot course is to design and develop an interactive information service application on the Web. The project integrates the knowledge and develops students' practical skills e.g. in application development methodologies, visual design, programming, project management and teamwork. Students' projects are organised as an application development process that covers the phases from an idea to a product. Students practice the use of basic methods and tools needed in project definition and planning, requirements definition, application design, and implementation.

The learning projects in Multimedia Authoring and Applications produce a multimedia product or service. The exact topic of the project was left open for each pilot site to define as the related course objectives and arrangements differ. The common subject matter was the design and production process of multimedia applications including: information content, interactivity, visual design, methodologies and tools used in production.

The objective of the Weather Station pilot is to establish and gain experience of a NBLE in the fields of physics, electronics and software engineering. The design of a weather station is used first for demonstrating the development of a simple electronic system in which physics, electronics and programming knowledge and skills are essential. The first implementations of the Weather Station pilot have focused into analogue electronic design.

Electronic System Design (ESD) stream of pilots has produced a learning environment for digital electronic design, investigating especially the applicability of the NBLE approach in the context of introductory courses (Donzellini, Markkanen and Ponta, 2000). It has also verified the functionality of the NetPro tools for managing large numbers of project teams, as well as the possibility of implementing new formats for inter-institutional cooperation.

Course-specific learning environments

In addition to the general purpose project management structure, a NetPro course may need a specialised environment supporting the student in the project development. It may consist of technical and pedagogical resources, such as multimedia trainers and simulators.

We developed a learning environment for digital electronic design for the ESD stream of pilots, in view of their particular nature of introductory courses. They target a student population non-homogeneous in terms of background and motivation and, therefore, they cannot replace completely traditional lectures with project-based activities.
The core of the learning environment for digital electronics is represented by simulators specifically designed for educational applications. They are extremely useful to students in many phases of project development, from producing drawings of digital networks and timing waveforms to checking the behaviour of the blocks designed for the project. Their pedagogical orientation avoids the unnecessary cognitive overhead that the students should take for learning how to use professional simulation tools.

Feedback from students and teachers

A comprehensive evaluation of the NetPro project has been carried out by a partner institution, Scienter of Bologna, Italy. It covers not only the experiences of students and tutors at the operational end of the scheme but also the management of the NetPro project itself. The following are extracts and elaborations from the evaluation reports.

Students' view

Students' data and opinions related to various aspects of the course have been collected by means of an anonymous questionnaire. The evaluation report is based on the analysis of 350 returned documents. Below we show a brief synthesis of the opinions expressed by the learners about project-based learning:

- In general, students accepted to change their usual learning methodology.
- Learners appreciated to have more responsibility, more freedom and to work in a group.
- Although students show a high level of autonomy and maturity in carrying out their work, they still need some control and some guidance.
- Most found project-based learning closer to real-life cases and said that it makes learning much easier and more motivating.

The following views refer specifically to network-based project learning:

- Students would like to attend again a course involving network based project learning/project work. A few asked for some changes.
- Peer reviews were considered a good idea in principle, but many expressed concerns on their practical implementation.
- The interaction among students was, on the average, judged only marginal. Many complained about the scarce attitude toward communication of their peers and the overhead represented by the use of the SIG tools.

Of special interest is the synthesis of 99 questionnaires of the Electronic Systems Design 2 pilot (ESD2), because all the teams had the experience of the previous pilot course ESD1. The questionnaire was designed in a way to investigate the confirmation or denial of prior outcomes.

In fact, students confirmed many positive judgements expressed in the ESD1 evaluation. They, again, found NetPro useful, interesting and stimulating. They also appreciated more than before the possibility of working in teams, to learn to manage their own time and to develop material for the net.

A problem common to all pilots has been the reluctance of students in using SIGs. Many students found them time-consuming, awkward to use for the necessity of typing and using a foreign language, not able to provide timely information. In ESD2 we tried to encourage the communication on SIGs by assigning problems that required an intense exchange of information to define their final specifications. A comparison between the two project sites shows a vast increase of communication and an improvement on its quality.

Teachers' view

Teachers agree with students that project learning increases motivation of both actors of the learning process. They see NetPro approach as a very valuable one not only for project-based subjects, but also for those taught by traditional classroom-lecturing, where the project can form part of practical sessions and can be integrated into the curriculum. The main points highlighted by teachers concerning network based project learning were:

- NetPro tools facilitate management and supervision of projects
- Learning of personal skills is emphasised
- The sharing of knowledge is encouraged.
- The focus of the learning is on working processes, in addition to the factual content.
- Learners become the centre of the process, instead of tutors.
- Project work provides learning experiences that are similar to working life situations.
- The networked environment extends the boundaries of the learning community.

Key success factors identified by teachers were the following ones:

- The change in the tutor's role should be supported by the organisations.
Networked learning activity support learning well but they needs to be carefully planned (integrated in the local curriculum, explained to the students).

- Project teams' failure to meet deadlines causes heavy problems for the networked learning activities.
- Students need to be motivated and to clearly understand the benefits of project work.
- The use of peer reviews was seen (but not by everybody) as entertaining and exciting, but this approach should be introduced in the first phase of the project so that groups can have real communication.

**NetPro2: the continuation**

The project resulted in novel pedagogical approaches and an original set of network based tools that support project based learning (PBL). The large-scale evaluation of these tools proved their effectiveness. However, during the validation of the pedagogical models and tools, the need to extend the existing approaches and to develop new ones has been identified. Therefore, a new proposal for 2001-2003 has been submitted to the European Union, in order to continue the activity, under the name of "NetPro 2".

The novel pedagogical models to be developed will respond to the need for closer integration of vocational training to working life. It will be solved by applying models of network based collaboration used in modern work organisations. The learning models and network tools will also be piloted in further vocational education courses where students are working by combining their work projects as part of their curriculum.

Current stable technologies accessible to educational institutions do not support effectively innovative pedagogical approaches based on models of collaboration used in modern working life (i.e. work of geographically distributed teams). The intensive interaction required by such teamwork has so far not been possible without expensive investments in special technologies. The technology is finally approaching the stage where many threshold-type of products and services, such as Internet based audio and video communications, data format for structured document interchange (XML), meta-data standards for educational purposes (ARIADNE, IEEE/LOM), will be available for larger user communities.

NetPro 2 will take advantage of these emerging standards to develop more realistic collaborative pedagogical models. The partnership will focus on the transferability of the tools as the emerging standards make this feasible. The project will also start the preparation for the large scale transfer activity by prototyping the concept of "NetPro Learning Communities". The long-term goal is to develop a self-funding organisation for promoting and developing project based learning on an Europe-wide scale.

**Conclusions**

A successful network-based learning environment for project work has been developed. It is useful for local work, but is particularly convenient for inter-institutional working including international co-operation. It has been used on several pilot projects, and development is continuing in a new project. The feedback of students and tutors is generally favourable. In addition, a "handbook" for tutors (in on-line form) has been prepared.

Abstract: NetPro is an European project to develop methodologies and Web tools for collaborative project learning. The project is creating Web tools and services that facilitate the collaboration in cross-institutional learning communities. Tools for publishing, accessing and controlling of project deliverables have been developed, as well as tools to support collaborative activities such as peer reviewing of deliverables. The toolbox includes also a component for on-line peer assessment. The outcome of the NetPro project also includes practical Web based handbook for students, tutors and trainers to support them in making full and effective use of the network based project learning.

NetPro Project

NetPro is a European project that develops methodologies and tools for supporting network based project learning within the engineering curriculum. The NetPro tools facilitate communication and collaboration between distant students, and simplify the management of project-based learning activities, saving time for staff and students.

The project has developed an easy-to-use and functional set of Web based tools to support collaborative project learning. The tools are useful for local work, but are particularly convenient for inter-institutional working including international co-operation. The tools have been tested in several courses with more than 1500 users. The feedback of students and tutors is generally favourable. The tools significantly reduce the time that the instructor needs to spend on the administration of the student work. The tools are applicable in various pedagogical approaches where students need to produce work that can be uploaded into the Web for assessment or review.

Collaborative Project Learning on the Internet

Project based learning is a common form of collaborative pedagogy in engineering education. Although there are many variations of the project learning, often the collaboration between learners is strongly focused, if not limited, within one local project group. In the NetPro approach the different project teams form a learning community where learning within and between international project teams is supported. This happens through sharing and peer reviewing of project deliverables, and interaction in special interest group discussions. A "deliverable" is a document submitted for assessment or review, such as an engineering design, a progress report, or a review of another group's work.

NetPro Learning Environment
The NetPro learning environment takes full advantage of the inherently distributed nature of the World-Wide Web to allow local information to be embedded in a centralised system, thereby avoiding the difficulties of imposing uniformity. Even when student groups in different institutions are working on the same project, each group can be assessed according to local practice.

The NetPro learning environment is a distributed system where each participating pilot site has its own local learning environments integrated to the collaboration space provided by the project. The collaboration space is a database application with user specific Web interfaces which facilitates sharing and peer reviewing of project deliverables, and interaction in special interest group discussions. The inter-institutional learning activities have been designed to provide opportunities for collaboration between students from several universities, regardless of how their studies are organised locally.

For tutors the NetPro learning environment provides management tools, e.g. indexing of projects and their required deliverables and setting-up of collaborative learning activities. For learners tools are provided for distribution and sharing of project deliverables, collaborative learning activities, peer assessment and access to project and learning related information sources.

**Project Deliverables Centre**

The Project Deliverables Centre (PDC) is the core component of the NetPro learning environment. It has two primary purposes: to support knowledge sharing between students, and to ease the tutor's workload in high level project management. The main view of PDC is a graphic that shows which items have been delivered, using a coloured-smiley metaphor (Figure 1).

The PDC is an interactive database application that is used through a standard Web browser. User does not need any knowledge of Web authoring or special tools to use the application. The application can be linked to any Web page (or course site created with Web course tools) by inserting a single URL in the page. This URL is link to a script that interfaces with the relational database. The system has been implemented with mySQL and scripted in PHP, which are, in our case, running on an inexpensive Linux server.

![Figure 1: Main view of the Project Deliverables Centre.](image-url)

**Administrator tools**
The Administrator tools help the instructor to establish and maintain Project Deliverables Centres. The PDCs can be categorised based on the discipline and subject matter that the PDC is related to. Instructors, who want to develop cross-institutional co-operation around student projects, can group their related PDCs into a Learning Community. For maintaining a PDC, the Administrator view provides various forms to:

- create, modify and delete PDCs
- create, edit and delete student groups for a PDC
- define deliverables for a PDC
- assign groups for peer reviews
- view peer assessment results

The PDC software has been designed so that the instructor can include in the learning environment only the features needed in the particular course. Optional features include peer review, deliverable grading, peer assessment, and individual documentation (e.g. learning log, portfolio).

Student tools

When a new project group is created, the system sends a computer-generated email to the project manager giving the identity and password for access to their record, and other operational details. The project manager can then update the group details and insert the other group members into the PDC. Features of the student tools are:

- view the status of deliverables
- deliver work for assessment or peer review
- access other groups' work for reviewing
- assess group members' contributions to the joint effort (self and peer assessment)

The instructor has a possibility to choose from two different ways that the students can deliver their work for assessment and/or peer review. The files can be uploaded through a Web form into NetPro server, or by providing an URL of a file existing on any Web server. In both cases only the URL of the deliverable is inserted into the Project Deliverables Centre and the file is located on a Web server.

Further Development

The project resulted in novel pedagogical approaches and an original set of network based tools that support project based learning (PBL). The large-scale evaluation of these tools proved their effectiveness. However, during the validation of the pedagogical models and tools, the need to extend the existing approaches and to develop new ones has been identified. Therefore, a new proposal for 2001-2003 has been submitted to the European Union, in order to continue the activity, under the name of “NetPro 2”.

NetPro 2 project will develop new pedagogical models that are based on modern work practises, such as knowledge management and sharing, and geographically distributed teamwork. Current stable technologies accessible to educational institutions do not support effectively these kinds of innovative pedagogical approaches. The technology is finally approaching the stage where many threshold-type of products and services, such as Internet based audio and video communications, data format for structured document interchange (XML), meta-data standards for educational purposes (IEEE/LOM, SCORM), will be available for larger user communities.

Objectives of the Session

The objective of the session is to demonstrate the NetPro toolkit and show examples on how it has been used in pilot courses organised during the project. The procedure of setting up the learning environment and students' tools will be demonstrated. Participants will have an opportunity to try out the application themselves.

Intended Audience

Teachers and trainers interested in a tool that supports pedagogical approaches where students need to produce work that can be uploaded into the Web for sharing with peers, assessment or review.
AulaWeb: a WWW-Based Course-Support System with Self-Assessment and Student Tracking

Raquel Martínez, Angel García-Beltrán
División de Informática Industrial
Universidad Politécnica de Madrid (Spain)
raquelm@etsii.upm.es, agarcia@etsii.upm.es

Abstract: This paper describes AulaWeb and its implementation experience. AulaWeb is an interactive training, self-assessment and tracking system of the student learning progress about one subject. This intuitive and easy-to-use tool is use-restricted for students and teachers of this specific subject and the whole interactivity is carried out by means of a computer connected to Internet and a WWW browser. AulaWeb has been designed to be implemented for any subject to be taught. The system, with the ad hoc contents, has been used by more than one thousand of Computer Science students at the División de Informática Industrial of the Universidad Politécnica of Madrid (ETSII-UPM)

System description

AulaWeb is a WWW-based interactive training system and allows a student of a specific subject to study the subject contents, to deliver practices and to do self-assessment exercises (Martínez et al. 2000, García-Beltrán et al. 2001). Students and teachers only need a computer connected to Internet and a WWW browser to take advantage of all the application functions. The system architecture, the graphic user interface design and an on-line help system make easy the user interaction with it. The system uses a set of databases:

a. Subjects and users database, including students (personal data and learning activities record) and teachers
b. General resource database: subject theoretical contents, on-line calendar, references, WWW links, newsgroups and related software
c. Self-assessment system questions database
d. Electronic survey database
e. Access statistics database (by hour, day, month and year)

and includes the following four modules (the last three modules need a password authentication for students and teachers):

An information system module about the subject

This non-restricted module is open to all users and incorporates theoretical contents, general information about the subject: teachers, syllabus, frequently asked questions, timetable, calendar, bibliography, references, WWW links, related software, previous exams and practices and solutions, chat rooms (similar to ICQ), newsgroups and forums. No programming required: there is a system wizard in order to help the teacher to add or update contents.

A collect and deliver module of practices, homework and exercises

First of all, the teacher can use an assistant (no programming required) to publish an exercise for his group of students. Then each student can retrieve it and send, using an ad hoc form, an electronic file with the answer of the exercise in HTML, Word or another format. The file is stored in a documental database, and the corresponding teacher can access to it. Once the content of the exercise is revised, the teacher can mark it, and send his comments to the student. Also, the teacher can publish the exercise solution and controls the group of students that have sent it.
A self-assessment module

The self-assessment modules is based on a question database about the subject, with a friendly and easy-to-use interface for adding, updating and activate/deactivate questions. The students can configure an exercise depending on the number and difficulty level (five levels) of questions and the didactic units of the subject. The teachers can also configure exercises for a student or a group of students. The student can interrupt and postpone the end of the exercise in any moment, in order to revise the acquired knowledge. After that, the student can carry on with the exercise. When concluding it, the system allows the student the possibility to check his exercise and to compare his answers with the right solutions. The resolution of the test provides the user's level in that moment and updates the values of the database. The evaluation of the exercise is, therefore, automatic and the student and his/her teacher can access the results of the student self-assessment activities. So, the system allows the teacher to track the student progress during the courseware. Moreover, the system provides some statistical tools to compare the theoretical and experimental difficulty level of the questions and to revise the first ones.

A booking module of computers in labs for students

This user-restricted module provides the administration and management of educational and training resources. For instance, students and teachers can do the booking of computers and classrooms for the laboratory practices.

Results

AulaWeb has been applied at the ETSII-UPM since 1999 as a didactic support to all the computer programming courses taught in the Computer Science Department. Students and professors have been able to use the system anytime, from anywhere there were a WWW terminal, during the whole courseware. For example, during the last implementation course more than 500 students did more than 500 self-assessment exercises. The system have helped the students in these Computer Science subjects, and also assisted the professors to evaluate the students and to know exactly the level of the students and adapt their subjects to the students group they had to deal with.

AulaWeb is also been applying to high school students with learning problems in subjects like Algebra, Geometry, Arithmetics and Statistics.

Conclusions

A WWW system for the assistance of students and teachers has been developed. This software solution gives the possibility to each student to select his particular training trail and to contact to his tutor and other students. The system helps the teachers in tracking his students performance progress during the course periods. With the adequate contents, AulaWeb can be implemented for any subject to be taught.

Acknowledgements

The authors express their gratefulness to the Sociedad de Amigos de la ETSII-UPM for the support and to M. Aza, J.A. Criado, P. García, J. Granado, I. Iglesias, J.A. Martín, F. Ory, L.M. Pabón and A. Valero for their collaboration on the implementation work.

SPECIFICATION OF AN ONLINE PROGRAMME FOR SOUTH AFRICAN TEACHERS

Mashile Elias Oupa
Faculty of Education
University of South Africa
South Africa
mashieo@unisa.ac.za

Abstract: This paper reports on the development of an online teacher education programme for South African teachers at the University of South Africa (UNISA), a distance education institution. Currently, no online courses are offered in the faculty of education. The Internet is used only for email communication and administrative support. The paper represents work in progress and reports on the specification endeavours in the development of a Master of Education programme. Three areas regarded as critical in specification are addressed, namely technology, teacher- and student characteristics.

Background

Online education is reported in the literature as a mechanism that can be used fruitfully in distance education programmes (Muirhead, 2000). Higher education institutions are turning towards online education in order to meet the needs of clients who cannot attend classes on a full-time basis. Time and cost to clients are advanced as major reasons for the move towards distance education (Raymond III, 2000). The University of South Africa has been providing distance education for over fifty years, mainly through print-based materials circulated through the postal system. Telephone, audio and video conferencing infrastructure are well-developed although the latter is not used extensively. Recently, a students online system was launched which provides electronic mail contact with lecturers and administrative support. The study material that is available online is equivalent to the print-based material only. The practice of dumping study material used in the print version (or in the contact sessions in full-time study) is not regarded as good practice in online education (Volery & Lord, 2000). As such, an online programme for Masters of Education (science education) is being developed. Besides increasing accessibility and embracing institutional transformation (Volery & Lord, 2000), the rationale of developing an online programme is to equip teachers with the knowledge and skills to use computer technology in schools. The premise is that teachers need a model that they can follow in implementing a paradigm shift from transmitter of knowledge to mediator of learning and other roles prescribed in the new Outcomes-Based Curriculum in South Africa. A study by Muirhead (2000) indicated that teachers who use computer technology often do not have confidence because they received no formal training in using the technology. The development of the online programme was started in January 2001 and will be piloted in the 2002 academic year. The project is at the specification stage.

Specification

Specification was informed by the following principles. Enhancing teaching effectiveness in online education requires consideration of three main variables, technology, instructor characteristics and student characteristics (Leidner & Jarvenpaa, 1993; Volery & Lord, 2000). Technology characteristics relates to reliability, quality and medium richness. A rich medium is one that allows for both synchronous and asynchronous communication and supports a variety of didactical elements (text, graphics, audio and video messages). Instructor characteristics include attitude towards technology, teaching style and control of the technology. When a number of instructors are involved, as in a programme, instructor characteristics becomes crucial. This is particularly evident when instructors complain that the development of an online course is labour intensive. Of particular interest to this study is student characteristics. In the literature variables such as prior experience, having a computer at home, personality, the geographical area of origin and self-efficacy seems likely to influence enrollment and performance in online courses. In a study of social influences and Internet use, Klobas and Clyde (2001) reminds us that quality and access are not the only factors associated with online education (Internet). They aver that the context is also critical. The results of their study indicated that social influences on Internet use for work and study are very broad and probably very powerful. Social influences significantly change perceptions of the Internet, its value, and a person’s ability to use it.
The context of the project is therefore essential. Currently, approximately fifteen students are registered on the print-based version of the Master programme - raising questions as to its accessibility. The university does not provide tutor sessions for postgraduate studies, especially in courses and programmes with small student numbers. Interaction and collaboration among students is therefore problematic. All the students registered for this programme are school teachers, mostly in secondary schools. Six staff members are involved with the instruction of ten compulsory modules which weighs 50% of the programme. The other 50% is a made up of a dissertation of limited scope. Assessment is through written assignments, examinations and portfolios.

The product of the specification endeavour is now described. The transition to online education provides opportunities for restructuring the programme. Collaborative learning rendered impossible by geographical constraints becomes possible. Action learning, which is necessary to enhance development in the workplace, especially in developing nations, becomes possible. An outcomes based education approach can also be accommodated. Learning can thus be structured to address issues and problems in the workplace rather than covering content. The dichotomy of tutored coursework (examination based) and research (dissertation) can be transformed into an integrated action learning experience. Students will interface with a limited number of lecturers, thus enhancing the learning experience. Based on these considerations, the following structure of the programme is suggested.

The programme will follow the action learning approach. Courses will be issue-led and problem based. Each lecturer will be responsible for managing a collaboration unit of 20 candidates. Learning sets of 5-6 candidates will be drawn from the collaboration unit. All material and interactions will be online. Since tutors cannot be employed to lead sets and thus constantly monitor online interaction, lecturers will be set advisors for scheduled compulsory set meetings. Other communication will be through the web forum and email. For coursework, interactive computer-based systems will be used (eg WebCT). To entrench online education and action learning features in the programme, the coursework component will be marked as follows. Participation in web forum (5%), participation in set meetings (5%), group assignments (10%) and portfolio of an action learning project (15%).

Successful specification hinges on the three principles described earlier. Challenges to meet the specification above rests in the following. The availability of suitable technology in the university infrastructure. Candidates will probably need support in accessing the technology. Commitment from management to finance such endeavours is therefore pivotal. A change in university tuition policy to accommodate diverse assessment is needed. Professional development needs of the staff needed to implement the project and freeing them from other duties need to be prioritised. Finally, issues related to student characteristics needs to be considered. The social transformation imperative requires capacity building of previously disadvantaged candidates. The latter may however not be socialised into taking perceived risks associated with online learning. The immediate benefit of going through all the trouble of learning the technology before actual learning, and the paradigm shift required by action learning, may pose problems in enrollment for the programme.

Abstract: We have developed three component-based software applications, and fifteen reusable software components for English as a Foreign Language (EFL) education. Componentware is an object-oriented software development method that uses components as essential building blocks. An advantage of the componentware methodology is in meeting requirements for computer usage in the real educational world. We can categorize teachers into three groups: advanced, intermediate, and beginners. The advanced group develops components, and provides them to the intermediate group; the intermediate group is able to use components for their own unique designs and can provide new educational software, which they provide, using pre-existing components, to the beginner group—the beginner group is able to make use of the software in classes. This flow enables computer-based education to be implemented more effectively. All of the three applications described in this paper can be used for EFL education. This paper describes the developed components and applications.

Background

Although a large number of multimedia computer-based teaching materials have been developed for both classrooms and self-instructional learning, in practice, these materials have not become prevalent. Some of the reasons are that 1) commercial software is for the most part too costly, 2) after a teacher or student obtains an educational software package, the application is likely to become obsolete, possibly after one year, due to rapid changes in multimedia technology, and 3) commercial software is designed to be non-specific/universally used, and thus is often unsuited to individual classroom requirements because instructional methods (and student comprehension) are highly variable and specific to unique educational environments. One solution to this problem is for the individual teacher to create his or her own computer-based teaching materials in the same way as he or she makes printed materials with word processors. However, developing multimedia teaching materials requires computer programming, which may be an insurmountable obstacle for teachers who want to develop such materials. As a solution to this dilemma, we propose a componentware methodology. Componentware is an object-oriented software development method which uses and integrates components as essential building blocks (Aoyama, 1996; Jacobson et al., 1995; Udel, 1994). Componentware methodology allows us to develop software systems in both a top-down and a bottom-up fashion. This is an essential aspect of educational software systems development. The bottom-up approach can allow a teacher to easily develop a new educational software system by assembling pre-existing components. In the case where a teacher wants to develop a new type of teaching material, the top-down fashion can be adopted to break down a teacher’s requirements into functionally modular components. Another advantage of the componentware methodology is in meeting requirements for computer usage in the real educational world: We can categorize teachers into three groups—an advanced group able to develop original program components, an intermediate group able to assemble pre-existing components into educational software, and a beginner group who can use pre-existing educational software systems in their classes. The advanced group develops components, making full use of their specialized knowledge and provides them to the intermediate group; the intermediate group is able to make educational software by using given components (i.e. they can produce specialized software systems without specialized knowledge); and the intermediate group is able to provide educational software to the beginner group—the beginner group is then able to make use of the educational software.
in their classes. If this flow from the advanced group to the beginner group is made to function smoothly, computer-based education can become more effectively and easily implemented.

Our aim is to create this flow, on an experimental basis. In researching how multimedia computer systems and software could best contribute to education, we focused on the educational field of English as a Foreign Language (EFL). In the EFL field, teachers have not only been using multimedia devices such as tape-recorders, CDs, and videotapes, but also have been using computers from the advent of the institutional computer lab. In order to increase the developmental-efficiency of both EFL education software and reusable components, we divided the ingredients for EFL education into three parts, that is, a) English Skills (listening, speaking reading, and writing), b) Learning Methods (the practice and it's ascertainment), and c) Supplemental Tools (tape recorder, video, dictionary, and etc).

Next, we will describe the component-based educational software and software components that we have developed from the three ingredients of EFL education, above.

Description

We have been developing educational software and software components for EFL education using an iterative and incremental method. First, we developed "a Hypermedia Pronunciation Power Program (HPP)" (McCarthy, Matsuno, and Swan, 1996) (see figs. 1,2), which aimed to help EFL students improve their listening and speaking skills. We defined nine reusable components in developing the HPP program. These components can be used to develop educational tools for the English Skills of listening and speaking; improvement of ability though practice and it's ascertainment, in terms of Learning Methods; and, HPP allows for the use of Supplemental Tools: a tape recorder and video. Second, we developed a “Multimedia Authoring System for Teaching EFL (A-MATE)” (Matsuno, Tsutsumi, and Ushijima, 1999) (see figs. 3,4), which aimed to help a teacher belonging to the “beginner group” to make several types of quizzes for teaching EFL. We reused five out of the nine HPP components, and made two new components in developing the A-MATE program. These components can be used to develop educational tools for strengthening Learning Methods. Third, we developed a “Multimedia Bilingual Dictionary for JFL/EFL Learners (MBD)” (Gilbert and Matsuno, 2000a) (see fig. 5). MBD is a multimedia bilingual dictionary for beginning students of Japanese or English. We reused four components out of eleven pre-existing components, and built four new components. These components can be used for developing various dictionary tools (Supplemental Tools). Currently, we now have fifteen components, and are developing a new educational program, a “Multimedia Vocabulary Concordance and Academic Lexis (VOCAL)” (Gilbert and Matsuno, 2000b) (see fig. 6), for students in the Sciences using components which enable students to strengthen reading and writing English Skills. Below, we will describe in more detail these three programs as well as the program currently in development.

A) HPP: Hypermedia Pronunciation Power

HPP aims to help EFL students to improve their listening and speaking skills. HPP includes video clips of a native speaker pronouncing individual sounds, words, and sentences. Students can then imitate mouth positions as well as the sound of a native speaker. In addition, students can record their voice and can compare graphically their intonation with that of a native speaker. Moreover, students are able to practice their listening with environmental noise added intentionally. This feature is useful for EFL advanced-class students who can understand the speech of native speakers relatively well, but have difficulty with variation and environmental interference.

HPP is composed of five sections for EFL practice: the Explanation Section, Listen and Repeat Practice Section, Visual-Voice Section, Minimal-Pair Practice Section, and Quiz/Games Section

The Explanation Section

The Explanation Section presents a diagram of the organs of speech, the phonetic alphabet, and a consonant and vowel chart in this section.

The Listen and Repeat Practice Section

The Listen and Repeat Practice Section allows students to do "listen and repeat" type exercises (see fig. 1). Students can select the vowels/consonants, and then also select those words they wish to practice. As shown in Fig. 1, students can listen to and see a video of the teacher. Thus, students are able to study the tongue position, mouth, and lip movements produced by a native speaker.
The Visual Voice Section

The Visual Voice Section allows students to see both the waveform and the spectrogram of the phonemes of a word which the teacher pronounces (see Fig. 2). HPP also allows students to record their own voice, and shows this waveform and spectrogram as well. Thus, HPP allows students to compare their voice with the teacher's, both visually and aurally. This method has been used for teaching speech pronunciation to the deaf (Potter, Kopp and Green, 1947) as each phoneme has a characteristic (visually apprehended) waveform and spectrogram.

The Minimal-Pair Practice Section

The Minimal-Pair Practice Section allows students to practice listening to minimal-pair words. In Japanese, for example, there is no difference between the "th"-sound and "s-sound," and the "l"-sound and "r"-sound. Thus, typical Japanese people often have great difficulty distinguishing "sink" from "think," and "light" from "right." Minimal-pairs are composed of paired word-sets similar to those above.

The Quiz/Game Section

The Quiz/Game Section allows students to test and verify their listening ability. HPP is able to give quizzes of minimal-pair words, and students then answer the quizzes. In this section, HPP does not show video clips. If students were able to see tongue positions and/or mouth movements, they could then possibly infer the correct answers. Students can however see the video clips after they answer the quiz, and so can confirm tongue positions, etc. HPP randomly chooses 10 pairs from the minimal-pair word list (the sample database contains 50 pairs—a teacher can increase this database), and also randomly chooses one word from each pair selected and then displays this word to quiz the student, each time the student practices. So, HPP randomly plays either "light" or "right" from that particular (light-right) minimal-pair. Due to this feature, students are unable to predetermine the correct answer.

Evaluation of HPP

Quantitative Evaluation

A t test was used to compare the difference between pre- and post-test scores on students' listening and pronunciation ability. Average listening-ability scores rose to 79.1% in the post-test, from a pre-test average score of 70.5% ($t=-4.69$, $p<0.001$), and average pronunciation-ability scores increased to 77.2% from 39.8% ($t=-6.15$, $p<0.001$). The pilot study indicates that HPP appears to be a useful tool for improving both English listening and pronunciation ability.

Qualitative Evaluation

A student survey was conducted using two separate research instruments. The first asked students to rank, in order of preference, which one among conventional media types such as CDs, cassette-tapes, video-tapes, and laser-disks, was most suitable for certain tasks. In the second survey, students were asked seven questions relating to HPP usage and functionality. Students' responses to HPP were quite positive.

Components of HPP

We developed the following components to be reusable: (a) a fundamental utility component group, consisting of (i) high quality timer, (ii) count up/down timer, (iii) data randomized shuffler, and (iv) file operations; (b) voice recording and playing component; (c) video recording and playing component; (d) voice spectrograph component;
(e) oscilloscope component; (f) voice mixer component; (g) volume control component; (h) multiple-choice quiz component; (i) and a multimedia database component.

B) A-MATE: A Multimedia Authoring System for Teaching EFL

A-MATE aims to help a teacher to create Web-based exercises and quizzes for their classes without requiring any programming. An EFL teacher will be able to create various types of exercises by preparing teaching materials, according to a simple format, without the need to use any programming code. A-MATE will be able to automatically create the appropriate HTML/JavaScript forms and pages by extracting necessary information from prepared materials.

The user interface of A-MATE should be as easy to use as possible, so that an EFL teacher can devote his or her main energies to developing teaching materials, rather than struggling through a computer program. After our analysis of TOEFL and TOEIC exercise texts, as well as EFL textbooks, we found that we can abstract typical EFL exercise activities as follows:

1) Present example problems utilizing a (multi-)media type and format.
2) Choose one out of a group of question/answer patterns.

We have plotted our program strategy to produce student exercises based on above two EFL development activities adopted in general:

1) A teacher chooses one exercise pattern from the group of exercise types.
2) The teacher also chooses one question/answer pattern from the question/answer groups.

That is basically all that a teacher has to do to create Web-based exercises and quizzes for their classes.

Components of A-MATE

In order to develop A-MATE, we reused five out of nine HPP components, which are (a), (b), (c), (g), and (h), added two features to the component(i) of HPP in order to manage the quiz "type" and "difficulty," and developed (j) a "new quiz generation" component which generates "Fill-in blanks" type quizzes, "Connect -n to -n items" type quizzes, and "Arrange items into proper order" type quizzes.

C) MBD: Multimedia Bilingual Dictionary for JFL/EFL Learners

There are various types of electronic dictionaries and software on the market, but not many are compiled for beginners. A beginning-level CAI dictionary can incorporate features important to both EFL and Japanese as a foreign language (JFL) learners. For instance, 1) many EFL beginners have a strong desire to acquire accurate English pronunciation, but it is difficult for these students to pronounce English words correctly (even with aural cues), without demonstrable knowledge of the mechanisms of pronunciation, such as tongue position, lip movements, etc., so, to benefit learners, video clips of a native speaker pronouncing terms can be included in the dictionary software; 2) For JFL learners, dictionary word look-ups often include unknown kanji, which can create frustration and confusion—therefore, rapid kanji-to-kana translation can be provided for all kanji appearing in the dictionary; 3) Typical dictionaries do not contain semantic look-up categories, which are beneficial to learners and speed learning. Through software implementation, it is possible to design a variety of look-up methods and particularly, lexical look-ups can be included in the dictionary design; Both EFL and JFL learners can benefit by hearing as well as reading all terms and sentences contained in the dictionary, in both languages—voice-synthesis technology allows for this possibility. Thus, we began the MBD project in order to effectively eliminate shortcomings and aid learners in their desire to acquire a target language. Essentially, novel voice-synthesis elements have been integrated into the MBD program and pilot-tested. Program software allows the database to be
accessed and searched by several methods, including: 1) Word Entry; 2) Partial-Word Entry; 3) Jump Searches & Jump Searches Across Languages; 4) Lexical Category Searches; 5) Lexical Correspondence Searches. Program software also allows for text search-strings to be entered in the Roman, kana, and kanji alphabets.

Figure 5 shows a screen shot of MBD. For JFL learners, a means of converting kanji to kana has been implemented—the learner right-clicks the mouse and selects “KANA” from the menu that pops open. The kana associated with the kanji then appear in a small window. EFL learners can benefit from associating written English, with its many spelling idiosyncrasies, to the spoken word. Students can practice English by playing multimedia clips that demonstrate a native-speaker’s mouth-movements. For both JFL and EFL learners, all mirror-sentence pairs can be listened-to by utilizing the text-to-speech voice-synthesis feature, which functions in either language. We believe that these design features can make a contribution to foreign language education and provide enjoyable learning opportunities for students.

Components of MBD
We reused components (a),(b),(c),(g), and (i) of HPP, and made four new components: (k) a full text search component, (l) a dictionary component, (m) a Japanese Kanji to Hiragana converter component, and (n) a Text-to-Speech synthesis (TTS) component. Currently, MBD is accomplished through one associated external software package for the converter component (the Japanese “language pack” freeware support associated with the Microsoft Internet Explorer 4/5 browser (IE-4/5)), and two external packages for the TTS component (IBM’s “Via-Voice” for English TTS, and Catena’s “D-Talker” for the Japanese TTS.). Concerning the TTS, MBD allows users to switch to another speech synthesis engine, if users have an available speech synthesis engine that uses Microsoft Foundation Classes.

D) VOCAL: Multimedia Vocabulary Concordance and Academic Lexis

Although computer-based concordance programs are available for the researcher, a multimedia concordance program has not yet been authored that is specifically designed to both meet the needs of academic, learner-centered reading programs, and which seeks to increase student comprehension of scientific texts in ESP (English for specific purposes) settings. The VOCAL program presents a computer assisted language-learning (CALL) software design and rationale for a tripartite concordance and lexis that reflects the three major groupings of English vocabulary deemed particularly relevant for English for academic purposes (EAP) science study, as well as other academic fields. The ultimate goal of the program under development is to enable vocabulary study to be further integrated into EAP reading classes, with the potential of accelerating students’ comprehension of the vocabulary, texts, and contexts in which the vocabulary items are contained (see Fig. 6). The VOCAL program consists of several modules. The SRT (Source Reading Text) module is the central module of a projected multi-module, multimedia CALL reading program, designed to provide (a) vocabulary, (b) reading materials, (c) student assessment, (d) test creation, (e) data collection/compilation of study and test histories, and (f) grading functions for the teacher (or independent student). Teachers and departments will be able to utilize the total program as an educational tool in designing distance learning and student self-study courses, as well as integrating the program into courses which make use of computer labs.

Components of VOCAL
Concerning the VOCAL program, we are reusing components (a),(b),(c),(g),(i), (k), (l), and (m) without alteration, and are creating an additional component for the concordance function.
Conclusion

We have described three serviceable programs, and a newly designed program for EFL education. We made fifteen components in the course of developing the three programs, and designed one additional component for the new VOCAL program. The “reuse rate” of existing components in each of the programs is 71% for the A-MATE program, 56% for the MBD program, and 89% for the VOCAL program. Although the reuse rate of the existing components of the MBD program (the second program developed using existing components), is lower than that of A-MATE (the first program), this is because the MBD needed several special components for Japanese language processing and speech synthesis. As shown in the results of the VOCAL program, the reuse rate of existing components of a new program will generally increase as additional programs are developed. Typical EFL learning activities aim at improving three abilities: communication ability, reading ability, and writing ability. All of the programs we described here can be used for improving these abilities: the HPP program can be used for improving communication ability, the A-MATE program can be used for improving all three abilities, the MBD and the VOCAL program can be used for improving reading and writing abilities. The beginner group (one of three groups we categorized teachers into, in the background section of this paper) is able to use all of the programs as-is. Further, the fifteen components in the overall componentware environment can be used by the intermediate group for their own unique designs to produce additional EFL educational materials. As a practical matter, a student who had taken only one introductory course in C programming was able to create a useful application for English dialogue-practice in two days using pre-existing components (this does not include time spent preparing instructional materials such as video-taping and digitizing). We will report our findings in more detail after documenting further case studies.

Outside of the field of EFL education, if a programmer in the intermediate group wants to develop a Spanish language learning program for instance, he or she would be able to create the program by assembling the pre-existing components without having to acquire a knowledge of sound analysis or text analysis. (Of course, such a developer would have to have knowledge of the Spanish language.) As well, the oscilloscope component, which was designed for HPP, can be used to simulate oscilloscopes for observing electro-magnetic properties, such as radio-wave frequencies. In the future, the advanced group will be designing and building various, additional components and offering them to the intermediate group. In this way, a large number of useful educational programs will become available for teachers interested in utilizing CALL programs specifically tailored to their needs, in diverse educational settings.

Abstract: In this paper we will argue that mankind is just about to take one more big developmental step due to continued progress in information and communication technology. Current and further developments are making huge bodies of knowledge available to everyone, everywhere and whenever needed. This has deep implications for all of mankind, but particularly also for the whole teaching and learning process.

Humanity on the Road to a Collective Organism

The proverbial “cavemen” lived in small groups: different tribes were basically autonomous, i.e. independent of each other. Even a single person was able to survive at the then usual standard of living for years without outside help if necessary. However, slowly more and more interaction between different population groups developed, starting with trade between neighboring tribes and turning into long distance trade of growing proportions. As a by-product different parts of the world became increasingly dependent on each other. With urbanization, industrialization and Taylorism the web of mutual dependence started to be incredibly dense: nobody in our Western civilization can survive without activities of many others anymore, at least not at the standard of living we today appreciate. In a way, individual persons have turned into a collective organism, into a new kind of “animal”: mankind. We as persons resemble cells in animals, or ants in an anthill, or cogwheels in big machinery, much more than we resemble independent, autonomous individuals. When we will sit together at lunch, we will sit in rooms built by persons from numerous professions: on furniture fabricated by some other sector of our industry, eating food coming from a huge agricultural complex; we will eat with tools such as glasses, plates or spoons yet originating in an other part of our society...and all of us belong to still a completely different type of profession.

What is true for physical things like food or furniture just mentioned is equally true for knowledge. Once it only existed in isolated brains of persons who may have communicated it to their children or pupils, more often by showing rather than what we would call teaching. Yet, over time knowledge became a more widely available commodity: by archiving it in books, by introducing schools and universities, by communication between a community of scholars. Consider how even just a few hundred years ago knowledge was “fragmented”, large libraries rare, the exchange of knowledge even between giants of science like Newton and Leibnitz by means of mail slow and cumbersome. However, we are now already in the process of leaving large and easy accessible scientific libraries of books behind, in favor of materials available over some kind of communication network, the World Wide Web (WWW), its successors or variants. This allows not just easy access to huge bodies of information but also impromptu discussions, criticism and comments: individual pockets of wisdom are merging into one large pool, individuals not just being networked for their physical needs but also their knowledge needs.
This new animal mankind will have, as it is sometimes said, as blood the transportation systems of our world, as muscles the energy networks spanning all continents, as nerves the glass-fiber or wireless information channels, and as brain a mixture of human brains and huge data bases.

We Have Seen Nothing Yet

When we look at the largest (and at this point also the most chaotic library) the world has ever had, WWW, it is clearly starting to have some impact on many areas of life. There is a growing amount of information on just about any topic available, a growing number of transactions (from booking a flight to ordering a book) are possible, and communication between physically arbitrarily far apart persons is avalanching.

Before we discuss what this means for education as one application area it has to be clearly understood that what we see now is just the “tip of the iceberg”, the real changes and challenges are still before us. It is worthwhile to list some of them:

- The number of books and particularly journals on the WWW will increase dramatically
- The number of learning, teaching and training material on the WWW is going to multiply
- However, despite such growth it will become easier to find reliable information in the field desired due to three facts: (a) “information portals” (sometimes now also called vertical search engines), (b) “meta-information” and “grades” that will be attached to documents to allow more specific searches than is
  - profiles” that will assure that persons receive (automatically and in time intervals they decide on) information on topics of their interest.
- Most important of all, the WWW is going to turn increasingly from an information medium to a communication medium; this change will take many forms. Email is going to further explode but will slowly be integrated into knowledge-pools; discussion “forums” or “bulletin boards” will gain more popularity, expert online advice will be increasingly available, just to mention three of the many variants visible on the horizon.
- Knowledge management (KM) now in its infancy will gain much weight in the decade ahead of us. The idea comes from the frustrated statement of a director of some organizations who once said: “If our employees just knew what our employees know, we would be a much better organization”. We believe that anyone in charge of a substantial group of persons will agree that it would be great to get (at least part of) the knowledge of persons in that group into a computer system so that everyone can profit from it: this is what KM is all about.
- In connection with KM there is also our vision of “active documents”. The idea is this: whenever you see a document in WWW (or in your internal database) you can ask (e.g. type) an arbitrary question and the document (!) gives you immediately the desired answer. Sounds like science fiction? Well, it is not really. A good approximation can and has already been implemented by the group in Graz. The basic idea is that when documents are available to e.g. 100.000 users than after the first 1.000 users have seen them, asked questions and the questions have been answered by experts, the other 99.000 users are very likely to ask similar question. The KM system remembers all questions asked and their answers. When someone else types a question the system “only” has to decide whether a semantically equivalent question has been already asked before, and if so, the system can give the answer without expert consultation.
- However, the biggest and most dramatic change will come from the fact that PCs and Laptops and such will fade in the background, and will be replaced by very small yet powerful devices that will act as computers that are hooked (wireless) into the WWW or its successor. Such “omnipresent computers” (let us call them OCs) will be available within the next 5-8 years and will be a necessary part of the life of everyone: all persons will always carry such an OC with them. (We are always referring to our Western world, not the whole world). It is the OC and the successor of the WWW that is going to shake the fundaments of many of our cherished and important activities, including communication and education.
The Omnipresent Computer (OC)

The Omnipresent Computer (OC) will be a cellular (mobile) phone with high communication rate. Just remember the (in)famous UMTS auction that has recently taken place in Germany to be able to introduce wireless telephony with higher bandwidth suitable for transmitting pictures, movies, etc. The OC will have a variety of standard functions that come with it, and some of the more obvious are listed below:

- It has an integrated camera that shoots both still pictures and videos. However, it is not just your digital photo or video camera; rather, due to its zoom function it can act as high power telescope or as low-power microscope; since it is able to work in the infrared spectrum it produces pictures both at night or in dense fog, and, yes, of course it acts as video phone. Make no mistake: the attraction of a video phone is not just that you can see the person you are talking to but you can show to that person what is going on around you: a view of your current vantage point in Graz, or a part of the movie you are just watching, or your children under the Xmas tree when you are calling your parents on Xmas day, etc.

- It is a full-fledged PC. So whatever you do today with your PC, you can do with the OC. And of course you can work with the WWW. “Work”, because you may not just want to surf around, you may want to send some mail, participate in a discussion, ask someone for an opinion or perform some transaction.

- The OC will have a built-in global positioning system. Whether this is satellite based or will use the gridpoints of the wireless communication system to determine the current position is anyone's guess. However, it will not only allow you to locate exactly where you are on a map or consult the pages of a relevant guide book, but is likely to offer much more: sensors that determine the direction the person is looking in will allow to explain exactly what you see right now; speed sensors may help you to answer questions such as “how long is it still going to take me to reach the restaurant where I booked my table”; road maps will turn into “backseat drivers”, i.e. your OC will tell you exactly when to turn at some junction, etc. And maps will be dynamic: when it is very hot lakes and beaches will be highlighted, as will shops selling umbrellas when rain is impending. And the right kind of food place will be shown to you depending on the time of the day, your location, the direction and speed of your movement.

- The OC will also be your electronic wallet. Securely and anonymously you will be able to pay both in the real world (i.e. shops) and the virtual world of WWW or other electronic shopping malls. Sooner or later, cash, credit cards and such will be as unknown as means to pay as gold coins are today.

- The OC will have both speech input and speech output; this will be convenient in many ways. It will also mean that it will act as your personal translator. When you use English/German, you will talk into your OC in English and it will generate a fairly good translation into German for your counterpart who feels more comfortable in this language.

- Of course the OC will be a portable radio, a TV and the equivalent of a CD player. CDs will be by then replaced by other devices (like MP3 files stored on the OC), TV will have changed (when you want to watch a movie you just select one from a data-base and play it), and the radio will also have continued to evolve in what it offers: the same station different types of audio depending on your personal profile. The stations may not transmit to you like today, but via the WWW which you happen to receive maybe wireless! Clearly, you will have access to all information on the WWW, but you may also carry a selection of electronic dictionaries and books directly with you on the OC without needing the WWW.

You want to buy such an OC? Ok, just wait five years or so. But don’t be disappointed if the first OCs do not have all the functions described; they will have enough surprises that have not been mentioned! Also, don’t be surprised that the OC might not be much larger than your wallet, that some version may come as wristwatch, and some may be small enough to fit into some boy-cavity. How about instead of a porcelain tooth filling?

Well, the “clearly” is put in quotation marks on purpose: technology that allows displays to be folded, or rolled, or feels like a piece of paper but really is a display (the digital ink of MIT) is advancing. Most important, it is quite possible that we will not use screens in the future at all. Rather, to look a bit in the future, we might be
wearing glasses that direct the audio output of the OC directly to the ear and the video via glass fiber to the front, projecting the picture through the pupil directly on our retina: projecting two different pictures for the two eyes the image can be three-dimensional and can act as "overlay" over what you see through the glasses. Thus, when you look at something, your OC (if you have chosen this option) gives you as overlay a description of what you are seeing, potentially with all kinds of additional information. Cute for a tourist who gets all the details he wants as he looks at a building, maybe more than cute for learning purposes!

Thus, receiving visual and audio information from the OC will be easy. At this point it is not clear which input device will win-out: keyboards that consist of cloth and are part of your jacket, voice activated input, or other input device that are currently experimented with. I will show a few pictures in my talk. I cannot include them in the printed version for copyright reasons, but if you check with any of the WWW search engines under +computers +wearables you are in for a surprise if you have not seen such gadgets before.

There are other issues. How are the various parts I have described networked, what additional sensors and devices might be useful and available: for the purpose of this paper what counts is one fact: before the end of this decade information and communication tools will be omnipresent, will be used by everyone, and will be small enough that one may hardly notice them or that they are in use.

What Does This All Mean for Education?

It needs little imagination to understand that such new technology will influence many of our habits, our life-style and our work. And this surely includes all aspects of education.

The very first question that comes into ones mind is: if all information or human knowledge is present everywhere at any time anyway, is learning still a necessity?

The answer - and some may breathe a sigh of relief - is "yes". Not only is it unclear how we can think within information in our brain, even the retrieval of information is a non-trivial matter, particularly since we are just starting to learn that remembering content is often easier than remembering the source (i.e. where we found the content).

Thus, learning will remain, but will be quite different from what we now often see on the WWW:

When we look at the WWW today we find thousands of efforts to use it for educational purposes. However, most attempts are limited to a sequence of HTML pages, sometimes including interactive features like quizzes or simulations, and often a smattering of communicational features based on email.

From what has been said above it should be clear that WBT or as it is now often called "e-Learning" can and must be much more than this. It must include powerful collaborative features, use the WWW and other sources a omnipresent background library, and must be based on the assumption that different persons have different knowledge backgrounds and different learning styles.

Thus, an ideal "e-Learning environment" must include at least partial solutions of the following issues:

- Educational material comes in small modules that have meta-data associated with them to be able to find what one wants. The modules must be related by a "dependency network" to allow individualized instruction.

- Using the dependency network mentioned it is possible to customize material for each user as follows: when a module is selected the system determines all modules that are necessary to understand the one chosen: by asking questions the system determines which of those "auxiliary" modules have to be presented first before the actual module of interest can be used.

- In ideal environments, the system should not only customize the knowledge level as explained above but also the learning style (more audio, more video, more haptic actions, etc.) most suitable for the current learner.

- As persons work through the material they must be able to add material and links for their own benefit, or for the benefit of later users. I.e., the system must provide a powerful "annotation mechanism" including authorization for individuals and groups.

- Users must be able at any point to consult background libraries, be it on the server they are currently working with or somewhere else on the Internet or the Intranet; and they must be able to incorporate such
information found for themselves and for others. Note that this is just one of the features that assures that
the material gets richer (more knowledge is generated) as more persons use the system.

- Users must be able at any time to chat with others online, to work with discussion forums, to use
collaboration spaces and to ask experts. Note again that the questions and the answers given will enrich the
educational material, turning documents into "active documents" as mentioned earlier.

Summarizing, the traditional notion of "courseware" that is made available once and for all for users has
to be replaced by the notion of a network of learners working with and enriching existing material, their
isolation broken by the Web, their individual level of knowledge and style of learning respected by the system.
Then and only then can e-Learning be successful and is an important component of knowledge management.
First attempts in this direction can be found in a number of systems. The GENTLE system (GEneral
Networked Teaching and Learning Environment) at http://www.gentie-wbt.com is one of them. It is now
available free of charge for universities and schools. It is marketed by the knowledge management company
Hyperwave at http://www.hyperwave.com. It is available free of charge for non-commercial use for schools and
universities, see http://www.haup.org.

Summary

In this somewhat provocative paper we have tried to argue that powerful networked computers (OCs)
will be omnipresent within a decade, and will influence all areas of education. We have tried to show that
"WBT" or "e-Learning" should not be seen a isolated phenomena but as part of knowledge management.

Abstract: Situation Learning (SL) is a new hypermedia knowledge module for on- and off-line use. The presented solution offers a new approach to knowledge module presentation that is different from the majority of presently used approaches. The interactive component of the SL approach increases students' involvement and motivation for learning. Learners can experiment and investigate within the 'virtual world' of the SL knowledge module. Such experimenting and interacting with different knowledge presentations makes it possible to construct own specific knowledge thus making the factual knowledge more permanent.

1. Introduction

Many scientists [Bates94] [Lennon94] [Maurer94] [Maurer97a] [Maurer97b] [Maurer99a] [Maurer99b] [Maurer99c] [Valley95] have observed disadvantages of early attempts in CAL (Computer Assisted Learning) such as the courseware being strictly bound by subject matters and the presentation techniques making it difficult to alter the content of the courseware. Knowledge Based Courseware (KBC) is a more recent approach that tries to improve disadvantages of CAL KBC, with separate knowledge representation, merges artificial intelligence approach with CAL and CBT (Computer Based Training) approaches. However, the main goal remains the same, which is to effectively develop computer-based learning materials that facilitate learning in the best possible manner. An experience provided in the virtual world can be considered, where people would have a chance to learn incidentally [Holzinger99], without special effort, similar to small children where the learning process through trial and error is part of life. As [Stilborn96] expressed..."our aim should not be to replicate the classroom on the desktop, but to use the technology available to us through the Internet to significantly improve the teaching / learning process." Research has been focused on finding ways that help people to learn how to solve problems and perhaps enable them to adopt new ways of reasoning. The learning process should be interesting, easy and it should be fun to learn. It also should fit with everyday tasks and the working environment in order to achieve optimum results. Therefore, information technology should not be used to automate an existing learning process that no longer meets the requirements of the society, but to enhance a new one.

2. SL

Situation learning presents a non-hierarchically structured hypermedia knowledge module. The learning goal is embedded in the context of a situation. To get maximum involvement and attention a situation has to be created that is interesting for the users. A storyline that users can identify with is most preferable. An example of a well-known and easily understood situation by the majority of people is the "waitress example". The learning objective of this story is, "how to carry a load correctly". Users

1 When carrying loads incorrectly we may also risk ankle or knee injuries and / or referred pain of the lower back area (to mention only few possible issues).
are confronted with the situation where a waitress has pain in her wrist while working. There are many different suggestions provided as to what the waitress should do. Some suggested actions are correct, others provide only a temporary solution, others again could cause severe inflammation. While trying to find the solution for the waitress, users learn incidentally the optimal behaviour and also the correct way of carrying the load. Situations are subject and domain specific e.g. emergency room where medical students have to decide which tests should be made first in the case of a head injury patient and the sequence of actions to be taken. The idea of situation learning is to create a variety of different plausible courses of action that will eventually lead users to the decision that yields the most appropriate action.

General Idea

A Situation Learning knowledge module can consist of one or more related situations. The term "Situation" in the context of Situation Learning denotes a specific simulated environment in which the learning objective is embedded. The situation is a collection of different scenes that are related in the sense that they describe a certain event or task. The "scene" consists of several hypermedia and HTML documents (e.g. on request available additional information). The displayed hypermedia document consists of an image, video / audio, text, meta-instruction and for example four selections. Only a few possibilities (in general 2-6) are offered to users. Based on users chosen courses of action, they then proceed to the next scene and eventually to the end of the situation e.g. summary. Each consecutive scene is different and depends on the previously made choice. Users are stepwise being confronted with the consequences of chosen courses and on their choices made. With the help of the "virtual" world users can explore where a chosen course of action could lead them in the "real" world. In the same way, users can safely explore possible outcomes when less appropriate choices are made. Using an SL knowledge module, users get the opportunity to learn appropriate responses for different situations / cases. Such opportunities enable users to improve their ability to discern relevant from irrelevant information and to combine unrelated (or less obviously related) elements. The interaction provided within each consecutive step encourages users to think about the case and to reflect back on their own knowledge base. Based on this they make a decision. In this way SL effectively facilitates the decision-making process.

A knowledge module presented in SL mode has the following expectations of learners:

- To explore circumstances with the help of situations (to get text and picture information, to acquire provided additional information and eventually to leave the situation to search external sources and acquire any further related information)
- To make choices / decisions (based on the facts provided and given possible solutions, users should decide the appropriate course of action)
- To understand the evaluation of their choices (through immediate feedback and feedback through path evaluation where all courses of action are transparent and evaluated)

Through the process of utilising knowledge acquired learners can build their own mental concepts e.g. can check the understanding of the material learned within the concept. Situation learning may bridge the gap between isolated learning of theory and practical work i.e. applying theoretical based learning to a practical situation. Situation learning is a way of facilitating the natural learning process, whereby the successful acquisition of new facts is enhanced by the learners ability to consolidate this information with their own knowledge base and experience. Such links allow people to master very complex or seemingly unpredictable situations. Situation learning helps to build and improve learners' mental model. Several use cases are described in [Pivec01].

Prototype Implementation

Each presented scene of the situation can be divided into four main areas as follows:
(i) situation description - upper right, (ii) meta instructions - upper left, (iii) user selection - lower left,
(iv) media display - lower right part of the screen.

The upper right part of the screen is used for scene description. In this area a short text description is displayed that explains the current situation. This screen area can also be used to set a link to a page with additional information or a list of additional sources or to a background library. Below the
description, on the lower right screen side, there is the area reserved for media display. With help of multimedia, e.g. pictures, animations, videos and other types of multimedia objects, users can get additional information about the scene or visual help to create a mental picture of the scene.

The left screen side is reserved for the interaction with users. On the upper left side messages concerning the further progress of the demo and the tasks that have to be carried out respectively are displayed. The users are e.g. asked to make a selection as in the example above or are told to proceed to the summary or to have a look at additional information source e.g. lecture chapter, video presentation, etc. The lower left side of the screen is for users interaction based on multiple choice selection. The number of selectable possibilities ranges from 2 to 6 items. This means that by selecting one of the suggested courses of action users get to the next scene as shown in the example above. In exceptional cases only one possibility might be given with the intention of guiding users through an out-tunnel leading to a specific scene or a summary.

3. Integration of SL Knowledge Module into the Hyperwave eLearning Suite

At first the SL knowledge module prototype implementation was an independent application that one could use with a regular browser such as Netscape or Internet Explorer. In further research the integration of the SL knowledge module prototype example into the Hyperwave eLearning Suite learning made it possible to investigate:

- Whether the environment supports such an application type like SL knowledge modules and to what extent authoring is influenced.
- How the SL knowledge modules can benefit from the environment.

At present the Hyperwave eLearning Suite environment supports only linear approaches such as behaviourist teaching. The learning material in Hyperwave eLearning Suite is structured much like an electronic book and supports so-called "step-by-step" learning. The material is presented to students in a way that facilitates the understanding of material in a certain area like physics, mathematics, statistics, etc. The students have the possibility to browse through the topics following their own interests and preferences.

Within the SL knowledge module a complex situation is presented to the students. Students, encountered with the problem, are expected to work through the situation to be able to solve the problem. Students can navigate through the situation based on their choice of one of several offered alternatives. To be able to choose one, students have to reflect on the problem presented along with several possible combinations of causes and consequences. At the same time students could benefit by having the possibility to use all of the different communication capabilities offered within an on-line learning environment, as in the case when they work with linearly structured learning material. Students could then mark difficult scenes, ask questions, make public notes and post hints for other students. Questions and answers could be visible to all students as well as help others to understand the specific scene or to point out the purpose.

Within the following subchapters the application of the communication support provided and resulted advantages when working with the SL knowledge module are outlined.

Annotations

The Hyperwave eLearning Suite system supports private and public annotations (Notes and Question/Answer Dialogs). Public Hyperwave eLearning Suite notes can be used by teachers and tutors to give hints in certain scenes. Some relevant explanation or additional material can be pointed out when using public notes. Students' attention can also be drawn to relevant chapters of the courseware that provides background information necessary for better understanding the particular scene or the situation. Students can use public notes to warn other students, to give hints, or to pose questions. With the application of a public note of the type question, a student can ask the tutor what they are expected to do in case they do not agree with any of offered courses of action. Because the note is public and visible to all other course participants, others could benefit from the answer to help solve similar dilemmas.

Private notes are used mainly to comment on a certain course of action so that the student's reasoning can be recalled and reviewed whenever he or she returns to this point in the future (see Figure 1). To
consider an example, a scene has been annotated by a student. In the first field of the form, the student has written the title "Attempt one" that indicates that student encountered the situation for the first time. In the field "Content", the student has written a brief explanation why this particular course of action was chosen. Changing the value of the field "Rights" from public to private assures that this note will be visible only to this particular student. When working through the situation again, he or she can read the note and get information about the decisions made in the past. Using this information combined with experiences learned when working through the SL knowledge module, students can reflect on past decisions and make new choices. The system's notes feature making it possible to comment the reasoning within each scene, is a powerful tool that facilitates knowledge acquisition.

![Figure 1: Annotations](image)

Discussion Forum

Using the Discussion Forum within Hyperwave eLearning Suite, certain topics related with the SL knowledge module and points of interest to all students can be discussed, different students' misconceptions can be pointed out, and additional knowledge sources can be published.

In this particular prototype application of the SL knowledge module, one of the possible topics for discussion could be how the previously presented problem of carrying a tray is relevant and how it can be applied in practice. Similarities to carrying suitcases and shopping bags could be outlined. The tutor could also invite students to share their experiences with carrying heavy loads with the group. The group could then discuss those examples and outline different ways of preventing injuries that could occur, if the action is undertaken in an inappropriate way. At the end, the tutor could summarize the discussion and point out several video clips that augment the discussed topic.
Messaging

Messaging is an internal communication facility with similar functionality to e-mail. A tutor can use messaging to send a hint or additional information to a student or a group of students. For example, the tutor can make a suggestion to the students to work through the SL knowledge module several times before taking the exam. The tutor could also provide additional explanation as to which topics in the SL knowledge module are relevant in particular. The provided example with all its variations makes it possible to apply the acquired theory to real-world situations.

Chat

In the Chat module students can discuss in real-time details about a situation and exchange their experiences and thoughts. Students can use private and general or course specific chat. Using private chat, a group of students could work together through the SL knowledge module discussing which choice to make and working on compromise solutions. General chat can substitute the informal class related conversations that takes place in the hallways.

4. Evaluation

For the evaluation of the SL knowledge module, the waitress prototype application was used. The situation was presented to two groups of people with completely different background knowledge. One group had knowledge of health care and professional injury prevention. The other group had background knowledge in computer science (e.g. students and people working at the ICM).

The evaluation was done in two different ways. With the first group an evaluation in the form of a demonstration was made, whereby the prototype application was presented and the SL principle was briefly explained. The opinions were collected in an informal way, through discussions and informal interview i.e. one-to-one conversation.

For the second evaluation the prototype application was published in the Hyperwave eLearning Suite as a course. The participants had the possibility to work with the application at any time appropriate i.e. when they had time and want to explore the situation. The evaluation conditions (of environment and of application use) were very similar to the real practice. Each participant then answered the questionnaire distributed via e-mail and delivered the response also in an electronic form.

The SL approach was very well accepted. Some positive opinions came from those with knowledge of medical injury prevention where one of the comments was that exploring a SL topic is much more thrilling than watching a small video clip about the same topic. Another opinion was that SL can be used for the knowledge mediation in many different ways (e.g. situations for stress management, therapy, professional injury prevention).

Most people indicated they would prefer to get additional information (i.e. at least additional explanation and eventually deeper medical information) about the topic presented in the evaluated prototype. This shows that SL, due to its informal structure, is an appropriate tool to be used for motivating of learners to seek out more information about a certain topic.

Difficulties appeared because of misunderstanding the text of the situation (that was written in English) which appeared to influence the work with the situation. This indicates that the descriptions and expressions used in situations should be appropriate for the target population and should be applied to SL as a general rule.

Furthermore, it can be said that the SL proved to be successful. The result of the acceptance was the LIFFE (Leben-Inspiration-Fortbewegung- Essen) project, financed by Fonds Gesundes Österreich. The goal of the project is to educate the population in the areas of fitness, stress regulation and nutrition, in order to increase the common awareness of the importance of these factors on our lives. Furthermore, citizens can thus be encouraged to take responsibility for their behaviour and to realise the possible
consequences of their present life-styles. SL modules were created for knowledge mediation in each of the topic areas (fitness, stress, nutrition).

LIFE uses primarily the Web as a medium for the content mediation. This means that the targeted population is in general young people and the population that uses the Web. SL modules have been further embedded in the environment from Infomed-Austria (www.infomed-austria.at). Infomed Austria is a medical portal server that provides additional features such as discussion forum, public and personal annotation possibilities, expert advice, additional medical contents and rated medical references, etc. LIFE will also be published in an off-line version of Infomed Austria server in an edition of 1000 copies. CD with LIFE content will be distributed for free over the Infomed-Austria server and make presentations at different press conferences and discussions.

Abstract: This paper gives a brief overview of the concept of online learning communities introducing a reference model for learning communities. Using the example of the "Executive MBA in New Media and Communication" at the University of St. Gallen, the article shows how an online learning community can be implemented. The reference model for learning communities was followed for designing this community.

1 Introduction

What is media-supported learning? Some think that a presentation with some fancy graphics on a computer and beamer already qualifies as media-supported teaching or learning. But the mere employment of music or graphics in a lecture does not justify the use of the term "media-supported". Media supported learning is not only enhancing a lecture with fancy technological gadgets, but a complete program including communication and document-sharing technologies (e.g. the Internet) (Mohd Najib & Zawawi 1999). It can excellently be utilized to enhance the building of a learning community. In that case, media provide not only knowledge in a network in the form of hypertexts on a content side, e.g. using Internet technologies, but the participants of an educational program can also benefit personally from a network that is developed in online supported learning communities (Paloff 1999).

Some may argue "why not media-conducted learning, then"? There is a difference between distance and online learning. Distance learning is clearly a form of learning where teacher and students are in different places, and often work at different times on a class. A mixed concept integrating online and offline learning methods and using the advantages of both kinds of learning communities is media-supported learning rather than media-conducted learning (Euler 2000b).

This paper pursues two goals:
- **Introducing the concept and the goals of online learning communities**: We show some advantages of learning communities, define the terms "online learning community", and introduce the reference model for learning communities.
- **Illustrating a way of designing an online learning environment**: Using the learning community of a Master's program at the University of St. Gallen, we show how an online learning community can be modeled.
2  The Structure of a Learning Community

Developing communities is an important motivation aspect for students not only on a professional, but also on a personal level. The exchange between the group members helps to assess and enlarge their own knowledge. Simultaneously, studying in a group is easier because different points of view of a topic are presented and more aspects are considered; the mutual, thus mostly deeper, examination of learning materials helps to extend knowledge. Mutual studying also creates a feeling of affiliation that can tie a learning community together even after the training. Maximal affiliation of members to the community is reached by considering formal learning goals as well as common social interests. This is an important aspect in the context of the shifting demands of today’s professional environment. Fast-changing standards require the increasing ability of professionals to continually learn and enlarge their knowledge. A learning community environment tries to prepare students for this requirement by creating team situations and in showing forms of learning that may appear in a professional environment as well.

Furthermore, learning communities are an appropriate vehicle to acquire soft skills such as empathy that cannot be learned in a standalone environment (Paloff 1999). In this context we correlate soft skills mainly with social skills, e.g. problem solving skills, team skills, or self-reflection competencies etc. (Becker & Carnine 1980), (Euler 2000a).

The learning community also shifts responsibilities for lecturers. Firstly, learning is no longer focused on one-teacher-many-learners-scenarios but favors group and self study. This allows the lecturer to assign content preparation and presentation to students and to encourage them to active participation, thus culminating in stronger learning experiences and deeper knowledge. Secondly, learning is no longer a teacher-learner-only relationship, but also a learner-learner relationship. Students take responsibility for each other and consult the teacher if they can’t solve a problem in their team, thus allowing the teacher to concentrate on difficult problems and to spend more time coaching students who need help more intensively.

2.1 Definition of Online Learning Communities

A community is a group of actors (Armstrong & Hagel 1996) who are connected by a common interest, common goals, or common actions in a commonly used channel system (Schmid 1997a). The channel system is part of the medium through which the exchange between the group members is maintained. According to Beat Schmid, a medium is a system consisting of the components logical space (semantics and syntax of a common language), channels, and organization (the structure with the definitions of roles and their rights and obligations, and the process with protocols and processes) (Schmid 1997a), (Schmid 1998). A community can be called an Internet-based community (online community), if it uses the Internet as its "channel system" for exchange between the members (Lechner & Schmid 1999), (Mynatt, Adler, et al. 1997), (Rheingold 1993).

An online learning community (Harasim 1995), (Paloff & Pratt 1999) has learning as its common interest. Actors involved can take on certain roles and the resulting rights and obligations in the community, in a narrow point of view: teachers and students; in a broader understanding: teachers, students, staff, alumni, or corporate partners. When designing this community, it is useful not only to consider the advantages of online media, such as flexibility and independence of place and time, but also the advantages and approved methods of the traditional university, such as bonding between group members and sharing of experience through group work. A successful online learning environment, e.g., would be the depiction of a university on the online learning platform, including a classroom community and a campus community.

- The classroom community, the community within the course or in the "classroom", is mainly determined by learning objectives and teaching arrangements; this "formal", closed community follows a didactically structured course design (e.g., a study program or training course); the formation of several sub-communities (e.g., student groups, project teams) is possible.

- The campus community characterizes a campus-wide, more informal community and reflects the "campus life" that takes place beyond the didactically planned study offers; it is designed comprehensively, focusing on informal exchange of knowledge and experience.

- The campus community characterizes a campus-wide, more informal community and reflects the "campus life" that takes place beyond the didactically planned study offers; it is designed comprehensively, focusing on informal exchange of knowledge and experience.
2.2 A Reference Model for Learning Communities

This chapter shows a potential way to design an online learning community including the two sub-communities (classroom and campus). Platforms of Internet-based learning communities can be modeled – referring to the media reference model for communities of Beat Schmid (Schmid & Lindemann 1998), (Stanoevska & Schmid 2000) – in four designs (derived from four views) (Seufert & Gerhard 2000). Since campus and classroom communities have different focuses and different functions, the design for the two is shown separately (see Fig. 1).

- The **organizational design** shows the community view. It defines the structure of the community, the community interests, the actors and roles, their common language and the process with protocols and guidelines for the community. The organizational design is adapted to the needs of a specific online learning community. Differing focuses and goals of campus and classroom community require different roles, languages, and protocols for those two sub-communities.

- The **interaction/process design** is seen from the viewpoint of the implementation view and connects the preceding organizational design with the subsequent service design. Based on the organization of learning communities and supported by the services offered by the platform for learning communities, the processes and scenarios are depicted. The (media supported or presence) phases of particular learning processes are designed. Considering the learning community as a whole with its specific contents and activities as well as the sub-communities with their campus and classroom situations, interactions and processes will be specialized to the needs in that context.

Figure 1: Reference Model for Online Learning Communities (Seufert 2000)

- The **channel design** represents the service view; the channel systems and services offered to the different communities and their members are described and the web interface is determined. We take the processes and scenarios that we have defined in the interaction design and think about how to support them best.

- The **IT design** is presented from the perspective of the infrastructure view (technological aspect). In this part, the decision about where to develop which new technological tools and where to use which standard tool is made. For spotlighting the user needs, not the technology, the level "IT design" is only performed after the community, its interactions and processes, and the required services are specified.

This general reference model for learning communities can be utilized for the modeling of learning communities which perform all their communication and learning processes on the Internet, but also of learning communities combining attendance classes and online phases, using the Internet for certain functions and selected learning...
processes only. We now want to show how we used the reference model to develop an online platform for the MBA program at the University of St. Gallen.

3 Developing the MBA Platform

Beginning in February 2001, the Institute for Media and Communications Management (mcm institute) at the University of St. Gallen offers a new "Executive MBA in New Media and Communication". Students in this Master's program will achieve competencies in business administration, knowledge about technological and economical components of new media, and the interaction of new media with sociological aspects. An online learning community for (partial) support of the "traditional" (or on-campus) learning community is created for several reasons: Firstly, following the goal "learning new media through new media", we think that hands-on experience with new media is a critical factor for successful dealing with this complex topic. Secondly, the goal of the MBA community is to create a feeling of life-long affiliation and to provide a network for all members of the community. The online community can be a platform for easy access of all members, on and off campus. And, last but not least, the goal of preparing the students for life-long learning can be reached through establishing a learning community among the students, and through creating strong bounds of the community members to the MBA community.

Establishing the structures and services required for this MBA learning community is part of the ongoing development of an already existing Internet platform, the "NetAcademy", an online instrument for discussion, publication, and knowledge exchange of research communities. The goal is to create a flexible and generic platform for both the scientific community and learning communities for exchange within and between those communities.

3.1 The NetAcademy as Generic Platform for Learning Communities

Following the idea of Beat Schmid (mcm institute), the NetAcademy (www.netacademy.org) was founded in 1997 as a platform for the exchange of knowledge, for publications and discussions (Schmid 1997b). It is an interactive online Handbook (e.g., digital libraries, connected with glossaries) for research communities. At the moment, researchers of five research communities in the field of media and communications management exchange their knowledge on this platform (Lincke, Schuber et al... 1998).

In autumn of 2000, the NetAcademy was made accessible for learning communities. The first Internet-based learning community on the NetAcademy will be the "Executive MBA in New Media and Communication" of the mcm institute. Numerous services already offered to the research communities by the NetAcademy (e.g., the libraries) will be used by this learning community as well. Additional services, such as curriculum catalogs or teaching templates, will be developed specifically for this community "type" on the NetAcademy platform.

Connected to the NetAcademy is the idea of a "generic" platform, i.e. a new research or learning community can choose and combine existing services of the NetAcademy according to its needs and also add other required services.

3.2 Modelling the MBA Community

The reference model for online learning communities provides a framework for the development of our MBA community. We follow the approach of depicting a university on the Internet platform and therefore also distinguish between classroom and campus community. At a (real) university, numerous activities are located in each room or location, therefore we arrange each MBA service in the online room logically corresponding to a room at the real university.

Processes that are related to the formal goals of the classroom community, such as lectures, group work, discussion about class subjects and the supply with course material are located in the vicinity of classroom community. They therefore take place in the classroom.
Processes related to campus activities (such as applications, research, general news, etc.) and social activities are located on the campus area of the online platform. You will find, e.g., an application center, a library, a meeting point, and a news room. Figure 2 shows a (graphically enhanced) screenshot of the MBA webpage’s sitemap. Visitors, students, etc. will find brief descriptions for all the rooms in the MBA community and gain quick access by clicking on a room.

3.2.1 Community View

Referring to the MBA program, actors involved perform their roles as students or faculty in the closer classroom community and as students, faculty, alumni, staff, or corporate partners in the campus community. Each actor fulfills certain functions and obeys either more formal protocols, e.g., curriculum structure or assessment rules, or follows more informal social protocols, e.g., interpersonal behavior, netiquette, etc. MBA community members develop their own language by establishing a common understanding and use of certain words and/or phrases the may be defined in a glossary.

The example of a "thesis marketplace" shows how the previously described model for online learning communities can be concretely utilized for the MBA community. The marketplace is located in the classroom and is a new service, therefore being implemented by the MBA group. The main idea is to bring students’ topic requests and faculties’ topic and tutoring offers together. Several actors are involved in this marketplace: students who act as willing thesis writers, on the one hand, and faculty members who act as thesis supervisors and tutors, on the other hand. (see Fig. 3). All actors have a common understanding ("language") of theses (e.g. what size a thesis should have, which genre of work a thesis has to be, etc.).
3.2.2 Implementation View

The implementation view concentrates on the processes and interactions in different scenarios in learning communities. The activities defined in the community view are now examined in terms of their process and scenario involvement. Every scenario encounters several phases not all of which have to necessarily be media supported but can also contain face-to-face elements. Structured work orders can be generated for some processes that are strongly automated (e.g., subscribing newsletters); other phases can be structured only basically (e.g., interactive face-to-face sessions).

Table 1 shows a process related to our example, the thesis marketplace.

Table 1: Thesis Writing Process

3.2.3 Service View

Pursuing the idea of the NetAcademy to provide modular services some or all of which can be chosen by each community, the MBA community was able to integrate already existing services of the scientific platform (e.g., the library modules, case repository, newswire). Other services that had to be developed were designed modular to allow their use by other communities.

Our example: The "thesis marketplace service" (see Fig. 4) offers a platform for trading topics and finding supervisors or students who are interested in working on specific topics. Later on, the service can provide support in phases of tutoring. To support these (already depicted) processes we develop some tools for the thesis marketplace:

- In the cooperation tool, students can place a topic proposal and search for a supervisor, a tutor, and writing partners. Faculty members can provide topics and search for students interested in those topics, and they can respond to students who require tutoring services;
- Materials can be exchanged in the content repository tool;
- Administrative issues are covered in the managing and reporting tool.
Although the marketplace is used only for the thesis context in the MBA community, its use is neither restricted to this specific learning community nor to theses. It could be used by a scientific community for coordinating book chapters as well as by a learning community for handling all kinds of assignments.

3.2.4 Infrastructure View

The technological design of the MBA community includes the supply of discussion databases for team work, synchronous chat tools, asynchronous discussion tools, content databases for class materials, cases, and assignments, etc. Also, it includes the graphic design of the platform which is managed in a separate design repository to allow quick adaptations independent of the technological design.

The decision of how to implement the infrastructure is not only determined by the three layers above but also by several other circumstances, such as already existing technological framework, financial and personal resources, time frames and so on. Considering those prerequisites, a trade-off between choosing a low-cost standard service solution and a high-cost customized service solution or even development of new services has to be reached. The services provided by the NetAcademy already exist and can be adapted or customized. For other services, there are very good market solutions available. Some are very specialized and require complete customized development. The MBA platform is therefore implemented as a combination of standard software (e.g., Lotus LearningSpace) and individual software solutions engineered on Lotus Domino technology (used by the NetAcademy).

4 Conclusion and Outlook

We have given a brief overview of the concept of learning communities. A reference model for learning communities was introduced. We then showed how an online learning community can be implemented, using the example of the "Executive MBA in New Media and Communication" at the University of St. Gallen. For designing this community, we followed the reference model for learning communities. To allow members of the learning community easy handling, we followed the idea of depicting a university on the web platform.

We now stand at a point where the conceptual work is almost finished, and the implementation phase is in its peak. We plan an extensive test phase before students arrive, but are convinced that a lot of adjustments are required. We see the critical factor for acceptance and use by the community members in the fulfillment of their needs. Therefore, continuous diligent observation and critical investigation of student, faculty, staff, guest and business partner needs will be our everlasting challenge to lead the MBA online learning community to success.

Abstract: Closed-loop adaptive education is an emerging concept that integrates object-/objective-based adaptive interactive multimedia instruction (IMI), intelligent tutoring system (ITS), and modeling and simulation technologies. The result is an inherently learner-focused approach that manages mastery of knowledge and skill learning objectives dynamically. The following is a discussion of our approach to implementing the closed-loop paradigm. We discuss what we view as the major components of such an approach, including the Learner Model, adaptive IMI, and simulation-based adaptive education. We conclude by discussing how these elements can be combined within a closed-loop system.

Introduction

Closed-loop adaptive education is an emerging concept that integrates object-/objective-based adaptive interactive multimedia instruction (IMI), intelligent tutoring system (ITS), and modeling and simulation technologies. The result is an inherently learner-focused approach that manages mastery of knowledge and skill learning objectives dynamically.

The closed-loop, object-/objective-based adaptive education concept has evolved over several years (Morris, et al., 2000; McCarthy, et al., 2000; McCarthy, et al., 1998. McCarthy, 1996; McCarthy, et al., 1995a,b; McCarthy, 1994; McCarthy, et al., 1994) and is conceptualized below (see Figure 1). At the core of this approach is a dynamic Learner Model. The Learner Model contains current mastery information for all covered learning objectives, as well as data relating to learner characteristics, instructional history, and feedback history. The Learner Model sends and receives data from a family of domain and instructional expert software that guides the learner’s instructional experience. In addition to considering the state of the learner (captured in the Learner Model), the experts consider the goals of instruction (captured as course data). Armed with current and historical information on the learner, and the goals of the course, an adaptive learning system can employ IMI- or simulation-based learning and assessment activities (shareable content objects; SCOs) that are linked to specific learning objectives.
The following is a discussion of our approach to implementing the closed-loop paradigm.

Major Components

A closed-loop adaptive education approach is supported by interaction among the following components:

- Learner Model,
- Instructional Engine for adaptive IMI, and
- Instructional Engine for Situated Learning.

In this paper we discuss our approach to implementing each of these components.

Learner Model

An objective-based Learner Model is the cornerstone of the adaptive education approach supporting both adaptive IMI and simulation-based education. The Learner Model represents what a student knows and
does not know based on recorded mastery of learning objectives. The Learner Model is student-specific; each student has his/her own Learner Model.

Essentially, an individual’s Learner Model is a database comprising:

- Learning objectives for a given student and associated mastery status,
- Learner instructional history (record of IMI instruction),
- Learner feedback history (record of scenario-based coaching), and
- Learner characteristics.

The Learner Model can be updated in real-time for automated education methods or non real-time for semi-automated or manual education methods. In other words, updates to the Learner Model can be accomplished automatically during education by the education system itself or manually by instructors. Manual updates to the Learner Model can be facilitated using automated and semi-automated data collection techniques.

**Automated Adaptive Interactive Multimedia Instruction**

In an IMI context, adaptive education implies an instructional engine that delivers IMI that is tailored to specific, identified student needs. Here, automated adaptive IMI refers to the capability to automatically create and deliver an “individualized education plan” (i.e., IEP) at run-time, based on the student’s mastery of defined learning objectives, available content objects that support those learning objectives, course/instructional definition data, and instructional history. In other words, adaptive IMI is defined as the capability to create an IEP and deliver tailored multimedia instruction based on individual needs reflected in the Learner Model (see, for example, McCarthy, et al., 1998; McCarthy, 1996).

Each learning objective is associated with one or more methods of teaching the content associated with the objective (see Figure 2). The media content plus the data that describes the content (i.e., metadata) and associates it with the learning objective is referred to as a Shareable Content Object (i.e., SCO; Dodds, 2001). SCOs may be grouped as necessary to provide the requisite instruction and practice for a given learning objective. The number of SCO groups per objective represents the number of different ways to teach that objective.

In a similar vein, each learning objective is associated with one or more methods of assessing mastery of the objective. Therefore, assessment SCOs can be created in the same manner as content SCOs.

![Figure 2. Adaptive IMI Instruction](image)

Using learning objective mastery data, instructional history, and learner characteristics from the individual’s Learner Model, as well as information about course goals stored as course data, the instructional engine creates an IEP that utilizes available SCOs. The instructional engine then executes the IEP by providing content, practice, and assessment activities until mastery of the requisite learning
objective(s) is attained. The on-going IEP is updated as these activities are presented to the student and he/she responds.

Simulation-Based Adaptive Education

In a simulation-based context, adaptive education implies an “expert instructor” that creates a scenario tailored to specific, identified student needs (based on learning objectives from the Learner Model) and provides coaching that is sensitive to the student’s needs and task demands. Automated simulation-based adaptive education refers to the capability to automatically:

- Create a tailored event-based scenario based on the student’s mastery of requisite learning objectives (Stretton, et al., 1999; Stretton, et al., 1997a; Stretton, et al., 1997b);
- Monitor and assess student performance during the exercise;
- Provide feedback to the student as required during the exercise;
- Update the Learner Model; and
- Develop an IEP (IMI, simulation-based exercise, etc.) to remediate deficiencies and facilitate mastery of those learning objectives yet to be mastered.

Fully automated simulation-based adaptive education for an individual employs an intelligent tutoring approach. This approach uses artificial intelligence (AI) technology to create an instructional system that can sense and adapt to the needs of an individual student. In a simulation-based context, adaptive education implies an “expert tutor” equipped with a wide range of instructional tactics to assess, diagnose, and remediate the student during an exercise. Remediation methods may vary as they are tailored to the student's level of understanding.

The primary components of an intelligent tutoring system (ITS) are:

- Domain Expert - A software module that represents the knowledge of an expert in the subject-matter domain, and assesses the student's performance.
- Learner Model - The Domain Expert updates the Learner Model in real time as the student interacts with the simulation.
- Instructional Expert - The Instructional Expert, based on input from the Learner Model, generates a tailored scenario to support mastery of required learning objectives during the exercise. Then during the scenario, the Instructional Expert takes input from the Learner Model and the Domain Expert, and produces an instructional decision. It is the Instructional Expert that determines whether to intervene in the student's activity, what issue to address if an intervention is warranted, and which type of intervention to employ.
- Learner-Device Interface - The interface is the medium of communication between the student and the ITS. The Learner-Device Interface creates the learning environment by presenting the student with engaging stimulus events and by providing the student with the ability to respond to those events.

A description of how these components interact during a simulation-based education session is presented in Figure 3.

For simulation-based education, the student is placed in a situated learning environment in which scenario events invoke expectations in a Domain Expert. The Domain Expert monitors the student's response to scenario events and assesses whether expectations were met or violated. These assessments are then passed to the Instructional Expert and used to update the Learner Model. The Instructional Expert, using the input from the Domain Expert and information from the Learner Model, determines the appropriate instructional feedback and provides it dynamically (audio, text, pointer, modify scenario, present IMI, etc.). This cycle of stimulus event, student action, assessment, and feedback continues throughout the exercise (see, for example, McCarthy et al., 1995; McCarthy et al., 1994).
Closing the Loop

Combining the fully automated IMI- and simulation-based adaptive learning approaches results in a true, automated closed-loop education system that supports individual education (Morris, et al., 2000, McCarthy et al., 2000). For example, suppose that a student has problems with some specific procedure during a simulation-based refresher education assessment exercise conducted on a personal computer. This deficiency would be noted and his/her Learner Model would be updated to reflect lack of mastery for the associated learning objective(s). The Instructional Expert, using the Learner Model as input, would create an IEP that uses IMI to address the particular learning objective(s). The student then works through the IMI until he/she masters the learning objective(s). This mastery can then be confirmed in another simulation-based assessment exercise using a scenario tailored to stimulate demonstration of mastery of the required learning objective(s). This paradigm can be accomplished without human intervention.

Although our discussion has focused on individual education, the power of the closed-loop approach can also be applied to team development. The team setting provides opportunities for assessing different types of learning objectives and supports different types of instructional approaches, but the essential framework remains constant: Mastery of learning objectives (individual/team) is monitored in media- and simulation-based learning environments and leads to the construction and execution of tailored instructional plans.
Varying degrees of automation can be applied to the above model where necessary; however, the core component remains the Learner Model. It is the Learner Model that provides the glue for the adaptive education approach by providing the data to the human and/or machine that specifies the degree of mastery for all required knowledge and skill learning objectives for every student.

Conclusion

Closed-loop adaptive education represents an exciting evolution in the realm of interactive learning that has broad applications within the educational community. Students can learn new concepts, practice associated skills, and be assessed on their mastery of the requisite knowledge and skills, all under the supervision of the Domain and Instructional Experts that interact with the integrated Learner Model. Because the Learner Model is endorsed in real-time and contains in-depth information regarding student mastery of required learning objectives and instructional history, the human instructor can target his/her efforts to those students requiring additional help or greater challenges. Closed-loop adaptive education supports initial instruction, refresher instruction, and on-demand instruction with equal ease.

Online Pedagogy as a Challenge to the Traditional Distance Education Paradigm

Abstract: This paper briefly discusses the educational context at The University of Southern Queensland (USQ), Australia where many courses are delivered solely online. It provides a comparison between online and traditional distance education and reflects on how online pedagogy challenges traditional distance education pedagogy. The pedagogy of print-based distance learning materials has tended to incorporate instructional design strategies aimed at providing an independent learning experience. Internet technology has created opportunities for interactive and collaborative learning which represent an alternative to traditional, autonomous approaches to the delivery of academic content.

Introduction

In recent years, use of the Internet has developed phenomenally, and worldwide access to communication and information technologies presents educators with opportunities to create learning environments different from those possible with preceding technologies. The Internet provides instant access to a huge range of resources (information and human), with the ability to search across and within web sites and the facility to work collaboratively with colleagues at a distance.

The traditional paradigm of education and training has been based on standardisation, conformity and compliance. Typically, teaching has been conducted by giving large groups of learners the same content in the same amount of time, and for on-campus students, at the same time. Learning is often directed by a trainer or teacher, with learners having little opportunity for self-directed learning or interaction with peers. However, changing expectations reflecting the move to a knowledge society mean that learners are demanding customisation of their education/training and employers are requiring graduates who display initiative, adaptation to diversity and problem solving abilities.

Traditional Australian Distance Education Context

The traditional distance education paradigm, within the Australian context, has been that of the “Birdsville student” - a remote student, an independent learner, with a standalone package of study materials. The independent learner model is similar to what some refer to as “content-learner” interaction (Miller & Miller 1999) with learners having little or no interaction with others. To use the opportunities provided by the Internet, there is an obvious need for the design of learning environments which use the interactive capabilities to the best advantage and are not merely the transformation of print-based material to online delivery.
Online Pedagogy – Design of the Learning Environment

At the USQ, an institution with twenty-five years’ experience in the delivery of distance education, online pedagogy is aimed at shifting learners from passive to active learning, from teacher-centred to learner-centred environments and from decontextualised tasks to authentic, meaningful experiences. The online environment creates an opportunity for interactive and collaborative models of learning, including the creation of learning communities involved in interactive activities using electronic discussion areas. It also enhances the independent learner model by providing media-rich resources and the opportunity to self-manage learning in a flexible mode (McDonald & Reushle 2000). Many of these learning strategies have not been available in the traditional print-based delivery of distance education which, for access and equity reasons, has often been designed within the framework of independent learning.

The collaborative learner model acknowledges the importance of the co-construction of knowledge through collective learning and peer exchange, often referred to as a many to many learning experience with less of a focus on instructor contribution.

In educational literature (Bates, 1999; Jonassen, 2000), it is argued that learning within a constructivist environment promotes meaningful learner engagement and critical, creative and complex thinking by learners. This paper has a focus on communication technology, while noting that other technology-based learning/teaching tools such as Jonassen’s (2000) ‘Mind Tools’ also support ‘engaged’ learning by students. The idea of constructing knowledge using technology, rather than using technology as an information-gathering tool, is an important aspect of online pedagogy. Conversation and collaborative tools (such as online discussion groups) enable communities of learners to negotiate and co-construct meaning for problem solving and knowledge construction. Online discussion groups can provide a permanent record of discourse, a collective memory resource for subsequent reinterpretation. Buckingham-Shum et al. (2001) discusses different learning media and techniques used for closing the gap between distance students and their tutors. However, they note that the Internet is widely acclaimed as a medium to revolutionise distance teaching, but its primary role to date has been the convenient publishing of ‘digital paper’ plus simple hypertext, and that convincing examples of shared, networked multimedia are still relatively scarce.

Conclusion

Interaction is an integral component of learning, and communication technology has provided opportunities for educators to implement this at a distance. If the “ideal” educational experience is the Oxford style interactive tutorial, is this where instructional design efforts for the online environment should be focused – interaction using electron

Abstract: This paper explores the application and implications of imperceptible digital watermarking technologies in learning environments. Using Digimarc MediaBridgeTM software, traditional print educational content is transformed into digital media that challenges the boundaries of text, audio, video, and graphic elements.

Few resources are more prevalent in schools than textbooks; yet, in many cases, textbooks inadequately address the needs of students and teachers. Outdated information is common due to the nature of textbook adoption cycles, and the information often is ill-suited to the curriculum and assessments. It can also be argued that textbook development is driven by market demand and that states with large student populations have the greatest impact on textbook development. Some states, such as Texas, are experimenting with replacing textbooks with laptop computers; however, this does not eliminate the need for quality instructional media. The World Wide Web, with its vast resources, can be burdensome to teachers charged with searching for the most appropriate information and media for their students. Compounding this is the assertion that individuals read from a computer screen approximately 25% more slowly than from a printed page. While this problem could be solved by using 300 dpi screens, the expense of these high-resolution screens makes them an unlikely option at this time (Nielsen, 2000).

Another possible replacement for traditional textbooks is e-books—single-purpose devices that display reading materials in ways similar to traditional books. Two of the most current types of e-books range in price from $200 to $600 and rely on proprietary file formats, making them less attractive (Ditlea, 2000). According to Steve Ditlea (2000) “At some point in the future, however, e-books and print are bound to diverge. Lurking amidst e-publishing today is the notion of multimedia books that seamlessly incorporate hypertext, sound and animation” (p. 78).

In the midst of the growing e-book industry, imperceptible digital watermarking, a technology most often associated with copyright protection (Dugelay & Roche, 2000) offers a viable alternative to the single-purpose devices known as e-books, particularly in learning environments. At the present time, e-books do not appear to be replacing print media but rather supplementing it (Ditlea, 2000), indicating that print-based textbooks are likely to remain dominant in classrooms for some time. The continued use of textbooks is not necessarily undesirable. McKnight, Dillon, and Richardson (1996) state, “We have had nearly 500 years experience of using printed textbooks, and they not only support a wide range of applications, but users also have such a strong mental model of their generic structure and organization that they can successfully adopt an equally wide range of usage strategies” (p. 631). They further suggest that while hypertext can support activities that would be difficult, if not impossible, to accomplish with printed text, we must be sure that these capabilities are used in pursuit of valid learning tasks: “It is not sufficient that we can browse a million pages on our desktop, or link 100 articles together for rapid retrieval at the click of a mouse button: such capabilities are only important in terms of their utility to human learners. Yet there are few signs that most learning scenarios require such support, and little knowledge on how we might best provide it in terms of usability, even if it were required” (p. 631).
There is much to be learned about how to best use the technologies available to us to support teaching and learning. Shneiderman (1998) contends that exploring vast holdings of information has become increasingly difficult as the quantity and diversity of the information has grown. He suggests that while the computer is an effective tool for searching this information, it is far from adequate. He points out that novice users are often impeded by cumbersome user interfaces.

It appears that a logical approach to designing the dominant instructional media for classrooms is to begin with what McKnight, Dillon, and Richardson describe as our most successful information technology—the printed book. We propose to develop a prototype interactive textbook using digital watermarking technology, commercially available from Digimarc. Digimarc MediaBridge™ technology creates an imperceptible digital watermark consisting of XML-based mark-up language embedded in a graphic or other media element. With the aid of an optical reader device, such as a digital camera connected to a computer, Digimarc MediaBridge™ software "reads" the watermark, activates a standard Web browser, and delivers the user to a specified Web site. The Institute is currently exploring digital watermarking as a means to supplement print media with current, up-to-date information delivered via a safer, more efficient Web environment. It is important to note that this interactive textbook is an extension of text information. Any function now possible on the Web, including chat, interaction with experts, data visualization, and virtual reality also is plausible within the context of the interactive book. We are also actively considering potential uses of an imperceptible digital watermarking scheme for various forms of data, including audio, two-dimensional graphics, video, three-dimensional models, animation sequences, and other digital media elements.

We have selected a widely adopted middle school science textbook as a basis for the prototype. Typically static information is presented in a generic textbook format and organizational structure; other information is dynamically linked to the printed page with an imperceptible digital watermark. For example, students exploring the immune system can use information created by content experts such as the National Cancer Institute or the National Institutes of Health. They can view videos to better understand the experience and need for using an iron lung or listen to audio interviews of survivors of major epidemics. Students can visit the Howard Hughes Medical Institute on-line and participate in a virtual lab simulation to better understand the role of antibodies. Students studying AIDS and HIV can use real, up-to-date data provided by the Centers for Disease Control (CDC) or the AIDS Education Global Information System (AEGIS) for their own analysis and study. We intend to transform one chapter of the textbook into an interactive textbook prototype that will demonstrate appropriate and effective uses of electronic media.

References

Abstract: This paper introduces a case study in its earliest stages that will study the impact of technology infusion throughout coursework and the preservice teachers choice of technology usage for teaching assignments and practica presentations. Zayed University has made a commitment to the infusion of technology throughout university education for all students based upon the limitations described in research regarding stand-alone classes on teaching. Early data suggests frequent student choice to use technology in a variety of ways, but that actual usage may be mediated by physical conditions in the teaching.

Introduction
This case study will inform teacher preparation regarding the effect of an immersion in technology on the selection of technology supported instructional strategies at the classroom level by preservice teachers. The study will follow three cohorts of students through their teacher training program at Zayed University which includes field experience increasing in responsibility over four semesters and a one year internship. The students will complete from four to eight semesters program that includes a significant amount of English language training, technology education, and Arabic and Islamic Studies courses prior to entering the teacher preparation program.

To set the stage—the place has a familiar feeling. The grass is green, flowers bloom on the campus lawn, classrooms are full of students, a students sit on a bench studying, another group is in the library, faces intent, professors bustle about. This is a university campus. All of these students are wearing black abayas which cover them from head to toe, many peer over a veil. They are all young women. Everyone is carrying or attending to a laptop computer, and the green grass is in a courtyard amidst palm trees under a hot desert sun.

This is Zayed University located on the Abu Dhabi campus in the United Arab Emirates, a small oil-rich Arab Gulf state. Designed on an American model with predominantly western teachers and programs and with English as the language of instruction, the university is new. Opened in 1998, ZU is now functioning with approximately 2500 students and 300 staff on both the Dubai and Abu Dhabi campuses and is known locally as the ‘Laptop University’. The mission of ZU is “to produce graduates who are masters of the computer, well grounded in the academic disciplines, fully prepared in a professional field and capable of providing leadership in the home, community and nation”. Within a strong commitment to provide an outcomes based environment for all students, the six colleges offer majors or specializations to students beginning in their third year of university study: Arts and Sciences, Business Sciences, Communication and Media, Education, Family Sciences and Information Systems. The young women who study in these colleges are viewed as the future of the UAE.

The current educational paradigm of the United Arab Emirates is very traditional and generally described as teacher technicians transmitting the presently limited curriculum provided by the Ministry of Education and Youth. A very teacher-directed lesson format is delivered with no technology supported or experiential opportunities for students in most of the government schools. In partnership with Zayed University, a constructivist theory base for teaching and learning, a focus on learning outcomes rather than teacher input, and the integration of technology as a tool of teachers are the component parts of this joint change endeavor of the College of Education. The change process requires the preparation of new teachers who are problem solvers, inquirers, action researchers and leaders who are able to fuel the new learner-centered approach.

While the present state of technology in government schools is weak, the technological support of the future is considered to be much brighter. The graduates of ZU are all computer fluent in technology-enhanced instructional practices. Preservice teachers interact with professors via interactive reflective journals that are web-based, they prepare electronic professional portfolios that showcase the instructional products the student has learned to develop, they access their grades via the Internet, participate in courses supported by Blackboard.com, and they demonstrate their achievement of outcomes required for graduation from the
influencing change in the schools is an important component of each course.

Method
Students in the study will belong to three cohorts of students with each cohort starting the teacher education program successively. Each cohort contains approximately 15 students who are all Emirati national women who have been educated during the early years of compulsory education and who have high grades culminating in a secondary school diploma. Each woman has completed general education requirements (although varied between the three cohorts) and maintain a 2.5 grade point average on a 4 point scale. Cohort 1 students entered the university in 1998 and began the teacher preparation program during fall semester 2000. Cohort 2 students entered the university in 1998 and 1999 and began the teacher preparation program during spring semester 2001. Cohort 3 students entered the university in 1999 and will begin the teacher preparation program during fall semester 2001.

Students choice of technology, manner in which it is used, reasons for selection/nonselection will be gathered through faculty evaluation of projects, micro-teaching, and practica teaching. Reasons for use and non-use will be gathered from student interviews about their choice of instructional tools in their projects.

Preliminary Findings
Observations and review of student selection of technology for instructional purposes began Fall Semester 2000. Following are some of the preliminary findings that suggests, but is as of yet inconclusive, that technology is selected more frequently by students immersed in an environment of technology than those who have had stand-alone course with the promise of later application.

Limited generalizations from early data are:
Students (n=15) working in a more student-centered environment of a private American format school, have been observed to use computers and projectors to display pictures of base-10 blocks in various configurations to teach about place value, and by a second student to provide primary source material while teaching a lesson on an Islamic principle.

However, students use of technology for instructional support has been mediated by the environment of the classrooms where they teach. Classrooms that are not able to be darkened required some problem-solving as to backgrounds and text color. At present, students in this environment seem to be selecting technology support for teaching less often. New lessons have not been taught since the problem-solving session has taken place.

Students observing and teaching in the traditional teacher-directed government schools (n-13) emulate these methodologies in presenting micro-teaching assignments and in planning lessons for the mentor classroom. Students to date do not regard the modeling of more student-centered strategies or use of technology supported instruction that they observe their professors using as choices while they are in these placements. The students of Cohort 1 who had this assignment have moved to more student centered approaches this semester.

However, these students use technology to show pictures of interactions between students and use of technology to facilitate transmission of content knowledge through such things as diagrams of water movement through the stems/leaves of plants, the water cycle, diagram of nuclear power plant to support an activity the preservice teacher leads during a micro-teaching lesson on the university campus. A number of the students developed fill in the blank worksheets that were projected onto a whiteboard so that students could work collectively on completing the sentences by writing the required vocabulary words onto the board. One aspiring computer teacher used her computer to demonstrate how to use a component of an application while directing her students to use their own computers to open and use the application to accomplish a product to be submitted at the end of the lesson.

This paper describes a study in progress and data collected to date is highly inconclusive, but suggests potential patterns of interest. The authors appreciate all feedback given and ideas that emerge from collaborative dialogue. While initial student interviews regarding decisions to use technology for various components of the teaching enterprise have not yet been conducted, it is believed that these will inform the project.
Learning with cyberfriends: The development of professional reflection-on-action skills through online partnerships

Catherine McLoughlin,
Teaching and Learning Centre, University of New England, Australia
mcloughlin@metz.une.edu.au

Joe Luca,
Edith Cowan University, Multimedia Department, Australia
j.luca@ecu.edu.au

Abstract: One the crises facing the professions is the scepticism surrounding the nature of professional knowledge and whether individuals can cope with the increased complexity of society and the changing demands of the workplace. Tertiary institutions have now strengthened their links with industry and have produced lists of attributes and communication skills they aim to cultivate in graduates. In order to develop these skills students need to be able to reflect on their learning experiences, integrate them with prior knowledge, self-evaluate and develop their own decision-making and planning processes. Online technologies can be used to support the process skills underpinning reflection-on-action (reflexivity). The development of reflexivity is presented in the context of an online tertiary unit where students proceed through the cycle of action, reflection, planning and abstract conceptualisation by engaging in a range of communication skills including peer assessment and problem solving. The study shows how online tasks can support reflexivity.

Introduction

Information and communication technologies have the capacity to support a wide range of learning goals and are now integrated into teaching approaches of many higher educational institutions. Laurillard (1993) for instance suggests that computer-based learning has a major role in promoting quality learning outcomes such as:

- self-directed learning and increased student autonomy;
- keeping the educational system in line with technological development;
- increased information literacy, ensuring that graduate skills are in tune with those of employers; and
- increased productivity and efficiency in higher education.

Through computer facilitated learning, students can access WWW sites, bulletin boards and on-line resources to support their own learning and consequently promote the development of generic research skills, information literacy, retrieval and management of data. However, many students find their experience in tertiary institutions too general or out of context, and cannot transfer these skills into realworld contexts, or link them with prior knowledge (Taylor, 1997). The use of information technology within a structured environment can offer learners contextualised support within which to anchor their learning and reflective skills.

Development of reflective skills in higher education

One of the characteristics of being considered professional is having the capacity for self-direction and being able to apply practical strategies and skills in contexts that require them. Professionals have a body of expertise that is developed through experience within community of practice and lifelong learning skills. Boud and Keogh (1985) suggest that the capacity for self-directed learning includes elements of independence, dependence and interdependence and propose that these form a continuum whereby the learner progresses from dependence, to independence and then to interdependence (Figure 1). Each of these stages requires learners who are able to reflect on and assess their own skills and capacities.
It is widely accepted that graduates should not only be technically competent but they should also be skilled in communication and teamwork, have social and global awareness, be self-directed and be prepared for life-long learning. However it is much less clear how these "soft skills" are best developed in undergraduate students in the context of their studies. One recommendation is that pedagogy needs to change from transmissive, didactic approaches towards transformative, student centred approaches. In the present study, this has been achieved in the context of a project-based unit of study, involving both individual and group work, located within a Web-based learning environment.

Theoretical framework: experiential learning and reflective processes

According to several theorists, authentic learning occurs only through reflecting upon personal experiences (Dewey, 1993, Schön,1990). Reflection is often defined as a process that enables connections between the various elements of an experience, and Dewey refers to reflection on experience as a learning loop that 'runs back and forth' between the experience and the relationships being inferred. The concept of the learning loop has gained popularity through the work of Kolb (1984) and his four stage experiential learning model in which learners move through a series of phases involving experience, reflection, generalising/theorising and planning. Therefore, the ideal experiential learner will be able to:

- involve themselves in new experiences without bias
- reflect upon experiences from multiple perspectives
- integrate their observations into logically sound theories, and
- use these theories in decision making and problem solving.

This kind of practice is being promoted by new accreditation processes for graduate engineers in Australia (Jolley, & Radcliffe, 2000) and has the potential to deliver on many of the recommendations about graduate attributes now recommended by Australian Universities (McLoughlin & Luca, 2000).

The terms reflection and reflexivity need to be clarified at this point. Reflection has a focus on phenomena more divorced from the practitioner, whereas reflexivity is reflection based on personal experiences of learning, which fundamentally changes the relationship between the learners and the learning process. To illustrate this point Argyris (1988) distinguishes between single-loop learning and double-loop learning. Single loop learning occurs when the learner detects an error and corrects this without questioning or altering his/her learning approach. Double loop learning occurs when errors are corrected by examining and altering the learning processes and the actions surrounding learning in general. The distinction is important as reflection merely changes the outcomes of learning, while reflexivity changes the person and the process. Schön (1995) also makes a similar point by distinguishing between reflection-in-action and reflection-on-action. Reflection-in-action is tacit and is designed to improve action and performance. Reflection-on-action (reflexivity) is a higher order skill designed to improving self and future practice. These processes can be supported and fostered in Web-based learning environments.
Design of the learning environment: using technology to support reflection

The connectivity and communicative possibilities offered by online technology make possible a range of cognitive and metacognitive processes including the capacity to reflect, both individually and as a group. Reflective dialogue using computer-mediated communication is enabled when learners engage in collaborative tasks (McLoughlin & Oliver, 1998). Revision, reconstruction and rethinking of ideas occurs when tasks enable students to exchange ideas, comment on each others’ work and engage in critical self-assessment (Seale & Cann, 2000). In other studies, both individual and group reflection are fostered when gaps and contradictions in knowledge are identified and by using technology to support self-explanation and articulation of ideas. In this case, the emphasis is usually on immediate reflection rather than reflexivity, which is the higher order cognitive process. In the study reported here, online debate and problem solving were regarded as the primary mechanisms to support both individual and collaborative reflexivity. The combination of problem solving tasks with collaborative social discourse were investigated as triggers of metacognitive thinking in the learners who participated in the study.

Context of the study

The context of the study was tertiary level online unit in project management that is part of a degree program in Communications and Multimedia. The unit of study on project management is currently delivered online using WebCT software, and is available on-campus and in the distance mode of study. Project management skills such as needs analysis, design specifications, storyboards, concept maps, evaluation, legal issues, quality auditing, and scheduling are developed and applied in the creation of a Web site by "project teams", or small groups of students who work collaboratively as they would in an industry context. The objective of the team project is to promote team and client collaboration skills by focussing on a common task. Learning and assessment processes are integrated throughout the duration of the one semester unit. The assessment consists of project team-based work, team problem solving, peer assessment, individual reflective reports, a client mark and individual postings to a weekly online forum.

Assessment in the online unit is based on authentic tasks planned for their relevance to workplace settings. Students worked in teams to create a product that is offered to clients (peers) for evaluation, and tested for functionality in a real context. Working online enabled students to provide multiple forms of peer support though shared tasks, teamwork, collaborative work, and opportunities for feedback and peer review. These supportive processes developed communication skills while creating an affective climate of support for thinking skills, discussion, negotiation and reflective processes.

Figure 2: Reflection before, during and after experience
Theoretical framework: experiential learning

Through the design of problem solving tasks, the project management unit introduced learners to situations and ways of working with others that were experientially based. The processes of learning were emphasised from the outset and students were encouraged to have ownership of the learning, assessment and reflection processes. For Kolb (1984), the actual experiences people go through become the starting points for learning, and this underlying educational approach was reflected in the design of the online environment. Emotion and reflection are also an integral part of the cycle of learning, and reflective processes are intrinsic to learning from experience. In an experiential learning cycle, the learner passes through each of four stages: concrete experience, reflective observation, abstract conceptualisation, and active experimentation. Our design ensured that we linked the experiential learning cycle to the online environment and the collaborative tools afforded by the technology as follows:

- **Active experimentation**: Students engaged in the discussion and resolution of problems through online discussion using multimedia tools to support the display of responses (e.g., Cox, 1994).
- **Task engagement**: Peers analysed the output of the task, and compared problem-solving approaches through discussion, email and conferencing activity (Bonk & Cummings, 1998).
- **Reflection**: Individuals analysed and reflected on the learning tasks, group processes and self-development as they tested new ideas and perspectives in virtual learning groups (English & Yazdani, 1999).
- **Formation of abstract concepts**: Utilising peer and tutor feedback, students developed understandings of key course concepts through engagement with new ideas supported via communications networks (Collis, 1998).

![Diagram of the experiential learning cycle](image)

**Figure 3: Course pedagogy**

Experiential learning was reinforced in various ways through the course pedagogy, which focussed on both process and content aspects of learning. (See figure 3). Students participated in decision-making processes by choosing and defining a topic for their project, creating and managing their own development team and negotiating peer assessment. The design was based on pedagogical and curriculum philosophies that acknowledge group work, peer feedback and support as essential to the development of independent learners and practitioners (Candy, 1994; Boud, 1985). Reciprocity in giving and receiving peer feedback provides learners with opportunities to deepen their interpersonal skills. Through these processes they also developed reflective skills, and learnt to monitor their own learning and appreciate the contribution of others to their learning. Thus, by focussing on learning process and peer supported activities, the learning tasks took on a broader perspective, to include the totality of the learning experience while consolidating those aspects of professional learning that would enable the learners to develop transferable skills.
Student reflections on problem solving strategies

The student participants formed four teams who engaged in problem solving, giving feedback on each others' solutions and peer assessment processes. These students completed authentic problems, where they were required to implement these skills in a 'real' environment, with 'real' clients and produce 'real' product. This work place component is designed in order to engage students in a range of experiential learning tasks in which they give feedback on each others' performance in groups and reflect on their own and others' performance. In the first task students were asked to reflect on the problem-solving processes they had engaged in while solving problems and then asked to articulate these during class discussions. This enabled the students to reflect on their own strategies, to identify areas of weaknesses and to conceptualise ways of addressing those weaknesses. Students were asked to write down the major strategies used when solving problems. As shown in Table 2, the salient features of student problem solving strategies were:

- researching the topic thoroughly;
- reading the question carefully and considering different angles;
- checking that the content used is correct;
- comparing ideas with other students; and
- brainstorming to consider different views and ways of approaching the problem.

While these processes represent some of the major elements of expert problem solving strategies (Lipman, 1991; Paul, 1994), they nevertheless do not include all of the possible expert problem solving strategies such as planning, testing possible solutions, revising and checking details.

Student perceptions of peer feedback as support for learning

Students were encouraged to articulate the changes they would make to their solutions in the light of feedback from peers, and to use this feedback to improve their own learning and problem solving. This form of reflective practice is part of experiential learning and supported by the work of Mezirow (1990) who emphasises the role of critical reflection in self-directed learning. On-line learning can support critical self-reflection and peer reflection by providing access to others' work, but the actual reflective process needs to be facilitated by a tutor. Comments made by learners on how they would improve their problem solving strategies included the following:

- Do more research;
- Plan my time;
- Read the questions and predict what the solution might be;
Develop my solution further with examples; and
Add specific details on various points and provide examples of these.

In addition, students were asked to document and explain the impact of peer feedback on their own learning approaches. They found this task unusual, and had not previously considered that other student views would influence their own ways of thinking and problem solving. The responses demonstrate that students did in fact adopt a deep approach to learning and that the peer support promoted reflection and further dialogue. Table 3 provides examples of comments made and links these comments to implicit learning processes. The learning processes identified in Table 3 are indicators that student learning was enhanced by peer support and feedback and that participants raised their awareness of other’s perspectives and became more aware of their own strategies.

The tasks that fostered reflective practice were built into the learning environment and also integrated with the assessment tasks that students were required to complete. Each assignment required students to record their reflections on self, task and others. Table 4 shows the summary of typical responses from individuals.

Conclusions

It could be argued that the best way to make expert knowledge accessible to non-experts is to foster the use of reflective activities on successes and failures. This was achieved in the online environment by enabling group and individual reflection through both online and offline activities. In the study reported here, this combination
proved to be very productive, where reflection was systematically built into the environment through both task design and assessment. The learning activities helped students develop responsibility for their own learning, and gave them the scope to develop personally and professionally. The technological support afforded by online communication tools and asynchronous conferencing were integral to the development of the course.

Abstract: On-line forums provide opportunity and potential for collaborative work, dialogue and study that can increase the flexibility of learning while motivating participants. By enabling teacher-learner and learner-learner interaction online systems can support the essential elements of a learning conversation by providing scope for discussion, dialogue and interaction. It is argued that this medium presents a socio-cognitive educational domain, unique in its potential for dialogue, participation and collaboration and a departure from face-to-face didactic paradigms of learning. Often, the types of verbal interactions and the means by which new knowledge is created on-line are not well understood. The paper provides frameworks for tertiary teachers and moderators of computer conferences that can be applied to the analysis of processes and activities that occur in text-based conferencing.

Learning on-line: Social aspects of knowledge construction

Theories of social learning emphasise that learning involves social processes and the use of tools. There is much common ground between sociocultural theory (Vygotsky), situated learning theory and cognitive apprenticeship theories (Brown, Collins & Duguid, 1989). All theories emphasise that use of tools, both tangible and intangible including language and technologies shape thought and action. Research on computer conferencing has been positive about its potential and outcomes, promoting its advantages and merits as a form of socio-cognitive experience. However, it may be best to adopt a more skeptical and critical view and to question whether the advantages of computer conferencing may be exaggerated. While online forums claim to enrich student learning and collaboration, many researchers have dedicated their effort to ascertaining whether in fact text-based interaction leads to learning outcomes (Hammond, 1999; McConnell & Banck, 1998; Hara, Bonk & Angeli, 2000; McKinnon & Aylward, 2000). Recently, online forums have been lauded because of their capacity to sustain collaborative learning by enabling sharing of views, resources and ideas through peer support. It is claimed that the social, interpersonal and interactive features of online forums are most supportive of collaborative dialogue, as they reduce isolation and increase group participation in learning.

From the perspective of assessing student learning, it is important to establish how knowledge construction is achieved within a computer conference, and how text-based interaction achieves learning outcomes. By conducting an analysis of the dynamics of on-line forum discussion, it is possible to understand the depth of inquiry, the quality of dialogue and outcomes of interactions and to build on these aspects in order to improve the design of conferencing activity.

Context of the study

The final year students in the Interactive Multimedia course at Edith Cowan University are required to develop skills and expertise in project management. A unit of study on project management is delivered on-line using WebCT software, and is available on-campus and in the distance mode of study. Students learn about project management methods (such as needs analysis, design specifications, storyboards, concept maps, evaluation,
legal issues, quality auditing, scheduling and costing) and put them to practice by creating a web site in project teams. The objective of the team project is to promote team and client collaboration skills by focusing on a common task.

Students are continuously assessed throughout the duration of the one semester unit. The assessment consists of project team-based work, task-team work, peer assessment, individual reflective reports, a client mark and individual postings to a weekly forum. Participation in the conferencing task is continuously assessed throughout the semester. The task team assessment requires the team to publish a short summary paper on the bulletin boards at the beginning of the week on an aspect of project management such as team dynamics, legal issues, scheduling etc. and to raise issues for discussion. The task team is also responsible for moderating the discussion during the week and then providing a synopsis at the end of the week. Usually students assume roles within the forum so that each team member participates in a task such as production of a short outline/issues paper discussion moderation or synopsis and summary.

Students are assessed on bulletin board contributions which account for 30% of their total mark. Participation in the forum is compulsory. There is little intervention by tutors in the discussion forum except to provide explanations and procedural information when required. Students are left to develop a discussion which is relevant to the assigned topic and the forum is therefore truly “student centred”. The structure of the weekly contributions and roles of team members do not vary, and each week there is a forum leader, questioner and summariser of information.

Investigative Questions

The focus of the research was to evaluate the educational potential of the forum by investigating the quality of interactions that occurred. Specifically, the aim was to investigate:
- the nature of the text-based interactions and whether the contributions were educationally valid and led to knowledge-construction processes or merely social interchanges;
- the nature of group information processing and group dynamics
- whether students regarded the discussion forum as a serious learning tool.

The primary objective of the research was therefore to analyse the value of the discussion forum for knowledge construction, to refine the assessment instrument used by tutors, and to assess the activities planned for the forum. A further goal was to go beyond the superficial counting of utterances and quantitative analysis of messages to a deeper understanding of communication and learning processes on-line. The need for more research in this area is becoming more urgent as off-campus modes of delivery utilise computer conferencing and several Web-based course support systems provide functionalities that enable discussion between learners. Up to now the adoption of computer conferencing has flourished despite the paucity of research and theory on which to base its contribution to knowledge development in learners.

Linking on-line discussion to learning

The on-line forum developed for Project Management is an asynchronous learning environment in which group collaboration takes place through the mediation of technology. The participants in the on-line forum in the first semester 1999 could be regarded as a community of adult learners. Some learners had extensive practical experience in project management for interactive multimedia. Others were relative novices. The aim of the forum was to provide a constructivist learning environment where participants could share knowledge, discuss ideas and contribute to each other’s understandings of important issues in the management of multimedia development.

In reviewing literature relevant to this unique community of on-line learners, a socio-constructivist perspective seemed most appropriate. The socio-cultural approach to learning requires close examination of the contexts in which the learning occurs, and is illustrated in the work of a number of practitioners and researchers (Aviv & Gola, 1997: Bonik & Sugar, 1998; Gunawardena, Lowe & Anderson, 1997; Laurillard 1995). A social-constructivist approach to learning is also reflected in the words of Säljö (1994: 91) who states that “... it is important to consider seriously the role of communication and interaction for learning, and to employ
analytical perspectives in which the natural habitat for individual action is shared human activity'. Analytic approaches consistent with this focus on communication and interaction are linked to socio-cultural theory.

**Approaches to the analysis of on-line talk**

Recently, there have been several attempts made to provide an analysis of ‘cybertalk’, though examination of the transcripts of text-based discussions (Eastmond, 1995; Gudzial, 1998; Jarvela et al, 1999; Salmon, 2000). At the same time there is well-documented evidence of strongly opposing views as to how talk should be treated as evidence of learning and of thought (Edwards & Westgate, 1994). Among the approaches to talk-analysis which have contributed to our understanding of classrooms there are several: sociolinguistic, ethnographic, conversation analysis, systematic observation, and interaction analysis, each with a distinctive array of analytic procedures and conventions for setting out transcripts of data, drawing inferences and analysing cognitive processes.

Originating with Flanders (1970), interaction analysis describes and categorises various forms of instructional practice that take place between teachers and students where there is a teaching-learning speech transaction. Such categories tend to be prescriptive and narrowly defined, reflecting static rather than dynamic patterns of interaction. All categories are a priori, and assigned to the talk by observers who systematically record occurrences. As the categories are predetermined, this seriously restricts observation of behaviours, as only those categories defined in the observation schedule are recorded. Other studies have used variations of the coding process. A recent study of peer interaction during collaborative writing with computers (Kumpulainen, 1996) used a system of analysis which classified linguistic utterances according to the functions displayed. In a study of the development of scientific reasoning, Azmitia & Montgomery (1993) used a coding scheme to quantify features of scientific reasoning which included justifying solutions, evaluating, clarifying, questioning and explaining. This research, like that of Nastasi & Clements (1992) was based on the Piagetian concept of cognitive conflict, which related success in problem solving to the degree of conflict or verbal disagreement that arises among peers. The data analysis procedures were nevertheless of interest to the present study as they highlighted the role that dialogue and transaction played in supporting reasoning and testing of ideas which are outcomes expected of tertiary students. A related approach to data analysis is content analysis (Henri, 1992), which highlights critical dimensions of the learning process and conducts an analysis on a multilevel basis, assigning behaviours to different features of the learning process. Henri developed a content analysis model based on four dimensions, relating to the educational quality of messages. Four dimensions were proposed for transactions: social, interactive, metacognitive, cognitive. A further dimension relating to the analysis was a quantitative dimension, to reflect the total number of messages posted by one person, as an indicator of the level of participation. Henri’s method of analysis has been elaborated and transformed by Gunawardena, Lowe and Anderson, (1997) who propose a social constructivist approach to knowledge building in on-line environments. Their analytic model proposes that knowledge construction moves through five phases (1) sharing ideas (2) discovering different perspectives (3) Co-construction of knowledge (4) Testing and revision of ideas (5) metacognitive awareness of newly constructed knowledge.

**Methodology**

The study used a combination of research instruments and approaches. The researchers conducted a transcript analysis using the text-based interactions of the weekly forum and created a survey instrument which elicited students' views. This approach enabled triangulation of data sources and provided multifaceted analytic tools with which to analyse the dynamics and processes of on-line discussion.

**Survey**

The survey instrument consisted of two sections each with a number of Likert scale questions. Part one focussed on the knowledge creation aspects of the forum (Table 2) and asked students to rate the value of the forum in terms of its relevance, opportunities for collaboration, reflection, discussion, exposure to new ideas and understanding. Part two of the survey asked students whether the forum supported group work, collaboration, feedback and collective goals.

Transcript analysis

The analysis of the forum transcripts consisted of a number of procedures. In the first stage of analysis, the overall pattern of talk was reconstructed by means of a concept map showing the flow of interactions, and the number of postings that each thread attracted from students. This visual approach enabled the researchers to make sense of the data. The second stage of analysis involved assigning each message to one of the phases of the model. Discrepancies were discussed and an agreement on coding was concluded from these discussions.

Results

Because of the amount and complexity of data in each of the weekly discussions, it was decided to investigate only a portion of the whole corpus and to analyse three consecutive weeks of the forum discussions. Weeks 3, 4 and 5 were selected for content analysis, and the researchers assigned each message in one of five categories. Table 4 shows the total number of messages posted for each of these weeks and the number of messages in each phase. The results indicate that most of the forum messages were in the first category of comparing and sharing information. These interactions were forms of social interchange between group participants. There was little evidence of construction of new knowledge, critical analysis of ideas or instances of negotiation. Instead, it could be concluded that the majority of on-line interactions were related to the elaboration of existing beliefs and knowledge (Table 4). This exchange of information consolidated participants’ existing knowledge schemata and therefore
performed an important aspect of the learning experience. However, while this kind of activity added little to the knowledge base, it nevertheless offered a forum for display of existing knowledge. The forum did not appear to foster testing and revision of ideas and negotiation of meaning. Table 4 shows that only 1%-3% of contributions could be categorised as knowledge testing and awareness of knowledge building.

**Student perceptions of the discussion forum**

The responses to the survey instrument were tabulated and displayed using descriptive statistics. The survey instrument provided insight into learners' perceptions of the knowledge construction opportunities and group work processes. The survey instrument was designed to determine learner perceptions of the conferencing experience, and to explore student attitudes to the dimensions of knowledge building and support for group work in the forum. The results of the questionnaire were every positive, showing that students found the discussions relevant, engaging, a source of new ideas and capable of increasing understanding. However, the quality of the on-line interactions showed that the majority of exchanges did not contribute to new understandings or to revision, challenging of ideas and reflection. With respect to group work, students perceived the forum as affording opportunities for group discussion, clarifying ideas, team work and group feedback. The open-ended questions showed that students considered the process very time-consuming, but appreciated its capacity as a communication tool.

**Discussion**

The analysis of data gathered from the transcripts showed that participants engaged in display of knowledge, comparison of ideas and elaboration of personal knowledge. The processes underlying these exchanges were social and participatory, and did not involve learners in conflict, challenging or revision of ideas. According to constructivist theory, knowledge building involves learners in negotiation of meaning, reasoning and reflection on authentic tasks and engagement in conversation where knowledge is revised (Luarillard, 1995). These processes were not evident in the dialogue, although student perceptions of the discussion forum showed that they were positive and committed to group processes. The forum was supportive of group dialogue, social cohesion and sharing of ideas, and for many learners these aspects of on-line dialogue consolidated their understanding and were regarded positively. The fact that this pattern of interaction characterised the discussion forum for the entire duration of the course may have conditioned participants to engage in surface level processing and display of knowledge. The dominant social transactions and protocols that occurred can be classified as communication, negotiation and consolidation. This findings concur with those of Jehng, (1997), who emphasises that psycho-social messages tend to dominate in online forums and that virtual groups tend towards social and collaborative interactions.

**Implications for practice**

The study provides evidence that if forum discussions are to become knowledge construction events, we need to provide orientation and support to learners to help them engage in critical analysis of their own views and revision of concepts in the light of multiple viewpoints and disconfirming evidence. This can be achieved by the tutor modeling the kinds of processes that aim at inquiry into concepts, rather than display and comparison of existing ideas. It would also require students to learn how to articulate their current understandings and misconceptions. However, this process is constrained by the need to socially edit one's contribution in order to appear 'correct' and to maintain the illusion of being knowledgeable. Affective concerns in relation to computer conferencing should also be considered, as social constraints operate to constrain open inquiry and construction of new ideas, particularity if all contributions are being assessed. Group moderation, task design and the scaffolding of dialogue towards refining, defending and elaborating ideas is essential if participants are to move beyond display of ideas.

Abstract: In this paper we bring together two different strands of research and apply them in the development of a technology-based metacognitive support tutorial. The first strand of research relates to the finding that effective problem-solving can be fostered by enabling students to apply metacognitive strategies when solving tasks. The second finding is that metacognition is best developed through process-based approaches in which structured forms of social interaction and learning are implemented. We describe a web-based tutorial being developed at the University of New England that is based on these two findings, and which helps to develop the metacognitive skills of first year science students. The tutorial is designed for students in Biophysics, Biology and Chemistry, studying both internally and externally. Metacognitive skills are fostered in the tutorial by developing learners' awareness of the problem-solving approaches of their peers and experts, by offering modeling and coaching in problem-solving strategies and by employing pedagogies that enable learners to monitor and self correct their own problem-solving approaches and become more reflective learners.

Introduction

In this paper we discuss a project that is directed towards the effective development of metacognitive skills among first year science students. We do this in the light of current findings on the lack of well-developed metacognitive skills in learners and also by drawing on our own experience of teaching in a regional university catering to both internal and external students.

The changing profile of students currently entering universities in Australia is creating pressure for change in teaching approaches. Current student intakes include students from diverse backgrounds with a significant proportion arriving without a strong background in science. This requires university teachers to support learning in what is for many first year students a new area of learning. Diversity in learning backgrounds also characterises the student body. Many external students have been away from study for a number of years and may not have the learning skills required for tertiary study. Moreover they may feel a sense of isolation in not being able to work cooperatively or see the quality of their own work in relation to others enrolled in their units. It clearly is important to generate positive feelings of success in study by integrating appropriate learning skills in the teaching of science. Separate study skills programs can lead to short term improvement in some learning strategies, but are less successful in the longer term. "Students do not always apply strategies they have learnt to other contexts, because they are unaware that they are relevant to the task. It may be that even when they recognize that a particular strategy is relevant, they do not know how to apply it" (Chalmers & Fuller 1996). In our experience many students do not see the relevance of general study skills programs as they cannot apply them directly to what is being taught, and often their first priority is to complete the next assignment. Recent studies on constructivist learning in science have in common a movement away from teacher driven paradigms of learning, a greater emphasis on understanding how students approach their own learning and the use of constructivist, small group techniques to foster higher level cognitive goals.

Harnessing technology to support thinking processes

As information and communications technologies for both on-campus and distance education students are developed, progress is being made in using this technology to teach science at the university level in exciting new ways. For instance, in chemistry, innovative, interactive visualisation programs give students vastly improved opportunities to understand processes occurring at the molecular level (Kozma, Chin et al, 2000). In many science subjects simulations of processes and experiments allow students to explore concepts in new ways, enabling them to become self directed learners. For example the Cognition and Technology Group at Vanderbilt (CTG, 1992) has
developed and evaluated multimedia based instruction that is designed to help students to think, reason and solve problems.

Networked learning environments enabling student-student and student-lecturer communications are now open, flexible and more democratic through the use of email, bulletin boards and chat rooms, while students enjoy the autonomy of gaining access to expertise worldwide through Internet resources. However, structured learning environments that support specific skills relevant to problem-solving in science are much needed. In response to this, there is also a growing emphasis on developing higher order cognitive skills among university science students (Barouch, 1997), (Sleet, Hager, Logan & Hooper, 1997), (Bucat & Shand, 1996). Essentially what matters most in learning in the sciences is the capacity to analyse and classify data, to gather evidence about solutions, to solve problems and to apply and test theories. Clearly, the knowledge base in science is expanding too fast to ensure that students cover all aspects of scientific knowledge within the duration of a university course. The alternative is to offer students learning experiences that allow for conceptual exploration and acquisition of the thinking skills needed for their future learning. It is on this assumption that we seek to develop an online environment for development of metacognitive skills.

Teaching science: Problem-solving or content coverage?
Let us consider briefly how first year science subjects are taught in many universities. Over emphasis on rote learnt content and terminology still characterises much science teaching at tertiary level, to the detriment of student learning. First year biology students typically have to cope with as many new terms as a students learning a new language, apart from trying to understand the new concepts being introduced. If lecturers still hold to a transmission approach in their teaching combined with a focus on content coverage, this forces students into surface learning approaches.

Another characteristic of university science subjects is that scientific concepts may be largely removed from the everyday life of students and real world applications. Students in chemistry must struggle with unfamiliar names and symbols, while they also need to understand new concepts, which are often presented in a decontextualised, abstract manner. Often the pace of delivery is such that there is little opportunity for students to understand new concepts in a qualitative way first, to explore them and to verbalize their ideas, before applying these concepts to less familiar situations. However, teaching in science need not be about content coverage, factual recall and the application of formulae, but about problem-solving.

There is a vast literature on problem-solving in the sciences, which is a largely untapped resource (Gabel, 1994). There is also a growing emphasis on developing higher order cognitive skills of university science students (Barouch, 1997, Sleet, Hager, Logan & Hooper, 1997, Bucat & Shand, 1996). Problem solving is the skills most central to successful learning in the sciences, and this assumes that students can generate questions and apply metacognitive skills to help them achieve solutions.

Metacognitive skills in science learning: Operationalising the concept
The term metacognition refers to a learner's knowledge about his or her processes of cognition and the ability to control and monitor those processes as a function of the feedback the learner receives via outcomes of learning (Metcalfe & Shimamura, 1994). Thus, two essential components comprise metacognition: knowledge and control. Metacognitive knowledge refers to what a learner understands and believes about a subject matter or a task, and the judgments s/he makes in allocating cognitive resources as a result of that knowledge (Flavell, 1987, Brown, 1987). Metacognitive control refers to the tactics and strategies a learner devises to achieve specific learning goals and the degree to which the learner organizes, monitors, and modifies those operations to ensure that learning is effective (Jacobs & Paris, 1987).

With regard to metacognitive control, Schraw (1998) explains that attention resources, existing cognitive strategies, and awareness of breakdowns in comprehension are all enhanced by metacognitive knowledge and skills. Learners who use both improve their academic performance. Thus, metacognition is important to an understanding of learning in the sciences because learners must regulate their cognitive tactics and strategies in order to construct meaning from their reading, lectures, and laboratory experiences. Moreover, as science, physics, chemistry, biology, etc. are new and relatively unfamiliar informational fields, learners have to be more active, exploratory and self-regulated during the comprehension-building process (Tergan, 1997).
Development of metacognitive skills in tertiary contexts
To date much work on developing metacognitive and problem-solving skills has been done at the primary and secondary level (De Jong, 1992). Research at tertiary level is less, but there have been studies in the sciences in physics (Mettes 1987), mathematics (Schoenfeld, 1985) and computer programming (Volet, 1991; Volet, McGill & Pears 1995). In Volet’s (1991) study, computer programming students coached in the use of a metacognitive strategy for writing programs over a semester achieved better overall course results than a control group. Longer term benefits were also seen in that more of these students enrolled in and passed the advanced computing unit in the following semester.

Outside the area of science, business economics students given a series of sessions over the academic year related to orienting (problem identification or task definition) achieved superior results, not only in this subject, but also in a statistics unit (Masui & de Corte, 1999). Both these studies emphasize the importance of the design of the intervention and metacognitive training for effective outcomes.

Design stages for the online environment
Based on extant research on metacognitive training, a Web-based tutorial has been developed to support the metacognitive skills of science students. The environment for metacognitive training will combine Web-based scenarios with problem simulations in order to engage learners in actual problem-solving and reflection on their own problem-solving strategies. Eight phases of learning are involved.

In Phase 1 the concept of metacognition is operationalised. For the problem in question, the students need to become aware of the problem-solving processes involved. For example this requires analysis of the question, planning a solution, selection of strategies and self-monitoring skills that can be used.

Phase 2 involves the design of the problem environment. For particular problems in a topic in Physics or Chemistry for example, examine the different ways in which an expert and a novice student might answer the problem. The problem is then presented to the student to work on in Phase 3. Student responses are monitored in Phase 4 to decide if any Intervention (Phase 5) is required. Phase 5 presents students with a scenario or problem where they are assisted in the processes and procedures of problem-solving, and made aware of their own problem-solving strategies.

In Phase 6, successful students are presented with further problems in the topic area to check whether they have transferred the strategies learnt during Phases 3 and 4. If they have not, training continues. In Phase 7 students are given the opportunity to reflect on their problem-solving. The final Phase 8 involves a refinement of the training to create design guidelines for a problem-solving environment in different subject areas (biology, physics and chemistry) in order to foster metacognition.

Instructional design principles applied to metAHEAD program to support metacognition
How might these instructional design principles to develop metacognitive awareness and problem-solving skills be implemented in a technological environment? In the design we have combined both constructivist and adult learning principles to support student self-direction on problem-solving and reflection.

The design of the environment must builds in from the beginning three important implications of social constructivist theory concerning reflective thinking. First, in order to foster reflective thinking students need multiple sources of feedback on their understanding gained through social interaction. Second, reflective thinking will most likely occur in situations where problems are complex and meaningful to the student. Third, reflective thinking requires the student to organise, monitor and evaluate their thinking and learning to come to a deeper understanding of their own processes of learning. Bearing these aspects of reflection in mind, the technology-based environment can provide scaffolds to enhance reflection through four types of feature (Lin, 1998), (Elen & Lowyck, 1999). MetAHEAD supports the following processes:

Process displays: where the strategies adopted by the student are explicitly shown what they are doing in performing a task. Both the processes used by the student and the responses created by the student will be made visible, thus enhancing self-awareness.

Process prompting: asking students to explain what they are doing at different stages throughout their problem-solving procedure.
Process modelling: Students will have access to databases and video displays explaining what, how and why other students and experts do what they do in solving a specific problem.

Reflective social discourse: This is an online discussion space where students share their learning experiences and gain feedback from a community of learners.

To evaluate the success of the tutorial, it was considered important to assess the degree to which the program was successful in supporting metacognition, rather than produce evidence that problems had been solved. Two types of evidence were gathered: process evidence and product evidence. Process evidence was gathered during problem solving while students discussed their strategies in action using a bulletin board, while product data in the form of written learning logs indicated how students worked through problems.

Implications for practice in other settings: Designing problem-solving tasks

In creating a supportive environment for development of metacognitive skills, we have not limited our focus to developing metacognitive skills with individual students studying science. Instead, we have created a social, interactive Web-based environment that provides support for metacognitive skills such as the development of self-reflection, peer-assessment and revision.

These generic aspects of design have implications for the development of metacognition in other settings. Student awareness of their own skills, self-directed learning and intergroup communication between learners is fostered by Web-based functionalities, such as bulletin boards and shared discussion spaces. We assume that a limited number of problem-solving and metacognitive skills are applicable to the domains of chemistry, physics and biology as taught in first year of study. Nevertheless we assume that many aspects of successful metacognitive development require knowledge of the subject domain, thus we situate the training within particular disciplinary knowledge rather than attempting to develop a decontextualised set of metacognitive competencies and skills. Metacognitive skills are developed in functional contexts providing multiple domain application examples and experiences.

The selection of contextualised problems for students is an important one, with implications for practice in other settings. Too much of what is required at present in first year science is concerned with factual recall and only exercises lower order cognitive abilities. We intend to progress from the level of drill type exercises to more ill defined, real world problems involving higher level cognitive abilities. One of the objectives of MetAHEAD is to bridge the development of metacognitive skills across a range of subject areas, integrating subject learning with metacognitive skills training. By explicitly and continually emphasizing metacognitive aspects right from the outset, significant benefits will occur for students.

Conclusion: Supporting metacognitive processes in computer supported environments

The project described here is the initial phase of a two-year research project dedicated to development of metacognitive skills in science. We believe that students' metacognitive skills can be developed significantly by taking a proactive approach and by designing an environment specifically for problem-solving and metacognition. Teachers who are expert in one or more of the respective domains come to the teaching/learning transaction with well-rehearsed knowledge about their own skills and procedures in the domain. For a teacher, this metacognitive knowledge has developed over years, for example, through professional expertise, personal reflection and making observation of student learning, and noting conditions and situations in an everyday environment that reveal relationships and realities of pertinent phenomena. Indeed, most teachers begin to derive significantly more metacognitive knowledge when they actually teach. That is, the process of teaching drives them to think of the material in terms of the way the information will be learned. New learners, on the other hand, come to the subject matter domain naive with respect to this knowledge.
Figure 3 Flow chart diagram for metAHEAD tutorial

This project proposes that metacognition can be developed in contexts that engage students in self-monitoring their own problem-solving approaches, in scenarios where they can ultimately use that knowledge. This requires creating real life anchors for development of problem-solving skills and enabling students to explore, test and review their own strategies. Though the project is still in the initial phases, we anticipate that the research will result in significant changes to the way teaching in the sciences is currently conceptualized.

Abstract: Self-Regulation has long been seen as a desirable but difficult to achieve instructional aim. This is particularly true of on-line learning, where users have limited instructional support and where attrition rates tend to be greater than in face-to-face teaching. This paper examines the nature of self-regulation, identifying affective and cognitive skills which make for self-regulated learners. The broad psychological states of metacognition and self-concept are identified as well as the motivational and cognitive processes that underpin them. The volitional, learning, and regulatory strategies which learners use are delineated. These are placed within the context of on-line learning. Aspects which characterise learning environments which support self-regulation are identified, and suggestions are made as to how self-regulation can best be enhanced within on-line courses.

A Need for Self Regulation

Universities are moving more and more towards flexible modes of delivering courses; a trend which is impacting on the nature of both teaching and learning. Educators are coming to terms with the challenges of developing courses to be taught remotely and asynchronously, while students, too, are battling with these new modes of delivery. While high school has traditionally been a face-to-face experience, post secondary and tertiary education is limited in its contact time and is being increasingly channelled through Multimedia and Internet resources. This lack of close social interaction significantly diminishes the regulatory mechanisms that ensure students' smooth progression through their course.

This is not necessarily a bad thing. In the end, students must be responsible for their own learning. After all, "learning is not something that happens to students; it is something that happens by students," (Zimmerman 1989, p 21). However, it is unreasonable to assume that students will be coming into a course with the skills to regulate their own learning. (Bockaerts 1997) describes formal schooling as 'outcome based practice sessions' with teachers as experts and students as novices. In more flexible approaches, as in on-line tertiary education, this paradigm is no longer appropriate. Students need to become protagonists in their learning process, using the Internet as a resource for their own learning goals.

It is hardly surprising that there is a high drop-out rate for students with poor study skills when they venture on-line (Loomis 2000). Brooks (1997, p. 135) goes so far as to claim that students "who are poor at self regulation easily can be slaughtered in www-based courses". This does not however acknowledge some of the main benefits of on-line learning – that it is an efficient and flexible environment for users to meet their own learning goals. Attempting to
remodel on-line learning on a face-to-face paradigm would dilute these benefits. Perhaps most importantly, there is also a need to acknowledge that self-regulated learning is a desirable thing that is important to life as much as school (Boekaerts 1997). If an educator’s role is to assist students in becoming better learners, then courses need to be designed not just to meet specific unit outcomes but to scaffold the development of learner’s self-regulatory skills. This is particularly true of on-line learning. Rather than throw students ‘in at the deep end’ mechanisms must be in place which bridge the nexus between supported and self-regulated learning. In order for this to happen, however, a sound understanding of what self-regulation is, and how it can be inculcated within in students, must be developed.

A definition of Self Regulation

Self-regulation is somewhat easier to define than understand. It has been described as ‘the process whereby students activate and sustain cognitions, behaviours, and affects, which are systematically oriented toward attainment of their goals’ (Schunk & Zimmerman, 1994). This definition is reinforced by (Brooks 1997), who argues that that it is active and goal directed, resulting from self control of behaviour motivation and cognition. This emphasis on multiple constructs places Self-regulated Learning at the junction of several fields of research (Boekaerts 1997). It emphasises students' reliance on their own internal resources to govern their learning, but these resources are not easy to delineate. Self regulated behaviour is an end process, dependent upon the affects and cognitions that precede it. These are to a certain extent inaccessible, since they are internally constructed and not always explicitly articulated by individuals. Also, the notion of self-regulation is prone to multiple interpretations based upon educational philosophy. (Zimmerman 1989) identifies it in terms of Phenomenological, Social Cognitive, Volitional, Vygotskian and Cognitive Constructivist Theories. All of these approaches bring a unique framework to the concept. Behaviourist approaches emphasise self-monitoring, self-instruction and self-reinforcement, while a phenomenological approach defines it in dimensions such as self worth, planning, and goal setting. Common to most of these however, is an acknowledged of the interaction of affective and cognitive processes at a level of abstraction. Self awareness at a cognitive and emotional level would appear to be the key enabling process in the development of self-regulatory strategies.

A model of Self Regulation

A number of models have been developed to explain the processes that underpin Self-Regulated Learning. (Boekaerts 1997) provides a six component model based upon the following notions:

- Content domain
- Cognitive strategies
- Cognitive regulatory strategies
- Metacognitive knowledge and motivational beliefs
- Motivational strategy use
- Motivational regulatory strategies

These elements are co-dependent and interact with each other in the application and development of goals, strategies and domain-specific knowledge.

(Garcia 1994) articulates self-regulation in terms of knowledge and beliefs, strategies used, and outcomes. Each of these is moderated by motivational and cognitive components such as personal beliefs and conceptual knowledge, motivational and cognitive strategies, and quantity and quality of effort.

Common to both models is an integration of both affective and cognitive issues:

"Neither motivational nor cognitive models alone can fully describe the various aspects of student academic learning, yet the two types of models are complementary due to the respective strengths and weaknesses of motivational and cognitive models." (Garcia 1994)

Figure 1 represents a synthesis of the above frameworks. It accommodates the role of both affective and cognitive aspects of self regulation, but also acknowledges the effects of external environmental factors upon an individual's ability to regulate their learning. Self regulation is viewed here as the intersection of self awareness at both a rational and emotional level. Metacognition and self concept are seen as the primary enabling process in this model, with self
monitoring and motivation as subordinate processes which are involved in the development of cognitive and motivational strategies. Each will be discussed in turn.

![Figure 1 - Model of Self-Regulation](image)

**Metacognition and Self-concept**

Self awareness has always been an important educational construct. Metacognition can be defined as "knowledge and beliefs about thinking and the factors affecting thinking" which regulate "the articulation of strategy and knowledge" (Pressley 1998). As such it is a necessary precursor to self regulation. Flavell (1987) identifies three types of metacognition: knowledge of self, knowledge about various cognitive tasks and strategy knowledge (Boekaerts 1997).

The first of these should not be confused with self-concept, which appears to be quite a subjective element, although there have been attempts to delineate it in a more hierarchical way (Zimmerman 1989). While metacognition is often associated with issues such as self-efficacy, which involves "personal judgements of one's capabilities to execute courses of action to attain academic achievement" (Bandura, 1977), self concept is more aligned with self-esteem, a personal and less concrete construct. When one considers that students who don't see themselves as 'smart' or able enough often adopt self-handicapping strategies or overcompensate with effort (Brooks 1997), the centrality of self-concept to self regulation is immediately apparent.

Markus and Nurius, 1986 cited by (Garcia 1994) introduce the notion of self-schemas, which combine the cognitive and affective elements of self awareness as "the cognitive manifestation of enduring goals, aspirations, motives, fears and threats." This overarching notion highlights both the similarities and differences between self concept and metacognition. At the heart of each is an awareness of self, and while high self-consciousness is associated with a desire for self-knowledge, low self-consciousness breeds intellectual defensiveness.

**Self-monitoring and Motivation**

(Weinstein 1986) see all metacognitive activities as partly the monitoring of comprehension, and it would appear that this ability to monitor oneself is what distinguishes metacognitive activity from domain specific cognition. Self-monitoring is an initial step towards the development of cognitive strategies, but as will be shown later, continuous self monitoring is also a strategy in itself. Depending on ones theoretical orientation, this component can manifest itself as social cognitive self-observation, Vygotskian inner speech, or behaviourist self-recording (Zimmerman 1989). Regardless of whether one views cognition itself as an important construct, however, self-monitoring is a pervasive key process to self-regulation.

Motivation results from the actualisation of self-concept. Anxiety, for example leads to a low level of motivation (Zimmerman 1989). While it has been argued that all people are inherently motivated to learn, most of us have experienced difficulties in maintaining motivation, and research has shown that in education, intervention that impinges on self-concept such as unfavourable appraisals by teachers can result in drawing learners' attention away from the learning process (Boekaerts 1997). The ability to maintain motivation is one of the main tenets of self-regulation (Zimmerman 1994).
Self-monitoring and motivation are the primary internal sources of self-regulated strategies. However, there are also factors which are external to the learner which directly affect self regulation.

Environment and Context

Social cognitive approaches have long asserted a bidirectional relationship between external and internal states - role models who overcome adversity might encourage observers to try a task for themselves, for example (Zimmerman 1989). Not only the quality of teaching, but other factors beyond the learning situation have a direct effect on self regulation. (Ertmer 1996, p 747) claims, "outside pressures in students lives may increase their vulnerability to other instructional factors (type of case, time of day, length of lab) that impede [students'] use of self-regulation skills." Ertmer's study relates to the use of case studies for self regulated learning and this highlights another important issue.

The nature of a discipline itself is a unique context, with differences in both teachers' and students beliefs about learning. (VanderStoep 1996) observes different levels of regulation across multiple disciplines, and this has a profound significance for self-regulation, because while self-regulation itself may be viewed as a generic skill, some of the strategies employed may be pertinent only to specific domains.

Volitional and Cognitive Strategy formation

As the end product of self regulation, a student is able to activate strategies which enhance their learning. These take the form of volitional strategies, as well as cognitively based learning and regulatory strategies. It has been argued that Self-Regulated learning is "a fusion of skill and will" (Garcia, 1995, cited in Brooks 1997), and certainly effort, stemming directly from motivation, is a concept that most students are able to recognise as a controllable aspect, using it to explain their performance to themselves rather than other explanatory mechanisms (Pressley 1998).

Volition differs from motivation in that motivational processes mediate the formation of and promote decisions, while volitional processes enact and protect them (Corno 1994) Therefore motivational self regulation is dependent upon strategies that activate effort to achieve learning goals. (Garcia 1994). There are several strategies that students use to control effort.

Self handicapping is the withholding of effort or putting obstacles in the way to maintain self concept, while self affirmation maintains self concept through reassessing the value of different domains (Garcia 1994). Defensive pessimism is a coping process which enacts effort through the fear of failure (Boekaerts 1997). Motivational attributions refers to the causality students use to explain performance both retrospectively and prospectively, but regardless of the strategy used, they are all "affectively laden processes" that are related to an individual's self concept.

At a more objective level, students use self-monitoring techniques to support their learning as well as to regulate external factors. Cognitive learning strategies include rehearsal, elaboration, and organisational strategies, as well as memorization through clustering, imagery, use of mnemonics and so on (Weinstein 1986). Typically, deeper cognitive processes (such as transformation - the creation of something new out of existing information) are more successful than ones which engage in knowledge as a static entity, such as rehearsal (Risemberg 1996). It is important to note, however, that knowledge of these learning strategies is not enough to ensure that they take place. Regulation strategies must be implemented to co-ordinate effort and task.

(Garcia 1994) identifies three regulatory strategies that are highly correlated but do have some differences. These are planning, monitoring and regulation. While learning strategies are usually internally developed, regulation strategies have a role in accommodating the environmental and contextual factors discussed above.

One central concept to planning is that of goal formation. Typically, teacher goals are more distant and abstract than students', and those students who set more proximal goals tend to perform better academically (Boekaerts 1997). Goals are best when they are developed by the student rather than imposed by the teacher, in which case they tend to be viewed as obligations (Brooks 1997). While achieving good grades is a frequently stated goal for students (Pressley 1998), process rather than product goals are more closely correlated with self-regulation (Ertmer 1996).
Monitoring strategies can include tracking of attention, self-testing and self-questioning, as well as monitoring comprehension during learning activities. These are closely linked to regulation which manifests itself as a controlling process that results from monitoring (Garcia 1994). An example of this might be a student who reads a passage in a text slower upon arriving at a section which he or she finds conceptually challenging. A final cognitive strategy is resource management. Tied in directly with environmental factors, these involve the regulation of external aspects such as time, study environment, and help-seeking, as well as teacher and peer interaction (Garcia 1994).

Enhancing Self-Regulated Learning

The above framework can provide a useful heuristic in the development of Web based courses. A well designed learning environment should be able to operate on both affective and cognitive processes to activate self-regulated learning. However, while the above model articulates the dimensions of self-regulation, it does provide prescriptive information on how to enhance it.

In the broadest psychological terms, the self-regulated learner operates at a high level of self awareness and self concept. The learner activates self-monitoring and motivational processes, which are enabled through the use of volitional, cognitive and regulatory strategies. As teachers, however, the need is to work at the process level. The learning environment needs to activate motivational and self-monitoring processes, through the implementation of strategies that involve volitional, cognitive and regulatory mechanisms, with the end result being a confident self-aware learner.

It would seem, therefore, that design for self-regulation should treat metacognition and self-concept as an end product. The key processes of self-monitoring and motivation can be enhanced through the integration of the strategies which self-regulating learners typically access to facilitate these processes within themselves. It needs to be acknowledged that the implementation of such strategies is not going to automatically create self-regulation. In fact, it could be argued that self-regulation is contradictory to teaching actual strategies since it is something that comes from the student rather than being externally imposed (Brooks 1997). This paradox is obviously untenable.

For students to develop self-regulatory strategies, they need to be made aware of them and use them in an initially guided and structured manner. (Oliver 1999) identifies three components which are integral to the learning process: Learning Supports; Activities; and Resources. Typically, on-line learning includes a high level of resources and incorporates activities, but is often designed to be ‘teacher free’, and thus impoverished in learning support.

![Figure 2 - Self-Regulatory Processes](image-url)
While this is not usually an issue for students who have a high level of self-regulation, the lack of support is problematic for students without this skills. Therefore this paper advocates a process of scaffolding and fading. A high initial level of support for learners is faded over time as they develop their own regulatory and learning strategies (Winnips 2000).

Figure 2 indicates how the self-regulatory processes of motivation and self-monitoring may be enhanced through the integration of learner activities, learner supports and learning resources in an on-line environment. The contention is that the strategies inherent in these elements can provide the necessary learning, regulatory and volitional tools to activate the processes that give birth to self-regulation. Students engage in the resources and activities in the context of support which both models them and makes their role in Self-Regulated Learning explicit for them. As the level of support is reduced, learners may then initiate the strategies themselves in their own ways.

Discussion of Enabling Strategies

The strategies presented above represent, while not intended as a complete or authoritative list, can assist designers of on-line learning environments when considering how best to activate regulatory processes. Activities which stimulate reflection such as journals have been promoted as effective prompts for students own initiated approaches, integrating techniques such as progress worksheets and behavioural graphs (Zimmerman 1989). Also, encouraging students to solve problems while simultaneously reflecting on their own problem solution process can improve their metacognitive knowledge & skills as well as performance (Boekaerts 1997). Activities can also be grounded in authentic and relevant situations to enhance their level of motivation (Keller 1983), and it has been argued that “challenging tasks stimulate self-regulation better than do routine or boring tasks” (Brooks 1997) p. 141.

At the resources level, techniques such as instructional games can provide the impetus to assist in volitional control while narratives can engage the curiosity inherent in motivation (Malone 1981). Keeping resources, complex and real, providing multiple rather than single perspectives can enhance both their relevance and challenge, as well as stimulate the depth of processing required for self-regulation.

This is not to say that the learning environment should be excessively ill-structured. Indeed, having a narrow focus for self -monitoring gives better results than having a broad focus (Brooks 1997). However, “the most strongly advocated approach to including opportunities for student self-regulation is to give students choices” (Brooks 1997). Offering them different ways of learning material and have them compare them, for example, can be an excellent way of allowing users to customise their own relationship with the environment and help their metacognitive processes. Thus, environments that can be customised can assist users in setting their own learning goals.

Learner support can be provided in many forms – through techniques which are automatic such as self-assessment, as well as through peer and tutor interaction. Above all, it is important that users receive encouragement in order promote their self confidence in learning. (Zimmerman 1989). They need to be made aware that learning is hard, even for good students. This allows them to elaborate their motivational beliefs and relate them directly to strategy and capacity beliefs (Boekaerts 1997). A flexible non-threatening approach to feedback and remediation can go some way to achieving this. It doesn’t mean that the teachers’ role is reduced to that of security blanket or background facilitator – there is still a role for direct instruction, particularly in making explicit the implicit conventions of discipline specific knowledge. In fact teaching students ABOUT self-regulation is important (Brooks 1997). This can involve telling students to find a quiet place to study, planning adequate time etc. Having formal activities in which students consolidate and organize what they have learned combined with more implicit forms of support such as expert modelling, engages the user in self-regulational approaches and makes the strategies purposeful for them.

It appears then, that Self-Regulation is not an easy instructional aim. Those who are poor regulators aren’t likely to be changed quickly; even when students know WHAT to do, it doesn’t necessarily mean they’ll do it. (Brooks 1997). However, research has shown that it IS teachable, and certainly not ineluctably tied in with intangible and unalterable concepts such as intelligence (Symons, 1986). Learners will not always have access to the level of support which they receive in formal education, and this is particularly true of on-line learning, which is currently prone to high levels of attrition. It is important therefore that thought needs to be given to the process involved in users becoming aware of themselves and their own understandings, which in the end will only make them better learners.

Abstract: Definitions of literature are evolving to embody a wider range of cultural practices which can include interactive multimedia (IMM). Also the study of literature is undergoing a philosophical change, where traditional notions of literature as canonical and embodying universal human qualities is giving way to a more relativist epistemology. The act of reading, is not seen now as a passive process, but readers are constructing meanings which are also informed by their own values and cultural milieu. This paper argues that as IMM becomes more integral to the teaching of a wide variety of subjects, students need to be equipped with the skills to analyse IMM as a cultural artefact. As an illustration, a 'reading' will be conducted of the multimedia CD-ROM From Alice to Ocean.

How should we Analyse IMM?

Literature is a broad term encompassing many modes of communication. Traditionally it has been thought of in terms of a 'Canon' focusing on authors such as Joseph Conrad, Jane Austen, and Wordsworth and embodying some kind of universal 'truth', forming part of what Leavis termed 'The Great Tradition' (Leavis, 1946). It was assumed that meaning was inherent in the text and that "the meanings of literary texts could remain the same over long periods of time, even though the 'real' world changed." (Moon, 1992; p 80).

Such tenets are hard to justify, however, since both the American and British critics argue from an explicitly political viewpoint that is representative of the post war and post industrial epoch. Traditional theories have come from a broad range of ontologies and epistemologies that, whether focusing on the relationship between language and meaning, as in a structuralist paradigm, or the cultural politics of Marxist and Feminist approaches, have as a common basis the rejection of the absolutism and perceived elitism of traditional Literary Theory. It is now argued that the study of Literature is neither a neutral, or, as has been claimed, 'common' pursuit (Leavis, 1962) but is mediated by the author, reader, and social milieu; that is, it results from an interaction between "the reader's expectations, projections, conclusions, judgements and assumptions" (Fish, 1980; p 2).

Crucial to a contemporary approach is the idea that the individual will is contaminated by institutional and cultural values (Marxism, Feminism, and other political theories) or even by unconscious impulses (as in a Psychoanalytic approach). In these views the author is as central as ever to the study of Literature, but the notion of the author as an artist with a conscious message will lead to only one limited (albeit dominant) interpretation of meaning since 'to suppose that an author is genuinely unconstrained, that a work could be authentically original is ... nonsense. Texts are cultural products, and say at least as much about the cultures that produce them as the writers that record them" (Saunders, 1993; p 12).

Multimedia and the Study of Literature in Schools

An argument can be made for the study of Multimedia as a literary artefact. While it is a relatively new form of discourse, it is certainly not an alien one. Its non-linear nature offers challenges to traditional narrative, but no more so than many contemporary novels or even older works such as Stern's Tristram Shandy which, it has been argued, anticipates many of the techniques of hypertext (Keep & McLaughlin, 1995). In fact, many "electronic storybooks" such as Broderbund's Just Grandma and Me (Broderbund, 1993) are adaptations of already existing Literature and use interactivity and other media to enhance the existing text.

Apart from the narrative elements, IMM, with its integration of sound, graphics, animation and video uses a familiar auditory and visual language combined with interactive control. The concept of readers as protagonists who use
"interpretive strategies [to] give texts their shape, making them, rather than, as it is usually assumed, arising from them" (Fish, 1976; p 196), for example, appears to sit comfortably with the nature of learner control in IMM, and how users carve their own path through hypermedia.

Interactive Multimedia, while in not, as yet, a dominant form of discourse, is one to which students are becoming increasingly exposed. However, the idea that IMM products are socially constructed and embody specific cultural value systems, is never explicitly stated. This paper argues that IMM is as accessible as the above genres to a contemporary critical approach, and will conduct a critical analysis of the Multimedia text From Alice to Ocean (Against All Odds Productions, 1992) to illustrate this.

Analysis - From Alice to Ocean

The analysis will be conducted from a broad critical orientation as a point of discussion rather than an end in itself. However, as a constructed narrative of a person’s journey by camel through outback Australia, it clearly demonstrates the role of Multimedia as a cultural artefact, with meaning being developed through the interaction between the narrator’s values, the interpretative assumptions of the reader, and the socio-cultural context in which it was created.

Character - Robyn Davis as Protagonist

As an account of a real journey, it is tempting to think of From Alice to Ocean as a ‘true’ representation of events. Of course, such objectivity is not possible since the very act of writing involves the interpretation and selection of detail. Robyn Davidson is both author and character in her own story. She narrates and mediates the events, privileging an interpretation which the reader finds difficult to resist. Her centrality is reinforced by the very structure of the narrative and its nature as a ‘bildungsroman’. This is achieved both through her ‘obviousness’ and her interplay with other characters.

Robyn Davis is ‘obvious’ both in that much of her monologue does not conflict with our preconceived notions (Althusser, 1971), and the directness of the voiceover, which naturalises her commentary and makes her more credible. Her authority, however, is rendered absolute by the juxtaposition between her and her photographer colleague, Rick Smolan, whom she describes as “one of those amoral immature photojournalists who hop from troublespot to troublespot without ever having time to see where they are or be affected by it” and the “droves” of “bad mannered, loud, insensitive, litterbugging oafs” who are the tourists she encounters on her journey. Against these characters, and the news reporters (“pariahs”) who hound her, Davidson allies herself more with the aboriginal people whom she encounters, suggesting that, despite her ‘etic’ perspective, she has an insight into her subject matter denied to other observers.

Landscape - ‘The Dead Heart’

Despite this, her commentary is very representative of her class and culture. She views the landscape through which she travels with Caucasian eyes. An examination of Australian art shows that she is not alone in her interpretations. Her descriptions are self consciously alienating. At times the land is described in cliched new age mystical terms; Davidson emphasises the ‘haunting hallucinatory quality’ of the desert. Yet she is at odds with it. The path she follows is ‘wide and dry and desolate with one dead bird and two empty holes.’ In this way she disenfranchises herself from the environment. Her exploration is a parallel to the early settlers’ eurocentricity. In the acknowledgement of a land that is different, this difference is described not only in terms of desolate beauty, but also hostility. After all, many of the early explorers died in their attempts to map the continent – this despite the fact that they were travelling alongside aborigines who have survived on the land for thousands of years.

Race - the Writing of the Other

Davidson’s ‘Mr Eddie’ is cast as a a ‘dingo dreaming man’, his character being highly romanticised; he never rises above these pixie-like qualities to the reader. Davidson’s depiction of the aboriginal children is little better; they are framed in terms of their difference to ‘regular’ children and drawn with sweeping generalisations, focusing on their directness and ‘joie de vivre’. Davidson personifies the sense of belonging she is seeking in her depiction of the aborigines, but she is so bound by her own culture that she can not achieve this goal. She criticises Smolen for taking photographs of a people who do not wish it, yet as both author and subject matter of the CD-ROM, she is complicit in this exploitation. Smolen’s claim that he has a job to do and willingness to photograph the less savoury side of life is perhaps more honest than the pretence of the romantic ‘lone voyage’ in which she engages.

The epilogue is particularly intriguing. The self discovery she describes is not one of union or harmony with the place or people, but is depicted in of self-determination and the imposition of will, with reference made to mundane issues such as changing a job and even divorcing a husband. In the end, the terms she uses say more about her than her
voyage. She speaks in the language of a white middle class woman, her values essentially defined by her status, and far removed from the land and the people with whom she claims a link.

Conclusion

Despite the best intentions of many, the study of Literature still carries the cultural baggage of its Leavisite beginnings. It is unlikely that texts like From Alice to Ocean will ever find a place on a the Senior High School recommended reading list, and it is not claimed that the CD-ROM has the depth and rich ambiguity in verbal language of a traditional literary text. However, it may be that perhaps the concise and somewhat reductive nature of Multimedia content may not always be a disadvantage. In this case, the product is the distillation of a larger work, and the process of selection of detail has made it particularly accessible to the study of its values.

It has been suggested that the text would be a suitable resource to be implemented across a range of curricula, including photography and geography (Squires, 1996). If this is to take place, it is important to ensure that students have the critical skills to evaluate the values in this and other Multimedia products.

Developing a Typology of Students in a Web-based Instruction Course

Patricia Medici <pr@ualberta.ca>
T. Craig Montgomerie <craig.montgomerie@ualberta.ca>
Department of Educational Psychology
University of Alberta
Edmonton, Alberta, Canada

Abstract: This paper argues that individual differences among undergraduate students is an important factor to the effectiveness of asynchronous learning and that students' needs and perceptions must be taken into account in the design of Web-based instruction (WBI). A student typology is presented based on evidence from an ethnographic study of a WBI undergraduate course.

Introduction

The Faculty of Education at the University of Alberta requires that all undergraduate students be prepared to integrate the use of technology into the curriculum. In 1997 we began to redesign EDPY202: Technology Tools for Teaching and Learning (http://www.quasar.ualberta.ca/edpy202) to provide undergraduate education students with the basic skills they will need to apply information technology in Kindergarten - Grade 12 schools. At the same time we were designing this course, the Government of Alberta published Information and Communication Technology, Kindergarten to Grade 12: An Interim Program of Studies (Alberta Education, 1998), which formed the basis for the provincial program of studies that was implemented in September 2000.

This technology curriculum provides a broad perspective on the nature of technology and its impact on society. Students are encouraged to grapple with the complexities, as well as the advantages and disadvantages, of technologies in our lives and workplaces. It is not intended to be taught as a stand-alone course but rather to be infused within existing courses. Activities, projects, and problems that replicate real-life situations are effective resources for learning technology (Alberta Education, 1998).

Since our graduates need to implement this curriculum, the expectations and philosophy provided in this document helped to guide development of our course. Although EDPY202 is primarily a software tools literacy course, it does provide the students with some exposure to curriculum integration. Thus, we hope that these soon-to-be teachers will be in a position to assist their students in using the information technology tools that are commonplace in modern society.

This paper reports some of the results of an ethnographic study of EDPY202 and proposes a student typology that can be relevant for designing and developing WBI courses and increasing students' satisfaction and performance.

The Course

EDPY202 is philosophically based on the perspective that learning is a process of constructing knowledge rather than a process of recording knowledge (Harel & Papert, 1991). From this perspective students are required to be “active participants” in their own learning, which implies substantial learner freedom to select learning strategies. To support this perspective we have designed the course to be self-paced with varying degrees of individualization, allowing students a higher level of flexibility with respect to course time commitments and the level of skills and knowledge they wish to achieve. Course materials can be studied individually, in collaboration with peers, or in collaboration with a more knowledgeable assistant. Further, we have focused learning activities on software tools used for problem-solving: Jonassen's (1996) “Mindtools.” This emphasizes students learning “with” the computer as opposed to “from” the computer enabling students...
to enter an intellectual partnership with the computer in order to access and interpret information, and organize personal knowledge.

The objectives for EDPY202 are directly related to the Alberta Education Program of Studies and students are required to complete either an introductory or an advanced module in each of five topic areas:

- Internet Tools (Email, Web-based conferencing, Internet searching, FTP, Telnet, Simple WWW page creation),
- Digital Media Processing (clip art, drawing, painting, scanning, digital photography, digital audio/video),
- Multimedia/Hypermedia Presentations: (PowerPoint or HyperStudio),
- Spreadsheets (e.g. Excel), and
- Databases (e.g. FileMaker Pro, Access).

While EDPY202 has been designed to be self-paced and modularized with a focus on independent study, three optional face-to-face lectures are given to familiarize students. The material covered in the lectures is also available on the course Web page.

Although students are encouraged to work at home, a 3-hour/week laboratory period is assigned where each student has access to equipment (computers, scanners, digital cameras, etc.), software and face-to-face help from an instructor or a teaching assistant. This has two major results: firstly, many students appreciate the opportunity to take the course wherever and whenever they wish, and secondly, the teaching assistants in the lab can concentrate on helping those students who really need help. A comprehensive description of the course is covered in Montgomerie, Carbonaro, Davies and Medici (1999).

The Ethnographic Approach

Anthropologists originally used ethnographic research to study primitive cultures. The technique has been adapted to study organizational culture, which is defined as patterns of shared values, and beliefs that, over time, produce behavioral norms adopted in solving problems (Hofstede, 1990; Owens, 1987). Similarly, Schein (1990) noted that culture is a body of solutions to problems that have worked consistently and are taught to new members as the correct way to perceive, think about, and feel in relation to those problems. The sum of these shared philosophies, assumptions, values, expectations, attitudes, and norms bind the organization together. Organizational culture, therefore, may be thought of as the manner in which an organization solves problems to achieve its specific goals and to maintain itself over time (Hofstede, 1990). In this study we examine the alternative delivery class as organizational culture.

Method

Qualitative data were collected from an EDPY202 class with an enrollment of 700 students between September 1998 and June 1999. A total of one hundred and sixteen students volunteered to be interviewed. The group of students was composed of 62 females and 54 males. The great majority of the students, 72, were 19 to 24 years old, 28 students were 25 to 35 years old and 16 students were over 35 years old. A subsequent analysis showed that students with lower final course marks were over represented in this sample. The course the following sources of information and insight were drawn upon:

- Knowledge of the course and the students stemming from researchers’ participant observations and as instructors.
- On-line discussion on the Web-board conferences and evaluation issues both as an integral part of the course.
- Students’ e-mail messages to the researchers.
- Students’ responses to open ended taped interview.
- Instructors’ responses to open ended taped interview.
- Teaching Assistants’ (TA) responses to open ended taped interview.

The method used to investigate the course relied in part on participant observation and in-depth interviews in order to construct the categories through which the participants themselves interpreted their experience. This
paper concentrates on students' point of view. Summaries of the students' comments on the course proved a valuable source of insight to develop a student typology and improve the course design.

Findings

The majority of students interviewed liked the course and spoke positively about the self-directed, active learning experience. One younger student who was quite adept at using computers before entering the course summarized the experience: "I think this course is fun. It's a breeze. The [Web] site is cool. I am pretty comfortable with all software. The TAs are great. I can do all these things - no problems." A mature, single parent identified a specific benefit: "I like this course. I don't need to be on campus; I can be at home with my two year old boy and work on the modules at the same time. It saves me time and money - I don't need to find a baby-sitter."

About 30% of the students who were interviewed found difficulty with the course. An initial question probed the participants' experiences in the course up to that point. The students' reaction varied greatly. Some reactions were very apathetic, some were very positive, and others were very negative. In telling the stories of their learning. Participants reflected upon the nature of their involvement with EDPY202. They detailed their experiences as they received their initial information about the course, and their development throughout the course.

Developing a New Vocabulary

Some students come to EDPY202 course with no computer literacy. The acquisition of a technology vocabulary is a fundamental part of this course. The EDPY202 Web site provides an on-line glossary of all computer terminology used in the course. One male student, 24 years old, attending Secondary Education program exemplified this problem: "It's so overwhelming... I have to learn [how to use] the Web site and there are so many new words, computer terminology... Searching the Internet is so frustrating... I never get the er choose the right words."

Written Versus Spoken Communication

Students are encouraged to use e-mail for communicating with instructors, teaching assistants and classmates. Although students did use e-mail many of them still preferred face-to-face interaction. One female student, 22 years old, attending the Elementary education program said: "I express myself better talking than writing.... In a distance situation I prefer talking on the phone. It saves time. In this course I have to write e-mails when I have problems... I have to wait for answers that usually don't help much."

We set up a WebBoard Web-based conference system (O'Reilly Software, 1999) to allow students to discuss course topics. During the first two weeks of the course they posted about 234 messages. However this volume was not continued throughout the term. Messages dropped dramatically as some of the students said that they did not read other students' postings because they thought they were useless. One female student, 20 years old, attending the Secondary Education program said: "I have difficulty expressing myself. I don't have much knowledge about computers... I don't know how to give smart or relevant contribution to the WebBoard. So, I don't use it... I don't go there... It doesn't help me... I don't waste my time reading it."

Difficulty with Active Learning

Although students had access to both a lecture and a Web page that explain active learning in detail, some students are unable to accept and internalize the process of searching and constructing their knowledge. One male, 45 years old, attending the Secondary Education program stated: "I need to be taught. After I can do
things [by] myself. I don’t like classes [where] I never see the instructor. The TA’s don’t know everything. I just can’t stand it. It is not my style... I am to old to change now.” Another showed frustration and lack of understanding: “In the e-mail the instructor told me I must be responsible for my own learning, but what does it mean? I am a responsible person. A female student, 20 years old, attending the Elementary Education program: “I don’t understand active learning. I am going to teach in a traditional way. I am in elementary. I” A male student, 23 years old, attending the Secondary Education program: “I am not an independent type of person. I need help to learn.”

On the other hand, some of the students had more positive reaction and they were very optimistic about active learning. A female student, 24 years old, a Secondary Education student explains: “I always have been very independent since school. I take this course from home... I don’t think I learned how to be independent. It is just the way I am. I don’t know if am practicing active learning in this course, but at least I am trying.”

Feelings of Isolation and Exclusion

Students who feel any kind of disadvantage may be affected by their perception of the group norms. Inevitably these students compare themselves with the group in terms of achievement. The impact of this mindset may be so strong that some students may drop the course. A female student, 19 years old, attending the Elementary Education program said: “The others are so smart. They talk differently, they know what is going on... they know that stuff... I just learned how to turn it [the computer] on. It is awful.” A male student, 23 years old, attending the Secondary education program said: “I feel isolated and in disadvantaged because I am slow... My TA doesn’t have the patience to explain things to me. He always says I should know how to do things by now but I forget stuff after a while... I have to graduate... I have to pass.”

Overcoming Technical Problems

The level of anxiety for some students is quite high, mainly at the beginning of the course. One of the most common reasons given is problems encountered with the technology. One male student, 22 years old, attending the Secondary Education program reported: “I want to drop out but I can’t. This is a required course and I Nothing seems to work for me.... The computer doesn’t like me. It crashes on me all the time. I lose my work and I have to start all over again.... It is a waste of time.”

One often reported problem is that the laboratory which students use is equipped with Macintosh computers. Some students who use Windows computers say the Macintosh interface confuses them. They feel disadvantaged because the examination takes place on Macintosh computers. A male student, 20 years old, attending the Elementary Education program reported: “They told us that we can take this course from home... it’s not true. I’m an IBM user... I have to come here [university] for the final... they have only Macs... It’s not

Marking Criteria

Some students perceived problems with marking criteria. One female student, 32 years old, attending the Secondary Education program: “If you don’t do the advanced ones [modules] you’ll never get a good grade. So, why are the intro modules there? You have to do the advanced [modules] anyway.” Others found the system of submitting their assignments for marking via the File Transfer Protocol (FTP) and the automated system, which kept track of submissions (Montgomerie, Harapnuik & Palmer, 1997) to be very frustrating. A male student, 25 years old, attending the Secondary Education program reported: “First my password didn’t work... now I never get my marks back on time. I sent messages to my TA but he never answered me.” Another said, “I always lose something [files] when submitting assignments. How can I prove I did it on time? I lose marks! The TA can’t be responsible but I would like to be able re-submit the stuff and get my marks.”
Developing a Student Typology

During the observations and interviews we have had the opportunity to identify individual differences in students’ perceptions, behavior, and learning styles. In discussing their expectations of their EDPY202 experiences, students provided large amounts of information about their understanding of themselves as learners. They discussed the ways in which they feel more comfortable learning and presenting assignments. A male student, 22 years old, attending the Secondary Education program said: “I have been dealing with computers since junior high. It is not a problem. I know all that stuff already. I hope I can get a nine.” A female student, 32 years old, attending the Elementary Education program said: “I feel comfortable in the traditional classroom. Computers frighten me a lot. I always think I can do something wrong. I don’t have much confidence in me or in what I can do in this course.” She also indicated that she always feel excluded during the lab sections: “TAs never look at me.” She also felt embarrassment at her lack of knowledge in I just can’t explain what is going on because I don’t know specific computer terminology
cited the excitement of learning through Internet and WWW and their worries with the completion of the course. A male student, 21 years old, attending the Secondary Education program said: “This is a good experience. I can stay updated, I can learn faster. It drives me... to go on, eh. Now everything is on the Internet and I have to learn how to use it properly in the classroom. It is a revolution. I like the way this course was set. Even when I am getting tired and I don’t feel like working on the course I realize. I’m getting behind and that’s the motivation to move on.” A female student, 42 years old, attending the Elementary Education program said: “I don’t know exactly what I am doing in this course but I now the importance of the Internet, so let’s see what happens. Well, I have to get credit too.” Another student, a male, 26 years old, attending the Elementary I now I need this course. I want to teach using technology. It is difficult sometimes,
but not impossible. I am confident using the Internet. I can work on my own pace. I can learn... and I need to graduate, of course!”

Students come to EDPY202 with very different expectations but with one thing in common they want to be successful. A female student, 21 years old, attending the Secondary Education program explains: “I want to learn but I also want to pass.” A male student 21 years old, attending the Secondary Education program sees himself as a very independent learner and he was expecting a interesting kind of course. He said: “Oh gee! This is really interesting stuff, I was expecting something like that, well, what can I say... It is just great, lots of fun, eh!”

This has led us to begin to develop a typology of students in this course. The first category of student is the Beginners. Beginners have little knowledge of the technology involved and appear to resist it because they are not fully aware of its implications and use. The challenge is to convince these students that technology can benefit their professional lives and their future students. The second category is the Skeptic. Skeptics are aware of the importance of the technology in their professional life but they are concerned about the amount of work required to develop the skills necessary to use the technology effectively. Skeptics often complain about the effort needed to complete the required tasks. The third category of student is the Explorer. Explorers are enthusiastic about the technology, have some previous knowledge and want to learn more. These students have a mixture of dependent and independent learning style and most of the time they are pleased to help others. A fourth category is the Optimist. Optimists have little knowledge but accept the technology at face value and want to learn as much as possible from TAs, instructors and peers. Explorers and Optimists are about 90% of the interactive learning community in the course. The final category is the Self Professed Expert. Self Professed Experts are very independent and never go to the lab sections. They often say they are taking the course only because it is required. Self Professed Experts appear to think they know everything and they don’t need help from instructors, TA or classmates. Often, Self Professed Experts obtain the highest final grades in the class, but this is not always the case.

Conclusion

The findings of the study point to many factors that can influence students to have either a successful or a disastrous on-line experience. Looking at the Web course structure and its impact on the students, it is clear the importance of knowing what kind of students instructors have in their courses. Successful or problematic experiences have strong impacts on class relationships and consequently on students’ performance and attitudes towards the course. Some of students with limited skills or knowledge feel like outsiders while other
students develop a friendly interactive group. Web-based course developers have to take into account students’ differences if they want to design truly individual instruction. Without a Web-based course that takes into account students’ individuality, students feel isolated and become anxious, defensive, and helpless.

Design and Implementation of a Multimedia Learning Environment for Spelling

Christina Metaxaki, Univ. of Thrace, Greece; Areti Baxevanidou, Univ. of Thrace, Greece; Eleni Ioannidou, Univ. of Thrace, Greece; Ourania Monouri, Univ. of Thrace, Greece; Georgios Kouroupetroglou, Univ. of Athens, Greece and Stavroula Lialiou, Univ. of Athens, Greece

According to the dual coding theory, we perceive and store words and visual images in two systems: one verbal and the other perceptual. We present in this paper the design and implementation of a multimedia spelling-book based on the above theory. The book presents the story of the "beautiful Helen" as Homer records it. The review of the current conventional spelling books for pupils combined with the characteristics of the Homer Epics and the different ways of using images, led us to the formation of a set of parameters, assumptions and aims for the interactive learning environment. The methodology we followed to end up with the design and development of the multimedia spelling-book is given in detail along with implementation issues and the description of the application. The system is expandable (more scenes) and transferable (other stories). The application is currently undergoing user trials in real life situations.
A Design Procedure for Creating Training Courses

N. Giannopoulos, economist, brs@mail.kapatel.gr

Introduction

The training is a key issue in our days. The training, retraining life-long learning are thought to be absolutely necessary for people sharing the labor market in the Information Society.

Ways of building curricula, planning of courses are objects of a very large amount of presentations, papers, good practices. In this work, we present an approach to face the subject on a systematic way.

The training of the employees of an organization is a difficult task, as they have to understand new trends and use the acquired knowledge and skills to improve their position and be more productive. Among the problems arising, during training is the restriction of available time. So, the courses must be well designed and delivered, to be fruitful and achieve their target. Another major problem, which is quite common especially with IT courses, is that they are quite similar for all employees and they are delivered on different levels including awareness. The highly interactive and graphical environment makes the training task more competitive for them.

The approach we present here is suitable for designing courses for trainees (employees, students etc) to achieve knowledge and skills. The approach consists of a good number of parallel phases which can be repeated. By every repetition the design is more detailed. The parallel phases are merged and split, starting a new parallel phase.

The whole procedure resembles the filling of an empty cell. The approach is transferable and the concepts can be used for evaluation and redesigning of the course.

Design Considerations

The procedure starts with the creation of a short list (SLP) of target identification. This short list is constructed by the policy makers. It contains general characteristics and specific ones. It can contain skills, levels etc. Another short list (SLS) is created by a specialist on IT responsible for the course, delivering. The SLS contains means, tools, course material, methods etc.

Each one of the lists is transformed to sets of key-words. Each set presents a target secondary or main. Using partitioning techniques, one can merge and split the sets and form the final sets (FS). Those FS combine means and targets.

In case the FS are poor or problematic, the procedure can be repeated by reviewing the short lists. The repetition of the phase can lead to a quite detailed presentation of the course.

We have applied this procedure starting by global descriptions. Those descriptions were combining the environment of the company. We have proceeded by analyzing further the FS. We needed three phases. We have tested the procedure by organizing a university level course on IT, following the same approach.

Specialists of IT and policy makers worked independently on the parallel phases and they met to merge and split. The descriptions are organized in set and subsets or they are the fields of an operator. The second presentation is more evident.
Discussion

We have used the here presented approach as the basic tool for designing a pilot course for the employees of a company. The company is under a renewal of its information systems and the relevant applications.

The short lists' description is a powerful tool as one can incorporate global characteristics which are usually ignored when designing courses for IT. The approach was applied too on CBT courses and it was extremely powerful.

We are now using this approach to re-design existing courses. We analyze the targets/means and we compare them with the outcomes.

We have some rules for the FS content which can support decisions. An interesting speculation on the FS is that, in case the short list of the means is more rich than the one of targets, the partitioning gives multiple sets. This multiplicity can support the delivering of more self-adapted courses. The decisions about open and flexible courses are strongly facilitated without loss of the overview and target.

Abstract: Metaphors are recognized as an help for learning concepts and are frequently used by teachers. And yet there is no computer-based training tool which fully takes advantage of this strategy. This paper describes an innovative learning environment implementing the metaphor strategy, and set in a constructivist approach. This tool is based on concept mapping and hypermedia as support for learning activities. The paper describes the generic structure of the tool, the prototype implemented for the domain of routing in computer networks and the experimentation carried with a small group of mature students pursuing continuing education.

1. Introduction

Concepts' learning has always been an important issue in education, and has a special importance in current technical programs, as the increasing growth of technologies brings a need to come back to basic points. Metaphors are recognized at a theoretical level for facilitating comprehension and memorization of concepts. According to Mayer (1983), teaching scientific concepts can benefit from metaphors because they can help to understand the scientific language. At a practical level, metaphors are frequently used by teachers in their lectures.

Computer-based training (CBT) tools use various instructional strategies for learning concepts, like simulation (in simulators) and visualization (in multimedia and simulators). Metaphors can be found in CBT tools, for example multimedia tools can contain metaphor images to illustrate some topics, or a simulation can include a metaphor, like in (Rieber, Noah 1997). But this use of metaphors is quite seldom and uneven, and it is not considered as a primary instructional strategy. On the other hand, metaphors are very frequent in CBT tools' human-computer interface, in fact in all software's interface (Caroll & al. 1988). But those metaphors are at the interface level and not at the educational content level. Actually, there is no real CBT tool that fully takes advantage of metaphors as an instructional strategy. There has been a first research on this subject in (Brna, Duncan 1996): AMPS is a prototype of an intelligent learning environment for electric circuits' domain, using the water analogy. There is a simulation of each domain and the learner can solve problems, edit analogy relations and use multiple analogy from a library.

This is why we are running an exploratory research whose aim is to conceive a new kind of learning environment, based on a specific instructional strategy: metaphors as an help for learning concepts. This tool relies also on concept maps elaborated by the learner and on hypermedia. It is grounded in the constructivist current, which gives importance to the learner as an actor of his own learning, and importance to previous knowledge.

In this paper, we will describe an overview of this on-going research. After introducing metaphors and concept maps in education, we will define the generic framework of the environment and the possible uses for the learner and for the teacher. Then we will describe the prototype we have realized for a particular training domain (computer networks) and the experimentation carried with a small group of students.
2. Metaphors In Education

The principle of using metaphors in education as a teaching strategy is to base the new knowledge (target domain) on prior knowledge in an other known domain (source domain), as illustrated in (Fig. 1).

![Figure 1: Principle of metaphors for learning](image)

The constructivist approach views learning as an active construction process, only possible if based on previous knowledge. Thus metaphors are an important instructional strategy in this perspective because previous knowledge is the starting point for learning.

The process of analogical reasoning has been widely studied in cognitive psychology producing various theories for how operate this cognitive process. On an other side, some researchers in the field of education like (Duit 1991) and of human-computer interaction like (Caroll & al. 1988), (Madsen 1994), provide pragmatic guidelines for how to use metaphors. For example, Madsen defines three stages for using metaphors in systems design: generate potential metaphors, evaluate the metaphors, and develop metaphors in the design task. Duit gives guidelines for using metaphors in education, like: "metaphors should be familiar", "use multiple metaphors", "guide the learner through the use of metaphors", etc.

In our work, we consider that multiple metaphors should be provided for each topic and that the limits of metaphors have an instructional value.

3. Concept Mapping

Concept maps are used in education for more than twenty years and are originated in Novak and Gowin's work (1984) on learning science. A concept map is a graphical representation of concepts (nodes) and relations between them (links). It is a kind of semantic network but naming of relations is free and, according to Novak, it should be structured from top to bottom, from general concepts to more specific concepts.

Concept maps can have a lot of purposes, in education and also in communication. In the education field, they can be elaborated by learners, teachers or CBT tools designers. When concepts maps are constructed by learners, they are a way of accessing learners' representation like in (Baron, Bruillard 1999), and a powerful cognitive tool allowing learners to organize knowledge in a more and more complex structure (Jonassen & al. 1997).

We had at first considered concept maps (elaborated by learners) as a mean for accessing learners' representations of the domain. But it soon appeared that it was also an important instructional strategy for learning concepts and that it could also be an aid for the reflection on metaphors. This is the reason why the environment we propose relies a lot on concept mapping. So we consider concept maps in the following aspects:

- As a tool for learners to manage their knowledge
- As a mean for accessing learner's representations
- As a tool for teachers or designers to structure the knowledge domain
- As a mean to present metaphors
4. Learning Environment Based On Metaphors, Concept Maps and Hypermedia

Generic framework: We propose a generic framework (Fig. 2) for an innovative learning environment, which makes possible to implement the metaphor instructional strategy. This tool is based on hypermedia representing the source and target domains of metaphors and on concept maps elaborated by the learner. The learner can navigate from one domain of the metaphor to another through hypertext links and can construct his own map of the target domain. This tool is intended mostly for learners but can also be used by teachers to study metaphors in a lecture.

![Figure 2: Components of the environment](image)

A hypermedia module represents each domain (several sources and one target). Analog concepts in source module and target module are linked with semantic hypertext links. The concept map can also be linked with documents in the target module or in the source module. Each module can be linked with online documents, like Web pages on Internet.

Activities for the learner: Learning activities can concern concept map elaboration, metaphors study, and hypermedia lecture and authoring. Concerning concept mapping, several different activities, discussed in (Meyer & al. 2000), based on metaphors and concept maps can be considered, depending on which concept map is constructed (source domain or target domain) and by whom. We retained activities involving the construction of a concept map by the learner (because of our constructivist perspective) and for the target domain (because it is the domain to be learned).

For example, the learner can be asked to build a concept map of the target domain and to indicate on it metaphors from source domains of his choice, taken from his reading of hypermedia. (Fig. 3) represents this possible concept map (the target domain is here computer networks). Concepts from source domains (rectangular shape) are set close to analog concepts of the target domain (oval shape). In this concept map, metaphors come from one source domain (road network) but metaphors from several source domains could be indicated. Concepts can be annotated, in order to precise their definition and in order to indicate the adequacy and limits of metaphors.
Activities for the teacher: Concept map elaboration can also be useful for the teacher because it helps him to structure his knowledge. But beyond this, it can be for him a tool to think about metaphors for a lesson's preparation. In effect, for a given target domain, he can indicate on the map what are the metaphors, for different source domains. Then he can visually compare the metaphors' richness of different source domains and choose the most appropriate metaphors for his lesson.

5. Prototype And Evaluation

We have realized a prototype for a specific domain, which is routing in computer networks. This domain is, according to teachers, complex and difficult to teach. It is also a noticeable metaphorical domain, maybe because several metaphors (road, mail) were used at the origin by searchers in computer networks' field. This work has been done in collaboration with teachers of two French "Grande Ecole" engineering school, Ecole Centrale de Lyon and INSA de Lyon.

5.1 Study Of Metaphors

We first have studied the concepts related to routing then we have thought about metaphors, which can be used for teaching routing, within three stages. The first stage was the generation of potential metaphors: we collected them in different ways, with students, teachers, books and Web pages on Internet. It gave us a base of approximately 50 elementary metaphors in 12 source domains. The second stage was to evaluate potential metaphors, their appropriateness, limits and familiarity for the audience. We retained three main metaphors: road network, railway network and post, illustrated by (Tab. 1).

<table>
<thead>
<tr>

<td>router</td>
</tr>
<tr>
<td>Postal communications</td>
<td>envelop, parcel</td>
<td>packet</td>
</tr>
<tr>
<td></td>
<td>sorting office</td>
<td>router</td>
</tr>
</tbody>
</table>

Table 1: Examples of metaphors
Other metaphors could have been kept, like ants routing or water supply, but we found that detailed study of metaphors brings about fundamental questions on the domain knowledge and is therefore time consuming, so we had to limit the number of metaphors.

The third stage was to develop metaphors in the design task, which is here to develop a hypermedia. The tasks involved text writing of the metaphor (explaining similarities and dissimilarities), search for meaningful pictures of source domains and linking analog concepts in the source and target domain.

5.2 Realization Of The Prototype

The prototype is a hypermedia composed of four parts: three source module corresponding to each source domain and one target module. The format is basic HTML pages, stored in an Apache Web server. Because of the limited time we had, we have realized a simplified version compared to the generic environment described above: hypertext links are "one-way" from source to target domain, links from the concept map to the hypermedia documents are not proposed and documents of the target domain come from conversion of PowerPoint slides into HTML pages (60 slides). Each source module contains text and images explaining the source domain, like in (Fig.4) which is a screen shot of the postal metaphor: those compartments, used in a sorting office to sort letters according to various destinations, are similar to a routing table in a computer network router.

![Fig.4: Example of hypermedia page for postal source domain](image)

Concerning the concept map construction, after an evaluation of various concept mapping and diagramming tools, we have choose a professional diagramming software, iGrafx 8.0, because it allows, in addition of diagramming and annotating features, several display levels which are useful to show or hide metaphors from different source domains.

5.3 Experimentation

We have carried an experimentation with a group of mature students pursuing continuing education (master degree specialized in management of computer networks at Ecole Centrale de Lyon). The objectives were to evaluate the features of the prototype, to evaluate the appropriateness of metaphors and to evaluate understanding of learners, trained with and without metaphors. Two training sessions of three hours with the same group of seven students were set up, after a lecture on routing. In the first session, they had to construct a concept map of routing (15
concepts were given and they had to add at least 10 other concepts). In the second session, they could browse the prototype and they had to work again on their concept map and to set metaphors on it. Collected data, for each session and for each student, were a questionnaire and a concept map.

This experiment showed, regarding the prototype's features, that activities and tools for concept maps' construction and metaphors' indication were satisfying, but could be improved. For example, one student suggested that a non-graphical method for concept matching should be more adapted because he had spent too much time to set the metaphors on his concept map. From the metaphors' point of view, all students told that learning with metaphors was interesting, and metaphors in the prototype were appreciated, the most quoted being the road network metaphor. From the learner's understanding point of view, 2 students told that it helped them a lot, 4 that it helped them slightly, and one person that it didn't help.

6. Conclusion

We have proposed a generic framework for an innovative learning environment implementing the metaphor instructional strategy. This tool is based on hypermedia and concept mapping and fits in the constructivist point of view. We found that it could also be used by teachers for thinking about metaphors. We have realized a prototype for computer networks, which showed that finding and implementing appropriate metaphors is time consuming. This prototype was evaluated with only a small number of students, but it has proved the interest of this metaphorical approach and showed that the features of the tool were convenient but could be improved.

It has also raised a lot of questions like: What are the most interesting instructional activities to propose? How to design the hypermedia source and target module? How can limits of metaphors be better taken into account in the tool? What are all the uses for the learner, the teacher and also the CBT designer? What is the best period for the use of this environment by students? How could this approach be integrated with other instructional strategies? A more elaborated prototype and other experiments should be set up in order to give some answers, and to finally develop a design method.

Beyond the fact that this environment should provide a more efficient learning, it may help the learner to develop his/her autonomy and reflection on the domain knowledge, especially in thinking about the relations between different domains. In this sense, this tool may also be useful to develop the sense of abstraction.

Teaching Science through Web Adventures

Leslie Miller, Janice Mayes & Donna Smith
Rice University
Center for Technology in Teaching and Learning
Houston, TX, USA
lmm@rice.edu, jmn@rice.edu, odlsmith@rice.edu

Abstract: This demonstration presents an interactive web adventure designed using Flash 4.0. The adventure series entitled, The Reconstructors, is funded by the National Institute on Drug Abuse with a focus on the history and science of opiates. It was created for middle school students to cover topics such as neurotransmission and involves virtual experiments. Students enter a futuristic world in which they become "reconstructors," members of an elite scientific unit charged with recovering lost medical knowledge. Episodes have been evaluated through a comprehensive process involving students, teachers, and scientists. Analysis of the pre- and post-test scores demonstrated significant knowledge gain that can be attributed to use of the game. Qualitative comments from students revealed that the key factors that kept students interested and motivated in using the game included an engaging problem, interesting characters, sound, and a contemporary appearance. The front-end research, development process, and outcomes will be discussed.
PEDAGOGICAL ISSUES ON THE USE OF WEB BASED RESOURCES

Isidora Len Mitchell
Mt. Hope Junior Secondary,
Ministry of Education, Trinidad and Tobago.
lange@tstt.net.tt

Abstract: Universal secondary education was introduced into Trinidad and Tobago in 2000. The immediate consequence is the placement in secondary students of students whose literacy and numeracy skills are inadequate for the successful access of secondary education. This has provided a challenge for ensuring adequate learning outcomes and appropriate instruction. It has been proposed to employ web-based resources and distance learning strategies to assist these students and their teachers. However, several pedagogical concerns have to be addressed:

i. the nature of the insertion of web-based resources into the instructional context;
ii. the choice of instructional objectives – imitative or creative;
iii. adequacy of teacher training; and
iv. students' perception of the instructional milieu.

Universal secondary education was introduced in Trinidad and Tobago in 2000. For the first time in our history, every child who sat the Common Entrance examination in Trinidad & Tobago was placed in an institution for the purpose of secondary education. There is a lack of places in the secondary school system and other post-primary were asked to accept students from the primary schools. Students have therefore been placed in a variety of institutions: state-funded secondary schools managed by denominational boards; secondary schools managed by the state; private secondary schools; vocational centres managed by NGOs; primary schools which are under-populated.

The placement of all students has provided a challenge for ensuring adequate learning outcomes and appropriate instruction. The immediate consequence is the placement in secondary institutions of students whose literacy and numeracy skills are inadequate for them to successfully access secondary education. The challenge is two-fold: to provide appropriate instruction to meet their needs of those whose skills are poor; and to provide adequate instruction to students in large mixed ability groupings. Remedial tutors have been hired and assigned to assist these students and their secondary teachers in the areas of Mathematics and Language. It has been proposed to employ web-based resources and distance learning strategies to assist these students and their teachers. The intent is that instructional resources and ideas and information will be communicated to tutors and teachers; and exercises and activities for students will be provided via the Internet. The classroom teacher would therefore be able to provide tasks for different attainment levels while having time to devote to those who need the most assistance.

A brief review of modern educational trends shows that every new technology is embraced as a panacea for educational ills. The proposal recognises that the Web will produce a change in the delivery of instruction. The instructor will be a facilitator assisting each individual as he/she tries to complete the tasks. Study will become more task oriented and allow for grouping according to interests. It is conceivable that while studying a specific region in Social Studies, one group would be chatting with students in another country or sending e-mailing, another would be scanning the fact sheet put out by international agencies or reading an on-line newspaper from the region or working on exercises or tests put on the Student Website. However, several pedagogical concerns need to be addressed before the project can be implemented.

The design of instructional media is determined by its insertion into the instructional context. Its role must be agreed if intended benefits are to be derived. Will the use of web-based resources be core or peripheral? Media can be used in at least nine ways in the instructional context:

- to gain attention;
- inform the learner
of objectives; stimulate recall of prerequisites; present stimulus material; provide learner guidance; elicit a response; provide feedback; assess performance; enhance retention and transfer (Gagne et al, 1988). The Web has the capacity for multi-media presentation but the use of various media must be informed by its purpose. Will its use be passive, active or interactive? Passive use should necessarily be brief. Interactivity demands particular sensitivity to the needs of individual learners. Where interaction with the instructional content is essential then design must facilitate control and repetition.

Is the learner to be shaped or is he an important actor in prescribing instructional outcomes.? Feedback is adaptive and imitative and so the design of instructional resources or courseware will seek to shape learning outcomes. However, creativity assumes assimilation and so the pace of delivery must be controlled by the student. Non-sequential presentation of material or ‘branching’ is more suited to such learning. The provision of remedial tutors underscores an assumption that the needs of students is remediation. Remediation presupposes that students need to be shaped to a norm and so instruction tends to be imitative. Material developed for this mode will not yield control to the student. Yet lack of opportunity for mastery reduces the motivation to learn.

The issue of teacher education is of paramount importance in this context as an understanding of theoretical underpinnings influence the role of the teachers, their perception of learner needs and consequent use of instructional resources. While media may be used as passive, active or interactive, each medium has its strengths. Gratuitous use of multi-media because it is available does not enhance the instructional context. One medium may distract attention from the other. If the resources provided are seen as teaching aids then the instructional mode is teacher centred. Media, adequately used, can facilitate student centred learning and promote mastery learning. Any use of Web-based resources must be appropriate to the culture, and the ability and experiences of students.

The capabilities of students limit the effectiveness of a medium. Language skills also determine the structure of the content. Content depth, length of passage, layout styles should be based on the need to sustain interest and motivation. Variety and diversity are watchwords but the ease of processing is the bedrock on which successful design is built. Whatever the medium or media used the instructional environment must ensure that students possess the skills necessary for successful learning outcomes. Mere exposure to various media does not guarantee successful manipulation of them or appropriate processing of information.

The novelty of the Internet and computers needs to be considered. Duby (1991) found that students’ perception of tasks influence their approach and motivation. If the medium is seen as entertainment little mental effort is invested and learning is minimal. Design should be culturally sensitive, taking into consideration the pace of life, colours and images. While motion may draw attention, excessive use may be distracting. The use of computers for higher order learning through simulations and animations is far more effective than ‘drills and practice’(Castro, 1998).

There may be no correct use of Web-based resources. Nonetheless, the use of media should change the form of educational structures as instructional objectives shape the nature of the instructional milieu. Given its capacity for multi-media representation and its non-sequential structure, it offers an opportunity for enhance learning. It also presents a challenge for informed planning if the potential is to be realised. In the context of this project consideration must be given to whether the medium - the Web – will carry supplemental or core material. On this decision hinges the objectives and the design of resources.

References.

Abstract: This paper uses the data from a longitudinal study to conduct a series of factor analysis to test the reliability of a set of items to measure the effectiveness of the use of computers in higher education. The results suggest that there are specific clusters of items that can be used to measure the effectiveness by using the surrogate measure of attitudes towards the use of computers in teaching.

Introduction

One of the thorniest problems following the introduction of computers in education has been assessing the efficacy of technology in improving the quality of education. There is little doubt that technology and education are now intimately associated and there is a growing application of technological tools in the educational process (see, e.g., Brown, 2000; Oblinger and Rush, 1997). This increased application of technology is constantly calling for the need for better assessment of the effects of technology and there are relatively few good methods of evaluating this efficacy (Reeves, 1998; Woodrow, 1994; Woodrow, 1996). There are several problems related to the process of evaluation with the primary being the lack of a good measurement tool to track changes in the educational outcome. This problem is also related to the fact that "learning" itself is a slippery term and defies universal definition, making the quantification and measurement of learning a tricky process. Indeed, without a robust definition it becomes particularly difficult to measure it.

It has been suggested that learning can be measured using other "surrogate" measuring techniques such as the evaluation of the changes in the attitudes towards learning and the changes in the learning process. Based on the examination of a series of assessment projects, Mitra and Hullett (1997) has suggested that attitudes towards technology can perform as an alternative way to measure the effectiveness of the introduction of technology in the learning place. This approach has been applied to various academic scenarios to report on the ways in which technology continues to impact the process of teaching and learning (see, e.g., Lawson and Pelzer, 1999; McQueen and Fleck, 1999; Merisotis and Phipps, 1999; Mitra, et. al., in press; Mitra, et. al., 2000; Mitra, et. al., 1999; Mitra and Hazen, 1999; Mitra, 1998; Phipps and Merisotis, 1999). However, what has still remained a challenge is trying to find a particularly robust set of measures that would address all the different aspects of the effects of technology in teaching. Woodrow (1991) reported on the analysis of four different attitude scales and all of them tended to measure different attributes of the outcome of the application of technology in teaching. Furthermore, with the changes in technology some of the specific aspects of the measurement continue to change as well, thus making some of the scales inappropriate for the current mode of technology intervention.

In this paper it is suggested that it is possible to identify some specific aspects of the outcome of the technology use in teaching where the factors being measured are not necessarily technologically determined. Instead, the factors being measured are more fundamental constructs of the human-technology interaction in the educational setting and thus can be applied more broadly to several different assessment situations and can be more universally applied. Using the data from an ongoing longitudinal study of the application of technology in an American private liberal arts institution, it is possible to show that there are certain fundamental aspects of the effects of the application of technology that can be measured using reliable attitude items.

Methodology and Data
This paper utilizes the data from a longitudinal study to assess the impact of technology introduction in liberal arts education at a non-technical small private university in the United States. The data was collected over four academic years and this post hoc analysis uses the data collected in the spring of 1999 from a sample of students who responded to a questionnaire mailed to them. The questionnaire was developed by conducting a series of focus group meetings that explored the various technology-related issues that the students were facing with the universal and standardized introduction of technology in teaching. The questionnaire included nearly fifty attitude items measured on a five-point Lickert-type scale. Of these fifty, there were several items that were specific to the local conditions of the university. The remaining items have been analyzed here. The entire questionnaire also consisted of usage questions and demographic questions.

Analysis and Results

The analysis included two components: first, a factor analysis that elicited four factors on the basis of twenty-five items that were selected as the general attitude items in the questionnaire and second, the items that loaded on the same factor were subject to reliability tests (Cronbach's alpha) to explore the levels of reliability of the similar items.

The 25 items were analyzed using a varimax rotation and this resulted in four major factor loadings. These are reported in the next table.

The factor analysis was followed by the computation of the inter-item reliability for the items within each of the factors. This correlation was high, with the Chronbach's alphas for the four factors reported in the next table.

<table>
<thead>
<tr>
<th>Factor Number</th>
<th>Alpha</th>

</tr>
<tr>
<td>4</td>
<td>.36</td>
</tr>
</tbody>
</table>

While the alpha values reported in Table 2 are relatively high, a second set of alpha values were computed after dropping from the set the item with the lowest factor weight from each of the factors reported in Table 1. This resulted in higher alpha values and thus a more robust set of items. These adjusted alpha values are reported in the next table.

</tr>
</tbody>
</table>

These results suggest that it is possible to propose a computer attitude scale with 21 items which could serve as a surrogate measure for learning outcomes by providing an evaluation of the attitudes of students towards the use of computers in teaching. The items all could use a five-point Lickert type scale with '5' being 'strongly agree,' '4' being 'agree,' '3' being 'no opinion,' '2' being 'disagree,' and '1' being strongly disagree.' The items are now presented with slight alterations in the reference to a specific university so that the items can be used at any place of higher education.

Discussion

The analysis presented here first suggests that it is possible to develop standardized items that can be used to measure the attitude of students towards the introduction of computers in teaching. The items, by clustering around four factors, also represent specific attributes of the effects of computerization that can become yardsticks for the more urgent question of measuring the effectiveness of computers in enhancing learning. In presenting the findings from several different studies, Mitra and Hullett (1997) have indicated that "predispositions" play an important role in the perception of the effectiveness of computer aided instruction. Within the notion of predisposition, the authors included issues such as comfort with computers, the rapidity of the introduction of computers and other such perceptual ideas. Additionally, the authors noted that technographics, context and technological sophistication could also play roles in the determination of effectiveness of computers in instruction.

The results of this study help to support the findings of Mitra and Hullett (1997), but also suggest that the idea of measuring predispositions need to be made more elaborate and must include a large array of perceptual parameters. Indeed, some of these parameters are no longer only predispositions but also include perceptions that develop as computer aided instruction becomes more prevalent on college campuses. In other words, the perceptions that can determine the effectiveness are not only the ones that the students possess as they are initiated to computer aided instruction, but the effectiveness could also depend on perceptions that develop with continued exposure to computer aided instruction. Indeed, the four factors identified here represent four major perceptual categories all of which arguably can have an impact on the perceived effectiveness of the computerization process. This is supported also by arguments made by authors such as Pacey (1983) and Negroponte (1995) who have suggested that the effectiveness of computers often depends on the way in which the users might perceive the values associated with the "practice" of using computers. Thus, by measuring the values and expectations related to computers in teaching, it might be possible to arrive at a more reliable measure of the effectiveness. The data from this study suggests that there are four key values that can be measured as represented in the four factors identified in the analysis.

The first parameter that needs to be measured can be called "climate of interaction." Clearly, the computer has become a key form of an interaction device for the students and the effectiveness of the computer as an interactive tool can have a large impact on the way in which the computer becomes effective in instruction. Consequently, by knowing how well the environment supports the interactive applications of the computer could have a lot to do with how students evaluate the effectiveness of the computer in education. Extrapolating from there, it is also possible to argue that if indeed the computer enhances interaction then it could begin to play a critical role in transforming the instructional environment. Thus it is important to measure the way in which students perceive the enhancements in interaction with the introduction of computers. Interestingly, this enhancement is not only with the use of computer mediated communication, but the very presence of the computer and the accompanying shifts in the climate of the institution can also affect the more traditional forms of communication such as "face-to-face" interactions. The data suggests that such attributes should also be measured to get a sense of the changes in the climate of interaction that follows the introduction of technology. Thus the following items could be used to measure the climate of interaction.

- Talking face-to-face with professors is generally gratifying
- The use of computers positively impacts the social life
- The use of computers makes the academic climate of the university intellectually exciting
- The use of computers is increasing cooperative learning at the university
- Computer mediated communication makes it easy to maintain relationships
- Computers provide a non-threatening way to communicate
- Computers allow me to communicate with people I would not normally be able to communicate with
- When communicating using a computer one does not need to be formal
- The use of computers is strengthening the academic climate
The second parameter that emerges as important is also related to communication and can be labeled, "communicative effectiveness." Unlike the earlier item which is broad-based and addresses issues related to the overall climate of an academic institution, this second factor includes attributes that focus primarily on the role of the computer in the pragmatic act of communicating. It can be argued that a change in the perception of the effectiveness of the computer in facilitating communication could have an impact on the learning outcome. Consequently, it is important to be able to measure how effective the computer is considered to be in communicating with various groups with whom students typically have to communicate in the course of their academic activities in college. The following items refer to the communicative effectiveness of the computer in education.

- Computers are effective for communicating with other students about class-related work
- Computers are effective for communicating with faculty about class-related work
- Computers are effective for communicating with other students about non-course-related subjects
- Computers are effective for communicating with faculty about non-course-related topics

The third parameter that is important to measure to obtain an evaluation of the computer in instruction can be called the "abstract expectations" of the students as they are placed in a computer-aided instruction situation. It is clear that the promises of technology tend to alter what students can expect from the computer and the instructional situation that they are placed in. These expectations, and how well they are met, can have a direct impact on the way in which students react to the overall use of technology in instruction. There are many facets of these abstract expectations and they include expectations about the level of use of computers in learning; apprehensions about the loss of privacy and concerns about the increases in the power inequity between the teacher and the student. In many cases these might strictly be perceptions and the changes are not as dramatic as the students might think they are, but it is still important to measure these expectations because people with different expectations could easily have different assessments of the effectiveness of the computer in teaching (see, e.g., Mitra, et. al., 1999). Therefore, the following items can be used to measure the abstract expectations related to the introduction of computers in teaching.

- I would stay away from classes that do not use computers
- The computerization process poses a threat to my privacy
- The adoption of computers will give more power to the instructors
- I prefer classes in which I get to use computers

Following from the notion of abstract expectations, there is a fourth parameter that should also be measured to develop an assessment of the effectiveness of the computer in teaching. The fourth parameter can be called, "pragmatic expectations." These items also deal with the notion of the benefits and burdens of technology, but focus more on the specific ways in which students anticipate using the computer in the process of learning. Students entering a computer-enriched environment often come with specific expectations about what the computer could do to transform the learning process. If they perceive that there will be a positive transformation it is possible that their learning will be enhanced as well. Thus, it is important to measure what the students expect in terms of what the computer can do to transform their comprehension of the material being taught. This change is in turn related to the ways in which the students feel about the extent of their computer use with "hands-on" application as well as the breadth of the computer use in terms of the number of classes in which they might be asked to use the computer. As pointed out in earlier research, these issues can impact the students' general assessment of the role and effectiveness of the computer in the practice of teaching. These items take the focus of attention away from a technologically determined, technology-centric view to a more sociologically determined focus on the practice of technology (Pacey, 1983). The following items attempt to measure this aspect of the pragmatic exceptions arising from the practice of using computers in teaching.

- Computer use helps me better understand the course material
- I prefer classes with "hands-on" computer experiences
- I expect that I will be required to use the computer
- I expect ALL instructors will use the computer in teaching
In summary, this paper and the data offers a valid and reliable measurement of four key parameters that can serve as indicators for the assessment of the effectiveness of computers in teaching. While these measurements offer an initial glimpse on the thorny question of measuring the effectiveness of computer assisted teaching, they do not, however, claim to be direct measurements of the teaching effectiveness. These items only offer alternative and surrogate measurements which, however, can be coupled with more direct measurements.

Abstract: Web-based Adaptive Educational System (Web-based AES) has actively been developed. However, it is doubtful whether the system is useful to learners, since the system mainly deals with Web pages fixed in one server. Web-based AES should deal with various Web pages distributed in some servers in order to fulfill the learners' diversity. We developed a Web-based AES named ITMS (Individualized Teaching Material System). ITMS adaptively integrates knowledge on the distributed Web pages and generates individualized teaching material that has various contents. ITMS also presumes the learners' knowledge levels from the states of their knowledge reference instead of tests or questionnaires. This paper describes the framework of adaptive knowledge integration, the method of the presumption, and the overview of ITMS.

Introduction

In the past Adaptive Educational System (AES) was developed as a stand-alone system. Web-based AES has recently come to be developed by the rapid increase of the Web (Brusilovsky 2000). Nowadays Web pages are expected to be teaching material for life-long learning. This expectation will strongly increase the development of Web-based AES. However, it is doubtful whether the current Web-based AES is useful to learners. This is because the Web-based AES mainly deals with Web pages fixed in one server regardless of the learners' diversity, namely it does not provide the learners with useful contents created by various authors all of the world. If learners only utilize search engines, they will be able to receive piles of various Web pages. However, the piles consequently will bother them, which is what is called disorientation (getting lost) and information overload. This indicates that the accuracy and the usability of search engines are not enough for educational usage. There are a few Web-based AESs partially deal with the distributed Web pages. For example, AHA adapts hyperlinks that connect with the distributed Web pages to learners' knowledge levels (De Bra & Calvi 1998). However, these systems do not seem to solve the disorientation and the information overload on the distributed Web pages, not restricting the learners' movement among the distributed Web pages completely.

Our research goal is to adaptively provide learners with useful teaching material created by various authors and furthermore is to avoid the disorientation and the information overload in the teaching material. We developed a Web-based AES named ITMS (Individualized Teaching Material System). ITMS adaptively integrates knowledge on Web pages distributed in some servers and generates individualized teaching material that has various contents. An adaptive aspect of ITMS is to inform the learners of knowledge they should/must refer to on the basis of their knowledge levels. ITMS additionally avoid the disorientation and the information overload by contriving knowledge presentation. Here, there is a problem how ITMS assesses the learners' knowledge levels. AES needs to assess the levels frequently for proper adaptation. However, frequent tests/questionnaires will cause the learners loads. We are trying to presume the levels from the states of the learners' knowledge reference.
Framework of Adaptive Knowledge Integration

Educational Web pages need to contain a lot of the related knowledge, taking into consideration diverse kinds of learners’ readiness. Especially prerequisite knowledge is essential in order to prevent novice learners from having a learning impasse caused by the contents of Web pages. However, it is hard for authors to create these Web pages by themselves. Even if they can do it, the Web pages will not have the contents organized with various viewpoints.

Hence we propose the framework that adaptively integrates a lot of the related knowledge and generates individualized teaching material. This knowledge, needless to say, is created by various authors and can be stored in distributed servers. We developed ITMS according to this framework.

Knowledge Creation

The authors create knowledge for integrating in the following order.

(i) They create educational Web pages.
(ii) They divide the Web pages into small fragments (For example, fragments on a certain formula in mathematics are “the formula”, “the explanations”, “the demonstration”, and “the exercises”).
(iii) They make an index of each fragment using HTML comments designated by ITMS (The fragments do not have semantic attributes).

The fragments can contain fragments created by various authors inside them, namely various kinds of knowledge can be structured hierarchically. The authors only describe the pointers (URLs) to the distributed Web pages containing the indexed fragments in order to structure the fragments. ITMS provides the authors with creating large-scale teaching material easily.

Integration Method

ITMS generates individualized teaching material in the following order.

(i) It receives the request of a Web page from a learner.
(ii) It analyzes the hierarchical knowledge structure through the pointers, regarding the requested page as the root.
(iii) It acquires sequentially the knowledge on the distributed Web pages on the basis of the analyzed structure.
(iv) It integrates the acquired knowledge into the requested page.

ITMS adopts hierarchical stretch-text as a method of knowledge presentation in order to facilitate the learners’ knowledge reference. Hierarchical stretch-text, which contains knowledge hierarchically inside it, is expanded and collapsed by the learners’ preference. When the learners need to refer to knowledge inside it, they click the title of the knowledge (the trigger of the stretch-text) and the knowledge is expanded beside the title. It is indicated that stretch-text (hierarchical stretch-text) is effective in the decrease of getting lost and information overload (Boyle & Encarnacion 1994)(Höök et al. 1996)(Murray et al. 2000). Although conventional stretch-text mainly deals with text data, hierarchical stretch-text in ITMS deals with various data such as images, movies and Java applet.

Adaptation

ITMS adapts the contents of the individualized teaching material to the learners’ knowledge levels by embedding visual annotation (Brusilovsky 1995) and knowledge hierarchy alteration. The two methods, which inform the learners of knowledge they should/must refer to, not only prevent the decline of their knowledge levels but also are useful in presuming the levels.

Taking into consideration the fine-grained knowledge for integrating, we simply classify the knowledge levels as follows: “understanding”, “unstable understanding”, and “no understanding”. The next section describes the presuming method. Table 1 shows the relation between the knowledge level and the adaptation. Figure 1 shows the overview of the adaptive knowledge integration.
<table>

</tr>
<tr>
<td>No understanding</td>
<td>Knowledge, which a learner must refer to, is transferred to the top layer of a new Web page and a circular red icon is embedded beside the title of the knowledge.</td>
</tr>
<tr>
<td></td>
<td>Additionally, a star-shaped red icon, which means the transfer of the knowledge, is embedded in the original location of the knowledge.</td>
</tr>
</tbody>
</table>

Table 1. The relation between the knowledge level and the adaptation

Figure 1. The overview of the adaptive knowledge integration

Method for Presuming Learners' Knowledge Levels

Fundamental Idea

Tests and questionnaires are methods for assessing learners' knowledge levels correctly. Frequent tests/questionnaires are necessary for AES to assess their latest knowledge levels, whereas the frequent test/questionnaires will cause the learners loads.

ITMS needs to assess their latest knowledge levels in order to provide proper adaptation. Accordingly it utilizes the states of their knowledge reference as elements for presuming the levels. Activities of their knowledge reference do not cause them loads basically, based on their intention.

Related Works

It is indicated that data on learners' activities in hypermedia is so insufficient that AES should not independently use the data to presume their knowledge levels (Brusilovsky 1996). Especially data from a Web browser such as browsing history may be unreliable.

There are some AESs that presume their knowledge levels from such activities (Hohl et al. 1996) (Wu et al. 2000). These systems, which mainly utilize data on the activities and data on knowledge structure of a domain (domain model) for the presumption, do not take into consideration the decline of the levels, namely it is difficult for these systems to assess their latest knowledge levels. Although some of these systems allow the learners to modify their own levels (user model), their modifications are not always correct and might be loads.
Method

We hypothesize that learners autonomously refer to knowledge if they do not understand the knowledge. Accordingly, this hypothesis indicates that the states of their knowledge reference are strongly related to their knowledge levels. Specific hypotheses are as follows:

(a) Learners do not refer to knowledge they understand.
(b) Learners refer to knowledge they do not understand.
(c) Learners understand knowledge just after referring to the knowledge.
(d) As the time passes, learners' knowledge levels decline.

On the basis of the above hypotheses, ITMS assesses the level of the knowledge that the learners can directly refer to at "understanding" regardless of the states of the reference. In other words, the level of the stretch-text that the learners can directly expand is assessed at "understanding". Hence it is important how ITMS presumes the level of the knowledge that the learners cannot directly refer to, namely hidden knowledge. To take an example in "Before Adaptation" in Figure 1, ITMS assesses all the level of A2-K1, A2-K2 and A3-K1 at "understanding" and cannot assess the level of the others in the case that a learner refers to A1, since it is unknown whether the learner is aware of the others.

ITMS presumes the level of the hidden knowledge from the frequency of sequential presence of the hidden knowledge. In the case that the frequency reaches thresholds that are related to the knowledge levels, ITMS adapts the knowledge presentation in order to make the learners be aware of the hidden knowledge. The knowledge hierarchy alteration presents the hidden knowledge that was presumed to be in "no understanding" on the front Web browser as a new Web page. By this alteration, the learners will surely be aware of the hidden knowledge of importance and ITMS assesses their latest knowledge levels. Table 2 shows the relation between the knowledge level and the threshold.

<table>
<thead>
<tr>
<th>Knowledge Level</th>
<th>Threshold (Initial value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>understanding</td>
<td>--</td>
</tr>
<tr>
<td>unstable understanding</td>
<td>2</td>
</tr>
<tr>
<td>no understanding</td>
<td>5</td>
</tr>
</tbody>
</table>

Table 2. The relation between the knowledge level and the threshold

ITMS modifies the thresholds from hypothesis (a) and (b) and realizes fine-grained adaptation. The rules for modifying the thresholds are shown below.

```java
if (Level of Knowledge X == "unstable understanding"){
    if (Learners referred to Knowledge X){
        Threshold of "unstable understanding" of Knowledge X -- (>2)
    }
    elseif (Learners did not refer to Knowledge X){
        Threshold of "unstable understanding" of Knowledge X ++
    }
}
elseif (Level of Knowledge X == "no understanding"){
    if (Learners referred to Knowledge X){
        Threshold of "no understanding" of Knowledge X -- (>5)
    }
    elseif (Learners did not refer to Knowledge X){
        Threshold of "no understanding" of Knowledge X ++
    }
}
```

ITMS

System Architecture

ITMS may be popularized from the reason of a client/server system with simple architecture, which does not need additional devices such as a proxy server. The authors can easily do setup of ITMS. All the learners have to do is
prepare a Web browser interprets Dynamic HTML and JavaScript. Figure 2 shows the architecture of ITMS. ITMS, which is implemented using Perl, consists of the following modules and databases.

**Data Receiving Module (DRM):** This module receives all of the data from the learners (login name, page request and the states of knowledge reference).

**Knowledge Level Presumption Module (KLPM):** This module presumes their knowledge levels from the data of their knowledge reference and the thresholds.

**Knowledge Integration Module (KIM):** This module adaptively integrates the related knowledge and generates individualized teaching material. It additionally attaches JavaScript that observes the states of their knowledge reference to the individualized teaching material.

**Knowledge Reference DB (KRDB):** This database has the data of the states of their knowledge reference.

**Knowledge Level DB (KLDB):** This database has the data of their knowledge levels (the thresholds of each knowledge).

**Knowledge Metadata DB (KMDB):** This database has the metadata (index and location) on the integrating knowledge.

**Teaching Material DB (TMDB):** This database has educational Web pages containing the integrating knowledge.

![Diagram of ITMS architecture](image)

**Figure 2. The architecture of ITMS**

### An Example of Adaptive Knowledge Integration

We created educational Web pages on CG (Computer Graphics), which contain the prerequisite knowledge of linear algebra and programming language. The prerequisite knowledge is created by two authors and is stored in two servers. Figure 3 shows a learning example in ITMS. The left Web browser shows one of the educational Web pages that a learner requested. The right Web browser shows a Web page that contains the related knowledge (the prerequisite knowledge) of "no understanding". Hierarchical stretch-text in this example has images and a Java applet. The learner acquires various kinds of knowledge of CG in accordance with the adaptation of ITMS.

### Conclusion

This paper described ITMS that has the framework of adaptive knowledge integration. This framework adaptively provides learners with useful teaching material created by various authors. A key feature of ITMS is to deal with Web pages distributed in some servers for the adaptive knowledge integration. ITMS additionally presumes the learners' knowledge levels from the states of their knowledge reference in order to decrease their loads.

The current ITMS has two apparent problems to be solved. One is to prune knowledge unnecessary for the learners. As the integrating knowledge increases, overload to ITMS increases beyond doubt. The other is to manage the knowledge distributed in many servers. The solution of the former may need analyzing the learners' knowledge levels in detail. The introduction of XML for solving the latter is now under consideration.

We are evaluating ITMS by experiments and planning to improve ITMS on the basis of the evaluation. In addition, we are currently applying the framework to exploratory learning in vast Web space.

SPicE Project: Web-based Instruction in Acquiring Science Process Skills

Rohaida Mohd. Saat
Faculty of Educational Studies
Universiti Putra Malaysia

Malaysia
rohaida@fp.um.edu.my

Abstract: The evolution of Web-based Instruction (WBI) has created an alternative approach in the learning of science. SPicE project attempts to explore the potentials of WBI in the acquisition of science process skills among elementary children. It provides the necessary elements for children to acquire process skills. This paper describes the rationale of developing the Web-site and the SPicE project itself.

Background

Since the mid-1800's, science educators have argued that the processes of science should be taught as a part of school curriculum. Gagne (1965) views science process skills as the foundation for scientific inquiry and sees knowledge develops inductively from sensory experience. According to him, the skills comprise of basic science process skills and integrated science process skills. Although emphasis on the process approach has been given for the past 50 years, there is no evidence that science courses have been successful in enhancing students' mastery of the science process skills (Yager & Lutz, 1994). The question arise now is to why it has not been successful in enhancing students' mastery of these skills. The answer probably lies in the approach being used in teaching of such skills. Alternative approaches and modes need to be explored. Several studies (eg. Santos & Oliveira, 1999) explored the use of Web in fostering skills such as thinking, problem solving and communication skills, and they found that Web technology can play a vital role in fostering the development of these skills. With the emerging of Web technology in the Malaysian education setting, probably this technology can be one of the approaches to foster the acquisition of science process skills among students.

The SPicE Project

Science Process Skills in Scientific Exploration or in short SPicE Project is part of my on-going doctoral work and it is an instruction in a Web-based environment. SpicE is developed specifically for children of Grade 4 to 6, dedicated particularly to the acquisition of science process skills and is written in the Malay language. Since this is a prototype of SPicE, the project will only focus on one of the 12 skills outlined in the Malaysian Primary Science Syllabus. Using computer in science teaching is not a common phenomenon in Malaysia. However, by 2010 most schools will adopt the Smart School Concept (Ministry of Education, 1997), where technology will be used as an enabler in the teaching and learning. After browsing the net for about three years, it was found that most science sites were dedicated to the acquisition of scientific knowledge and only a few gave focus to the acquisition of science process skills. Moreover, all the sites that emphasized on process skills were in English.

SPicE can be viewed at http://202.190.17.140/~spice/index.html and it is best viewed using Internet Explorer. Since the animation was programmed using Macromedia Flash v. 4.0, Shockwave Plug-in is needed to run SPicE. SpicE requires learner to login. SpicE will then take the learner to the Homepage and later to the main page. Learner needs to 'click' on Integrated Science Process Skills and then on Controlling Variables. On this page, SPicE is indexed into four sections: Aktiviti (Activities), Cabaran SPicE (SPicE Challenge), Forum (on-line discussion) and Hubungan (links to other related sites).

Activities

The main concern of this project is to give ample opportunities for the children to practice the skill. In this section, learner is given two choices of activities; namely the 'Hands-on' activity and 'Simulated Activities'. The
'Hands-on' activity requires learner to perform a pendulum experiment, where washer is used as the weight. Children investigate the effect of the pendulum swing when various length and types of strings being used. Upon completion, children click on 'Log Pemerhatian' (Worksheet) and another window appears where learner fills in the values of different swings and answer some questions related to the activity. Learner then sends the worksheet electronically to a database.

There are three types of 'Simulated Activities' in this program. These activities adopted the direct manipulation approach where students vary the variables by clicking the mouse and immediate feedback is obtained. Each activity is presented at different difficulty levels. Learner completes an electronic worksheet and sends electronically to a database. One of the features of the worksheet is the computer-generated graph.

SPicE Challenge

Besides having the various activities, SPicE also provides the learner with a 12-items quiz, aimed to reinforce the children's understanding on variables, controlling variables and the idea of fair testing. Each item need to be answered before the learner can proceed to the next question. The items are in the form of multiple choice questions and learner chooses the answer by clicking on the radio button.

Forum

Forum is a discussion platform. Learner poses questions, share their experiences and seek help from their teacher and fellow friends. The teacher can serve as an expert in responding to students' problem. This platform allows the children to communicate asynchronously since some students are shy to participate in any classroom discussion.

Linkages

Linkages are links to other local and foreign sites related to elementary science learning. These linkages allow children to explore other sites and interact with the activities available in the sites. This will certainly enrich the children's understanding.

Conclusion

SpicE provides the resources necessary for the acquisition of science process skills among elementary children. It provides a variety of activities for children to choose from, since SPicE's main goal is to provide ample opportunity for learners to acquire skills. SPicE provides an alternative approach for teachers and students to develop a community for exchange of ideas and for solving problem collaboratively. It provides self-assess evaluation to determine the one's own understanding of the intended learning outcomes. It also provides links to other related sources that will assist the children to further enhance their acquisition of the skills.

Abstract: Within all institutions, web developers are beginning to utilize technologies that make sites more than static information resources. Databases, XML and XSL are key technologies that promise to extend the web beyond the "information storehouse" paradigm and provide additional functionalities. Thus, the purpose of this contribution is twofold. This paper begins by providing background information and an overview to the issues surrounding the transition from HTML to XML occurring on the web today. It must be noted that the implementation of these technologies is not limited to research and development arms of business and industry. Educators can use them to create knowledge warehouses where students can search, examine and consume educational materials more quickly and easily. The second half of this contribution examines a database-driven, education resource used at Purdue University and the efforts to migrate it toward an XML and XSL-based implementation.

Introduction

A web convergence is beginning to dawn upon the horizon of this new millennium. It is a shift from the "immediacy reaction" that spawned the millions of pages in the later half of the 90's to "intelligent proaction" where information, communication, and applications are singular and are guided by a process-based backbone.

In the middle to late 1990's the major concern in education, business and industry was establishing a web presence, using it as a real-time but static information resource. Many institutions frantically invested, web-enabling massive amounts of their data. From the syllabi and supplementary content of educators to the marketing content and the snapshots of corporate entities, most of the attention was spent on just getting information onto the web, with little concern for how it looked, how it was accessed or how it was found. Today, however, the concern has shifted. The motivation is not just about producing pages and pages of static information floating in ethereal global and local domains. It is about managing the converging processes, information, communication and applications, making them readily accessible and intelligently presented when and where they are needed. With the multitude of data that exist on the web, managing, finding and quickly interpreting data while at the same time merging processes, communication and applications is critical.

Regardless of content domain, several features and technologies are integral in any effort to make web-enabled data more efficient, intelligent, and effective. Key to this is the understanding that no single technology fulfills all aspects or needed features. Convergence and integration are crucial to generating intelligent web sites. Features of the web-enabled, intelligent enterprise include:

- Dynamic content that changes to meet the needs of the user in a just-in-time fashion.
- Technology implementations that utilize database systems but also allow real-time information updates and customized queries with little management overhead.
- Global data classification and local labeling systems that provide a means for the user to quickly find and access information in a culturally and environmentally independent way.
- Effectively designed media assets that clearly and logically communicate content while considering bandwidth limitations of end users.
- Use of human-computer interface design principles and theory to provide adequate communication channels that are non-interfering, unimposing and transparent to the user.
- Integration of systems and software that link information, communication, applications with a process-based backbone.
- Software that assists, automates and initiates standard processes and provides ready access to the information on which decisions are made.

**Databases, XML and XSL**

Current literature reveals the significant research and development effort that has been invested in creating web technologies that make managing, searching and finding data and data nodes easier. Much of the literature focuses on the Extensible Markup Language (XML) (Cadinaels, Duval, Olivie, 1998; Fowler, Fowler, Williams, 1996; Harold, 1999). Although most browsers are only beginning to support XML, the implications of future XML and Extensible Stylesheet Language (XSL) solutions are quite significant. XML is not intended to be coded by-hand, as is the case with HTML. Similarly it is not about the aesthetic appearance or layout and design of pages. Rather, XML is much more complex and diverse. XML is a markup language that can be used to not only describe and classify the contents of a page, but also the tagging scheme itself. In this aspect it is considered a meta-markup language because XML classifies content but also includes a self-contained description of the tags used.

The implied result of XML and XSL is that the complete language and technologies used for web site development could turnover completely within the next five years. Also fundamental to this initiative are the integration of open databases or database-type technology structures that are diverse in their content support, easily extensible and web-enabled in all aspects (Hendrikx, Duval, & Olivie, 1999). The combination of these technologies promises greater flexibility and extensibility for web pages and easier development, maintenance and management for the developer. For the end user, searches are more accurate and labeling systems tend to be more logically named and structured. They also enable advanced technologies such as alternative browsing capabilities, voice-based services, and intelligent search and retrieval agents.

Aside from the aforementioned advantages of XML, it allows several unique benefits for the developer. The most insightful is the ability to create domain-specific markup languages. In fields such as chemistry, mathematics and music studies, representing domain specific content, such as chemical bonds, mathematical equations or musical scores on the web, is very difficult. HTML is far too limiting to represent these domain specific symbols and materials, not to mention the limits of computer-based fonts and their inconsistencies across platforms. XML enables the developer to create his own markup language. Because XML both classifies and describes itself, specialized symbol systems can be used on the web with less concern over end-user technology. Examples of XML implementations already exist for chemistry via the Chemical Markup Language – CML (XML-CML.ORG, 2000), mathematics via the Mathematical Markup Language – MathML (Kamthan, 2000), and music via the Music Markup Language – MusicML. Many other general markup languages are also under development, including those for the delivery of multimedia and vector graphics (World Wide Web Consortium, 2000).

As the convergence of technologies continues, in the public sector the transmission, interpretation and creation of data does not go unaffected by developments on the web. Here, too, XML has application and provides significant potential. One of the difficulties in the financial world is the data tracked on consumers. From personal data to financial records, exchanging data about a consumer from one institution to another is difficult due to the variety of software applications and data formats that exist. Another initiative for XML is to use it as an intermediate data format, that is a neutral file format, for storing consumer data so that information exchange can occur more readily.

**Migration to XML**

The migration path to the implementation of full-scale XML (and eventually XSL) solutions requires careful observation of established rules that make the migration more easily implemented. Additionally, it requires a different approach to development. Except in the case of database-driven sites, most pages today begin as a formatting exercise, establishing the design and visual aspects of the page and then adding content with little or no attention to what the content is (classification). Future implementations based upon XML and XSL reverse this process. With XML, document content is classified and then rules for formatting, based upon the content classifications, are applied. Most of the developmental sites that implement XML use HTML or CSS for formatting. However, future pages will use XML for classification and XSL for formatting, style and visual attributes.
Additionally, future browsers will be based upon XML standards and will be very restrictive of the content they will render.

The rules for enabling the XML and XSL transition, called rules of well-formedness, are style and coding modifications that have little adverse effect on the display of pages in today's browsers. However, the adherence and application of these rules to today's HTML-based pages is vital to the eventual evolution of pages implemented entirely in XML and XSL, as well as being able to correctly view pages in XML browsers. This is also true when content is pulled from databases, which tend house exponential amounts of data.

In general, the rules of well-formed HTML documents, usually identified by the extension .xhtml, are a means of providing "clean code" and "code mechanisms" on the web. It is given that the majority of pages available on the web are written poorly at best and inconsistencies reign supreme, particularly of those pages created by generators or site management applications. The rules for well-formed HTML documents are in most cases a standardization of features that are inconsistent within the HTML Document Type Definition (DTD). Following the rules of well-formedness when creating HTML documents ensures an easier transition to XML as well as compatibility with future browsers. However, since most of today's page editors and site management tools do not understand or utilize XML, implementing rules of well-formedness must, in most cases, be performed by hand. The following partial list presents the main rules of well-formedness as they apply to the creation of .xhtml documents:

**Close all tags.** Within HTML documents, there are many tags that do not require a closing tag, such as `<P>`, `<LI>`, and `<DT>`, when interpreted by the browser. However, within the HTML DTD, it is specified that these tags have closure. Yet, these tags when left unclosed in a page cause problems for XML interpreters and readers. Consequently, adding the closing tags causes no ill effects when rendered in an HTML browser because they are specified within the HTML DTD.

**Avoid orphaned tags or overlapped tags.** When generating HTML by hand with a text editor, commonly developers will overlap sets of tags. Many page editors and site management tools also allow overlapping tags. For example, a text segment that is to be italic and bold would include both the `<B>` and `<I>` tags, one inside the other. When creating composites such as this, it is imperative that the order of the tags be correctly written. If the `<B>` tag is identified and then `<I>` tag, the closing order should be `</I>` and then `</B>`. If the opening sequence does not match the closing sequence, an orphaned tag exists. Rules of well-formedness require that composite tags be used in logical groupings without orphaning tags.

**All attribute values should be encased in quotes.** As is common practice, some developers enclose all values in quotes and others do not. Consistency is what is usually stressed. Additionally, there are times when double quotations or apostrophes around attribute values are required by certain browsers, particularly in pages that utilize various scripting languages. Well-formed HTML documents surround every HTML attribute value with quotes for proper interpretation by XML browser.

**Use escape sequences for specific symbols.** HTML provides a means for providing special symbols within the text rendered in the browser. These escape sequences permit one to include symbols generally used by the HTML code, such as the less than (`<`), greater than (`>`), and ampersand (`&`) symbols. Often developers mistakenly enter these symbols into their content, without realizing that they may or may not be rendered properly. For example, if the developer wants to have an ampersand (`&`) in his document, `&amp;` should be entered rather than the symbol itself. For well-formed HTML documents, escape sequence use, as opposed to directly typing in the symbol, is mandatory. Also, the HTML version 4 specification included several additional entity references that can be used in pages. However, these character references are not supported and can cause problems in XML browsers. Developers should only use entity references for ampersand (`&`), greater than and less than symbols (`< >`), apostrophes (`'`), and double quotations (`"`).

**Include "required" structural tags.** Many of the browsers being used with frequency by the general public will ignore terse errors in HTML code, such as forgetting the structural `<HTML>` and `<HTML>` tags. For proper interpretation by XML browsers, developers must strictly adhere to the HTML DTD specification and include all required structural tags.
Observe case sensitivity. Unlike HTML, XML is case sensitive. It is best to enter all tags and attributes in lowercase or uppercase, preferably lowercase.

Close empty tags. As opposed to tags that require no closing tags, HTML includes several tags that are called empty tags, such as `<BR>`, `<HR>` and `<IMG>`. A specified in the HTML DTD, these tags have no official closure. Within .xhtml files, these tags must be closed, using `<BR />`, `<HR />`, and `<IMG />` respectively. Note that for proper interpretation by legacy HTML browsers and XML browsers there should be a single space between the tag name and the backslash (/).

Implementing the rules of web-formedness within existing large sites is a daunting task. However, where large data resources are concerned, the transition to XML must occur in steps, as it will undoubtedly happen on the web at large as well. The intermediate step is to implement the rules of well-formedness within today’s HTML documents. In the future, the complete overhaul of a site from poorly and loosely written HTML straight to the stringencies involved with XML will be significantly more difficult than the evolution from well-formed HTML to XML. Therefore, it is vital that educational institutions design pages according to the rules of well-formedness if they intend to eventually migrate to XML in the future.

At Purdue University

As the university strives to reach the next level of web integration (fully integrated or true distance education), many are concerned with the evolution of technologies taking place on the web. The most significant concern is the evolution from HTML and existing technologies to future XML and XSL implementations. To test the efficacy of this transformation, one of the major resources being used, the Computer Graphics Question Repository (CGQR), has been targeted for evolution to well-formed HTML, and eventually to full-scale XML and XSL. The CGQR contains over 700 questions that have been answered to date.

The CGQR is a database driven site that provides a means for students to ask questions and find answers to pertinent issues related to computer graphics and the courses they are taking. Several of CGT courses are quite large, some including as many as 50 to 200 people. In the past, one of the difficulties for professors was being able to have one-to-one contact with all of his or her students. The CGQR was created to allow professors to be able to impact all the students in the course while also allowing all students to have direct access to the professor in charge of the course, even if they have another individual within smaller laboratory settings. Even within smaller courses, professors have found that the CGQR strengthens the course and thus the CGQR is used heavily across multiple courses and therefore contains a variety of information.

One of the problems in almost all courses is that students are often disinclined to ask questions. This is sometimes due to fear; often the fear that the question they will ask will be a source of embarrassment when answered. However, if questions are not asked, the amount of cognitive processing is questionable. Accordingly, the primary purpose for the CGQR is to increase student inquisitiveness as well as increase the learning that occurs both inside and outside the classroom.

CGT professors can use the CGQR in several ways. Predominantly, content for the CGQR is a direct result of lectures and demonstrations in various courses. At the end of every lecture and demonstration, students are required to submit a note card or small piece of paper for attendance purposes. However, in addition to their name, the submission can also include any questions the student may have in regards to the lecture material, particularly those things that might have been confusing or things for which more information is needed. Questions may also be more general in scope or on topics related to computer graphics but not necessarily related to the course topic at hand. The professor then answers these questions and the questions and answers are placed online anonymously. Students can then browse the questions that have been asked and answered, which reduces the number of redundant questions over the life of a course as well as over subsequent course offerings. Consequently, students may also submit questions directly to the CGQR. In this way, the CGQR’s effectiveness can reach beyond a single course.

The CGQR provides several means for students to access the information. Every question can be tracked by current course, topic, technology, date as well as specific keywords. Which elements are tracked and recorded depend on what the professor enters when answering the question. When browsing, the student uses drop down menus that are constructed at run-time based upon the entered fields in the database. Students can examine questions related to their
particular course; other courses in the department; specific topics such as multimedia, imaging, et cetera; by technology such as HTML, Photoshop, Flash; by date; or by searching for a specific keyword. Once a student has made a selection, all questions pertaining to a particular topic, technology, et cetera are displayed in chronological order on the right hand side of the screen. Students can see the entire history of questions related to their query.

The CGQR has had many positive effects within the courses in the Department of Computer Graphics. The most significant effect is that use of the CGQR has alleviated student fear of asking questions. Students are much more open to questions concerning specific course materials as well as general topics. Although not quantitatively supported, it is assumed that free inquiry by students has been enhanced the CGQR. Additionally, student evaluations frequently comment that the CGQR is one of the best course resources that they have ever had the opportunity to use in any course at the university. Consequently, professors that choose to use the CGQR find that their student evaluation scores are higher as a result. It is assumed that this is due the ability to have oneto-one contact with students. Although face-to-face communication may not be possible in large courses, students perceive the CGQR as an adequate and effective alternative.

One of the primary concerns of professors new to the CGQR is the number of questions they might receive in a given course. With their time already pressed, many shutter at the thought of having to type in questions and their answers for numerous questions. However, within the courses in which the CGQR is being used, on average there are usually less than five questions per lecture or demonstration in a course of 100 students. Sometimes, there are no questions at all. Although the number of questions may vary, generally the time required to answer the questions is negligible, taking less than 15 or 20 minutes following each class meeting. Yet, as revealed by student evaluations, this time is one that is perceived as most valuable by students. Often even if a student asks no questions via the note cards, the option of being able to ask a question is perceived as significant.

Evolving the Computer Graphics Question Repository

The predominant technologies used within the CGQR include an SQL database, server side VBScripting (via Active Server Pages), client-side JavaScript, and HTML. Because most of the data for the CGQR is stored within the database and pulled via ASP pages, very few files required editing. However, the editing that was required was made more difficult due to the meshing of scripting and HTML. Although there are over 700 questions currently in the CGQR, the majority of the major search pages and form pages for the site number 15. As noted earlier, editors and site management tools do not generally support rules of well-formedness. Therefore editing the CGQR pages was performed by hand using a text editor.

Although the number of pages that required editing was few, the biggest concern for evolving the CGQR was the data contained within the database. Over the years, a variety of embedded HTML, that is HTML directly entered into a question or answer, had been placed into the database. As noted in the rules of well-formedness, specific character entities can be problematic. Similarly, open tags were also an issue because XML readers require closure on every tag for proper interpretation. To help resolve this problem, specific queries were developed within the database to help find potential problematic fields. Once found, the field data was modified to follow the rules for well-formedness.

Although minor issues concerning the evolution of the CGQR are still being dealt with, the predominance of the site conforms to the rules of well-formedness. Because of the limited number of pages, the CGQR offered an excellent and somewhat limited opportunity to determine the difficulty of evolving from HTML to xHTML. The time required was rather minimal, less than 40 working hours. However, it is obvious that larger sites with various complexities not dealt with in this example may pose more of a problem. The important point is that the evolution of resources such as the CGQR must occur in steps, if the evolution is to occur at all. Leaping from a very simple and base technology to one with the complexities defined in XML is a daunting task. Successful evolution requires small steps rather than major leaps. Additionally, the distribution of changes over time makes evolving from one technology to another much more cost effective and much more easily implemented.

Due to the success of the CGQR as a student and faculty resource, future endeavors will focus on continued technological evolution to enhance its features and functionality. Currently further tests and modification are being performed with XML browsers and XSL formatting to foster increased functionality.
Conclusion

Regardless of the capacity in which an institution is using web-based materials, it is imperative that they be created in a way that permits them to evolve as easily as possible to future technologies. Developers of content and the institutions that financially support the creation of these materials cannot do so in a vacuum. Wherever and whenever possible, materials should be designed with open-technologies and with foresight of coming technologies. Change is an inevitable part of designing for the web. Thus, educators and developers currently working on web materials should design those materials with the rules of well-formedness, and the eventual and inevitable evolution to XML and XSL, in mind.

Richard Wheeldon
Department of Computer Science, University College London, United Kingdom
P.Monthien@cs.ucl.ac.uk

Abstract: This paper investigates the usability of educational metadata schemas with respect to the case of the MALTED (Multimedia Authoring for Language Teachers and Educational Developers) project at University College London (UCL). The project aims to facilitate authoring of multimedia materials for language learning by allowing teachers to share multimedia materials for language teaching, and offering a comparatively easy interface for retrieving materials and composing exercises and courses from them. Although a brief description of the MALTED system is given, the paper focuses on usability problems encountered by the project during the development of the MALTED system. This work finds that there are serious incompatibilities between the current educational metadata schema, as promoted by the Learning Object Metadata (LOM) working group of the IEEE Learning Technologies Standardization Committee, and the way language teachers actually go about authoring teaching materials.

1 Introduction

1.1 Metadata
Metadata was introduced to facilitate searching for items not only via the items' technical attributes but also via additional information about the items. For example, web pages often contain metadata describing the content of the page, enabling search engines to determine the content of the page without having to search through the whole page. Consequently, rich metadata schema allows sophisticated or very specific search requests to be carried out.

1.2 Education and Metadata
The idea of searching for educational materials from external resources and reusing them is not new. Education professionals regularly use and reuse materials from outside their classrooms as part of their teaching materials, e.g., newspapers, videos, posters and other props. Educational metadata schemas, such as the one specified by the Learning Object Metadata (LOM) working group of the IEEE Learning Technologies Standardization Committee, aim to help teachers find the right multimedia materials that suit their pedagogic needs, by facilitating sharing of those materials among education professionals. LOM objectives go as far as to enable exercises to be automatically generated by computer agents that are given certain specific criteria. Consequently, LOM metadata schema is extensive. The schema archives a wide range of information concerning the materials, ranging from the description of the materials to the kind of student interactions the materials are authored for. This not only enables teachers to search for materials by subject or a particular course but also specifically by students of certain age, level of competence or the kind of interaction the teacher would like the multimedia material to use.
Other related metadata projects aim to deal with the practical problems of LOM extensive schema by either creating a subset schema that is compatible with the more extensive LOM schema (e.g. ARIADNE) or creating an alternative lightweight schema (e.g. Dublin Core Metadata Initiative).

1.3 The MALTED Project

MALTED (Multimedia Authoring for Language Teachers and Educational Developers) is a European Commission-funded project led by University College London (UCL). The aim of the project is to facilitate authoring of multimedia materials for language learning. Computer-based multimedia exercises can enrich the self-study part of language learning, which requires a certain amount of drill-style practice, for several reasons:

1. By utilising sound, video and animation, a wider range of language skills can be exercised than through paper-based exercises.
2. Computer-based exercises provide immediate feedback to the learner.
3. Well-designed multimedia materials appeal to many learners and thus increase the amount of self-study.

For these reasons, many language teachers would like to utilise multimedia exercises. Authoring effective and attractive multimedia materials is, however, time-consuming and requires a level of computer skills that many teachers do not possess or have time to acquire. Building a time-telling exercise with an animated clock and sound clips, for example, can take many hours. MALTED aims to reduce the effort required to produce effective and attractive materials by allowing teachers to share multimedia materials for language teaching, and offering a comparatively easy interface for retrieving materials and composing exercises and courses from them. MALTED collects multimedia materials in a repository for re-use by other teachers. To allow teachers to identify suitable materials for a particular exercise, materials submitted to the shared repository have to be tagged. Without tagging, identifying suitable materials would require tedious and time-consuming scanning of long lists of materials in the repository. Since effective and efficient re-use of educational materials is at the core of MALTED, it offered a case study of educational metadata in action.

While this work will outline the technical implementation of the MALTED system (Section 2), the focus of the work will be on issues concerning usability of metadata from the point of view of language teachers at UCL who are using the MALTED system to author teaching materials for their courses (Section 3). In particular, the work will highlight serious incompatibilities between the metadata schema advocated by LOM and the processes that language teachers actually employ to author teaching materials (Section 4.1).
2 The MALTED System

2.1 System Architecture of MALTED

The MALTED system consists of three main parts: MALTED clients, MALTED assetbase and the database backend. Figure 1 presents a simplified system diagram of the whole MALTED system.

The client application provides an interface for teachers to access and manage materials or “assets” and their metadata via the MALTED assetbase, allowing them to perform tasks such as searching for and adding new assets to the back-end database. It is solely through this client application that teachers will interact with the MALTED assetbase. The client application also provides facilities for authoring and managing materials.

The assetbase performs the standardisation of metadata between the client and the database. This is accomplished by converting a database query or an update requested by the client in eXtensible Markup Language (XML) into the appropriate Structured Query Language (SQL) query or update for the database and vice versa. A custom data dictionary (DD) -- containing a mapping of XML attributes to database tables or views, with associated typing -- is used together with a Document Type Definition (DTD) to enable the assetbase to store the assets and their metadata in the appropriate place on the database. This gives the advantage of flexibility as different subsets can be used for different asset types. For example, technical information such as resolution is appropriate for a video or image file, but meaningless for a text file. The same data dictionary is used to create the XML files to return to the client following a query by extracting and combining data from multiple tables, where each XML file represents the metadata associated with a single asset.

A database is used to store assets and their metadata in order to optimise the speed of access for queries and to enable complex queries, which may be inefficient if carried out via XML, to be performed. While it is possible to use other database packages, the MALTED system uses Oracle, which communicates with the assetbase via JDBC (the assetbase having been written in JAVA).

3 Handling Metadata in MALTED
It is possible to achieve a number of LOM objectives directly through the use of metadata to tag educational material with relevant information on the material. The following LOM objectives (LOM, 2000) are particularly relevant when designing a system to handle metadata:

- To enable learners or instructors to search, evaluate, acquire, and utilize Learning Objects.
- To enable the sharing and exchange of Learning Objects across any technology supported learning systems.
- To enable the development of learning objects in units that can be combined and decomposed in meaningful ways.

Teachers using MALTED first encounter metadata when searching for assets on assetbases and then while contributing new assets to assetbases. The MALTED project has encountered some significant usability issues concerning metadata while implementing facilities to support these two tasks. The following issues were raised during both formal and informal interviews and focus groups with users of the MALTED system. Consequently, for this section, the term "user(s)" will refer to language teacher(s) at UCL, unless explicitly stated otherwise.

3.1 Searching via Metadata

From the user's point of view, metadata is first encountered when searching for materials on an assetbase. To support this task, MALTED provides a search dialogue in which the user specifies what to search for in which metadata field. At this stage, large number of fields in the metadata schema is very useful to the user as a large number of fields allow the user to very specifically define a search. For example, the user can search for assets for French language teaching at first year undergraduate level with multiple-choice questions as the interaction type for students whose mother tongue is not French. Even fields that have little or no pedagogic value can be of some use for the user—the fields for file size and format can be of use if the user is concerned with download time or compatibility issues.

After a search request has been submitted, the search result is then displayed to the user showing information about the assets structured by the metadata schema. Again, the fields in the metadata schema are useful for the user as the schema gives structure to the information on the materials. However, if all fields are displayed to the user at the same time, some information that are given to the user may be irrelevant and, if there are a large number of irrelevant fields, the user may experience information overload.

3.2 Tagging Material with Metadata

The rich and extensive metadata schema that helps the user search for and view asset information are, however, significant overheads for the user when he/she is adding new material to an assetbase. There are a significant number of usability problems concerning metadata that arises when the user performs this task.

3.2.1 Too many fields

The problem experienced by the user, at this particular stage, is not so much information overload, but information "over-demand". Although almost all of the fields are applicable (i.e. the material does have attributes which can be categorised by the field), they may not be important. Users feel that it is not necessary to identify all possible characteristics of the materials they are submitting to the assetbase, just the "relevant" or "important" ones. We found that such overhead imposed on the user could deter the user from using the system because it takes too much effort to share materials. Previous research (Davis 1993) (Fullan 1982) on the factors influencing implementation of educational technology strongly suggests that the user's perceived practicality of the system is one of the main factors to influence whether the system will be used or not. In the case of MALTED, the user was spending a lot of time filling in each field and also working out the most appropriate content of each field. MALTED users feel that this process takes far too long.
3.2.2 Ambiguous field names

Often the user is presented with two or more fields that, in their opinion, refer to the same attribute of the material they are trying to add. For example, users often consider the fields “Content” and “Description” to be the same. Consequently, the user finds it difficult to fill in some fields as it is felt that the information has already been entered in a previous field. As in the previous problem, the user feels that more work than necessary is being demanded of them by the system.

3.2.3 Irrelevant fields

Users often do not think about their materials in terms of the fields offered. This is particularly the case with users who teaches modern languages. For example, if the user wants to add a picture of a cat to the assetbase, the user must specify which language and level of competency the material should be used for. While such information on an asset may be appropriate for a whole course, these fields are clearly not relevant for such low-level materials such as pictures. Furthermore, such material can be useful for authoring lessons or exercises for a wide range of subjects, from modern languages, art and even physics! Consequently some fields demand information, which are too specific for certain materials. Ironically, highly specific tags may prevent materials from being widely used; contradicting the notion that metadata was introduced to allow greater sharing and reuse of materials.

3.3 MALTED Metadata Interface

The design of dialogues dealing with metadata in MALTED has to solve the following problems:

- How to present large number of fields without overwhelming the user?
- How to get the user to complete the fields as quickly and accurately as possible?
- How to reduce the number of fields to be filled in by the user?
- How to determine which fields are relevant for a certain material?

3.3.1 Automatic Field Completion

There are a number of fields that can be automatically completed by the system. These are information that can be derived from the file system, such as file size, file format and other technical information. MALTED automatically fills these fields in for the user when the material is submitted. If the user is adding a course to the assetbase, all the assets in that course inherit the tagging from that course.

3.3.2 Reduction of the number of fields

MALTED reduces that number of fields for a material by displaying only the fields that are relevant to the type of material being added. Taking an earlier example, MALTED will not prompt the user for information concerning “Image Resolution” if the user is adding a text or an audio file to the assetbase. This helps to reduce the problem of having too many and/or irrelevant fields. Additionally, MALTED differentiates between mandatory fields and optional fields by hiding optional fields from the user unless the user explicitly requests to fill in those fields.

A possible counter-argument against reducing the number of fields can emerge from what has already been discussed in Section 3.1: Searching for Material. Large numbers of fields allow the user to define a search very specifically. There will always be a case where a user might want to search for materials under an obscure field, such as the "Semantic Density" and the "TaxonPath" of a material (LOM schema). However, by attempting to satisfy every possible use of metadata, the metadata schemas such as LOM may have made themselves unusable to small-scale or individual users.

4 Discussion

While the MALTED project has not been able to solve all the usability problems concerning metadata that it has encountered, it has managed to highlight issues that require further debate and enquiry. From a broader perspective, during the development of MALTED, knowledge about what functionalities are
required by language teachers when authoring electronic multimedia materials has been acquired. This in turn has raised the issue of the appropriateness of educational metadata schema in relation to how language teachers actually go about creating teaching materials.

4.1 Material Usage and Metadata

Problems discussed in Section 3, such as over-demand and overload of both relevant and irrelevant information about assets, raise the possibility that sharing and reuse of educational materials between users happens at a much lower level of granularity. In the case of MALTED, users just want to pick out elements of a course or just find a single diagram that they can use in their own question. The LOM metadata schema suggests that users would want to reuse other people’s whole exercises or even courses. This raises a fundamental question concerning how teachers and lecturers go about authoring their teaching materials and what kind of computer support they actually require.

4.1.1 Syllabus and Instructional Goals

The current view of the teacher’s task, in which constructing teaching material is one of adapting an existing course created by someone else to suit an area of the syllabus that he/she is trying to cover. The LOM metadata schema codifies the course in terms of the syllabus that the course is covering. This assumes that what the teacher is trying to accomplish in class – instructional goals – is very similar to the syllabus or at least derivable just from the syllabus. However, in the case of language teachers (users of MALTED), the task they engage in is a very different one. Instead of finding a course or exercise that deals with a certain part of the syllabus and adapting their instructional goals to suit the course/exercise, language teachers approach material authoring from the opposite end. That is, they first form a set of instructional goals and then find materials such as pictures, audio or a particular element of an exercise (e.g. time-telling elements of an exercise) but not a whole exercise or course – that can fulfil or be adapted for each individual instructional goal. The main reason for this “reversed” approach is because language teachers feel that they need to know the students’ abilities first before writing instructional goals that would be the road map for those students to accomplish what the syllabus have set out.

While the goal of creating teaching materials by reusing previously authored materials is the same in both cases, the sub-goals or how the main goal is achieved are very different. Teachers are not looking for “ready-made” courses or exercises to use. Users of MALTED feel that it is their responsibility as teachers to identify the instructional goals for their students. Moreover, other people’s exercises may cover the right part of the syllabus but not necessary via the most appropriate instructional goals. Supporting the task model where the instructional goals are set by someone else would be a critical failure to support the correct sub-goals.

5 Conclusion

While it was very important to solve technical problems encountered during the implementation of MALTED, the issues of the usability of metadata management facilities in MALTED are very significant factors in determining whether the system will be used or not by the teaching profession.

While extensive metadata schema for educational materials facilitates very accurate search queries, the schema has serious usability problems from the end-user’s (teacher/lecturer) point of view when contributing new materials to an archive. In order to use the extensive LOM metadata schema, a professional archive manager will be needed to perform the tagging as the process is too time consuming for the teachers to do themselves. MALTED uses a subset of the LOM schema that can be mapped to the more extensive schema.

A significant finding during the MALTED project is that language teachers reuse materials at a much lower level of granularity than LOM metadata schema would suggest. Language teachers write instructional goals based on the abilities of their students then find materials that would satisfy the
pedagogic needs of those instructional goals. Separate assets of a course or exercise, such as pictures or audios, are individually picked out by the teachers and are used to author a new course or exercise. Consequently, the user requires authoring support at a much lower level of granularity. While the highest possible level of granularity of reuse is using a whole pre-authored course, language teachers hardly reuse courses by adapting them. They reuse smaller components of courses that are appropriate for instructional goals that have been set by the teachers themselves. This model of usage may also be applicable to other cases where teachers reuse multimedia materials from resources other than their own. It may also be applicable to other subject areas and other levels of education.

Sonntag, Alexandre A.; Companhia Riograndense de Telecomunicações Brasil Telecom— asonntag@crt.net.br

Abstract: Online Distance Learning System from CRT Brasil Telecom, has showed that technology and education found a common point to perform good educational methodologies. Contents and ODL (Online Distance Learning) programs reached a very good point of performance and moreover, internal culture is much more prepared to use Online Learning than ever. The next target now is: how to orient employees to get good results on a "sea" of knowledge. CRT Brasil Telecom Knowledge Communities are assembled to give a natural orientation specifically prepared for professional and applied educational needs.

Introduction

CRT, a recently privatized Telecommunication Company in Brazil, is now very well positioned in the global arena of the competitive Corporations. Considering the increasingly need for education methodologies, CRT has developed a Distance Learning Strategy to prepare the Company for the future. Starting with the launch of a Distance Education and the establishment of a development team, now CRT has a full ODL (online distance learning) structure running over Intranet. So, what is the next corporate challenge for education?

Objectives and Constraints

The CRT Online Distance Learning structure, called SEND, was created to contribute on the search for an educational model for a Telecommunication Company, specifically adapted to internal culture aspects. This search started in December 1999 and already opened a full set of new possibilities of employees development. These opportunities could not be planned considering traditional paradigms of education. It was needed to embody aspects like continuing education and non presential training for the ODL development team and changes on internal culture for CRT employees. In short, CRT is an year old company trained over Intranet on a model that seems like to be definitive in terms of improvements on distance learning events.

These events reflect specific needs for technical, commercial (business) and administrative areas of CRT. That is why programs were created with different approaches in order to adequate the training to the employee. For sure though, this is not enough. Survival for CRT now means to reach telecommunication goals that will make possible to start competition on different areas of Brazil. The key for this objective is the strengthening of the knowledge community with an oriented educational plan.

Knowledge communities are composed by groups of professionals that share the same information and act on similar areas. As an example, it is pointed the Consultant Team which takes care of CRT business costumers. This group handles a lot of different technologies regarding telecommunication systems and also have to be well developed on communication, interpersonal and sales skills.

As a multidisciplinary group, training for this community is far away from exposing a deep set of distance learning contents and waiting for the conclusion of all events. As an example showing them a big library without orientation, employees usually don't have the aptitude of conduct their own development. So, the CRT Distance Learning System as being the system responsible for their education and development, has the mission of connecting suitable contents to specific knowledge communities.

Implementations

Some aspects must be considered in order to create and integrate a Knowledge Community. CRT Training and Development area have developed human resource instruments like education tracking and expert identification. This information composes data bases where it is possible to identify similar skills on education and job areas.

Training Consultants contribute with analysis of development needs, strategic plans and targets of each business department. With these information, it is possible to define communities with their respective plan of development and the nature of information needed to support a good job performance and communication flow for the teams.

SENDMeeting Forum

Fig. 1- Systems available to an ODL Student
Distance Learning programs developed on SEND can now be connected specifically to each knowledge community. It represents the content element of the diagram shown on Fig. 2. Connection elements are SEND services, that represent the interaction ways, giving access and further information for all online students.

**B. Connection Elements**

The implementation of interaction tools represents the students channel that enable him to keep in touch with other students and with Online Tutors during synchronous or asynchronous events. These elements must be positioned around the employee and must be accessible at any place. See Figure 1.

---

**Fig 2. Knowledge Community concept**

**C. Practical Developments**

**C.1 – Continued Commercial Education**

Commercial area professionals of CRT was divided in two communities in order to design the development programs to the follow activities: telesupport (teleatendimento) and Commercial Outlets.

As characteristics of telesupport team, there is a high turnover level of employees and some non-employees from partners companies. Premises for development skills of these students is the commitment with the Company by learning about telecommunications business, products & services and costumer needs. This community is developed with the production of instructional materials based on Video on Demand in the format of Learning Objects (small pieces of information for continuous education). With the use of Learning Objects it was possible to assemble an education path for each student in order to organize an individual professional career.

As a motivational aspect, students feel more comfortable being certified with professional improvements.

**C.2 – ADSL Team Community**

Implementation of new Telecommunications services motivated the creation of this community specific for Network Installers. New professional skills should be developed for these teams, since these employees were not skilled in dealing with Computers Architecture and Data Communication. During the installation process of an ADSL (for costumers) they must give all professional information about installation levels in order to reach targets, downloads of documents, contacts with equipments providers, access to Products and Services informations and costumer care proceeding. Also, the exchange of news and troubleshooting among professionals are shared with the use of mailing lists and forums accessible in a web site specially designed and developed for them.

**C.3 – Tutor Services**

Virtual Communities in CRT have a tutor, which is responsible for that community. This tutor shows a new model of learning-teaching (that came with the concept of virtual communities): now people bring their needs to the community and other peers can help them in these needs. It is a process where all people are involved and where everybody can teach and, at the same time, learn something. The old teaching is concept had to change: formal tutors are worried about how people work in a virtual community, that means that students became “actors” in their learning process, instead of giving the contents courses to the students and answering questions.

The virtual community success point is: people have to interact and feel that they are part of the community and responsible for it’s nourishing and growing and also for the contents application in the organization.

**Results and Conclusions**

SEND already trained about 3000 students, on 12 different development titles and 4 distance learning programs. For the near future, content development will not be the main success point for a learning organization, but the way students access all contents. Technology development in distance learning is also a technique used to conduct and orient professionals in order to support performance and efficiency on the job. SEND might be the most efficient one for a Telecom Company Environment. The new concept results showed that people learn more, get more involved and participate more on their own learning process, besides that, this process helps the company to manage it’s knowledge and also get more results on it’s business.

Abstract: The VETO project is part of the Ministry of Education national strategy to develop an Information Society Program in Finnish schools. The focus of the VETO project is to develop and identify relevant guidelines for the implementation and integration of network based education solutions in vocational schools. In this paper, we identified three major indicators of technology integration. These indicators were netpedagogy, technology, and usability and were studied within the context of vocational teachers’ planning, implementation, and evaluation.

The purpose of this study was to evaluate how and what kinds of learning contexts and processes network based education support in vocational schools and workplace. Several questions guided the study: What teaching practices (pedagogy) did network based learning environments support in vocational schools? What delivery and productivity tools were used to create and design NBL environments? What usability issues were associated with network based learning environments in vocational courses? What implementation strategies did vocational teachers use? Three underlying theoretical frameworks guided our inquiries: teachers’ pedagogical knowledge (Grossman, 1990, Shulman, 1986), constructivist and socio-cultural learning theories (Collins, Brown, & Holum, 1991; Jonassen, Davidson, Collins, Campbell, & Haag, 1995), and instructional design models (De Corte, 1995; Lehman, Newby, & Ahn, 1998).

Literature Review

The scope of the literature review is to describe the conceptual framework by which we evaluated network based learning environments in vocational education. The conceptual framework is grounded in the following principle: “Powerful learning is characterized by a good balance between discovery learning and personal exploration on the one hand, and systemic instruction and guidance on the other” (De Corte, 1995, p. 41). For this reason, we guided our research based on three technology integration indicators. These were netpedagogy, technology, and usability. We framed these indicators within the context of technology integration: Plan, Implement, and Evaluate (Newby et al., 1996).

Before the selection of delivery tools and any other technological devices, teachers must determine what exactly they want to accomplish. This begins by selecting a pedagogical strategy that drives the selection of the technological tool, which in turn must work well over the World Wide Web. The idea is not to use technology for its own sake but to be driven by pedagogical considerations (Chizmar & Walbert, 1999). A brief look at the research reports on online education shows that most of the issues pertaining to it are clearly pedagogical, not technological (Lee, 1997). Laurillard (1996) said this best:

So we must not begin with what the new technology offers. Examining instead what students need, we are led to a quite different analysis of how new technology can help. Most importantly, it should (a) give students more opportunities to engage with the practice of their subject; and (b) give them more opportunities to discuss and articulate their ideas.
Netpedagogy

We believe that good teaching practices should support deep approaches to learning by encouraging learners to participate in activities that promote "deep understanding of subject content, the ability to analyze and synthesize data and information, and the development of creative thinking and good communication skills" (Alexander, 1995, p. 6). Behaviorist learning theories are best known for supporting learning that its main goal is to impart facts, procedures and rules. Instructional goals based on behaviorist theories are frequently used in vocational education for facilitating initial factual knowledge acquisition in a field (Doolittle & Camp, 1999). Cognitive learning theories view learning as an active mental process of acquiring, remembering, and using knowledge. Learning is evidenced by a change in knowledge that makes a change in behavior possible.

When the instructional goals require that learners engage in the active production of knowledge, constructivist and social cultural theories of learning become the instructors' choice. Adherents of constructivism suggest that through the use of higher order thinking activities and the encouragement of ownership of learning deep understanding can occur. Some of the approaches used to facilitate higher order thinking are those that encourage analysis, synthesis, problem solving, reflective thinking, and metacognition (De Corte, 1995). By giving learners control over how to plan, design, and work, and encouraging them to generate hypothesis and to pursue the end result are some of the ways in which learners' ownership of learning can be supported. Social cultural learning theories, in addition to supporting these types of deep approaches to learning also advocates the use of authentic activities that simulate the level of complexity expected in the terminal performance (Lave & Wenger, 1991; Pantel, 1997). Another activity promoted by social cultural learning theories is the use of legitimate peripheral participation. That is, novices in the field observe experts and other learners from the side (Lave & Wenger, 1991).

On the whole, learning theories guide the development of instructional materials. They identify for the instructor the types of activities that must be available for the goals of the instruction to be achieved. Before evaluating learning materials, we must look at the pedagogical approaches chosen for the development of the materials. This means that the instructional goals and perhaps overall curriculum must be clear to the teachers, since these goals will drive the focus, evaluation, and ultimately the production and selection of network based learning materials and environments and other related network based pedagogical decisions.

Technology

Technology is a key issue in online learning. It deals with issues on how to choose tools that can best help prepare the individual components of the learning program, which tools can help bring together the individual components into a single course, and which tools are most effective in managing online learning (Carliner, 1998). Technology tools help to develop course materials and deliver these.

Developing [course materials] consists of the software used to prepare the learning materials for presentation online, such as the elements of a database used to manage knowledge, a module in an online tutorial, a lesson in a course that's broadcast on the Internet, or a tool to monitor a worker's performance and provide relevant coaching. Delivering [course materials] consists of the hardware and software needed to store learning materials and transmit them to learners when and where the learners need them (Carliner, 1998).

Usability

The issues that relate to usability in network based learning environments are enormous and range from design issues to technical issues. After determining the instructional goals and selecting the technology tools and pedagogical practices that can help us attain these goals, teachers are ready to develop network based learning materials. The teacher must decide on the most appropriate learning environment based on his or her pedagogical orientation, instructional goals, students' abilities, and resources available (Moreno, 1999). If the decision is for using computer mediated instruction, such as network-based education, then the teacher must be aware of some basic usability design issues that deal with content, navigation, layout, and interactivity.

Methodology

The underlying methodology of this study is phenomenology. Phenomenology is "the study of how people describe things and experience them through their senses" (Patton, 1990, p. 69). The basic assumption underlying this inquiry paradigm is that individuals can only know what they experience "by attending to perceptions and meanings that
awaken [their] conscious awareness" (Patton, 1990, p. 69). Hence, we can only get to people’s perceptions and meaning through interpretation. Interpretive research “is interested in including the meanings of actions from the actors’ point of view” (Erickson, 1986, p. 120). The interpretivists “focus on the process by which these meanings are created, negotiated, sustained, and modified within a specific context of human action. The means or process by which the inquirer arrives at this kind of interpretation of human action is called Verstehen (understanding)” (Schwandt, 1994, p. 120). Verstehen refers to “the process by which we make sense of or interpret everyday world” (Schwandt, 1994, p. 120). It is the “process of comprehending and grasping what has been interpreted in a situation or text” (Denzin, 1989, p. 32).

Site and Participants

The vocational schools were selected from a group of projects funded by the National Board of Education (Opetushallitus). The National Board of Education selected these projects because of their initiatives in using network based learning environments in vocational education. For this study, we chose three teachers. All participating teachers came from different vocational areas.

Teemu taught at a Vocational Institute. The teacher was in the process of planning and developing a course on the Basics of Multimedia. He expected to potentially teach hundreds of students at a distance. He used computers with his students because of the nature of the course. Even though WebCT was available to use, the teacher chose not to use it. He found that WebCT was good as a management system, but found it quite inflexible for producing content. He instead used other software for producing content. He found getting students to use collaboration and communications tools was “almost impossible”. He also chose not to use WebCT with his students because he had heard that students had difficulties learning how to use it.

Sanna taught at a Commercial institute. She supervised 37 students during their work place training. This was the first time she guided students training using the Internet. She participated in a training session on how to use WebCT, but felt that “it wasn’t enough” to feel comfortable with it. She and her students used the Internet for searching Web pages, sending and receiving e-mail, exchanging information and tasks. While using the Internet during one of her face-to-face sessions with her students, the server went down and students could not access any web sites. This experience taught her no to trust the technology and to have other options ready. Overall, this teacher kept a critical attitude toward the use of the Internet.

Marjut and Anni taught a course in Basics of Hygiene at a Health Care Institute. This was their fourth time teaching the course. They taught 20 students (5 groups during the school year) ages 15 to 16 years old. The teachers used the Internet to teach this course, because they believed that it helped increase student motivation for the course. Another reason for using the Internet (or network) for learning was the great possibilities to visualize concepts, besides the opportunity to learn the material out of class.

Data Collection

Interviews focused on how vocational teachers plan, implement and evaluate the learning processes (pedagogical practices, learning materials, and technology). The researchers contacted the teachers over the phone and arranged a face-to-face interview. In the future, we plan to observe the actual lessons as well as to go through their teaching and learning materials to make a thorough evaluation of the usability issues.

Data Analysis

The data analysis from the interviews was arranged in terms of teachers’ netpedagogy (i.e., practices for fostering learning, knowledge building, and stimulating environment) and technology uses for production of NBL environments and delivering of teaching and learning materials. There is a brief analysis on teachers’ navigation structure of their Web sites. A more formal evaluation on teachers’ usability issues will be performed later.

Practices for Fostering Learning and Knowledge-Building

The literature suggests three practices for fostering learning with network based learning environments (Pantel, 1997; Wilson, Jonassen, & Cole, 1993). These are scaffolding and fading, cognitive apprenticeship, and collaborative learning. All these practices originate from constructivist and social theories of learning. Besides fostering knowledge, we want students to use their knowledge in new situations. Some of the practices used to
bridge the gap between schools and job settings are case-based approaches, simulations, and microworlds (Wilson, Jonassen, & Cole, 1993).

**Scaffolding and Fading**

None of the teachers used sophisticated programs to allow for automatic tracking of students' performance and adjust the level/feedback of the instruction. The materials placed on the network (Internet) provided links to relevant information or self-contained instruction. For instance, in Teemu's course, Basics of Multimedia, students followed a module-based instruction that contained exercises and information. If students encountered any problems they could ask him or he would have them looked on the help manuals. Sanna, the supervisor of the Work-place training course, used the e-mail to help students with any questions. The nature of the course, work place training, may have allowed for scaffolding and fading, although no conscious planning for this was described. Sanna kept relevant links on the course web site to help students during the work place training. She also helped students through their face-to-face contact and e-mail. Marjut and Anni, the Health Care teachers, had instructional materials on the web to help students understand the basics of aseptic (e.g. hygiene) in health care. The course included a practical training session. To prepare students for the practical training we could assume that teachers might have used some sort of scaffolding and fading for fostering learning and knowledge-building.

**Collaborative Learning**

Only the Health Care teachers, Marjut and Anni, incorporated collaborative learning in their course, although individual work was also expected. The teachers arranged students into five groups. Within each group, students discussed the materials introduced in the classroom and/or WebCT. The teachers required students to bring their thoughts and answers to the specific tasks to the discussion forum and expected students to also comment on what other students had to say. To encourage the use of the discussion forum, the teachers evaluated the discussions that took place at the forum. Besides using Web-CT's discussion forum, students also used chat, e-mail, and electronic calendar. Teemu did not think of using collaborative and communication tools with his students. "I was thinking not to use any collaborative and communication tools in my own course, although many researchers emphasize the activeness of changing opinions and so on. I feel that it is almost impossible to get students involved in network conversations, especially in vocational education (intermediate level)." Having said this, at the end of the interview he felt that perhaps he should reconsider his view on collaborative learning and try to understand the gist of it. He felt that many times the "group work does not necessarily progress they way that is wanted." Moreover, he feels that the Internet feels more like a tool for behavioristic learning. In Sanna's course, students worked individually. She planned to incorporate this type of learning in the future. During the interview, she suggested that she could have a student who works on a travel agency share his/her experiences with another students in a hotel, and together they could compare their experiences by chatting.

**Cognitive apprenticeship**

Teemu considered himself the students' coach and expert. He would model for his students the different multimedia software. In terms of creating a real work experience, he had not thought about that. Sanna's practical training course allowed for cognitive apprenticeship to occur. At the workplace, students were placed with a tutor, who guided them and showed the basic details of their job. Marjut and Anni have incorporated into the course several hours of practical training that gave students the opportunity to learn while doing. From the feedback received from students, they planned to add to the instructional materials on the web some "unexpected things" to happen. These changes, however, would take place on their advanced course on Hygiene. One of the most significant changes was the inclusion of a patient that students could follow up on what happens to him/her when specific treatments are chosen or ignored. This would allow students to think critically about the information presented.

**Practices for a Stimulating Environment**

Any instruction must consider strategies in order to provide a stimulating environment where learners feel safe and motivated to learn. Network based learning environments must support ways in which learners perceived ownership of learning, become challenged with higher order thinking activities, and participate in authentic activities.
**Authentic Activities**

All three courses provided a level of authenticity to the tasks that students had to perform. Sanna’s course by its very nature gave students the opportunity to work on an actual setting (i.e., hotel or travel agency). Marjut and Anni had the practical training component in the course that gave students a sense of authenticity. Also, in the advance hygiene course by adding a “patient” to the instructional material on the Web, students could see the consequences of their actions. In Teemu’s course students learned the software program’s features that they most likely would use in a work setting. He does not try to teach as if all students would like to become multimedia designers. Insteady, he provided students with specific information that was pertinent to the specific software program.

**Technology**

**Productivity and Delivery tools**

For creating the instructional materials, Teemu used PhotoShop, Dreamweaver, Gleener5 and Sampletude programs. Sometimes, he just used the browser’s editor for coding html. Overall, he felt that the Macromedia tools were the most practical and popular. As a delivery tool, he used one of the Internet browsers available on the market, although he was aware that WebCT was a good tool for managing the content. However, he felt that for developing “flashy” or stylish material it was better to use one of the other productivity programs and then use WebCT as a management tool. Sanna used Word as a productivity tool. She gave a technical person a manuscript with information on the tasks and contents and other information on how she wanted it to appear on the Web. At this point, she was still not using WebCT, although she was positive about its benefits in the course. Marjut and Anni used PhotoShop, Pagemill, and Netscape’s editor. They used it because they were available when they started working on this project. They got professional help for learning how to use these tools. As a delivery tool, they used WebCT because the city where their Institute is located purchased a license for it. They had looked over Lotus Learning Space and thought that WebCT was a more simple and easy to use learning platform.

**Usability**

Teemu used a linear structure and organized the information in modules. The Web site in Sanna’s course was primarily used as a resource of Web site links. Marjut and Anni used the WebCT to manage the instructional Web sites. The navigational structure of their Web sites was referential.

**Discussion**

Network based learning environments provides unique instructional capabilities that never before could have been attained. Learners can link to a great array of information sources. They provide support for new instructional approaches, such as cooperative learning with other learners at a distance, demonstrations, online references, powerful simulations, tips, tutorials, and wizards (Carliner, 2000). Network based learning increases teacher productivity by providing accurate information about students’ progress more quickly, allowing teachers to help more learners at one time. They offer new ways to think about the design and learning processes. Network based learning can be tailored to individual learning and working styles, provides learners with different ways to experience the content (e.g., text, video, animation, graphics), allows learners to actively participate in the learning process by sometimes exchanging ideas, questions, and concerns with experts and other students. Ultimately, through effective design, the network based learning environment can track learners progress and provide alternative explanations and/or exercises until they understand it (Carliner, 2000).

In addition, for the power of network based learning to be realized, administrator and teachers must have a plan for the technology integration and management (Carliner, 2000; Newby et al., 1996). The first step is to form a technology committee. This committee should represent all the stakeholders including parents, community, and students. The second step is the development of a vision. The vision should meet students, teachers, curricular, and societal needs (Newby et al., 1996). The next step is the evaluation of the status of technology implementation. This step must be completed prior to the technology committee becoming too specific about its technology implementation plan. Some of the information that should be gathered during this step is to catalog hardware and software resources, identify current uses of technology, assess faculty and staff proficiency, and evaluate students’ use of technology. The final task of the technology committee is to develop a framework for integrating technology that takes into consideration the availability of hardware and software, curriculum, and individual’s teaching styles.
References

Introduction

Technology has become a major focus of education policy and reform in recent years. Both new and experienced teachers, however, are still not adequately prepared to teach with technology (CEO Forum on Education and Technology, 2000). This paper describes a graduate technology integration course offered at Teachers College, Columbia University. The purpose of the course is to help students learn about and learn with technology and its implications in education.

Background of the Course

Hypermedia and Education is an introductory course offered by the Department of Communication, Computing and Technology in Education (CCTE) at Teachers College. In this paper, we describe a section of the course that is collaboratively taught by the authors. Hypermedia and Education is a course that attracts students from a number of different departments at Teachers College. Students enrolled in the course are either pre-service teachers or experienced teachers who pursue a graduate degree on a part-time basis. They come from different academic backgrounds and are interested in integrating technology in a broad range of subject areas. Therefore, the purpose of the course is to provide students not only with technical skills but also with an understanding of why, when, and how they can integrate hypermedia in education.

Description of the Course

The course is comprised of three main areas related to hypermedia in education: a) Introduction to hypermedia: definition, evolution, strengths and weaknesses; b) Hypermedia in education (Hypermedia in Language Arts, Math and Science); c) Theories and principles for the design of hypermedia products. Although acquisition of computer skills is necessary for effective use of technology in teaching, the course places more emphasis on the pedagogy required for successful technology integration. Students in the class: 1) learn how to evaluate hypermedia products; 2) learn why and how they can use technology in teaching; 3) learn how to create effective technology-rich environments; 4) are exposed to exemplary technology-based projects, resources and teaching strategies;

The instructional delivery of the course is based on the assumption that learning is an active process and knowledge is constructed from experience. Moreover, the constructivist view emphasizes that students should learn to construct multiple perspectives on an issue. Multiple perspectives can be generated only through collaborative sharing of ideas. Consequently, throughout the course, in addition to arranging for resources, the instructors act as facilitators to student cooperative investigations.

Aside from the weekly readings and class activities, students are responsible for completing three projects during the semester. For the first project, students assume the role of educational consultants who need to convince principals of the quality, technical, and educational merits of some software package worth buying for their schools. The end
product needs to be a multimedia presentation developed in Hyperstudio, a popular multimedia program. There are	hree reasons why this assignment is valuable. First, students learn to develop and apply criteria for the evaluation of
educational software. Second, by creating a report in Hyperstudio, students learn how to author their ideas using
hypermedia. Finally, by working in groups, students refine their knowledge through argumentation, structured
controversy, and reciprocal teaching (Dunlap & Grabinger, 1996).

The second assignment requires students to select a topic related to hypermedia and/or education and construct an
annotated bibliography of resources. The bibliography needs to contain well-organized collections of web-sites,
software, books, articles, and journals with insightful comments on the value of each resource. The end product
needs to be presentable on the web. The assignment aims at helping students become critical users of printed and
digital information so they can become fully literate in our multimedia society.

For the final project students have two alternatives. They can either develop a working piece of software using tools
explored in class or design a lesson plan that can be utilized in conjunction with some existing software or web-site.
The nature of the final project allows students to reflect on their understanding of hypermedia in education while
considering key questions in the design of technology based learning environments. Some key issues that students
need to investigate in their final project include: a) the nature of the problem that their product seeks to solve; b) a
clear elaboration of educational goals; c) the rational for using hypermedia; d) characteristics of anticipated
audience; e) the learning theory that guides the design of their product; f) the setting and context in which the
product will be implemented; and g) plans for the evaluation of the product. The final project culminates with a class
presentation where students get feedback from their instructors and their classmates.

Learning by Modeling

Successful incorporation of technology in educational curriculum can not be accomplished without effective
modeling by teacher educators (PCAST, 1997). The following are some ways we have modeled pedagogically
appropriate uses of technology in our Hypermedia and Education course:

- Email: Email has always been the dominant means of communicating with students.
- Discussion Forums: Discussion forums are used for further analysis of topics addressed in the course.
- Presentation software: PowerPoint is used for the delivery of mini-lectures.
- Web-site Development and Online Resources: A web-site was developed to provide information for the course.
  The syllabus, readings, assignments and lecture notes are posted online. Moreover, the course site provides
  numerous links to online resources and tutorials that aim at helping students become more competent in the use
  of the various hypermedia tools (i.e. Hyperstudio, Dreamweaver etc.) introduced in the class.

Summary

Transforming computer machinery into tools for teaching and learning largely depends on educating teachers on the
pedagogical possibilities offered by new technologies. The course described in this paper offers an example of how
technology can be introduced in pedagogically appropriate ways. Students participating in this course do not only
become more technologically proficient in using hypermedia and multimedia tools but they also learn how to
effectively utilize these tools in their own teaching of various subject areas. Moreover, modeling activities by the
instructors expose students to examples of good practice. Currently, the authors focus on assessing the impact of this
course on participating students using extensive qualitative analysis of data.

Introduction and Research Questions

During the last twenty years, the introduction of new technologies in schools coupled with the recent growth of the Internet have allowed students access to a vast amount of educational resources. This vast increase in the amount of information, however, poses numerous challenges to teachers, since access to information does not automatically create better educational experiences for the students. The purpose of this study is to describe the nature of teaching and learning in six classrooms in which teachers used, for the first time, a web-driven science project known as Alpine.

The Alpine project is an effort to mobilize the resources of the web in order to create an information-rich and complex learning environment that can support sustained exploration in science classroom. We first give a brief description of Alpine. Then, we discuss two questions pertinent to the implementation of networked learning environments in education: a) How did teachers implement the features of Alpine? These features included problem-solving collaborative activities, authentic weather data, sharing of information and web based curricula material; b) How did the implementation of Alpine influence student interest and motivation in learning about weather?

Description of Alpine and Theoretical Framework

The Alpine project aims at helping students study weather concepts and learn scientific techniques through a pedagogical model called Goal Based Scenario (Schank, Fano, Bell, & Jona, 1994). Students spend 4 to 6 weeks assuming the role of the U.S. Ski Team coaching staff who need to decide on a location that would be adequate to host the U.S. Ski Team Training Center. Students form six groups and each group is assigned a specific location within the continental United States. Weather criteria for assessing the adequacy of each location are listed in the task description. In pursuing this goal, students are required to form hypotheses based on observations of weather products, collect and analyze archived and real-time data, construct interpretations of weather patterns, collaborate with other participating students, and make decisions. Moreover, a major goal of the program is to help students develop appreciation of science and instill an interest in the study of weather.

Methodology

This study took place in a mid-sized public school in the eastern region of the United States. The participants included six fifth grade school teachers and their students (N=126). There were four new Macintosh computers in each classroom and a television monitor connected to one of the computers. All computers were networked.

Data were collected from multiple sources, including: a) field notes of classroom procedures (e.g. teaching style, spatial arrangements, time usage, etc.), b) student and teacher pre- and post- surveys, c) analysis of student group folders, d) unstructured interviews and interactions with multiple groups of students from each classroom, and e) informal conversations with teachers.
Findings of the Study

Teacher implementation of the Alpine features in the science classroom: In orchestrating the resources available in Alpine, teachers followed a path aligned with their traditional teaching approach. All teachers focused on completing the activities rather than taking advantage of the web resources provided in the program and its interactive features. Therefore, students were restricted from using the discussion forums and sharing their findings with other groups in their school. Moreover, students were not given enough opportunities and stimulus to form questions, test hypotheses, solve problems, or discover new relationships. Finally, students were not allowed to collect real-time data or use web resources to support their investigations. It became clear that teachers did not foster emphasis in the processes of inquiry and invention and most resources available in Alpine remained unexplored.

Student interest and motivation for learning about weather: Student attitude toward science refers to positive or negative feelings about science (Koballa & Crawley, 1985). Motivation is also defined as the process by which goal-directed activity is instigated and sustained (Pintrich & Schunk, 1996). Findings from pre-surveys revealed that students exhibited a fairly positive attitude toward science. Most students (76%) stated that they liked science, although they liked other subjects better. A small part of our student population (19%) said that they were very interested in learning about weather while most students (63%) exhibited little interest in the study of weather. In addition, a small group of students (18%) reported that they had no interest in learning about weather. These findings did not change after the use of Alpine, despite the fact that instilling an interest in the study of weather was a major goal of Alpine.

Observation of students interacting with the program under the guidance of the researchers revealed encouraging messages. When students were given the opportunity to explore all features of the program, they became engaged in forming questions and exploring weather patterns. Many students became interested in visiting various ski sites on the Internet, getting snow reports, talking about their personal skiing experiences, and contacting meteorologists to ask questions about the weather. Other students accessed weather information and data available in the program in order to convert temperature from the Fahrenheit to the Celsius scale and forecast weather conditions in other places of the world. Furthermore, most students expressed real excitement in using all these unexplored features of the program. The above findings indicate that proper use of Alpine can result in self-inquiry and self-realization of the importance of weather in our life and can motivate students to explore available web-resources.

Conclusion

Teachers using networked learning environments for the first time often follow a traditional approach to teaching, similar to the one employed using textbooks. Students do not get engaged in a subject when all material is circumscribed. In the case of the Alpine project, teachers utilized the material using a step by step approach that failed to capitalize on the pedagogical potential of the program. In order to promote student inquiry and interest for learning about weather, teachers need to foster collaborative relationships, sharing of ideas, problem-solving, and decision making. These approaches, however, conflict with the traditional didactic approach prevalent in most schools. In order for new technologies to be successfully implemented in the classroom, there needs to be a shift in pedagogy. Therefore, adequate time must be devoted in helping teachers understand the purpose of educational technology in the classroom and the underlying philosophy embedded in the new inquiry-based approaches to learning. For this reason, our current studies investigate the influence of technology related professional development on the beliefs, knowledge, and practice of participating teachers.

Abstract: This paper is concerned with an automated system for grading students into an ability level in response to their ability to complete tutorials. This is useful in that the student is more likely to improve their knowledge of a subject if they are presented with tutorial material at or just beyond their ability (Bergeron et al 1989). However, dynamically responding to a student's changing knowledge about a subject usually requires the presence of a human teacher, an altogether expensive resource. The system discussed here can grade both a student and the questions in a tutorial with minimal input from the human teacher. In order to accomplish this a specialist neural network is employed. The design and operation of our system is discussed along with arguments as to why a neural network approach is suitable for this problem.

Introduction

The Tutorial Supervisor (TS) is an automatic system for grading a student into an ability level in response to the student's interaction with tutorial questions. Once the student has been graded then a question or tutorial can be selected which is inline with best pedagogic practice (Bergeron 1989). Our TS is an expansion of the TS designed by Bergeron et al (1989). Our TS improves on Bergeron's original specification by having the additional ability to adapt to both students and questions/tutorials as the system is in use, as opposed to requiring the system to be taken off-line and reprogrammed/trained. The TS's ability to respond in real-time to a student's changing ability and how a population of students perceive a particular tutorial or question is brought about by the use of a specialist neural network device that is able to learn and adapt without human intervention. A thorough description of our TS along with complete details of its design and testing can be found in Mullier (1999, chapter 8).

Operation of the Tutorial Supervisor

The TS is simple in operation. A set of questions to be given to the student is recorded in a database and is graded with a difficulty level by the author of the question. A student can then be given an appropriate question, depending upon the student's ability and the difficulty of the question. However, in order for a student to progress in their learning it is necessary to pitch questions so that they sufficiently tax the student without it being impossibly difficult (Bergeron 1989). Therefore it is necessary to track the student's change in ability as they progress through the learning material. Our system achieves this by recording the student's interactions with questions and mapping this onto an ability level. The system is robust to exceptions in the student's behaviour, since a student may generally perform well but make a mistake with one particular question. Similarly, the system is able to regrade questions in the question database. For example, a question may have been graded by the author as being relatively easy. However, it may transpire that a population of students actually find it difficult. This will be born out by most students who should have performed well with the question actually performing poorly. Such a situation negates the pedagogy stated above. Our system is able to statistically determine that a question has been misgraded and is able to remedy the situation. The remainder of this paper will discuss the issues relating to the design and implementation of our TS system.

Rationale for Using a Neural Network

A neural network is an Artificial Intelligence (AI) system that is able to learn rules in response to being presented with many examples. The neural network is said to learn the rules from the examples. In contrast a traditional rule-based system would have rules encoded within it that a designer has previously identified. The advantage of neural network systems is that it is not always possible for a human designer to express and encode rules in a reasonable time-frame or even express them at all. A
A further reason for choosing a neural network for the TS in preference to a rule-based system is that, unlike a rule-based system, a neural network can be domain independent. It is unlikely that, for example, a high level student produces results in the same range for every type of domain. Thus the rule "IF SCORE > 70 THEN LEVEL 10" is only likely to apply to the domain that it was initially defined for. This is the reason why Bergeron et al (1989) use a neural network for their Tutorial Supervisor. Their neural network holds the rules that it has learnt from its training data (the first domain). It is then able to change its rules in response to new data (new domains), by retraining off-line. In this manner the neural network can adapt to misconceptions or inaccuracies in the original rules and adapt to new situations. This would be a difficult and time-consuming process for a symbolic rule-based system, since it would require the re-engineering of the rule-base by a designer, in that the new rules would have to be identified and then encoded. In essence, the neural network is doing the job of the human rule designer. Designing such rules is not necessarily a simple matter, since it requires the human designer to examine many student interactions with various questions and tasks so that a valid grading of each question can be made (e.g. this question was answered well by novice students, it is therefore easy and can be presented to other novice students). The situation is further complicated by the possibility that different populations of students (students from different classes or tutorial groups) may have different previous knowledge of the domain and therefore the initial question gradings may not apply to them. It would therefore be helpful if an AI system could be employed to accomplish the task of dynamic question grading and therefore remove some burden from the author. However, Bergeron et al's (1989) TS is unable to adapt to different domains without being manually provided with new training data and then retrained off-line. The remainder of this paper describes the neural networks used for our Tutorial Supervisor, which improves upon Bergeron et al's (1989) design by allowing the automatic on-line adaptation to different domains.

Tutorial Supervisor Architecture

The Kohonen self-organising map is a specialist type of neural network with the ability to learn without human intervention (Hagan et al 1996). This is useful in our system since the distinction between a novice student and an expert student, in terms of marks at tutorial nodes, may be small, or may vary significantly from domain to domain. For example, the majority of students may achieve marks between 50% and 60%, with a few results between 60% and 75% percent and a few between 40% and 50%. There are therefore two large ranges of numbers that occur infrequently (0-40 and 75-100). If a standard type of neural network were to be used to model the above problem then these mark ranges must be identified beforehand or the neural network's outputs would have to be designed to produce student ability levels between 0 and 100, in order to accommodate a broad range of scores. Identifying scores beforehand is not likely to be practical since it would require the collection of a large amount of data (with no initial benefit for the student). Designing such a generic neural network also introduces the following difficulties. The standard neural network must have enough ability levels (outputs) to clearly demonstrate the distinction between students in these highly clustered areas, necessitating an increase in outputs for all areas to cover for all possibilities, even those that are unlikely. The increase in outputs renders the neural network more complex, resulting in a network that is more difficult to train. Further, and most crucially, once the trained standard neural network is used for different domains, then there is no direct correspondence between an ability level for one domain and an ability level for another. This is because an output of the standard neural network does not correspond directly to a student ability level, since the student ability level may vary between domains. The upshot of this is that the standard neural network would require complete retraining for different domains.

A Kohonen network can solve the above problem by continually adapting to input stimuli whilst it is being used by students. This is because of the way a Kohonen network operates. A Kohonen network is given a number of outputs by the network designer, representing the number of categories that the network designer wishes the network to identify (the number of required student levels in our case). It is left to the network itself to sort the input data into this number of categories, since it is not implied by the training data itself. In the case of a standard neural network it would be required to include an example solution with the training data. If there are ten or more distinct patterns in the data then a correctly trained Kohonen will learn by itself to distinguish them (Kohonen 1989, Masters 1993, Gurney 1997). Therefore, it is irrelevant to the network if the actual values of the input data change; it will still attempt to separate them into the number of categories represented by the number of outputs that it has. The outputs of a Kohonen neural network therefore behave as fuzzy sets, whose boundaries
may change over time. The Kohonen neural network is therefore simpler than the standard neural network for the TS in this case, since the number of outputs can be kept small since is not necessary to design for all unlikely possibilities (the network will adapt to them if they occur).

**Training Data**

A neural network has a number of inputs, which in our case represent the student's responses to questions and a number of outputs, each one representing a unique ability level. The inputs to the Kohonen neural network must incorporate history data in order to make a more informed evaluation of the student and therefore avoid a restriction of Bergeron at al's (1989) neural network, namely reacting to a one off error (or success) from a student. History data can be used to prevent the TS from making snap judgements on the student. For example, if the student is generally performing well, but gets one question wrong, then if no history data is taken into account the TS is forced to make a decision based only upon the most recent presentation and the student is likely to drop a level. The student ability itself represents a degree of history data, in that if a student is regarded to be an expert student, then they must have performed well in the past. However, the direct incorporation of history data prevents a continual changing of levels based upon one interaction only. The incorporation of history data can be achieved by presenting a number of previous interactions with tutorial nodes to the neural network.

Each time a new interaction is presented the previous interactions are shifted along the inputs to accommodate the new input and the oldest interaction is lost. Training data supplied to the neural network are figures that represent a percentage value of a student's interaction with a tutorial. For example, if the student achieved a 50% success level with a tutorial question, then it is this figure that is passed to the TS.

**Re-grading Questions Using Fuzzy Logic**

Each question level is generally presented to a student of the same level, or just below, a pedagogy used with success by Bergeron et al (1989), in that a level x student should be able, overall, to answer a level x question. A question may however, be graded incorrectly by the domain author. This can be determined by the system after a number of interactions with different students (a population of students who should be, generally, getting a question right are getting it wrong or vice versa). It is not suitable to immediately re-grade a question with respect to an interaction with one student, however. As has been discussed earlier, a student is a complex entity and it is difficult to formulate rules describing them accurately. In order to resolve this problem each question level is modelled as a fuzzy set. This allows a question's level to be adjusted slightly, within the level, without necessarily affecting the overall level (as presented to the student), thus there is a buffering effect and the question does not rapidly leap back and forth between levels. The use of fuzzy sets also provides a mechanism for allowing a question to belong to more than one question level set, providing a smoother transition between levels. This differs from Bergeron et al's (1989) approach in that they collect data from the students and then periodically use it to update the training of the neural network. There is therefore a delay, which ensures that the question levels do not suddenly change, which could potentially result in the question level continually changing and thus be distracting to the students. However, the drawback is that this is a manual process that requires the direct intervention of the system designer. The process for regrading questions described below is achieved automatically, whilst still maintaining the delay between the question being presented to a student and changing its level.

A question is re-graded by a population of students' interactions with the question being determined as incorrect by the TS, for the reasons described above. Such erroneous interactions cause the question ability to move within the fuzzy set until it crosses into a different fuzzy set.

A question's ability level is therefore only changed after a number of erroneous interactions with students, the actual number being dependent upon the size of the fuzzy set, the fuzzy set is therefore acting as a buffer. A simple fuzzy processor accomplishes question re-grading. The fuzzy processor compares the level of the current question and the student level output of the TS neural network. The buffer can be implemented using three fuzzy rules (Kosko 1996):

1. IF S_LEVEL > Q_LEVEL THEN Q_LEVELf = Q_LEVELf + 1
2. IF S_LEVEL < Q_LEVEL THEN Q_LEVELf = Q_LEVELf - 1
3. IF S_LEVEL = Q_LEVEL THEN Q_LEVELf = Q_LEVELf (remain unchanged)

where

1418

Page 1368
S_LEVEL is the level assigned to a student.
Q_LEVEL is the level of the question, used to decide whether it is suitable for the student.

Q_LEVELf is the fuzzy membership number of the question.

![Diagram of fuzzy membership sets](image)

Using the figure A, a question may belong to one or two of four levels. If the question has a value of Q_LEVELf corresponding to x, then the question is regarded as both level three and level four. If however, as a result of interactions with several students, rule one is repeatedly fired, then the value of Q_LEVELf will increase and the question will become graded as level four only. Conversely, if rule two is repeatedly fired then the value of Q_LEVELf will decrease and the question will be graded as level3 only. Such changes may result in further increases or decreases in the value of Q_LEVELf, which may become any of the levels available. The utilisation of this fuzzy system ensures that the level of a question is not changed (in terms of presenting to students) in response to individual interactions with students. The fuzzy logic is able to distinguish overall trends and is therefore robust in the presence of exception data.

The changing of levels is dependent upon the size of the fuzzy sets, since the size of the fuzzy set directly affects how many interactions are required before a question migrates from one level to another. These start and end points also define whether a question can belong to more than one level or not. It is intuitively sensible to provide a small overlap of neighbouring fuzzy sets. This provides a simple buffer that will help the question to find its true grade. For example, if fuzzy sets were to be defined separately (or as a discrete set) then a question may be presented as a difficult level but become graded as an easier level after several interactions. Once this change has occurred then the question is no longer presented to the original class of students that graded it. This may result in the question becoming stuck at a particular level. If instead the question is presented to both the original class of student and the new class of student, then a smoother progression from one level to another may result and the extra information enables the question level to settle more easily. If the fuzzy sets are defined so that a question may belong to more than two levels, then the question level may not settle at all, as one level of student may push the value of Q_LEVEL one way and another level may push it in the opposite direction.

**Experimental Trials**
Our TS was designed using a Neural Network package, NeuroShell2 by Ward Systems. Several configurations of neural network were built and tested with both simulated data and real student interactions. The most successful architecture is discussed below. A full description of the experimental trials can be found in Mullier (1999, chapter 8).

The Kohonen neural network proved to be a successful neural network architecture for the problem of grading students into ability levels. Most permutations of parameters produced neural networks that converged upon a solution. A fast and reliable neural network could be produced with between five and twenty inputs or outputs. It is possible to increase this number, but this is unlikely to be required, since it is not desirable to use information from too far in the past, since the network does not have any knowledge of time. It has been experimentally determined that the number of outputs should not rise above twenty. If more levels are required then the outputs may be combined to form fuzzy sets.

Parameters for a generic Kohonen Tutorial Supervisor, i.e. one that will converge on a solution and provide a high degree of student grading for a variety of domains are suggested as the following:
5 Inputs – this has been found to provide the network with enough information with which to evaluate the student. It is suggested that an input filter, as described above is employed if more than this number of inputs is required.

10 Outputs – corresponding to ten student levels, if more levels are required then it is advised that thirty levels is the upper limit, beyond this the neural network becomes less likely to activate all of its outputs.

Any form of data extraction may be used to form the training set, however a large number of examples are required to produce a fully trained network. One thousand student interactions provide enough examples. Note therefore, that for a network to be trained with real student data is probably impractical. However, since the Kohonen network is fully adaptable, it is suggested that a network be trained upon generated data and then allowed to adapt to real students. The generated data could be designed to represent realistic but uncomplicated situations. For example, training the network to model simple rules such as “If result in the range 40-50 THEN set student level to 5”. The neural network is then able to adapt to any misconceptions present in these rules. Once a neural network has been trained it may be saved and replicated.

Discussion and Conclusion
The Tutorial Supervisor is intended to be an automatic system for gauging a student's abilities with tutorials. This imposes a restriction upon the kind of material that can be offered in a tutorial, since it must be suitable for automatic assessment. Automatic assessment effectively rules out assessments that cannot be graded in a relatively simple fashion. For example, it would not be possible, with current technology, to have an essay automatically assessed, since this would require a complex understanding of the essay on the part of the assessor. Automatic assessment is limited to tasks that can be broken down into elements that can then be individually marked. A tutorial may, for example, take the form of ten questions, each of which could be answered by the student and graded as right or wrong, or graded as containing relevant keywords. However, assessment is not the role of the TS, which is presented with completed assessments (results). Assessment is therefore limited to multiple-choice questions or identifying that the student has visited certain nodes (or a combination of both).

A key issue of concern regarding the TS is the number of student levels that the TS is to recognise and output. Each student level should have tutorial material generated for it; since it is important to target tutorial tasks at the student's ability, this is seen as being of more educational benefit than offering the same tutorials to all students and then assigning a student level based upon the grade that the student achieves (Bergeron 1989, Hartley 1993), although there is no technical reason why the latter could not be done. The number of student levels therefore may change between domains, since some domains may have a richer set of assessment questions than others (for a number of possible reasons). A possible conflict therefore could arise between the number of student levels that has been designed into the TS by the system designer and the number of student levels that are required by the current domain author. A possible solution to this problem is for the system designer to provide a TS that is capable of outputting a large number of student levels and then each domain author can allow it to adapt to their domains and ignore the inactive outputs from the TS that will naturally arise if there is not sufficient input student levels. The benefit of this approach is that one TS configuration could be used for many domains without the need for reconfiguration. However, the drawback is that some outputs of the TS will always remain inactive, although the experiments carried out as part of the research demonstrated that active outputs tend to cluster together and so are easily identifiable. A problem related to the number of outputs is the number of inputs.

The amount of history data presented to the TS directly affects the grading of the student, in that the more history data presented to the neural network, the greater the effect of previous results with tutorials. This is a similar situation to that of the number of student levels, in that it is possible to design a TS with a large number of inputs and then use only the required amount. However, it is not a simple matter to determine how much history data to present to the neural network in order to aid the student the most. This issue is difficult to reconcile without extensive trials with real students and even if this were done it would still be unlikely that any real conclusions could be drawn since proving the effectiveness of educational systems is notoriously difficult in the educational field (Dillon and Gabbard 1998). The purpose of the TS here is to explore the technical issues relating to the feasibility of providing an automatic student grading system. Whether this facility is useful is open to educational
debate. However it is likely to be the case that it will be useful should the correct set-up of the TS be achieved during trials with real students, since Bergeron et al (1989) found their TS to be useful.

Further issues arise concerning the adaptability of the neural network used for the TS. The neural network architecture used by Bergeron et al (1989) requires off-line training and is therefore under the control of the system designer. The drawback with this approach is that it requires the manual intervention of a person who can interpret the student interaction data with tutorials and determine whether it should be represented to the neural network. The advantage of the Kohonen neural network architecture is that it is able to train continually without any intervention from a human. However, there are situations where this adaptation is undesirable, most notably when different skill levels of students use the same domain at different times. For example, if a class of first year students use the system followed by a class of final year students. However, this is not a problem if the questions and tutorials have been adequately assigned a difficulty level, since the first year students will only be offered easier tutorials and so can be graded only as lower level students (although they can still progress if they continue to achieve success with the tutorial). Problems can arise only if both the student abilities and the question difficulties are unknown beforehand. This is because the TS acts as a bi-directional mapping device, in that if either the student abilities or the question difficulties are known beforehand then the TS can produce the unknown parameter. It is not, however, able to produce values when nothing is known beforehand. The TS’s ability to re-grade questions automatically is an exploitation of this bi-directional mapping facility, in that the student ability can be changed in response to improving results and the question difficulty can be changed if a significant proportion of students who should get the question right in fact get it wrong.

Research into the TS has demonstrated that a fully adaptable system for automatically grading students is possible and practical. The approach of using an automatic tutorial supervisor has been practically justified by Bergeron et al (1989). However, their system requires manual periodic retraining which renders it unsuitable for a generic tutorial system, or a tutorial system that can be used without the need for reprogramming or otherwise rearranging the program code of the system.

Further research is concerned with incorporating the TS within a hypermedia tutoring system (Mullier et al 1999, Mullier 1999) so that the students’ interactions with the TS can be studied. It is anticipated that such a study will prove useful for determining how the TS reacts to different domain, where the rules that describe ability are different, with a view to reengineering the TS so that it is able to learn such a vast set of rules without conflict. A “superTS” such as this would be useful in a more generic tutoring environment such as may become more prevalent on the WWW.

1. INTRODUCTION

Today, eLearning is adapting to industry, corporate bodies and government departments at an ever-increasing speed. It is expected to be a product that will improve education and training and make learning time-independent. The main marketing feature of elearning in corporate education is that it is technologically enhanced learning. However, should we look at eLearning from a pedagogical point of view - not from a technology-oriented point of view.

In the future we will see a tremendous increase of wireless multimedia network terminals that are similar to mobile phones. These intelligent smartphones together with 3G networks and applications are able to access the Internet as easily as web browsers today. Furthermore, major mobile phone companies have agreed on wireless application protocol (WAP) that will "bring Internet content and advanced services to digital cellular phones and other wireless terminals".

Clearly, the Internet has proved to be a great improvement for learning and distance learning. Could wireless multimedia network terminals and mLearning be the next wave?

- 3G networks, devices and applications
- time-and-place independent learning
- learning materials in an online environment
- content production for wireless devices
- wireless devices and user interfaces
- mobile eLearning

In this panel, we will first briefly discuss the relationship between the concepts of eLearning and eEducation or eTraining. Then we will define the mLearning concept and discuss the pros and cons of mLearning.
2. CRITICAL ASPECTS OF MOBILE LEARNING (JAAK HENNO)

As "the prince of pop culture" Marshall McLuhan already observed, in our communication-based information society "all ... job patterns tend to blend ... into forms of work that more and more resemble teaching and learning..." This prediction has become remarkably true and even more; nowadays "lifelong learning" has become a necessity, especially in technologically developed societies, since success in global competition depends on our ability cope with new information. Nowadays explosive growth of new information also creates an explosive need for teaching and teachers. New information (e.g. scientific research, technologic news etc) is presented in high volume and in a very high-level form (language), which is difficult for laymen to understand. The main task of teachers and teaching is re-designing of new information (scientific research results, statistical data etc); to select the essentials and present them in form that is understandable to learners. And to cope with this task, teachers are the first "lifelong learners". The rapid ever-increasing demand of "digested information", teaching and education has created many new forms, both in the teaching organization and in teaching technology. Education was until lately mostly the concern of society and social organizations (governments); nowadays education is quickly becoming a market-driven commercial activity. In addition to traditional schools/universities forms of education, many commercial educational enterprises that are using new information technologies (WWW, mobile wireless etc) for distributing their educational product have appeared. In this new educational environment quick access to relevant information (in a suitable form), not diplomas, is essential. If the necessary information can be accessed by mobile, (information) consumers will use mobiles to access it.

Every piece of information/knowledge also has a life span - the period of time when this information is significant and essential (nowadays who knows Victorian mathematics or theories of flogiston?). With the increase in technological development and research the life span of new information is rapidly decreasing. While universities propagated "universal" and eternal truths using books and living scholars as a distribution media, new commercial educational enterprises distribute truths which have shorter and shorter life spans. They will be replaced by new, "better" truths tomorrow or next week. Since "I need to know (how to do) it by Monday", learners will be willing to pay to get those truths as quickly as possible - also by wireless, if the presentation of those truths can be adjusted under bandwidth restrictions. Modern media distribute truths, which are significant for the moment and (most probably) forgotten by tomorrow, thus they are becoming replacements for our (short-term) memory. Not "the media is the message", but the messages, our need for the latest, up-to-date, precise information is pressing the development of media, to allow necessary information to be available everywhere and every time.

3. ELEARNING IN MOBILE INFORMATION SOCIETY: WHAT TECHNOLOGY ENABLES US TO DO (JUHA PEKKA LIPIÄINEN)

3.1 Introduction

The advent of digital communications and rapid technological development are resulting in fundamental changes in how society and commerce function. Many have characterised this as part of the transformation from the Industrial Age to the Information Age. In the new net economy enterprises derive efficiencies and competitive advantages by capitalising on the technologies of Internet and mobile communications.

Consequently, competitiveness in the new global economy will be directly related to how well tools of the digital age are exploited and used. Citizens in the Information Age will need to develop new digital literacy skills and adapt to the needs of lifelong learning in an environment of constant change and greater access to information.

3.2 Technical Architecture for the Mobile Information Society

Nokia is developing a technical architecture that will address important issues when implementing mobile internet application. This architecture consists of three sectors: consumption, connection and
contents sectors. The architecture describes how these sectors are linked together and guidelines for constructing each sector.

The consumption segment corresponds to how (mobile) terminals will be used by the final customer. The connection segment corresponds to access networks and core network functionality managed by network providers and the content corresponds to the content servers managed by service and content providers.

3.3 A Reference Architecture for mLearning

Technical mobile Internet architecture enables the construction of an Internet infrastructure that makes it possible to implement seamless connectivity from a variety of devices to educational content. This reference model, for example, paints the picture of what sort of learning environment we may have in a few years time.

4. MOBILE DEVICES: A COMPLEMENTARY CHANNEL FOR ELEARNING (MATTI HÄMÄLÄINEN)

Can mobile devices play a significant role in the delivery of eLearning? If we consider mobile devices as complementary channels for learning delivery and interaction, instead of looking at their limitations as a primary delivery medium, we find a lot of interesting opportunities. For the sake of clarity, in this discussion mobile device means a mobile phone or other personal portable-computing device (e.g. PDA) that has wireless telecommunication capabilities. Also, we focus on data communication aspects even though voice communication is certainly a relevant channel for tutoring and other activities that otherwise would require face-to-face contact.

Mobile devices have certain inherent limitations: the user interface is one of the key constraints. The memory and processing capacity are also far from the capacity of desktop PCs. The wireless telecommunication networks will continue to have smaller bandwidth and higher network latency compared to wireline networks, limiting the data that can be transferred and the guaranteed response times. But the strengths are also clear: mobile devices, phones in particular, are personal devices and people always carry them (shower and sauna excluded). They provide freedom to move around and access to services wherever the user is. Mobile phones are considered to be trusted devices and we shall soon see several forms of payment systems available on mobile phones. User identity is closely tied with the phone. This makes it possible to create user-specific and profiled services. Mobile phones are also becoming location-sensitive, which enables location specific services.

It is possible to create eLearning applications on mobile devices that provide highly engaging and compelling interaction despite the limitations. Such applications include self-evaluation and testing, instant feedback, educational games, and various other forms of edutainment. These are highly relevant to improving motivation, guidance and responsiveness. For example, we have found knowledge and opinion games to be a good means for providing intellectually stimulating interactive content on mobile devices. Interactive question/answer applications are highly usable even on the mobile networks and devices of today. In the future mobile devices will have more local processing capability to enable downloadable and loadable applications with richer media, even though their user interface due to form factors will still be somewhat limited. Thus, we see mobile devices as a new complementary delivery channel for learning delivery and interaction. They provide the possibility of additional stimulus, motivation and feedback in situations where it would not be possible with conventional wireline solutions.

5. BIOGRAPHY

Jari Multisilta is a professor of multimedia at Tampere University of Technology, Information Technology at Pori, Finland. He got his M. Sc from the University of Tampere in 1992 in Mathematics and his Dr. Tech. at Tampere University of Technology in 1996. The title of his doctoral thesis was "Hypermedia Learning Environment for Mathematics". Prof. Multisilta has published over 50 articles for international conferences and journals. Prof. Multisilta has studied learning and modern communication and information technologies and has taken part in several research projects on this
area. Currently he is the chair of IFIP (International Federation of Information Processing) working group 3.3 on Reasearch on Educational Applications of Information Technologies.

**Jaak Henno** graduated in 1964 from Tartu University, Estonia in pure and applied math. Currently he is a docent in Tallinn Technical University and a visiting researcher at Tampere University of Technology, Pori. Jaak Henno has been a guest teacher and researcher at the Universities of Turku (Finland), Tampere (Finland), Moscow (Russia), Budapest (Hungary). His current interests include information technology, multimedia and its use in education.

**Juha Pekka Lipiäinen** graduated as a Master of Science in Geodesics and Cartography, Helsinki University of Technology, 1984. Currently he is the Director in system & application development at Nekia Net, Broadband Systems. His responsibilities include heading the unit, which has global responsibility for development of broadband IP network solutions and Internet applications.

**Matti Hämäläinen** is the co-founder and CTO of Codeonline Ltd, a company that develops technologies and concepts for interactive wireless entertainment, mobile survey and learning applications. Matti has a PhD in Information Systems from the University of Texas at Austin, where he worked on customized on-demand learning and electronic markets for learning. Before moving to Codeonline he acted as a Principal Lecturer at the Espoo-Vantaa Institute of Technology in Finland, where he was responsible for international projects in network-based education and training. Matti has initiated and participated in a number of international projects and lectured widely on enabling technologies for learning business in Europe, in the US and in China.
The Shadow netWorkspace

Abstract: The Shadow netWorkspace™ (SNS) is a web-based work, collaboration and learning environment designed to improve education by opening classroom and schoolhouse doors to advanced information and communication services of the Internet. It is called ‘Shadow’ because it follows you wherever you go; your network-workspace is accessible at any computer anywhere that has a connection to the Internet. SNS provides much of the functionality of a personal PC with the added benefit of being accessible from any computer via the World Wide Web. The SNS environment is designed to be installed at individual school locations, is provided for free, has an Application Programming Interface (API) so others can develop applications for it, and is open source (GNU Public License) so that everyone can participate in enhancing and supporting it. It operates on a Linux-based server and utilizes the Apache web server, MySQL, and Sendmail.

The Shadow netWorkspace™ (SNS) is an Internet-based workspace designed for opening the classroom and schoolhouse doors to improve the processes of learning and schooling. The Web-based Education Commission in its report to the President and the Congress of the United States starts its report (Web-based Education Commission, 2000) with the following quote, "Across America, people told us that the Internet offers one of the most promising opportunities in education ever. And yet they were troubled by their inability to harness its potential advantages." SNS is a type of new technology that helps schools bring the potential advantages of the Internet to all teachers, students and parents. An analogy is to imagine the desktop of a computer that has been specifically designed to support learning existing on the Internet. Using a browser, such as Internet Explorer or Netscape, the user connects via a secure login to a Shadow netWorkspace web site. Here she finds a desktop for accessing her files and applications. Several applications are currently implemented including a calendar, a graphic editor, a word and media processor, a portfolio manager, a homework notifier, and text conferencing. An on-line folder system that operates similarly to Windows or Macintosh is used to access and store files. Files can be uploaded or downloaded from the local hard drive and can be shared within groups or maintained as private information.

SNS enables the integration of Internet-based services to support a learning community. Imagine a team of third graders building their multimedia report on whales on the computer in Mrs. Smith's classroom. They are working in SNS and have a workgroup document. On the way home from school, Mary stops at the library and scans a picture as well as checks some facts. She accesses SNS from the library computer and adds the new information to the report. Meanwhile Mary's dad checks the Homework Notifier in SNS from his office to see what assignments the children have. His fifth grader has some math problems and dad is happy that the teacher has provided some links to helpful web sites. He sees that he will need to review the whale project document with Mary and wonders if mom, away on a business trip, could log in from her hotel room tonight and use chat for a family review. That night the family uses SNS to review the whale project using a scoring guide provided in the system by Mrs. Smith. Later that week all of Mrs. Smith's class will create
review groups for science education majors at the university to examine and provide feedback on their projects. All of these network services are available on the Internet today, but they are not integrated, nor easy for the teacher, student or parent to use. The above scenario depends on a network system that is secure, easy to use, customized, inclusive of all key members of the school community, powerful in representing media-rich information, and provides a variety of communication and sharing services.

A key aspect of SNS that is beneficial to schools is support for facilitating the activities of groups. Currently SNS has three primary types of groups: class groups, work groups and review groups. Groups are distinguished by the social roles within the group. For example, class groups have teachers with certain authority and responsibility; in work groups everyone is equal; and in review groups the owner can place items online for review and response by parents and other community members. Chat sessions and discussion forums can be invoked within any group at any time. The primary features and functions of SNS are intended to make the information processing of a school or class digital, accessible and shareable.

The Shadow netWorkspace is a system for enabling a learning community and is designed to be installed and operated within the school setting. In this way the school "owns" the SNS implementation. The school creates the rules and policies, establishes membership, adds software, customizes the implementation, and individualizes the system as its own.

SNS is licensed as Open Source software and operates on an Open Source platform. This means that users will not have to pay to use it. SNS operates on a Linux-based server and utilizes the Apache web server, MySQL DBMS, and Sendmail. The server-side application programming interfaces and applications are written in Perl. The client software is written in HTML, JavaScript and Java. The barrier to entry to begin utilizing SNS is low. The client-user only needs an Internet connected computer running a web browser. Several schools are currently using SNS to pilot networked learning capabilities in their communities. As of Nov. 2, 2000, SNS has been available for download, examination and use by any educator, developer or researcher at http://sns.internetschools.org.

SNS brings the advanced capabilities of the Internet to the teaching and learning process, not just for the few teachers and students who are technologically savvy, but hopefully to every teacher and student who has the basic capabilities of using windows, folders, and word processing. Our vision is that every student will be engaged in active, meaningful learning at an appropriate level and in an appropriate way to meet his or her needs and interests. The Internet is a powerful tool to move from vision to practice by building resourceful and resource full learning communities. However, to truly effect the education of students, we cannot simply improve the teaching of a few teachers or the technologically adventurous. We need to change the practices of the entire school. In order to do so, the Internet tools for representation, sharing, communication and collaboration need to be easy to use by all members of the learning community, and they must be available in ways that are responsive to the concerns of school leaders for accountability, costs, security, and ownership. SNS is an innovative new technology that substantially addresses these needs, and because it is an open source licensed application there is great potential for SNS to evolve and develop in ways that are responsive to the needs of school improvement and reform.

Emergent-Collaboration in Web-Supported Academic Courses

Nachmias, R., Mioduser, D., Oren, A., Ram, J.
Tel-Aviv University, School of Education, Israel
nachmias@post.tau.ac.il

Abstract: Emergent-collaboration is the process by which group configurations and transactional patterns evolve among participants during the course of learning. This study focused on the integration of a Web shell for supporting emergent-collaboration activities in six graduate courses (115 students) in the Tel-Aviv University School of Education. The research questions addressed: (a) the didactic modes that have been devised for supporting emergent-collaboration learning processes, and (b) the extent of participation of students and teachers in Web-supported emergent-collaboration learning processes. Quantitative as well as qualitative data regarding different modes of collaboration are presented. The results indicated that the use of the technology affected learning and teaching processes in significant ways, increasing the students' participation and involvement in the courses, supporting a wide range of transactional modes, and contributing to the groups' social climate and collaborative work.

Web technology has become a powerful instructional means in higher education instruction (Bates, 2000; Collis, 1998; Flanagan & Egert, 2000). Among other salient capacities of the technology, its potential for supporting collaborative learning processes deserved particular attention among scholars and developers (e.g., Anderson & Kanuka, 1997). Collaborative learning refers to an instructional situation at which students interact while accomplishing an academic task. According to the partners' (students, teachers) needs and goals while performing learning assignments, interactions (among students, students and teachers, students and knowledge resources) may fulfill varied functions, e.g., co-operation, collaboration, competition, distribution (of knowledge), or sharing (of knowledge resources).

New technology-based models of collaboration imply an expansion and even a transformation of the variables, components and processes characterizing collaborative learning events (Sharan, 1994). Examples of issues affected by the use of the technology are: the setting of the activity (e.g., asynchronous non-face-to-face interactions); the dynamics of the interactions (e.g., dynamic definition of ad-hoc roles and functions within the); the configuration of the group (e.g., occasional participation of additional partners according to emerging needs); or the variety of communication means used for interacting (e.g., mail, chat, collaborative-work tools).

In addition, we would like to distinguish here between two learning situations: structured and emergent-collaborative. Structured collaborative tasks are well planned didactic solutions that follow the conceptual guidelines proposed by researchers and practitioners. In contrast, emergent-collaboration is the process by which group configurations and transactional patterns evolve among participants during the course of learning, in correspondence with the (extent and quality of the) students involvement in the learning process and their commitment to different aspects of the task (Ogata, & Yano, 1999). As the task proceeds, transformations in the group functioning may occur, e.g., changes in configuration, exchange of roles, formation of ad-hoc subgroups. This shift in perception of collaborative processes has practical implications for the planning, implementation and research of collaborative learning situations. The planning process will focus now on the definition of goals and constraints, rather than on the detailed formulation of structural or organizational aspects. And as researchers, we will be more interested in the transactional fabric (among all participating agents), the emergent-collaboration patterns and their evolution in time, and self-organization mechanisms.

In the project reported in this paper, we adopted the emergent-collaboration approach. Within this approach, we refer to the whole range of interactions taking place among students in terms of educational transactions. These transactions, which are the building blocks of emergent-collaboration, comprise the many-to-many teaching and learning interactions by which partners (students, teachers), holding defined goals, both contribute to and are benefited from the course's course of events. In this paper we depict, both in quantitative and qualitative terms, different instructional models involving educational transactions and emergent-collaboration processes as they evolved with the integration of Virtual-TAU (a Web-shell for supporting online learning) in the teaching of graduate courses in the Tel-Aviv University School of Education. Two main principles guided the implementation of the Web-shell into the academic teaching: (a) Virtual-TAU is not intended to replace the "real" courses by complete virtual courses. It is rather conceived as powerful tool...
complementing existent face-to-face teaching; and (b) The participating teachers adopted the goal to develop different models of integration of Virtual-TAU in their courses, rather than adopting one common model.

Our study focused on the following questions:
1. What didactic modes have been devised for supporting emergent-collaboration learning processes?
2. What is the extent of participation of students and teachers in Virtual-TAU based emergent-collaboration learning processes?

Method

The study was conducted during the 1998/1999 and 1999/2000 academic years, focusing on six classes participating in four one-semester (12-14 weeks) courses. All courses dealt with theoretical and research aspects of using ICT in education: Cognitive technologies for learning (two classes: 'a' and 'b'); ICT-Based learning environments (two classes: 'c' and 'd'); Web-Based learning (class 'e'); and Virtual environments in education (class 'f'). The research population included 3 lecturers, 3 teaching assistants and 115 graduate students. Data were collected by means of: (a) log files of students' hits and page views within Virtual-TAU; (b) transcriptions of forums' and collaborative activities with the shell. Virtual-TAU, the Web-shell used in this project, is similar to commonly used shells (e.g., WebCT, Learning Space, see Collis, 1999).

Results

Web-supported emergent-collaboration modes

Our first research question relates to the variety of collaboration modes that emerged through the development of the Web-supported courses. The analysis and classification of the Web-supported educational transactions resulted in the following six functional categories:

1. Web-supported social interaction

This category refers to activities related to the consolidation and maintenance of the courses' social fabric. As an example of emerging social transactions, teachers reported all along the semester on the "Who's Tamy" effect: there was always a student, at the beginning of a class, asking to know who was her partner (i.e. Tamy) in the last night's forum discussion or chat exchange. In regular lecture-based courses it is a commonplace that participants get acquainted mainly with their limited group of friends or close classmates. There is little opportunity (and need) to interact, and therefore to want to know, "who's that Tamy". In contrast, within Web-based activities students meet each other (virtually) around different topics and discussion themes, prompting the motivation to meet each other (really) in the class. This emerging ingathering at the social level sets the ground for emergent-collaboration at the learning level.

2. Web-supported critical group-reading

In traditional academic courses reading is mostly an individual activity. Only part of the students participate in class discussions following reading assignments. In addition, the types of reading assignments are usually limited in format. Two outcomes could be clearly observed from the very early stages of this study. The first was the rich repertoire of reading-support tasks evolving as the courses proceeded, e.g., directed-reading discussion forums, e-papers contest, bibliographical-sources group synthesis and integration, or "apply-the-paper's-model" for group analysis of computer-based learning materials. The second was the dramatic increase in the students' reading performance, both in terms of scope and personal involvement. The requirement to participate in the group-reading tasks and to make concrete (written) contributions affected the students' disposition towards the bibliographical materials.

3. Synchronic and asynchronic issue-discussion

Exchange of ideas, opinions and beliefs about key issues can be considered at the core of group-based knowledge-building processes. The Web-environment offered the opportunity to expand (in frequency) and enrich (in quality) issue-discussion activities. For one aspect, these activities took place also in asynchronous
mode (in addition to only-synchronous class discussions), increasing considerably the number of group-
discussion events. In another level, a variety of discussion configurations emerged (e.g., student-moderated,
teacher-moderated, or non-moderated events at which the leading role in the debate passed among participants).

4. Peer evaluation and review

A key characteristic of knowledge generating communities, (e.g., scientific or professional communities)
is the dissemination and mutual review of ideas and intellectual produce. In regular courses based on traditional
teaching/learning means, there is little opportunity to exercise these types of transactions. In the courses
included in this study, several forms of Web-based peer evaluation and review activities were developed, e.g.,
response to peers' contributions, formative evaluation of peers' work-in-progress, or judgment of peers' contributions in selection or contest tasks.

5. Collaborative construction of knowledge bases

The idea of the cooperative accumulation and preservation of knowledge generated by the group members
stood behind the creation of activities at which the students were asked to contribute to a common knowledge base (e.g., the joint creation of an annotated database of educational Websites). The resulting knowledge bases not only served the learning of the original contributors, but also are now offered to new groups of students which in turn continue to enrich them.

6. Group-projects online presentation

A well-known phenomenon regarding courses' final assignments or projects is that these become mainly
a teacher-student event. The student (or small group) hand out the work to the teacher (possibly after a couple
of iterations), which is evaluated then stored with little chance that other students will read or use it as reference
for further work. Within Virtual-TAU a project-presentation mode was developed, offering the students a platform for developing their work and making it public at any desired stage.

The above presented six modes of Web-based transactions developed by the courses' teachers, are but a
sample of the promising ways the communication tools may contribute to both expand our repertoire of didactic solutions, and trigger more meaningful emerging-collaboration processes.

Students' Participation in Virtual-TAU Activities

Students' involvement and participation in Web-supported transactions was of no precedent compared to the situation in traditional courses. As students stated it: "I never worked so hard and so comprehensively in an academic course; I felt that the course is running after me; If two days pass without going into virtual TAU, I felt that I miss something important happening right now". Table 1 presents the extent of the students' participation in Virtual-TAU forums within the six courses participating in this study.

Table 1: extent of participation in the courses' forums

The overall figures reinforce in quantitative terms the students' subjective assertions. An average of 700
entries (site visits) per course (37 entries per student), and 237 messages per course's forums (12.3 messages per student), are indicators of intense Web-based activity. The individual student visited the courses' sites about 3-
4 times a week on average, out of which once a week on average contributed to a forum's discussion. These figures can be read also as indicators of two modes of engagement in the forums' activities, namely operational versus observational modes. About 3/4 of the times students entered a forum not to contribute a new message, but to observe what is currently going on in it (e.g., to trace the discussion, to check reactions to her messages). This is a clear evidence of the creation of a virtual-transactional-milieu within which the students' felt involvement and commitment to the course's concerns.

Table 2 summarizes data on students' participation in 25 forums, for different modes of emergent-collaboration. The two most intensive modes of emergent-collaboration in terms of students participation were the student-moderated issue discussion, and the collaborative construction of databases. The most frequently used mode by instructors was the Web-supported academic reading. Above half of students' contributions to the forum were responses to messages posted by others, implying an intense flow of transactions during the discussions.

Table 2: Students participation in selected activities

The following are examples of emergent-collaboration processes in two different instructional modes: student-moderated discussion and critical group reading.

Students-Moderated discussion groups

In course 'd' three issues were assigned for students-moderated discussion. For each forum, 3-4 students were appointed as discussion-moderation group. Their responsibilities were to work collaboratively aiming to (a) prepare the background for the discussion; (b) present it to all students participating in the forum (about 15); (c) open the discussion, and moderate it during two weeks; (d) summarize it with the class; and (e) post a report on it to the course's Website.

Two parallel processes took place during the moderation-group's work. The first was the collaboration process within the moderation group (e.g. meeting for planning, assigning roles, writing up the report) following structured collaborative learning schemes. The second process comprised the emergent-collaboration transactions between the moderators and the rest of the students in the course.

Table 3 presents the extent of participation of the students in the three discussion groups of the course. In all these discussions, the enrolment was very high. An average of 19 messages were contributed to the discussion by each participant, more than three messages a week. Moderators involvement was also very high, although varied among groups. The use of additional communication tools (e.g. polls, chat, e-mails) was also an initiative of the student-moderators.

Table 3: Usage of communication tools as facilitator of emergent-collaboration during three two-week student-moderated discussion groups (n=15).

According to the self-report of all the students that served as moderators, their role was extremely effortful, and meaningful. As one of the students stated it, "This activity was extremely demanding both because of the intensity of our moderation group interaction and the responsibility we shared in keeping the
discussion alive and on high level. However, I learned a lot from the processes, and enjoyed it very much. I think this kind of activity should be integrated in many more courses. One of the concerns of the moderators was how to engage the entire class in the discussion. Therefore, they invested a lot of time and creativity to create a contextual-framework to the discussion, and used e-mail to encourage their classmates to participate.

**Web-supported Critical Group-Reading**

Bibliographical resources are essential components of any academic course, serving as raw materials for the implementation of diverse learning formats (e.g., class debates, public trials, topical surveys). In most courses the students do critical reading at a limited extent due to diverse reasons, e.g., the size of the class, students' degree of motivation and perception of the readings' learning value, or even language barriers.

Figure 1 shows the evolvement of the transactional volume in quantitative terms. The course (22 students) included six forums focusing on critical-reading tasks. For the first two forums, each student entered one message, according with the minimal requirements. By the fourth task the participation increased notably, up to a triplication of the initial values in the last task. The interesting aspect of these figures are that the number of independent contributions remained the same for all tasks, while the amount of responses to each other messages increased –none at the beginning up to 45 in the last task.

![Figure 2: transactional patterns for two task forums](image)

**Figure 2**

However, a clearer evidence of the emerging collaboration patterns can be appreciated if the transactional map is depicted as in Figure 2. For clarity reasons, only half of the students are represented. In task forum 1 at the beginning of the course, all contributions were made independently (only one per student). This
configuration gradually changed, becoming in task 6 an intricate web-like pattern. Active subgroups emerged (e.g., students 1-2-4, and 7-9). And analysis of the content of the messages showed that this subgroups, besides participating in the debate, assumed a variety of functions (e.g., moderation, information supply).

**Discussion and Conclusions**

The first question addressed in the study focused on the different modes of Web-based transactions that emerged during the planning and implementation of the experimental courses. At the level of this particular study, the reported results show that even within its limited setting (e.g., six courses, three teachers, and a Web shell in prototypical stage) a fairly interesting set of learning assignments and collaborative tasks emerged. The learning events ranged from transactions aimed at supporting group reading and bibliographical work, up to the development and (digital) presentation of collaborative projects. At a more general level, the results represent a valuable (if modest) contribution to the endeavor shared by many educators and researchers aiming to define new pedagogical schemas (a Webagogy?) fitting the features and qualities of the Web technology (e.g., see Mioduser et al., 1999).

The second research question aimed to examine the extent and quality of participation of the students in the different activity modes, with the support of the Web tools. The results unveiled an intense involvement of students and teachers in the courses’ activities. The distinction between two modes for visiting the courses’ sites, namely operational and observational modes, was also a revealing indicator of the students’ continuous concern with the courses’ affairs. The students’ perceptions of their experience can be summarized by one participant’s claim that the course, instead of a “14-meetings-course”, became a “14-weeks-course”. The sense behind this claim is that while the traditional course was perceived as a series of discrete events (namely class meetings, and limited time spent in out-of-class assignments), it is now perceived as continuous intellectual engagement comprising face-to-face as well as virtual meetings, and anytime/anywhere transactions among all partners. However, it should be noted that the complementary aspect of taking part in continuous learning transactions and being mindfully attentive to the others’ (students, teachers) requirements -is an increase in time and effort devoted to a course’s affairs.

The experience reported in this paper also represents an alternative view about the role of advanced learning technology in distance learning processes. By the traditional view the main focus is on individualization of the instruction, allowing each student to engage in learning activities at her own pace and demand. In contrast, this study focused on harnessing Web-based tools in support of collaborative processes that are of great contribution to the individuals’ learning. From this perspective, we expect a major role of the Internet in education to be to support and enhance collaboration and socialization processes among students. In addition to the traditional model based on one-individual access to distant knowledge resources, we expect the multiple-participants transactional model to be come a central component in the development and implementation of novel distance learning systems.

Abstract

This tutorial will examine instructional designs for online learning and teaching in particular designs that stand to take greatest advantage of the unique attributes of online educational afford because of their time, place and pace independence; and b) electronic and flexible access to multimedia based resources. We will begin with an overview of contemporary innovative instructional designs such as: Distributed problem-based learning; Computer -ba based role play simulation; and Learning by designing. This part of the session will comprise demonstrations and critical of innovative instructional designs from a range of subject areas including ng for Entry-

Practice, International Politics, and architecture models. The most of the workshop will be the creation of online learning designs by participants that will be developed into articles to be published in a Special Edition of the "Distance Educ http://www.usq.edu.au/dec/decjourn/demain.htm

Intended Audience

This tutorial will be suitable for a range of skill levels (from novice to expert) from among:

1. Instructional designers, Educational developers.
2. Teachers involved in online learning and teaching.
3. Computer programmers and Web designers and developers.

Note: I confirm that I will be present at Ed-Media 2001 to run this Tutorial/Workshop.

Abstract

This paper describes work that has been in progress on the use of information and communications technology in the transformation of teaching and learning in several subjects in the School of Fine Arts, Classical Studies and Archaeology at the University of Melbourne, Australia. Its specific focus is on the "Virtual Print Room" project. This project involves the development of a rich database of high quality digitised images of a large number of prints (from the Baillieu Library's Old Master Prints Collection) comprising the works of famous artists such as Dürer, Marcantonio, Raimondi, Rembrandt and Hogarth. Most importantly, this database enables the study of fragile prints outside the "white-gloved" controlled environment of the conventional print room. One such novel form (which is described in this paper) is learning by designing a "Virtual Print Exhibition". Students involved in this subject create a virtual exhibition from the database of prints and experience at first hand, how to construct an art historical argument in the form of an exhibition. As part of this presentation, we will demonstrate the online learning environment that supports this group-based learning activity.

Keywords
Interactive learning, simulation, teamwork, collaborative learning, old master prints, renaissance, baroque.
The Virtual Print Exhibition: A Case of "Learning by Designing"

The "Virtual Print Exhibition" is a collaborative learning task in which senior students of Art History work in small groups to plan and present a virtual exhibition of prints from a database of rare prints. This task comprises a core learning activity in a subject on Museology and Curatorship. The principal attributes of this innovative learning task are as follows. First, it offers students the opportunity to acquire knowledge not only by being told about it, but also by being involved in the experience of designing an exhibition (i.e., learning by doing). Second, it enables the studying of renaissance and baroque prints (comprising the works of famous artists such as Dürer, Marcantonio, Raimondi, Rembrandt and Hogarth) away from the snobbery and preciousness of the conventional print room. This is made possible with the creation of a rich database of high quality digitised images of the selected prints which students can access in an online and flexible learning environment to search for, select and view images in a variety of formats (i.e., thumbnail, zoom-in and zoom-out). Third, by utilising group work, it fosters collaborative learning whereby students work in teams to prepare a concept for an exhibition, which is then presented to a director of a museum. Fourth, by being an online learning task, it provides access to a resource of rich and rare collection of renaissance prints that is otherwise not readily accessible for teaching and learning. This work is currently in progress in the School of Fine Arts, Classical Studies and Archaeology at the University of Melbourne. In this paper we outline the educational foundations of the project, report on its development, and approaches to the formative evaluation process.

The Case for "Learning by Designing"

Design as a means for acquiring content knowledge is very appropriate in practice-based disciplines (Newstetter, 2000; Hmelo, Holton & Kolodner, 2000). For instance, design experiences such as building models in engineering make it ideal for the understanding of the subject matter. The obvious benefit of a design task is its inherent situatedness or authenticity. In design-based learning activities, students' understanding is "enacted" through the physical process of conceptualizing and producing something. The designer's knowledge is embedded in, manifested through, and articulated by the design artifact. The structures created, the functions sought, and the behaviors exhibited by the design solution offer a means to assess knowledge of the subject matter. As such a student's conceptual understanding or misunderstanding of domain knowledge can be ascertained from that artifact. The failure of that artifact, for example, may suggest an incomplete understanding of the subject matter.

A big advantage of a design task is the variety of cognitive tasks required to move from a conceptual idea to a product. These include information gathering, problem identification and constraint setting, idea generation, modeling and prototyping, building, and evaluating. These tasks represent complex learning activities in their own right, but when they become the environment in which knowledge of the subject matter is constructed, students have the opportunities to explore that content in the different phases and through different representations. The complexity of design activities makes them excellent vehicles for knowledge acquisition. Domains of knowledge or skills that might be separated out or abstracted away for individual treatment in other situations actually coalesce and mutually inform one another in design tasks. Moreover, design complexity requires iterative activity.
toward better solutions that can support refinement of concepts. Design complexity also
dictates the need for collaboration. A workable team possessing different kinds of knowledge
and skills can tackle complexity more successfully than an individual. On student teams, one
student might have good research skills, another domain knowledge, another drawing and
representation skills, and another construction skills. When working together, the group can
take on design complexity, combining the varied types of knowledge and skills and ideally,
learning new things from teammates.

Implementing Learning by Designing

Implementing "learning by designing" tasks is a complex undertaking that needs to be
carefully orchestrated (Barron et. al., 1998; Kafai, 1996; Kolodner et. al., 1998). The process
of designing requires learners to manage multiple constraints while dealing with complex
situations. Schauble, Klopfer, and Raghavan (1991) reported that, when students carryout
design tasks, they tend to focus on creating products rather than "constructing" understanding
and meaning. This is understandable because the outcome (some artifact that works or looks
good) is a concrete product, whereas understanding the internal workings of a system or
process is more abstract and less tangible. These authors suggest that the many tradeoffs in
using design tasks to promote learning include:

- Striking a balance between having students working on the design task and reflecting
  adequately on the design activities. Incorporating reflection is important to encouraging
  an understanding-orientated approach.
- Being able to integrate real life experiences without letting it overwhelm the students with
  irrelevant information that might be distracting.
- Maintaining extended student engagement in a manner that emphasizes understanding of
  principles rather than task completion.

Our approach to the specification of the design activity in this project is based on an
awareness of the above and the principles of problem-based learning (Barrows & Kelson,
1995). A problem-based learning (PBL) session begins by presenting a group of students with
a complex problem to address. While working on the problem, students pause to reflect on
the information they have collected, generate questions about the information, and
hypothesize about underlying relationships that might help explain it, or potential solutions to
the problem they are working on. They identify concepts they need to learn more about to
address the problem and then they develop plans for proceeding. Students usually work
independently to research the learning issues they have identified. They regroup to share what
they have learned, reconsider their ideas, and/or generate new ones in the light of their
investigations. They continue by attempting to address the problem, based on what they have
learned, sometimes going over this cycle several times through question generation and
additional research.

The "Virtual Print Room" Project

The "Virtual Print Room" project is part of a larger effort to transform the approach to
teaching and learning of several subjects in Museology and Curatorship at the University of
Melbourne. This work recognizes the role of new learning technologies in the management of
collections, as one of the most important issues in contemporary museum practice. The
database of print resources that is being developed as part of this work will be used by
specific art history courses on renaissance and baroque art which incorporate the study of old master prints. In its fully developed form, the Virtual Print Room would comprise an educational resource that will allow the study of fragile images outside the controlled environment of the conventional print room, and also in novel and innovative ways. One such form (which is the focus of this paper) is the design of a "Virtual Print Exhibition" on different themes from the electronic database of the prints.

Students involved in this subject are able to create virtual exhibitions from the database of print resources and experience at first hand, how to construct an art historical argument in the form of an exhibition. Curatorial students are able to gain an important experience by participating in the creation of a virtual museum. Most contemporary job descriptions in Australian museums ask for some knowledge of the implementation of new technologies, such as knowledge of digital image databases as all museums are engaged in the creation of on-line catalogues for permanent collections and temporary exhibitions. Students involved in this project are able to study the print collection in ways that has the capability to modernize connoisseurship by a comparison of details on the screen, through the use of detailed and high quality images at varying resolutions (see Figure 1). Close study of details also result in knowledge of how to determine the authenticity of prints, the techniques with which they are executed, and the authenticity of signatures and printers' marks.

Figure 1

Prints have been scanned at high resolution allowing details to be shown on the computer screen at very high quality.
Getting Started

Students taking the subject that comprises the "Virtual Print Exhibition" project are presented with the following scenario at the beginning of the term.

The National Gallery of Victoria (in Australia) is planning a major exhibition to celebrate the re-opening of its print room in 2003, for which they have received a grant of $100,000. You and your colleagues have been asked to put together a virtual exhibition from the newly developed electronic database of Old Master Print Collection in the University of Melbourne Library. To accomplish this task, you will need to prepare a proposal, in which you design, install and curate an exhibition online, focusing on an appropriate theme of your choice.

The Director of the Gallery would like to see you put together a detailed plan with time lines, and a budget with a detailed rationale before it can release the funds for you to begin work. The group with which you will work will have access to an asynchronous computer conference facility, to which you and your colleagues will be automatically subscribed. You must conduct all your planning activity using this medium. You should complete the proposal in three weeks, submit it for discussion and feedback from other curators in the gallery, and the exhibition committee. You will be also required to present your team's proposal in a seminar to the director of the museum at a curatorial exhibition meeting.

This online learning environment that supports this group-based learning activity enables the use of a mixture of individual and team-based learning tasks. Students can work on their own to create exhibition proposals, for example, but must come to an agreement within their team about the content and layout of the final exhibit. As students engage in this type of learning activity, their work is stored in individual student folios, which are available for reflection upon by the students themselves, and which also comprise as records for assessment by the lecturer. Documents and messages produced for and by a team are available for review by all members of a team.

To produce the virtual print exhibition students have access to a very large online database of images and catalogue information about the prints. They can search this database for suitable prints, zoom in for detailed analysis, mark them for inclusion in their exhibit, and position prints on a "virtual wall" in the exhibition spaces (see Figure 2). We will be demonstrating the functionality of this environment as part of the presentation of this paper.
Figure 2.

The Virtual Wall: A layout tool that allows students to position their selected prints in various exhibition spaces.

Evaluation

The evaluation of the design, development and implementation of this project comprises:

- **Formative evaluation** (which focuses attention on improvement of the design and development processes of the teaching and learning environment. It comprises peer-review of the design specification and pilot testing of the course design with a sample of the users);

- **Summative evaluation** (which focuses attention on impacts, effects and/or outcomes of the teaching and learning innovation. It comprises evaluation of the full-scale implementation); and

- **Monitoring and on-going evaluation** (which attempts to keep abreast with the extent to which the innovations are being integrated into regular teaching and learning activities, and how students are coping with the innovation).

At the time of the writing of this paper, some aspects of the formative evaluation task (such as peer-review of the design specification) have been completed. More detailed data derived from other aspects of the formative and summative evaluations will be available at the time of the presentation of this paper.

Abstract

Over the past few years we have been working on the construction of a web-based interactive learning course for Japanese culture and language. Upon completion of this system named "Images of Japan," we conducted a survey on its overall framework and contents. The data were gathered from two groups of students: one from Dokkyo University in Japan, and, the other from University of Illinois in the United States. The results of the survey clearly showed that the informants had found this course quite interesting and informative.* (see Nakanishi et al 1999) They also responded that they were willing to collaborate with each other in learning more about Japanese culture and in exchanging ideas on this website. In the following months, however, we did not observe as much communication as we had expected. Thus, the purpose of this paper is to present possible interpretation for the lack of participation and to introduce the pilot study which we are now working on to further investigate the possibility to develop a system to encourage cross-cultural communication.

1. Introduction

"Images of Japan" has been constructed to disseminate information on Japanese culture and to encourage cross-cultural communication. We expected the users would obtain a deeper understanding about Japanese culture and ways of thinking on this website. The original data collected from over 200 students at Dokkyo University and University of Illinois respectively revealed a wide gap in the perception of Japanese culture. We expected that this perceptual gap would serve to facilitate cooperative and collaborative learning and sharing of knowledge between Japanese and non-Japanese students.

2. Results of the Survey

In the survey mentioned above, 100% non-Japanese students and 71% of Japanese students responded that they were willing to exchange ideas and to participate in the discussion on the Bulletin Board. Thus, we expected that we could observe an active discussion and be able to have enough data to investigate the process of cross-cultural communication. However, in the following months after the installment of this courseware we could not observe an active participation. Since the website counter shows a constant increase, though not sharp enough, and the results of the survey indicated that the informants responded rather positively on the usefulness and the attractiveness of its content, we need to figure out other possible reasons for this lack of participation. So far it seems reasonable to conclude that 1) users are not as much interested in Japanese culture as being willing to write messages on the Bulletin Board, 2) users may find it a little embarrassing to discuss certain issues with the people whom they do not know, 3) writing messages in a foreign language might be burdensome for them, and the last and most presumable reason is that it is not only difficult to write comments or messages without a specific issue in mind but also very hard as the given topics are too vague or too broad to discuss.

3. Improvements

3-1 A Pilot Study

Under these circumstances and judging from the results of the survey, we have decided to carry out a pilot study in which a certain number of students from Dokkyo University* and The University of Illinois are arranged to participate in the cross-cultural communication on the Bulletin Board. Through this pilot study we collect data to find out (1) how much knowledge sharing can be achieved, (2) what kind of problems they have with cross-cultural communication, and (3) whether the Bulletin Board will serve as a means of encouraging cross cultural communication.

Accordingly, we have newly conducted a survey using fourteen criteria to figure out what kind of images the Dokkyo students have about American people, and what kind of images the Japanese students about American people. Each criterion is assigned to a scale of -3 through +3. The scale is used to profile the informant's perception of the people as measured by each of the criteria. The fourteen criteria consist of kindness, assertiveness, preciseness, delicacy, reliability, conservativeness, rationality, independence, creativeness, intellectuality, cooperativeness, being traditional, being idealistic, and open-mindedness.

The exact same survey will be carried out after two months of discussion on the Bulletin Board and will be compared with the one before the discussion. Even though various factors need to be examined in detail, we have concluded that the difference in the profile before and after the discussion will indicate the effectiveness of using the Bulletin Board as a means of cross-cultural communication. We give here with an example of the findings in the Table No.1 to show what kind of images Japanese students have about American people before participating in the discussion. So far a total of 41 students responded. The students who have been to the United States and have some American friends have both strong negative and positive images about American people, while those who do not have any American friends nor have been to the United States have quite positive images about American people. In other words, the scale
shows that the Japanese students without any exposure towards American culture responded positively on all of these criteria, comparing to those students with some exposure the American culture.

3-2. Expanded Use of Bulletin Board

In order to facilitate the analysis of the data, we have constructed the "Bulletin Board" equipped with "additional linking and recording functions." With this "Bulletin Board," the names of the participants and the number of participations are to be automatically recorded. Whenever something is written on the Bulletin Board, the writings are automatically sent to another page and classified under the name of each participant with the date and the time. With this data collection system, we can accumulate data on each individual and observe 1) how do they develop their understanding of a different culture, 2) how do they share their knowledge, 3) how often do they communicate, and 4) what kind of problems do they have in cross-cultural communication.

4. Future Plans

Based on the findings obtained from the pilot study, we once again investigate what kind of measures need to be taken to encourage users to participate in the discussion. We also need much more participation of other universities in the United States, particularly those which they have Japanese language programs or courses on Japanese culture. We would like to think about installing a function to let the group of students have a real-time chat on the internet as well as audio communication as such facilities will further encourage students to carry out cross-cultural communication. In the meantime, we would like to find out the possibility of adding another version of "Images of Japan," namely "Images of America" made by the group of Illinois students. Then the users can compare the images held by either side of the Pacific Ocean and find this worldwide website more interesting and will be motivated to participate in the discussion.

Assessment of Class Organization based on the Computer Skill Level

Japan
naka@cmc.osaka-u.ac.jp

Akira HARADA
Graduate School of Human Sciences
Osaka University
Japan
harada@hus.osaka-u.ac.jp

Abstract We have been teaching a computer literacy course to over 140 freshmen a year majoring in Human Sciences in Osaka University. We adopted the ability grouping strategy for the course, and found the class re-organization based on the midterm exam score to be effective especially for low-skill-level students. In these two years, the differential of the computer skill level among freshmen became bigger at the enrollment. So, last year, we organized three classes based on the questionnaire survey at the beginning of the course. This trial was also successful. The questionnaire survey, however, showed there were students who felt more uneasy at the term end than at the beginning of the course. We left this problem to be solved in the course of this year.

1 Computer literacy class

This research focuses on the computer literacy course for freshmen majoring in Human Sciences, Osaka University. Five teachers including the authors have been teaching this class since 1995. We organized 140 students into three classes, which proceeded at the same time. Included in the course were, word processing, spreadsheet, HTML and presentation.

2 Class organization at the beginning of the semester

We had adopted the class reorganization method for three years based on the mid-term exam which requires hands-on computer operations. This experiment showed us that the class reorganization was effective especially for low-skill-level students. Since the differential of students' computer skill level has increased these days, we tried, in 2000, to organize three classes at the beginning of the semester based on their skill level.

Questionnaire survey at the first lecture

In order to assess the students' skill level, we used a questionnaire survey, which consisted of 9 items related to computer experience before enrollment, 9 items of self-assessment of computer operation skill, 12 items related to attitude to computers, and 18 items related to uneasiness to computers. Each item was 5 point or 7 point Likert Scale.

How to organize three classes

The method of the initial class organization was very simple. We gave higher score to positive response in the questionnaire survey, and summed up all the scores. Students were ordered according to the total score and put into three classes, namely, the most skillful students were in class A1, the least in class C1. Then we started teaching in a way which, we believed, would best-fit for each class level.

Validity of the class organization

To examine the validity of our class organization method, we introduced the factor analysis on the questionnaire survey items, then extracted factors. Among these factors we picked up the important factors for class organization and calculated the composite scores shown in Table 1. Each score was normalized so that full score should become 20 points. It should be noted that the higher were the scores related to uneasiness, the more strongly the students felt uneasy.

The one-way ANOVA of the scores showed statistical significance that the average score of class A1 were higher than scores of other two classes. That is, students of A1 would be more positive to computers than other students.

Results of mid-term exam

Table 2 shows the score of the mid-term exam, which would take about an hour to complete using a PC. The one-way ANOVA of the average scores showed that there were no statistical difference among students in three classes. The fact that the standard deviations are almost the same also tells there were no difference of computer skill level of the students in three classes. This does not mean that the class organization at the beginning of the semester based on the skill was useless, but means that the organization was effective. That is, the students in classes $B_1$ and $C_1$ became skillful by the lecture which would be well adjusted to their level.

3 Class reorganization in the middle of the semester

We showed that the class reorganization based on the hands-on exam score in the middle of the term was effective (Nakanishi, 2000). In 2000, we reorganized the students into four classes. We selected top level 12 students who got high scores and organized class $S_2$, in order to give them more challenging tasks. Three classes, $A_2$, $B_2$ and $C_2$, for the rest of the students were evenly organized, which means average score of the three classes were to be the same. The organization strategy of these three classes was contrary to the ability grouping.

Result of the term-end exam

Table 3 shows the result of the term-end exam score. The one-way ANOVA showed there were no difference among four classes (5% significance level). We think the exam was so easy that it could not clarify the students skill level at the term-end.

Uneasiness of students toward computer use

We will not show the detailed scores of the questionnaire survey at the term end because of space limitation. The multiple comparison analysis showed the increase of uneasiness of students in class $A_1$, which is significantly different with the students in class $B_1$ and $C_1$ (5% significance level). The students in class $A_1$ thought to be in good mastery of computer operations, however, this phenomenon left us a problem to be discussed and examined in 2001.

Abstract: Interactive E-Learning environments support knowledge distribution and facilitate proficiency. Learning activities in these environments are dynamic, and integrate multimedia, pictures, texts and graphic organizers (concept maps, tables, flow charts, etc.). Concept maps are one of the graphic organizers, that represent verbal and visual modes as well as the main ideas of texts and their interrelationships. As one of The Kaye College E-Learning sites, we have developed a course for teachers in training that combines e-learning with face to face activities: Using Concept Maps in Learning, Instruction and Assessment. In our presentation, we will demonstrate a few site pages, including text, relevant tasks, and a conversation thread in the discussion group. We will discuss the advantages and disadvantages of learning and instruction through this new experience. In addition we will present our plans for the ongoing development of the site as part of enhancing academic written proficiency in a computerized environment.

Introduction

Implementing the potential of multimedia E-learning environments aims at a number of goals: (1) Developing cognitive skills; (2) Making links between new and existing knowledge; (3) Presenting a variety of opinions and representing knowledge (Ayersman, 1996; Hewitt, Scardamalia, & Webb, 1996). These goals can be achieved by means of collaborative-cognitive tools, adapted to all kinds of interaction: between students and teachers/facilitators and between users and computers. E-learning environments (especially interactive sites, discussion groups, chats and e-mail), support knowledge distribution; learning tasks and operation of reflective processes performance; use of written discourse, especially discourse focused on text processing; writing of texts, and sharing new ideas or information. Users can move between the multiple representations through links, thereby becoming partners in a learning community, building data - bases collaboratively in divergent non-linear learning processes.

Graphic organizers are efficient cognitive tools that serve as external representations of the readers mental models constructed during text processing (Kozminsky, 1992). Graphic organizers represent, in verbal and visual modes, the main ideas of a text and their interrelationships. These can be used as learning aids before, during or after the learning process of a text (Simmons, Griffin & Kameenui, 1988). They can be constructed by an expert (e.g., a teacher), by the learner or both, in collaborative work, that enables the students to construct and alter the graphic organizers in use, in congruency with their knowledge and comprehension. Graphic organizers facilitate the retrieval of concepts and previous knowledge (Kozminsky & Natan, 1996). Jonassen, Reeves, & Hong (1998) emphasize, that the dynamic construction of concept maps is a result of text processing, and enables learners to be involved in their own process of learning. McAleese (1998) presents an explanation of concept mapping in terms of a learning arena, which is the concept map itself. The limited capacity of working memory leads to the theory of off-loading (Chandler & Sweller, 1991). The visualization – one of the characteristics of external representations – supports the students and decreases loading their working memory.

The concept map is a performance aid – a learning arena in which students can "interpret and organize their personal knowledge" (Jonassen et al., 1998). Concept maps can be hand-drawn or constructed via computer software. Using computers for concept mapping, can assist students in several ways: (1) The concept map can be seen on the computer screen – thus activating the learners' pre-existing structural knowledge; (2) The computer encourages flexibility during mapping; the location of the elements is easily changed; one can design, add/delete concepts or rhetoric-logic interrelationships; (3) Personal feedback is essential in the mapping process, which demands awareness and self-regulation. A computerized map facilitates these processes, mentally as well as physically; (4) The computer screen reflects the students thinking processes, so their working memory is free to assess,
elaborate and operate bugging and debugging processes in the concept map and mental model simultaneously, thereby stimulating higher order thinking activities; (5) Mapping software enables novices as well as experts, to create the required maps and feel successful.

Using the computer to create concept maps, as well as studying the advantages of concept map construction, led us to develop the framework and learning activities of the course: Using concept maps in learning, instruction and assessment, that can be integrated in a larger course: Academic Written Proficiency in a Computerized Environment. The characteristics of mapping as a learning skill can be implemented as an instructional skill, especially with pre-service teachers during their practice teaching. Using concept maps as an assessment tool for writing summaries or essays (Kozminsky & Natan, 1999), has an added value to the use of concept mapping as a learning and instructional skill.

The Internet site

The site is very dynamic, with many possibilities to add, delete or change texts and/or learning tasks, according to the context, or the needs of the students and teachers! A booklet that includes all the site materials and references accompanies it. The site represents the three main applications of concept maps: Learning, Instruction (with one full example of an instructional unit), and Assessment. Each section includes: (1) Theoretical review - references to the psychological and didactical aspects of mapping. (2) Concept bank - includes definitions and explanations of concepts that are cited in the texts, and can be reached through links. (3) A selection of expository texts – each including tasks.

Working with the site

We use a discussion group as an integral part of the learning process. Students send their maps, learning tasks and reflections to the discussion group, and write feedback to their peers' postings, in response to the instructional activities that took place during the class, and suggest new or different ways of mapping. The teachers react to the students' messages, answer their questions, and support their learning process. It is possible to use attaching files, created in Word, Excel, Power-Point, Inspiration etc., as well as to add links to references (URL's) in the site and to other sites on the net. The site is open to anyone who is interested in the subject, with no need to use a password and username.

In our presentation, we will show a few site pages, including a text, its relevant tasks, and a conversation thread in the discussion group.

The URL of the site (in Hebrew):

“Do no Harm”
A First Measure of Effectiveness in Small Distance Education Programs

Gerald "Jerry" E. Nelson, Ph.D.
Director, Distance Education
Casper College, USA

Abstract: Records of 406 students registered in both traditional and distance classes over six semesters were examined. There is a small but significant difference between the mean grades earned in traditional (2.99) and distance (2.81) classes, but the group as a whole outperforms the college overall average of about 2.75. Performance in subsequent distance delivered courses was as predicted by performance in the traditionally delivered prerequisite course. We can conclude that we are “doing no harm” to the academic progress and success of distance students.

Introduction

Is distance education as effective as traditional classroom based education? This is the first question asked by opponents and proponents alike, and it is one of the major areas of research by those involved in distance education. Many studies (see, for example the California State University Special Projects, 2000) focus on learner outcomes, comparing the amount learned by a group of students using one mode of instruction with that learned by a group of students using a different mode. Numerous studies purport to show “no significant difference” (see the website by this name maintained by Russell) between the learning that takes place in traditional and distance settings. Criticism of such studies is common—the bottom line is that it is very difficult to control for all possible variables that may influence the outcome.

Small colleges and universities worldwide are quickly developing a presence in the distance education arena. While we certainly have an interest in the question, “is distance education as effective as traditional classroom based education”, our concerns are more immediate and driven by rapid growth. We do not have the time or resources to perform large-scale, long term investigations to help us decide our most important questions: 1) Should we continue offering an increasing number of distance classes to an increasing number of rural Wyoming students without knowing for sure if these classes are as effective as traditional classroom based courses? 2) What is our measure for “effective as” traditional classroom based education?

Any measure we use not only has to comply with state and regional accreditation organizations, but also with the philosophy, mission and purposes of our institutions. The mission of Casper College, a comprehensive community college serving central Wyoming and the surrounding region, states that the college will develop and maintain educational programs appropriate to the needs of the communities served. In a statement of philosophy, the college supports the belief that equal opportunity for quality higher education should be available to all who can benefit. To fulfill this mission, one of the purposes of the institution is to provide innovative course designs, instructional methodologies, and delivery systems.

A college philosophy and mission statement in support of equal access to quality education and support of innovative course design and delivery systems gives us a starting point, but does not help insure that distance courses are as effective as traditional courses. We have chosen as our initial measure of effectiveness a concept borrowed from the medical profession, “do no harm.” If effectiveness is measured in terms of access and numbers of students served, we are effective. However, our fear (and that of many faculty, administrators, and members of the public) is that distance students would not gain what they need in order to be successful in subsequent courses at our school and beyond, in traditional or distance delivery modes.
Distance students at Casper College are more likely to be non-traditional students that are female, older than typical freshman and sophomores, with family and work responsibilities in addition to school responsibilities. An analysis of a group of students taking both traditional and distance classes demonstrates what others have discovered: distance students are generally dedicated, hard working, self-disciplined, motivated, and they get good grades.

Results of the Study

We have chosen as our initial measure of effectiveness a concept borrowed from the medical profession, “do no harm.” If effectiveness is measured in terms of access and numbers of students served, we are effective. However, our fear (and that of many faculty, administrators, and members of the public) is that distance students would not gain what they need in order to be successful in subsequent courses at our school and beyond, in traditional or distance delivery modes.

Records of 406 students registered over six semesters (fall 98-summer 00) were examined. To investigate our “do no harm” concept as an initial measure of effectiveness, we compared average grades within a group of students (n=406) who took both distance and traditional classes. There is a small but significant ($\alpha = .05$) difference in this group between the mean grades earned in traditional (2.99) and distance (2.81) classes, but the group as a whole outperforms the college overall average of about 2.75.

As a second test of “do no harm” grades of students were compared by pairing courses consisting of a prerequisite and follow up course in mathematics or English composition. One of the pair was a distance class and one was a traditional class; in 46 of the 51 cases the prerequisite course was a traditional class, in 5 cases the prerequisite was distance delivered. Performance in the follow up courses was as predicted by performance in the prerequisite course. We found insufficient statistical evidence ($\alpha = .05$) to rule out the hypothesis that the mean grade (3.12) for the prerequisite course was different than the mean grade (2.92) for the follow up course.

Conclusions

We cannot state that learning outcomes for distance classes are the same as for traditional classes, although we obviously suspect this to be the case. We can conclude that we are “doing no harm” to the academic progress and success of distance students. We should continue to develop our program because of the demonstrated increase in opportunity for access to education that it provides – the program is meeting the needs of the students.

Abstract: The paper describes a research and development project initiated by a network of European logistics educators to promote all types, forms and levels of logistics education by benefiting from the educational potential of multimedia/hypermedia as well as information technology and telecommunications. Main outcome of this project will be a learning process personalizing, integrating infrastructure that is manifested as the Logistics Knowledge Portal available on the Internet as a resource for developing a personalized learning path for employees, students, interested bodies, based on the in-depth understanding of learning needs and goals, managed under a classification method for learners and categorization method for all available technology-based learning material. With this the project aims at providing a solution to problems in logistics learning in Europe and world-wide. Furthermore, many of its results in both, research and development, are expected to be of fundamental nature and therefore applicable to other domains of knowledge too.

1 Current Situation in Logistics Learning

Logistics learning has been chosen as an exemplary area of elaborating concepts and tools for developing personalized learning paths because of some specific features of this research and practical discipline. Logistics – in its widest scope of understanding – is an extremely rapidly developing field of knowledge and practical applications. The development goes in different directions: the one of new concepts, strategies, organizational solutions on one hand, and the one of new technical applications (most of them IT based) on the other. Besides logisticians operate in a dynamically changing environment of globalized economies linked by international and intercontinental supply chains, new opportunities brought by e-commerce. These ongoing challenges demand for an ongoing updating of professional knowledge and skills by all who work in the field of logistics, who work in other fields but have to take logistics effects into consideration, who want to or need to understand the logistics context from the technological, economic, environmental, administrative or social point of view. Even initial logistics education processes at vocational and higher education levels must be a part of these dynamic changes to enable their graduates to meet employers’ needs and perform at the market. So, logistics learning is required to be flexible with respect to

- learners (in the widest sense) and their individual targets, motivations to learn, specific requirements and constraints,
- varying educational needs resulting from the learner’s targets, motivations, requirements and constraints, like e.g. scope and level of knowledge, particular skills etc., and
appropriate educational resources developed and used in form of modules and courses fulfilling the educational needs and helping the learner to reach the required, established goal.

Before this background the current situation in logistics learning can be characterized as follows:

(i) The educational resources in logistics are numerous, but scattered and not inventoried, so there is no structured access to what is available, just a little knowledge of gaps and no formal mechanism at all for identifying these gaps and filling them with good quality units.

(ii) There is a great need for various forms of education in logistics and a potentially large pool of supporting resources, but there is no interface between those two market sides (demand and supply).

(iii) Generally, learning processes are not supported by methods and tools enabling to configure personalized learning paths. Educational technology is selected intuitively with many important conditions not being considered. This often results in inefficient learning processes achieving results not in any case meeting the learner’s and/or teacher’s expectations.

Especially the latter is true not only for logistics learning, but for technology-based education in a wide range. So, it can be stated that there is a general need to help learners understand their targets and constraints, to translate them into educational requirements and to configure personalized learning paths composed of available resources. This is the clue to achieve the required and intended improvement of knowledge, abilities and skills, to reach the individual targets of the learning process in shorter time and better quality.

2 Portals – Technology to Provide Access to Information, Knowledge and Services

Diaz (2000) defines portals as web sites configured for each user in order to filter information. In the world of logistics there is a growing number of examples for such portals: LogisticsWorld (2000) understands itself as a directory of logistics resources on the internet guiding to thousands of web sites related to all aspects of logistics knowledge and business. Amongst many others there is also a category on education providing a list of 216 links to a great variety of educational institutions at all levels and a number of marketplaces providing educational products and learning material world-wide. transportal (2000) is a portal made and maintained by the Danish Board for Education and Training covering 130.000 people employed in transportation and logistics. It provides links to a wide range of information relevant to the portal’s users. Its major feature consists in giving an overview of all educational institutions having logistics related activities, from universities to vocational training schools, and supporting apprentices to get jobs and companies to look for people.

From the educational point of view many efforts are put into the creation of libraries of educational resources such as the EOE Java Applet Library (EOE, 2000) to reduce developmental efforts by sharing small units being building blocks of larger modules or enabling the re-use of materials and solutions developed for a particular purpose. For this, standards for describing resources stored in there as well as tools to develop learning content compatible to these standards are provided (see ARIADNE, 1999 or IMS, 2000). Other developments such as Braincapital (2000), transportal (2000) or Workingday (2000) aim at creating networks and platforms to bring together learners and those offering education and training or employers and those looking for a job. Such career networks are contact points providing access to a particular set of educational needs and resources.

Although a large amount of material exists in the internet, it is not an easy task to find what you look for. Seeing this problem, existing portals act as knowledge brokers linking knowledge users and knowledge providers with respect to a specific field of knowledge. They are more or less sophisticated search engines where users have to chose a particular topic from the list or specify a set of keywords in a dialogue or menu. Usually the portal’s response consists of a list of links with only a few information about what might behind them. In the end, the user would have to follow systematically all links to find the most suitable one for his or her purpose. Since this is very time-consuming again, the majority of users is selecting one of the links by randomness or according to the attractiveness of its description to see whether or not this fulfils expectations.

To help finding, structuring and delivering the best information matched with the particular needs of the learner(s) and with this to really serve educational purposes, a knowledge portal must offer additional functionality to determine the learner’s prior knowledge state, to determine the nature, the quantity and the level of lessons to be imported in order to achieve a specific learning goal, and to provide a pedagogical framework for supporting the learner achieving his or her educational objectives. To fulfil these requirements and truly assist the user in creating
educational or even better learning processes, a portal should be designed in a way brokering knowledge in form of educational resources from the knowledge user's, i.e. the learner's perspective rather than serving knowledge providers in selling their products. It should not only manage content, but also enable to match content more closely to the needs of users' sectors and communities. Pre-condition for this is to understand the learners' individual learning experience and behavior (expressed in different ways of learning and also different pace of evolution).

3 The Project

For promoting individualized logistics learning processes according to the specific needs of the individual learner and the particular domain of logistics a European project was initiated. Project partners are experts from areas covered by the project: Pedagogy, computing and logistics as the domain. In particular the consortium brings together experts in logistics and logistics education from universities and commercial training organizations from Denmark, Germany, Greece, Poland and Sweden and experts in computing, AI and IT from Denmark, Greece and the UK. Potential users are involved in all project phases via the European Logistics Association (ELA) representing 36 national logistics organizations from all over Europe and with this providing access to hundreds of thousands of logisticians. In addition to this the project is supported by local administration and further universities; it is linked to other educational logistics networks active in particular regions of Europe such as Scandinavia, Denmark, Germany, to a transatlantic network of European and US universities and companies providing intensive logistics education in a global frame and last but not least to the ELA-LogNet which is a European network of logistics educators representing all types and levels of logistics education to promote technology-based logistics learning.

The project aims at designing, developing, setting up, testing and demonstrating a sophisticated IT-based infrastructure enabling to match educational requirements with resources in a logistics learning information network. This infrastructure will provide potential users of varying types with appropriate, innovative methods and tools within a user-friendly, adaptable environment which guides users according to their demands and individual goals through the system's broad functionality. The special value and innovation of this solution consists in its user-centered approach for providing an integrated platform consisting of more or less known and already developed

Figure 1: Infrastructure to promote logistics learning
functional modules, supported by unique purposefully developed modules generating personalized, dedicated, tailor-configured learning paths. As a result three major components (see figure 1) will be available, each of them covering a set of methods and tools of immense, innovative, intelligent functionality and great complexity:

- **the Logistics Knowledge Warehouse** which is an on-line, computer-based storehouse of expertise, knowledge, experience, and documentation about logistics,
- **the Logistics Knowledge Portal** which is an IT-based infrastructure for providing access to and brokering of logistics knowledge to enable personalized logistics learning processes, and
- **the Logistics Learning Interface** which is an IT-based infrastructure for running and managing logistics learning programs and their users (learners and teachers).

At service level, work addresses Web based services including Web communities, agent-based services, user profiling, and content mediated transactions, together with contextual, intelligent or adaptive access to, and delivery of heterogeneous assets in large distributed and multi-owner collections. It covers technical areas like consumer protection and privacy, IPR, open standards for interoperability and access management guidelines and business models. With this the project aims at building a global knowledge, media and computing space providing the right/relevant knowledge of high/approved quality on time, in good order to the user and enabling interaction which is at the same time supportive and empowering.

4 **The idea and concept of the Logistics Knowledge Portal**

The heart of this innovative solution is formed by the **Logistics Knowledge Portal** which can be described as a set of intelligent engines (see figure 2) mediating between the various types of users and the enormous amount of logistics knowledge sources already available or coming up in future. It combines sophisticated functionality to understand learners and their very special learning needs by scanning and mapping them with truly innovative functionality to develop – this is to be understood in the sense of proposing and suggesting – individual, learner-specific, personalized logistics learning paths and courses by using AI-based configuration methods and tools to select suitable learning modules from the Logistics Knowledge Warehouse and link them according to the learner's particular needs.

![Figure 2: The Logistics Knowledge Portal – Schematic overview](image)

The **Logistics Learner Competence Profile Engine** characterizes a learner or a group of learners according to current knowledge, skills, abilities, learning styles and other personal information to be included in a learner model which is used as an identity card to allow access to specialized modules/courses, or as part of an intelligent tutoring system. Information required for this can be provided either directly by the user, i.e. the learner, teacher or employer defining learners, their targets as well as educational needs or indirectly e.g. by analyzing a company's need for providing logistics education to employees. The latter methodology is implemented in a tool identifying/measuring the company’s logistics maturity (represented by a radar diagram), recommending the target logistics knowledge for different categories of employees, and proposing possible educational activities. The results of this initial scanning and mapping process are stored to be the basis for evaluating the outcomes of the initiated learning process.
The **Logistics Knowledge Engine** links the Logistics Knowledge Portal to the Logistics Knowledge Warehouse by translating learning goals described in the learner model into a number of inter-related topics in the form of a specific domain model to be addressed including a rich set of examples, hints, simulation and usual misconceptions. For this, a contextual search engine selects those learning modules from a knowledge base which fit most to the learner’s needs and user’s specification and forward them to the configuration procedure. Carrying out the search for particular units and modules the system also identifies gaps in the sense of missing modules and transforms the search contents into a corresponding description of requirements to be fulfilled by a module closing this gap. With this, the stock of available learning resources evolves and grows over time in response to user demands.

The **Logistics Learning Path and Course Configuration Engine** contains a set of tools for the personalized configuration of learning paths for all possible established educational requirements meeting the learner’s needs and targets. In a first step, conceptual learning paths for present and future learning activities are planned by selecting learning patterns with respect to the learner model and adapting them to meet the specific educational needs of the course to be configured. This empty frame of a learning path is now filled with suitable units and modules as provided by the knowledge engine. Often there is more than one module meeting particular needs or more than one possibility to inter-link them or there is a variety of learner models to be served by the course. In this case alternative learning paths are configured. Completed by appropriate tutoring models, they form the new (or modified) course which is described and classified to be added to the stock of available courses. At another situation they could be selected directly with respect to the learner model to avoid additional course creation efforts. The final version of a course is integrated into the learning interface to be used by learners and evaluated at the same time.

Although the Logistics Learning Interface can be described as the output device enabling to run learning paths and courses, it is closely linked to the Logistics Knowledge Portal. This is caused in the **Logistics Learning Evaluation Tool** embedded in the learning interface, which helps to understand what and how the learners really learn and encourages them to reflect on their learning. Its concept is based on an existing tool for evaluating learning activities by carrying out reaction and satisfaction measurements (e.g. on course conditions and content, or on the improvement of knowledge and skills) with the help of automatically generated questionnaires and methods for advanced statistical analysis (CUE, 2000). Information provided by it are used to evaluate both the learning path/course as configured and the learning process as run by the learner by matching them against learning needs and expectations as identified by the Logistics Learner Competence Profile Engine to determine the usefulness of content, methods and modules as well as areas to be improved and future consequences of changes in the course.

The Logistics Knowledge Portal is expected to be a practical solution to the current educational problem in the field of logistics. It shall integrate developers of educational modules and provide them with the prompt information on desired directions of new developments. It shall help learners all over Europe (whoever they are: individuals or organizations) to gain the new knowledge and skills in the most efficient way in terms of required general target, quality, time and cost. With this the concept of a knowledge portal designed to assist learning is not limited to the logistics knowledge domain only. The presented solution is based on many generally applicable principles, methods and tools e.g.

- to identify learner’s capabilities and gaps according to personal objectives and market needs and to transform this input into adequate learner models,
- to describe and select learning resources and configure learning paths basing on suitable learning patterns, but adaptable to the learner’s individual needs,
- to encourage feedback from the learner and analyze the learning process to understand in which scale the configured learning path and course met the learner’s needs and expectations, or
- to guide the user through the configuration process and assist him or her according to the particular needs by intelligent agents

which easily can be adapted to other domains by implementing domain-specific knowledge on learners, educational needs, educational resources and last but not least the way of learning.

### 4 State-of-work and future challenges

As the first step for developing the Logistics Knowledge Portal a *prototype demonstrator* is going to be implemented to visualize the idea in principle, major functionality of the engines and the user-interface concept. It
transnational user groups to gain feedback on the basic approach and identify additional user needs. According to
being presented at the conference.

**Future challenges** consist in

- classification framework,

  - conditions, current and target skills -
  - identified learner classes and the developed learner categorization framework,
  - providing tools to establish educational requirements related to given or id respect to all specified constraints,
  - providing agent based tools for the personalized configuration of learning paths for all possible established

- odds and tools for encouraging and analyzing learners’ feedback on experience, impressions, criticisms provided while and after the learning process,
- providing mechanisms for identifying emerging gaps in the available pool of educational resources (Logistic Knowledge Warehouse) and
- providing all necessary tools for the system administration.

For this only those functionality (methods and tools) will be implemented which is necessary to reach these goals and enable the Logistics Knowledge Portal’s extended, valuable testing, validation and demonstration. To reduce the developmental efforts already existing approved solutions and products will be adapted and integrated as much as possible. Further research will mainly focus on understanding logistics learning needs and modeling logistics learners, identifying learning patterns typical for learning logistics, setting up a rule base for configuring learning paths according to the learning needs, enabling the system and the user to learn from the learning process, applying AI technology and providing intelligent agents to guide the user and give individual support.

A cost-effective way to teach scattered international students with the latest technology

Pekka Nieminen
Lappeenranta University of Technology
PL 20
FIN -53851 Lappeenranta
Finland
pekka.nieminen@lut.fi

Abstract: International students can't follow the native language courses, they need english education. With distance education technology one course was made available to two international groups of different universities at a minimal cost. The lectures were held in english and send simultaneously to the other university via IP-teleconferencing. Exercises could be made either in a network environment or normally in the near-end. Distant students had no tutor and they never saw their teachers live. The cost consisted of extra work of the assistant and two technicians. The results of the course and answers to a questionnaire show that no harm was inflicted in the near-end and learning was acceptable in the far-end. Some improvements can be done but the combination of the teaching systems looks promising for international students.

Introduction

Teaching through videoconferencing has become possible 1990's (Biner et al., 1994). The costs were initially high, the picture was jerky and dedicated rooms were needed. In last few years the technology has become cheap, pleasant and easy to use by teleconferencing through IP-network (Roberts 1997). The teaching place can be any room, where a network exists. The quality of audio/video is acceptable and the equipment is compact and affordable. The resolution and frame rate has increased from 160 x 120 with 6 fps (Kies et al., 1996) to 352 x 288 with 15 or 30 fps with the equipment used here. A lecture is practically unicast, but conversation is possible (von Wright, 2000). Videoconferencing can be extended to multicasting using bridge, so many universities can share same teaching. A digitized video can be taped or saved on servers to further use (CERN, 2001). Networked learning environments are rapidly evolving to support distant education (Korpi et al., 2000, Väliharju T. 1997). Each course has a private segment, that only teachers and accepted students can share. Teaching materials are easy to spread, testing the learning with quizzes is handy and student's assignments are collected automatically and evaluation of their work is recorded and displayed without extra work. These environments offer also extra communication tools to discuss separate topics.

The Case-Study

For growing need to skilled IT-professionals in Finland the universities are inviting international students. Networked learning can help to satisfy their needs with a reasonable cost. A normal course Artificial Intelligence was held in Lappeenranta University of Technology in the autumn of 2000 with some modifications. The language used was english and the lectures were presented as a live videoconference in the University of Joensuu 250 km apart. Normal www-pages of the university contained course structure, lecture notes, links to related www-articles and link to WebCT-pages. Exercises were presented in WebCT-learning environment, where far-end students could answer the quizzes and submit their practical assignments. E-mail was used for communication with the course assistant. Near-end students could also take guided exercises and present their assignments live. Some lectures were recorded on tape in both ends and recording were studied to see the quality of the presentations, image and sound and to find out possible deterioration of information in the network.

From the tapes we could see that the quality of video and audio was very near watching TV. All pictures, text and speech were comprehensible. Local students didn't complain in any point of the course. The questionnaire showed
similar results. "Speaker's interaction with video equipment did not disturb me" was disagreed by only 15%. The same amount was slightly suffering the use of computer, but almost all others had no complaints. 75% agreed that this arrangement was just as effective as a standard lecture and 15% was neutral. Some answers are presented in table 1. The same questions were asked in an earlier study (Kies et al., 1996) in the 7-point scale.

Answers from the far-end show that the technology was good enough, but not for all. The picture and the lighting was acceptable to 75% and audio and noise level to 60%. The texts were legible, but not always. 80% stated that the on-line transfer computer system did not obstruct their understanding of the material and 70% that videolecturing system was an appropriate mean for presenting this material. Likewise "In a future I would be willing to take a class taught on an On-Line" was accepted in the near-end (3.7) but much less in the far-end (2.4). Minor but clear differences were found in understanding and being influenced by the system. In the first exam near-end had clearly better average (3.9 against 2.2, 1-5 degree).

Conclusions

The results seem to show that: 1) near side doesn't suffer when the lecture is transmitted, 2) the far site gets the information. 3) The distant learning experience isn't worth live person and some students have difficulties with this arrangement. 4) For the teacher extra work is feasible, except the assistant if the number of students is high 5) Cost is feasible. 6) A bit of human touch is beneficial for learning and learning as a group gives better results. Starting with live lecture and local exercises in the comparison course seemed beneficial. The cost of equipment can be very low, because common PC-packages contain almost all the needed hardware. For the convenience a dedicated videoconferencing package is advisable. If equipment can be fixed in a dedicated room, lecturing is easy and takes no extra time.

Abstract: We present an educational application in virtual environment, intended for teaching and demonstration of fundamental astronomy and astrophysics. The application uses special methods to display the astronomical objects realistically, as they are visible by astronauts of a real spacecraft, preserving correct visible sizes of all objects for any viewpoint and using 3D model based on real astronomical data and images. The model represents 3200 brightest stars, 30 objects in the Solar System, including 9 main planets and their largest satellites, interactive map of constellations, composed of ancient drawings, a database, describing astronomical objects textually and vocally in English and German languages. Stereoscopic projection system is used to create an illusion of open cosmic space. The application is destined primarily for large-scale virtual environment systems (Cruz-Neira 1993) (Gobel et al 1997), giving a perception of complete immersion into the scene, and also works in simple installations using a single wall projection. The application was presented to public at exhibition ZeitReise/TimeJourney opened in May-June 2000 at Academy of Arts in Berlin.

Main software component, driving the installation, is created at GMD Avango application development toolkit.

Avango (Göbel et al 1997) is a programming framework for building distributed, interactive VE applications. It is based on IRIX Performer to achieve the maximum possible performance for an application and addresses the special needs involved in application development for virtual environments. Avango uses the C++ programming language to define the objects and scripting language Scheme (Dybvig 1996) to assemble them in a scene graph. Avango also introduces a dataflow graph, conceptually orthogonal to the scene graph, which is used to define interaction between the objects and to import the data from external devices into the application. Currently Avango has implementations on SGI computers and Linux-PCs.

Non-linear geometrical model (Klimenko et al 2000) was used to represent the objects in the Solar System, overcoming a problem of "astronomical scales". This problem consists in the fact that a size of the Solar System (diameter of Pluto orbit) and a sizes of small planets (Phobos, Deimos) differ by factor more than 10^9, as a result single precision 4 bytes real numbers, used in standard graphical hardware, are insufficient to represent the coordinates of objects in such scene. A special non-linear transformation should intermediate real scale astronomical model and its virtual analog, mapping astronomical double precision sizes of range 1 .. 10^{10} km into VE single precision sizes of range 1 .. 20 m. Such transformation was chosen, satisfying two requirements: (1) it preserves actual angular sizes of planets for any viewpoint to achieve realism of presentation, (2) it prohibits penetration inside the planets to implement no-collision algorithm. Analogous transformations are also applied to the velocity of observer, to make the exploration of near-Earth space and distant planets possible in one demo session.
Navigation in large-scale VE system is performed using electromagnetic 3D pointing device (stylus), or joystick/mouse in more simple installations. User can manipulate by a green ray in a virtual model, choosing the direction of motion and objects of interest. A navigation panel, emulating HTML browser, is used to display the information about selected objects and to choose the route of journey. In the vicinity of planets completely free manual navigation can be used.

Sound accompaniment includes two musical themes, representing the rest state and fast motion, which are mixed dependently on the velocity, and voices, describing surrounding objects. Several samples are available in each sound category. Particular sound scheme can be selected and reconfigured during runtime.

Sources of planetary images and stellar data are public Internet archives and databases available at NASA: http://photojournal.jpl.nasa.gov, http://adc.gsfc.nasa.gov and U. S. Geological Survey: http://wwwflag.wr.usgs.gov. Images were imposed on a spherical geometry as textures and were enlightened by a composition of bright solar and dim ambient lights. Positions, intensities and colors of stars in the model correspond to astronomical data from catalogue. Additionally, high resolution images of constellations can be displayed in the sky. Source of images is ancient stellar map (Doppelmaiero 1742).

Fig.2: navigation panel.

Fig.3: images of constellations.

Abstract: We have designed a computer simulator to explain the architecture of the computer systems. In this simulator, components of an arbitrary abstraction level can be defined, and a virtual computer system can be constructed by freely connecting the components that appear on the screen. For example, the computer components can be either pre-designed by the instructor or prepared by the students themselves and computer systems can be constructed by assembling the available components. At an elementary level, the students can passively observe a computer system being constructed by the instructor. Moreover, the degree of details that are offered can be controlled so as to offer two or more levels of observation. In this paper the design and implementation of the computer system simulator is discussed.

1. Introduction
As it is impossible to investigate the internal transition of the computer systems, it is not easy to form a conceptual model for the computer system. It is known that understanding the architecture of computer systems would become easier by using the visual appeal offered by a computer simulator. However, the kind of architecture that should be visualized and the degree of details of abstraction that needs to be offered depends on the purpose of education and the level of comprehension of the target audience. If the abstraction level is high, it is easy for the beginners to have a rough understanding of the whole system, but it is difficult to comprehend the details. On the other hand, if the abstraction level is low, it is easy to understand details; however, it may be difficult to grasp the working of entire system. In this paper, we have discussed the design and implementation of a computer simulator that can be set to an arbitrary abstraction level and can simulate various system architectures. This simulator has a capability of defining any kind of sequential circuit as a circuit component. By defining the abstract circuit component, a computer system can be fabricated even with a high level abstraction. Moreover, since the user can observe the transition of the computer system from multiple viewpoints according to their interests, this simulator can be used widely.

2. Education Using the Simulator
Our simulator can be adapted to various levels of proficiency. We describe below some possible scenarios where the simulator can be put to practical use.

Observing Prefabricated Computer Systems: The user can observe the working of a prefabricated computer systems presented by the instructor using the simulator. The instructor can choose the appropriate abstraction level to show the computer system's workings according to the purpose of the lecture and the level of comprehension of the target audience. Some students might have interest in the computer systems and would like to acquire deeper knowledge. Our simulator should be able to change a level of abstraction with a simple operation so that it meets the user's requirements. In addition, the instructor can construct arbitrary computers for their purposes. To construct a new computer, the teacher can define new components in addition to system defined components.

Student-Designed Computer - Using Components: This simulator can be used to teach the design of the computer architecture; students can construct computers in the simulator using set of components provided by a teacher. The actual hardware are mostly used in such lectures. However, most existing components are not suitable for education purposes. Using our simulator, instructors can effectively teach the design of the computer architecture because she/he can provide components that are suited for individual needs. General-purpose CAD tools are also used in such lectures(Knox 1997). However, such tools are tend to have too many complexities and are difficult to use. The level of complexity in our simulator can be easily controlled by minimizing the set of components that are provided.

Student-Designed Computer - From Scratch: To promote further study, teachers do not provide components and make students design a computer from scratch; students design components. This methodology is expected to help cultivating students' originality.
3. Description of an Architecture

3.1 Definition of Components
Each component of a computer is defined as an object based on an object oriented model. Each component has some input/output ports and internal states. Getting an incoming message with a timestamp, a component puts a message out according to the incoming message and internal states. The system assigns a timestamp on an output message calculated from the timestamp of the incoming message and a particular constant duration corresponding to the propagation delay in the component. A connecting wire between components are also treated as a component, that gets messages from one component and pass them to another.

3.2 Simulation Engine
Signal flows between components are simulated as message passing between objects. Each component sends a message triggered by a message from an autonomous “clock” component mimicking that real circuits are synchronized by a clock generator. The simulation engine sorts all these messages by their timestamp and puts them into a queue. Queued messages are sent one by one. This makes the simulation engine possible to suspend and resume a simulation at any time by the user's request.

3.3 Building a Computer Using the Simulator
Our system has a library which contains frequently used components like basic logic gates, registers, ALUs, buses, memories, and so on. We also prepare a gate controller, which interprets machine instructions and operates gates in other components. Users can build simple computer systems with these components in the library. The system can simulate a part of a computer with a clock device even if other part of the computer is incomplete. This feature makes it possible to build a whole system by a step-by-step manner verifying each part of the computer. In order to build a computer which using components that are not available in the library, users can define new components that perform any specific functions. Each component is defined by (1) actions (i.e. outputs with some delays and next state) determined by inputs and current state, and (2) a graphics image to be shown on a display. Our system provides a graphical user interface resembling CAD tool.

4. Observing Behavior of Computer Systems

4.1 Function for Observation
Our simulator has a probe component that can monitor signal flows on input/output ports. We can observe the behavior of any port by attaching the probe component to the port. In addition, there is another probe component called “Timing Chart Probe”, which gather the information from several probe components and can observe the transition of signal flows. Moreover, our simulator has a function that shows which wire or component the signal flows are on using a one by one animation, so that users can easily observe the signal flows.

4.2 Unit of Execution
Since our simulator processes messages in a single event queue in order of the time when they are issued, users can pause/resume the execution of the animation at any time. In addition, our simulator provides the following units of the execution: system clock, machine cycle, machine instruction, and macro instruction. Consequently, users can execute the animation of computer systems by any unit of the execution.

4.3 Abstraction of Component
For example, to explain how the register works, the flip-flop level of abstraction is required. On the other hand, to show the register as a component in a whole computer system, only input/output signals and control lines of the register should be displayed. By hiding the internal details of a component, our simulator can define components at a high level of abstraction. If teachers/students define components at both levels of abstraction and construct a computer system by using such components, they can change the level of abstraction of the computer system seamlessly and dynamically.

5. Conclusions
We have discussed the design and implementation of the computer system simulator for education. It can meet various purposes of education by its flexibility. Now we have made a primary version of the system. We implement it in Java in order to be a platform independent application. We are planning to use the system at various educational scenes and evaluate it.

Bayesian Modeling Approach to Implement an Adaptive Questionnaire

Petri Nokelainen
Markku Niemivirta
Henry Tirri
Miikka Miettinen
Jaakko Kurhila
Tomi Silander

Complex Systems Computation Group
University of Helsinki

Abstract: An adaptive questionnaire, named EDUFORM, is based on Bayesian statistical techniques that both optimize the number of propositions presented to each respondent and create an individual learner profile. The preliminary results show that reducing the number of propositions we may still moderately control the error ratio. The respondents' profiling information is in most cases obtained after one third of propositions.

Major goal
This paper describes design and implementation of a software module, named EDUFORM, which allows for dynamic optimization of questionnaire propositions and profiling of learners on-line. This tool is based on the probabilistic Bayesian modeling (Bernardo and Smith 2000), and many of the features used in this restricted evaluation task can be directly used in the wider context of modern computer based learning environments (Dillenbourg 1999).

Bayes methodology
In the questionnaire context it is quite natural to model the problem domain by (m) discrete variables $X_1, \ldots, X_m$ and that a data $d$ is sampled from the joint distribution of these variables. In finite mixtures we now make an additional modeling assumption that the data $D$ can be viewed as if it were generated by $K$ different mechanisms, all of which can have a distribution of their own. Furthermore, it is assumed that each data vector originates from exactly one of these mechanisms. From these assumptions it follows that the data vector space is divided into $K$ local regions usually called clusters or profiles, each of which consists of the data vectors generated by the corresponding mechanism. The underlying intuitive idea is that a set of data vectors can be modeled by describing a set of profiles, and then describing the data vectors using these profile descriptions. Each description gives the distribution of the variables $X_1, \ldots, X_m$ conditioned that the data vector belongs to the cluster. The cluster descriptions should be chosen in such a way that the information required to describe data vectors in the cluster could be significantly reduced because they are similar to the "prototype" described by the profile. In such a "profile language" a data set $D$ can be described by first giving the profile index for each data vector, and then by describing the differences between the observed and expected values. Construction of mixture models from a given data set $D$ by using the Bayesian approach is described in Tirri et al. (1996).

Implementation of EDUFORM
The instruction data set (1800 students of a Finnish educational institution.) was collected in December 2000 with both traditional and Bayesian optimized questionnaire. Motivational profiling in this study is based on the Motivated Strategies for Learning Questionnaire, which is developed on the basis of motivational expectancy model (Pintrich 2000).

The EDUFORM user interface is shown in Figure 1. The propositions are on the middle part of the screen, and as seen, the seventh proposition has inspired the user to write an open comment regarding the proposition.

The left side of Figure 2 presents a dynamic situation where user has actually given 24 responses; EDUFORM has reasoned 24 responses and 37 propositions are open. Visualization of the current learner profile (groups of learners), is shown on the right side. The users are divided into different groups of learners based on their answers on the questionnaire.
The profile in Figure 2 gives an estimate where the learner is most likely to fit into group four or one, but the groups two and six are very unlikely.

**Conclusion**

The explicit advantages of applying on-line adaptive questionnaire on educational domain included a) increased task-related participation, b) absence of both second level coding errors, and c) respondents' exhaustion effect, d) reduced number of propositions and e) fast feedback. The implicit benefits of EDUFORM covered matters like a) adaptation to respondents' learning, cognitive and motivational strategies, b) increased reliability, c) means to implement collaborative actions and d) flexible changeovers made possible between theoretical viewpoints. Preliminary results for optimization show that error ratio is reasonable (Part A: 64% / 12%, part B 54% / 22%) and controlled within the instructional data set sub sample (N=230). Statistical techniques explored here are one possible solution to provide an intelligent messenger (or agent) to intermediate knowledge between collaborating students (Hoppe and Ploetzner 1999, 147). The architectural question (i.e. platform for software modules like EDUFORM) is difficult to solve globally due to different goals of open and distance learning research teams.

A Model for Online Unit Development: Necessity, the Catalyst for Invention

Maria Northcote

Perth, Western Australia
m.northcote@cowan.edu.au

Dr Tony Fetherston
School of Education
Edith Cowan University
Perth, Western Australia
t.fetherston@cowan.edu.au

Abstract: Theoretical frameworks and practical processes driving online course development in tertiary institutions are currently under pressure, scrutiny and review and online courses are increasingly seen as an answer to these problems. Useable procedures, guidelines and tools are required to achieve the development of suitable courses. The new model for online unit development presented in this paper was developed by considering processes implemented in the fields of multimedia production, project management and distance education. Based on four main phases, the model recognises the centrality of issues such as course planning, media development and evaluation. As well as being suitable for a range of educational contexts, the model appears to be well suited to different cultural settings, particularly those involving Indigenous staff. Based on a semi-cyclic process, the model recognises the significance of tight timeframes, useable tools and supportive resources, and identifies the responsibilities of the major players in the development process.

The Topic and Context

This paper presents a model for online unit development which was formed to meet the specific needs of a school within a university involved in online unit and course development.

An examination of the context in which this model was developed is essential to understanding its purpose and intended outcomes. External conditions existing in the broader educational arena as well as the internal requirements of the school where the first author works were significant factors which both influenced and directed the development of this model. Instead of being inappropriately “seduced by the technology” (Buchanan, 1998-1999), the school wanted a plan which could sustain long term online unit development based on contemporary and culturally appropriate instructional design principles.

Worldwide, the theoretical frameworks and practical processes driving online course development in tertiary institutions are under pressure, scrutiny and review. In many settings, this has created an almost frenzied attempt to adopt the new technologies, one that has not always been characterised by rigorous pedagogical support (Zakrzewski & Bull, 1998). Instead, the current environment of technological change in tertiary education presents different curriculum development and presentation requirements, needs which are currently being determined by educators and student groups. Growing student demands for flexible courses combined with a resource-stretched university environment have combined to create a context where the online preparation and delivery of university courses is increasingly seen as a solution. Traditional models of unit development and delivery are no longer adequate to meet the latest needs of these two groups. George and Luke (1995) recognise that universities will have to change their methods of delivery to meet the challenges of the new age:

“... with the public funding base for universities shrinking, and with a major shift to competitive forms of funding and serious competition from external providers, the long term viability of universities is becoming increasingly
dependent on their capacity to diversify their services to meet the educational needs of new client groups.” (George & Luke, 1995, p. 3).

At a local level, the need for this model of online unit development was even more pertinent and pressing. The School of Indigenous Australian Studies, Kurongkurl Katitjin, at Edith Cowan University in Perth, Western Australia, has recently begun to develop a number of online units for their Indigenous students who typically study off-campus from metropolitan or remote areas of Western Australia. With the extension of the school’s curriculum and staffing levels, combined with a recent national and international demand for the courses offered by the school, the unit development plan for future semesters has been greatly increased. For example, next year the school intends to increase online unit development outcomes by at least 500% in comparison to previous outcomes. This situation has directly created a strong demand to create useable procedures, guidelines and tools to achieve the development of such courses. The authors believe that such an increase in output must be accompanied by an appropriate model of online unit development, one that is steeped in sound instructional design and based on a succinct and flexible pedagogical approach. Such a model must also incorporate practical procedural guidelines and supporting tools of implementation to be able to direct staff roles, budgets and production outcomes.

Background

Since 1998, the School of Indigenous Australian Studies has been involved in the development of online units and converting current units of study to online mode. Due to the newness of this process and the changing needs and skill levels of both students and lecturers, the process hasn’t always been as efficient as the school’s management would have hoped. However, within the school is a large bank of resources including skilled staff with a history of serving the needs of distance education students. For example, since 1973 the school has developed many effective strategies to develop, deliver and assess a variety of subject areas including Aboriginal cultural studies, computer skills and social science. Furthermore, many of the Indigenous and non-Indigenous staff within the school have valuable distance education, instructional design, multimedia and project management experience. From an institutional perspective, the online unit development process has met with sustained support from Faculty management and it seemed that the only element missing was an appropriate model to guide the development of educationally sound online products. The model of online development presented in this paper has utilised and accounted for this range of supporting and surrounding resources.

The individuals and groups from Kurongkurl Katitjin who have been directly and indirectly involved in the development of this online model include:

- The online development team comprised of an Instructional Designer, a Web/Multimedia Designer, a Web/Multimedia Programmer and a Coordinator of External Programs.
- Academic staff who have provided consultation regarding the model’s components, review of procedures and evaluation of online curriculum content.
- Students who have provided the development team with valuable anecdotal and evaluative comments about current online units.

The development of the model was led by the first author of this paper, the school’s Instructional Designer, who instigated the process of establishing a model of online unit development.

Review of Recent Research and Literature

By considering similar processes that have been successfully implemented in the fields of interactive and culturally appropriate multimedia production, project management and distance education, the new model presented in this paper is applicable to current contexts as well as being based on a sound theoretical framework, primarily driven by instructional design (Tam 2000; Weston, Gandell, McAlpine, & Finkelstein, 1999; Gustafson & Branch, 1997; Henderson, 1996).

This model is contextually specific in that it is characterised by extensive consultation processes which drew on the expertise of the school’s staff as well as input from the wider community and student body. To ensure the efficiency of this process, various “sign off” milestones are integrated throughout the model. Furthermore, the model takes into account the specific needs of the students for whom the online units are being developed. By acknowledging general Indigenous ways of learning and the particular preferences of Kurongkurl Katitjin’s students, the model’s overall instructional design basis promotes processes in which units can be tailored to suit
specific groups of learners. For example, the interface of our online units must be sensitive to, and reflect, Indigenous culture. This need was catered for by enlisting the talent of Indigenous artists from both within the university and the local community. As more online courses are developed and presented on a global scale, the necessity of culturally appropriate interfaces is becoming more important (Moore & Marshall, 1999; DelGaldo, 1990, cited in Lanella, 1992, p. 94). This model for online unit development acknowledges the fact that learners come to study these online units with an already developed accumulation of background and cultural knowledge and experience (McLoughlin & Oliver, 1999; Henderson, 1996). We hope to enable students to develop their knowledge base, skills and attitudes:

"... instruction should be geared not just toward imparting a knowledge base, but toward developing reflective, analytical, creative, and practical thinking with a knowledge base. Students learn better when they think to learn ... They also learn better when teaching takes into account their diverse styles of learning and thinking ..." (Sternberg, 1998, p. 18).

Furthermore, this model has attempted to create procedures whereby the units developed incorporate mechanisms which encourage students to manipulate the content presented to them, rather than just interpret it (Bell & Kaplan, 1999; Harper & Hedberg, 1997). In turn, the learners are empowered by being able to control their own pathway through the unit material and develop new learning strategies as a result (Reushle, 1995). Overall, the model for online unit development aims to create learning materials in which the student concentrates on the overall content of the unit rather than smaller components such as the details of the interface or individual assessment tasks (Misanchuk, 1992).

Addressing the Problem: Goals, Approaches and Outcomes

The major problem was the fact that a clear set of workable guidelines and supportive implementation tools were required to sustain a long-term pattern of online unit development, a pattern in which quality outcomes were achieved in a flexible manner that could adapt to future needs and demands. This situation required a solution that incorporated a supporting pedagogical framework which was directly linked to practical and procedural guidelines, and suggestions for implementation at each step of the process. The implementation of this model for online unit development was based on five major goals:

- create pedagogically sound and culturally appropriate products;
- increase productivity of the online unit development team through more refined role definitions;
- establishment of an overall format of online units within the school;
- establishment and maintenance of a workable, resource-efficient pattern of curriculum design and development; and
- recognition of student and lecturer needs within the process of online unit development and delivery.

The basic approach adopted to construct the model of online unit development involved three major phases. Firstly, an analysis of the current context and existing procedures was completed. Next, a literature review and practical survey of current and recent models of online unit development was carried out. Staff within the school were also consulted during this period to ascertain their views of the online unit development that had already occurred in the school. This research then informed a draft model of development which was presented to staff for review and refinement. It is the product of this final review which will be implemented for trial in the first semester of 2001.

Solution to the Problem: Development of the Model

To date, a model for online unit development has been developed which provides a suggested set of procedures for creating online units of study for adult Indigenous students. This model is based on a semester based timeframe to design and develop the unit, subsequent semesters being devoted to the revision of future versions of existing units. It is expected to be particularly useful for the online development team within the School of Indigenous Studies at Edith Cowan University as well as the associated academic teaching staff who typically fulfil the content expert role in the development process.

The model is based on a series of four main phases, recognising the centrality of issues such as course planning, media development and evaluation. Each stage is comprised of a list of suggested tasks which are supplemented by a number of practical implementation tools.

The Preproduction phase is where the unit’s underlying theory, purpose and outcomes are considered. This is one of the most crucial phases as it sets the scene for subsequent development. The entire Production phase is driven by the decisions that are made in Preproduction. After the unit has been thoroughly designed, the design specifications are then passed on to technical staff in the online development team to create the website and any other multimedia that is required. After the first prototype of the online unit is created, it is then evaluated and the final product produced. The Implementation phase involves distributing the material to students, teaching the unit online and collecting feedback about its delivery. Lastly, the revision phase encompasses a number of semesters in which the unit’s outcomes are reconsidered and changes are recommended for future versions.

The model outlines a suggested timeframe of online unit development by indicating when phases and stages should begin and end, and when it would be convenient to adopt a cyclical rather than a linear process within the model for review and evaluation purposes. Although based on a semi-cyclic process, the linear restrictions of timeframes and sign off dates are still recognised. As well as acknowledging the significance of tight timeframes, useable tools and supportive resources, this model identifies the major players in such a development process and outlines the responsibilities of each one. Role definitions are included of staff including instructional designers, multimedia developers, unit writers (content experts) and computer programmers.

The model for online unit development will be completed by the end of 2000. During Semester 1, 2001, the school plans to trial it with a view to reviewing this initial implementation period in the middle of next year. At the close of 2000, the school plans to extend the staff resources allocated to the online development process and it is hoped that with this extra amount of staff and a more streamlined process of development, ten new online units will be developed throughout 2001 in preparation for delivery in Semester 1, 2002. These expected outcomes will provide a challenging and practical context for the trialling of this model for online unit development.

The Future: Application and Implications

After six months of operation, the model will be revised and evaluation will be sought from all stakeholders including the school’s teaching, administrative and management staff. The data from this review will be utilised to modify the current version of the model for online unit development with the aim of creating a new, improved version. Pedagogical results of the trial will be reported in the conference presentation.

Due to the processes employed to create the model, the authors also hope that it may be adopted by other educators who are involved in creating online units for particular cultural groups. It is hoped that the model may also be trialled, or at least tried, in similar tertiary educational institutions involved in the business of online unit development.

Designing an Intelligent Math Tutor for At-Risk Students

Emily O'Connor, AlphaBeta Learning Inst., USA

This paper describes the development of a smart learning software designed to sharpen students analytical reasoning skills. The impetus for this project came from a desire to help middle school at-risk students to successfully pass a standards-based math exam in order for these students to advance to the next grade. The software uses a "guided" coaxing mechanism to improve students' analytical reasoning skills. The software was designed to drill students on basic math concepts, diagnose student deficiencies, tailor an instructional module to address the deficiencies, and monitor student's progress. The instructional module or "virtual tutor" would correct deficiencies by guiding the student through step processes leading to a correct mathematical approach. This paper discusses in detail the issues involved in the development of the software. Preliminary data on the impact of the software on middle school at-risk students will also be presented at the Conference.
The presentation will present a progress report on the research and development of a user interface for an educational CD-ROM. The CD-ROM's aims are to assist in the education of risk assessment and hazard perception in young New Zealand drivers. The user interface will be an interactive multimedia interface and the research on the interface looks at how the interface should be designed to support effective learning.

The theoretical background of the research is based in advanced learning technology research specifically the work on learning environments. This research also attempts to use game design theory to assist the design of the interface, this is a new approach to traditional interface/learning environment design.

Initial findings suggest that using elements of game interfaces and the approach to game environment design is appropriate for the intended audience.

The work is still in progress, but initial findings suggest that the learning is improved.
A Framework for Self/Collaborative-Learning in the Internet Environment

Toshio Okamoto
University of Electro-Communications Graduate School of Information Systems
okamoto@ai.is.uec.ac.jp

Abstract: With the rapid development of information technology, it is widely accepted that computer and information communication literacy has become extremely important, and is the main new ability required from teachers everywhere. Therefore, for enhancing their teaching skills and information literacy about the Internet environment with multimedia, a new teachers' education framework is necessary. The purpose of this study is to propose and develop a distance educational system-RAPSODY, which is a School-based curriculum development and training-system. In this environment, a teacher can learn subject contents, teaching ways, and evaluation methods of the students' learning activities, related to the new subject called "Information", via an Internet based self-training system.

Introduction

Recently, with the development of information and communication technologies, various teaching methods using Internet, multimedia, and so on, are being introduced. Most of these methods emphasize, in particular, the aspect of collaborative communication between students and teacher during interactive teaching/learning activities. Therefore, now-a-day it is extremely important for a teacher to acquire computer communication literacy (Salvador, 1999). So far, there were many studies concerning system development, which aim at fostering and expanding teachers' practical abilities and comprehensive teaching skills, by using new technologies, such as computers, Internet, multimedia, and so on. In Japan, systems using communication satellites such as SCS (Space Collaboration System) are developed and used as distance education systems between Japanese national universities. In the near future, a teacher's role will change from text based teaching, to facilitating, advising, consulting, and his/her role will be more that of a designer of the learning environment. Therefore, a teacher has to constantly acquire/learn new knowledge and methodologies. We have to build a free and flexible self-learning environment for them under the concept of "continuous education" (Seki et al., 1998). At the same time, we need to build a collaborative communication environment to support mutual deep and effective understanding among teachers. Here, the word of "self" means "autonomous behavior" for either individual or group learning, including the collaborative attitude. In general, a system for supporting distance education is categorized into two classes. One represents seamless systems for smooth communication among sites. The other class represents collaborative systems that positively support users' various learning activities related to distance education.

In this paper, we propose a Distance Educational Model, which is based on the concept of School Based Curriculum Development and Training System, advocated by UNESCO (Phoenix university homepage) and OECD/CERI (Center for Educational Research and Innovation), and describe the structure, function, mechanism and finally the educational meaning of this model. Based on such a background, it is necessary to construct an individual, as well as a collaborative learning environment, which supports teachers' self-learning/training, by using Internet distributed environments and multimedia technologies. A teacher can choose the most convenient learning media (learning form) to learn the contents (subject units) that s/he desires. The new information and communication technologies bring with them rich and useful opportunities for the self-development of people. With this goal in mind, we are developing the integrative distance education/training system for supporting teachers' self-learning/training, called RAPSODY (Remote and AdaPtive educational System Offering DYNamic communicative environment).
Distance Educational System- RAPSODY

Until now, when a teacher wanted to take a class on “IT-education”, s/he had usually to leave the office or school. However, now it became possible to learn various kinds of subject contents by building a virtual school on the Internet environment.

RAPSODY is an integrated guide system that can logically connect individual learning units, called CELLS. The CELL corresponds to the Learning Object Metadata proposed by IEEE-LTSC(IEEE-LTSC, 2000), and is intentionally focused on three primary aspects in order to represent educational meaning within the distance learning environment: learning goals, learning contents and learning media. We call this conceptual scheme the Distance Ecological Model. Each of the CELLSs has also the other several attributes (slots) such as features of the material, available tools, a related CELL, Guide-Script, and so on, besides those three primary aspects. From a user’s (learner) point of view, this model seems to be quite transparent in order to identify/select his/her leaning conditions, and the system can easily guide towards an adequate Learning Object, according to his/her requirements. The word of “Ecological Model” in distance learning means multi-modal “learning gestalt” reflecting learning goals, learning contents and learning media/environment including any situation of individual/self and group/collaborative learning. We use the ecological model in the wider sense of ecology, as a closed, perpetuum-mobile system, which functions without interference from the outside, once the actors (such as designer, author, and learner) and their interactions are defined.

In this research (system), the word “designer” means a person who designs/describes each value of a Learning Object Metadata (CELL) and a Guide-Script. On the other hand, the word “author” means a person who produces digital course materials such as Web-based contents, movies and sound of VOD, etc, by means of any authoring tools. A Learning Object Metadata for any learning course-material would be defined, modified and registered from far sites by designers or authors according to a certain educational goal. At the same time, authors such as schoolteachers, university professors, etc., would produce and store their digital learning contents in their local server machines individually. Of course, each of contributors may play any of the two parts. This system can logically link the CELLS based on the Distance Ecological Model of RAPSODY, which provides the learning guide environment by taking into consideration of each user’s individual learning needs/conditions.

Our Distance Ecological Model is built on three aspects. The first one represents the learning goals, which are 1) the study of subject-contents, 2) the study of teaching ways (knowledge and skills), and 3) the study of evaluation methods of the students’ learning activities. The second one stands for the aspect of the curriculum (subject-contents) of “information”, which represents what the teachers want to learn. From the third aspect, the favorite learning media (form) can be chosen, e.g., VOD, CBR, etc. By selecting a position on each of the three aspects, a certain CELL is determined. A CELL consists of several slots, which represent the features/characteristics of the Learning Object. Especially, the most important slot in the CELL is “Script”, which describes the instruction guidelines of the learning contents, the self-learning procedure, and so on. In the following, we will explain the meaning of each aspect in more details.

Learning goals aspect: For this aspect, we have already proposed three sub-goals, which are:1) subject-contents, 2) teaching ways, and 3) evaluating methods, for “information” classroom teaching. It is extremely important for teachers to achieve those sub-goals for understanding how to use and apply information technologies in order to enhance a student’s problem solving ability. This involves comprehensive learning activities, such as problem recognition, investigation and analysis, planning and design, implementation and execution, evaluation, reporting and presentation.

Subject-contents aspect: In this study, we focus on the subject called “Information”, which is due to be established as a new obligatory subject in the regular courses of the academic high school system in Japan.

Learning media (form) aspect: This aspect represents five different learning environments, as follows: 1) Distance teaching environment (Tele-Teaching) based on the one-to-multi-sites telecommunications. 2) Distance individual learning environment (Web-CAI) based on CAI (Computer Assisted Instruction) using WWW facilities. 3) Information-exploring and retrieving environment using VOD, CBR (Case Based
Reasoning). 4) Supporting environment for problem solving, by providing various effective learning tools. 5) Supporting environment for distributed collaborative working/learning based on the multi-multi-sites telecommunications.

CELL definition: The concept of the CELL in Distance Ecological Model is quite important, because it generates the training scenario, including the information to satisfy the teacher’s needs, the learning-flow of subject materials and the guidelines for self-learning navigation. The frame representation of a CELL is omitted for lack of space. The frame slots are referred when RAPSODY guides the process of the teacher’s self-learning.

Conclusions

This paper proposed the Distance Ecological Model for building the integrated distance learning environment. This model stands for the networked virtual learning environment based on a 3 aspects-representation, which has on the axes 1) learning goals (on the study of the subject-matter, teaching knowledge/skills, and evaluation methods), 2) subject-contents in the designated subject-matter, and 3) learning media (forms). This represents a new framework for teachers’ education in the coming networked age. We have mentioned the rationale of our system and explained the architecture of the training system via the Distance Ecological Model. Furthermore, we have described a Guide-Script language. The aim of our system is to support teachers’ self-learning, provided as in-service training. At the same time, we need to build rich databases by accumulating various kinds of teaching expertise. In such a way, the concept of “knowledge-sharing” and “knowledge-reusing” will be implemented. As a result, we trust that a new learning ecology scheme will emerge from our environment. RAPSODY is a platform that provides various kind of learning places based on the Distance Ecological Model according to the learner’s need in consideration of the relationship among Learning Objects. In this system, the function of a Tele-conference with real video/sound and the shared window of chatting/application software are provided. So, if a learner wants to change the mode of the learning media from the individual (self) one to the collaborative (group) for some reason after he/she has finished with a certain Learning Object, then the system asks a group manager for permission to attend this discussion group to satisfy lecturer’s request according to the Distance Ecological Model. As another example, the system may recommend a selection of the collaborative mode for encouraging deeper recognition/understanding for that learner, if such a navigation message is described in the Guide-Script. In this way, RAPSODY provides the integrated/free environment for distance learning that can adaptively change between self/collaborative mode according to a user’s needs based on the Guide-Script in the Distance Ecological Model. In this sense, the Guide-Script contains the core information about the stream developed between Learning Objects by reflecting both the learner’s needs and curriculum relationships. With this system, we can construct various kinds of learning forms and design interactive and collaborative activities among learners. Such an interactive learning environment can provide a modality of externalized knowledge-acquisition and knowledge-sharing, via the communication process, and support learning methods such as “Learning by asking”, “Learning by showing”, “Learning by Observing, “Learning by Exploring” and “Learning by Teaching/Explaining”. Among the learning effects expected from this system, we also aim at meta-cognition and distributed cognition, such as reflective thinking, self-monitoring, and so on. Therefore, we expect to build a new learning ecology, as mentioned above, through this system. Finally, we will apply this system to the real world and try to evaluate its effectiveness and usability from experimental and practical point of view.

Pieter de Vries
Center for the Innovation of Education and Training
Pvries@cinop.nl

Abstract: The use of network technology allows an extension of the learning activity beyond the formal act of learning. In the pilot project executed at CORUS Steel, learning and information were conceptually and technically integrated in one Internet-based system offering a practical solution for combining learning with updating, archiving and the option of retrieving information on the work floor (see Nonaka & Takeuchi, 1995). From the start on the system was very well used both by trainees and senior employees. On the basis of these findings CORUS decided to continue and widen the scope of their e-learning activities.

Introduction

Defining e-learning solely as a means of reducing distance and time constraints for training, is an inadequate description of the possibilities network technology has to offer. In this case study we will describe a pilot project executed at CORUS, the British-Dutch steel producer, showing the strengths of e-learning as an enabler for enhancing learning and the process of information retrieval on the work floor. The study focuses on the use of e-learning along the production line in one of the steel strip mills at CORUS in the Netherlands.

Purpose of the pilot project was to gather knowledge and experience in the use of e-learning for the theoretical training of basic technical skills. The activities included the development of web based training material, study guides and the establishment of an electronic e-learning environment on the company’s intranet. The pilot was executed from March till August 2000 by a team of experts from CORUS and CINOP (Center for the Innovation of Education and Training). The first experiences of the user group with the e-learning environment were evaluated and a follow-up of the project is on its way.

Why e-learning?

CORUS wanted to develop a system for time and place independent self managed learning to acquire the theoretical knowledge in support of the training in operational knowledge and skills by the coach on the work floor. The reasons for this renewal were:

- Difficulties in planning for training,
- Poor educational quality of the existing materials
- Heterogeneity of the workforce in relation with prerequisite knowledge, learning styles, learning skills and tempo
- Improvement of the integration of theory and job practice and the effectiveness of learning
- More efficiency needed in the organization of the learning process by means of a learning management system
- Better use of tacit knowledge and more flexible storage of information for retrieval and easy update.

The deliverables

- A model for the development of learning-information units, so expert knowledge could be used as learning and information material
A model for the electronic learning environment in which the integration of information management (CINOP development) and learning management (Blackboard 4) was a central issue.

Development and storage of the expert knowledge in learning-information units in the database, which could be accessed as an information source for learning and a reference guide for information retrieval.

Development of study guides to support the learning process. Each of these guides contain information on the topic at hand, the content, learning goal, related topics, time involved and a self test of randomly chosen questions.

Interaction design for transparency in structure and functionality of the electronic learning environment.

Evaluation report on user experiences in the first phase of implementation.

Conclusions and discussion

The integration of information and learning in one internet-based system was an important issue and turned out to be successful. An eminent reason for that is the usability of the system for both the trainee and the senior employee (see Rosenberg 2001). What needs to be improved is the production process of the learning and information material as well as the guidance of the learning process. Also a check is needed to see if there are software systems coming on the market, that will better fit the needs of the CORUS learning environment. Current instruments for evaluation fail to clarify the return on investment issue both from an educational and a financial point of view.

Abstract: Teamwork is a desired pedagogical method both for learning and for the development of socio-cognitive skills. Collaboration within a team is expected to promote activities like elaboration, justification and argumentation that trigger learning mechanisms. Albeit the expectations, there is no guarantee that these activities will occur without additional educational design constraints. We describe the main design decisions that we made, which relate to (a) the structure of the setting, (b) the design of pertinent assignments, and (c) a motivating scoring plan.

Introduction

Teamwork is a desired pedagogical method both for learning (Springer et al., 1999) and for the development of socio-cognitive skills. Collaboration within a team is expected to promote activities like elaboration, justification and argumentation that trigger learning mechanisms. Albeit the expectations, there is no guarantee that these activities will occur without additional educational design constraints. This paper describes design decisions for an on-line JAVA programming course for computer science students in India. Programming is a complex cognitive activity. Programming involves tasks where teamwork is important and sometimes necessary, especially for object-oriented programming where elements (classes) can be shared and reused. Programming involves iterative activities of problem analysis, generation or adaptation of respective algorithms, design, implementation (code writing), and debugging (syntax and logic). Within all these activities collaborative work can promote both learning and the quality of the final product. In addition, collaborative work might influence how students think about the nature of working in this domain and might help to better prepare them for real-life programming projects. The project explores ways to encourage and support teamwork and team learning processes. New insights, derived from the course implementation, can be used for improving the course, as well as for the design of other on-line collaborative learning courses. In this paper we describe the main design decisions that we made, which relate to (a) the structure of the setting, (b) the design of pertinent assignments, and (c) a motivating scoring plan.

Main Design Issues

Considerations regarding team characteristics. Decisions regarding team characteristics include decisions such as team size, relation between teams, initial assignments of students to teams and the assignment of roles within a team. For the project, the initial group is divided into teams of five members. The teams’ membership won’t change throughout the course to enable natural development of a team micro-culture. There are no initial assignments of roles, or a structured exchange of roles, as the development of the social and communication skills is not the main goal. Within the designed assignments specific domain related roles are expected to evolve.

Considerations regarding the design of tasks for the students. The design of appropriate variety of assignments for the learners has a major impact on the achievement of the project objectives. Main assignment types:
1. Programming assignments where students are expected to solve given problems individually and then the individual solutions are presented to the team for further discussion aiming for the submission of a consolidated solution. This involves cycles of individual work and collaborative work.
2. Collaborative generation of a pool of useful examples and reusable elements.
3. A team project, based on a real-life problem. Team members have to analyze the problem, prepare some initial design for sharing the work, implement and integrate. These activities are performed through a structured (and tracked) combination of individual and collaborative activities.

Considerations regarding procedures and tools to support collaborative interactions. Any tool or procedure entails some affordances and constraints, and so shapes the learning processes in some way. We use the course communication and collaboration tools of Blackboard 5™, as this is the platform used for this on-line course. The application tools, such as the discussion board, the group pages, virtual chats, and e-mail; can be used in different ways and with additional structure and this is what we are trying to explore here, mainly with regard to individual and team activities and with regard to the collaborative communication interfaces. Design decisions regarding the interplay between individual and teamwork aim to provide learners with opportunities for both reflection and communication. We try to make sure that individual and collaborative learning opportunities complement and mutually enhance each other. Research shows that individual preparation before a collaborative learning task results in better learning results (Van Boxtel et al. 1997). So most of our designed assignments start with some individual work, and continue with a structured combination of individual and team activities.

The collaborative communication interfaces should serve various goals such as post, read and track inputs; enable various search options; provide methods for referencing; support focusing etc. For the project, within the discussion board, pre-defined forums and threads are assigned to scaffold grounding and focusing processes. Students have to use the given threads and are encouraged to add relevant threads as the discussion develops. The threads provide content and goals structure for the ongoing learning activities. Collapse options enable an overview, while students can watch thread details for any message. We use structured activities to support the transitions between information interface (related to JAVA programming activities) and the communication interface as suggested by Hoadley and Enyedy, (1999). Through the combination of tools that we use we enable students to refer to specific code and to execute while discussing it.

Motivation considerations. For this project we are interested in the motivation of students to develop and continue relevant conversations. The previous sections can be also regarded as dealing with motivation. The tasks were actually designed for motivating collaboration and the communication protocols ensure students’ commitment to continue a conversation. We use also a scoring scheme, which is expected to promote motivation. As students inputs are tracked it is possible to score their input into the conversation. This involves a special scoring scheme that takes into account not only the number of inputs, but also the quality. The quality is measured by letting experts judge the contribution to the discussion. More research is needed for fine-tuning of our scoring scheme.

Evaluation and Further Research Plans

Literature review shows that various means were used to investigate collaboration, from experimenting with respective computational models as employed with “Clarissa” (Burton et al. 2000) through experiments in authentic academic situations, along with research of the methodological issues involved in the analysis of computer conference transcripts (Rourke et al., 2001). Our main research tool will be the analysis of the logs from the discussion board of Blackboard. The logs will be analyzed both for structure and for content. Structure means patterns of use (e.g. changes in number of inputs during the course, or during various types of tasks). Content will be analyzed with regard to the contribution to team learning (e.g. justification, critique, elaboration, elaborating question etc.). For the evaluation we will investigate things such as the correlation between the quality of the assignments and some quality measure/s for the respective discussions; content and evolvement of the examples’ pool and also use patterns of the examples’ pool.

An Online Simulated Golf League Multimedia Environment: A Case Study from a Postgraduate Computing Module

Peter K. Oriogun, Wanda K. Roberts, Mustapha Zaouini, Nicholas J Swann
Learning Technology Research Institute
University of North London,
166-220 Holloway Road, London N7 8DB
E-mail: p.oriogun@unl.ac.uk, wanda@wizardsolutions.co.uk
Tel: +44(0)207 973 4852

Abstract: This paper describes the top level design, implementation and the overall development rational for the first operational version of a simulated remote access golf league ranking system in response to a problem set as coursework for postgraduate software engineering module at the School of Informatics and Multimedia Technology (SIMT). It concludes with the lessons learned from applying the chosen software lifecycle methodology, the Theory-W Based Spiral process model.

Introduction

This paper report on a case study based on a piece of coursework (Software Engineering Page 2001, Oriogun 2001) completed as part of the MSc Computing course at the University of North London. It describes the development of a software solution using the Theory-W Based (Boehm et al. 1998, Boehm et al. 1999, Oriogun 1999) Spiral process model. It looks at technical specifications of the finished operational model, and primarily focuses on the challenges and applicability of the chosen process model in terms of its use within a semester framework. The student project team "WizardSolutions" consisted of seven members of varying backgrounds and knowledge of computing although all students had completed required preliminary modules of initial programming and systems analysis and design.

Development Process of the SIMT Online Golf League Application

In developing the SIMT Golf League system, the student group applied processes, methods and tools common to software engineering in order to achieve the rationale and timely development of the required software. In line with the Theory-W Bases Spiral methodology (Boehm et al. 1998, Boehm et al. 1999, Oriogun 1999), the student group held sample requirements elicitation meetings with role-playing customers (the Golf League) to define the needs of the system. Stakeholders were identified as League official, Club officials, Players, Software Analysts, Project Manager, Programmers, Designers. Through a series of stakeholder (Boehm et al. 1999, Oriogun 1999) meetings, the student group analysed and detailed the initial requirement specification, adding more detail and refining requirements at each cycle of negotiation to produce satisfactory 'win conditions'.

System Architecture and Technical Specification

The project objective did not specify either the development of either a standalone executable or an online system. However it was agreed fairly early in the project to design a system which would exploit the strengths of web-based client-server technologies (Chang 2000) to deliver a robust, fast, remote system which met the user requirements. The top level systems architecture is shown in Figure 1 below:
Implementation of first version operational system

The system was delivered on time to an estimated 90% functionality according to documented requirements. The group also purchased their own internet domain name which was re-routed to point to the host server. The online system demo can be accessed at (WizardSolutions 2001). A username of: 4 and password of: pass4 are required to be able to view all implemented modules. Fig 2 shows screen shot of the League Administrator menu and 'Update Club Details' applet; Figure 3 shows the report of League members displayed using Jackson Structured Programming, King and Pardoe (1992) and a conventional modelling paradigm (Lejk and Deeks 1998).

Conclusions

The project provided the group the chance to develop an application that actually mirrored development of such systems within real-time environment. One of the main drivers within the industry at present is the interface of mainframe and standalone systems with the World Wide Web. The use of new technologies provided the group with a considerable challenge which at times seemed fairly daunting especially with the tight timescales that all group members needed to adhere to in order to deliver the required system within the project deadline. The initial planning of the project schedule was through lack of experience in this field - perhaps a little over zealous and certain aspects of the project, such as the coding, took up a far higher percentage of the available project time than was at first thought. The main reason for this was due to the limited technical resources that the group had available to them.

Hosting the application on a 'free' site was perhaps not an ideal solution, as lack of support from such sites can give rise to connectivity and performance issues, both of which the group experienced. It must be said however that the dedication and enthusiasm of the student group was a major factor in
overcoming many hurdles, demonstrating that the people are often the key asset in producing a successful project. The student group who took part in this case study consisted of a wide range of skill sets and backgrounds. Each member of the team brought something different to the project development, whether that was coding ability, negotiation skills, review techniques, design knowledge etc. Many members of the group had certainly never carried out a technical project on such a scale before. The 'real world' application of techniques taught in the lecture component of the module gave insight to their applicability to different situations and their usefulness as elements of a project lifecycle.

Mobile technology and the social context of distance learning

Carljohan Orre, Ulf Hedestig, Victor Kaptelinin
Department of informatics,
Umeå University,
Sweden
{cjorre, uhstig, vklinin}@informatik.umu.se

Abstract: This paper reports an ongoing study of how distance teaching and learning activities can be enhanced by using mobile technology. The importance of supporting the social context in order to enrich the learning environment is emphasized. The study will employ ethnographical methods and techniques to analyze emerging uses of mobile technology by students and teachers. Hopefully, the work in progress reported in this paper can help find and shed some light on the issue of the social consequences of a widespread use of mobile technologies, as well as suggest solutions to some of those questions raised by the current trend towards mobile learning.

Introduction

In recent years new information and communication technologies (ICT) have made us reconsider our basic assumptions about the nature of education. For a number of reasons ICT have important implications for learning in general. The emerging consequences are both positive and negative. They allow for much more flexibility and the possibility for a larger group of people to take part in education. However, at the same time they trigger major transformations of learning environments. Consequently, there is a number of alarming trends that we need to consider. Firstly, distance education puts enormous pressure on teachers because of the constant switching between different students and subjects. Secondly, it increases the complexity of communication between students and teachers. These trends indicate the importance of the problem of supporting rich social context for all actors, a problem combines technical, logistical, political, educational, and social dimensions of distance education. The latter, the social dimension, is of crucial importance for solving problems concerning of high dropout rates, lack of motivation, lack of everyday support from the teacher and peers, feeling of alienation, perception of tele-learning sessions as "broadcasts", and other phenomena common for that distance education. In our view, mobile technology and artifacts have the potential to address the above problems of distance education.

The importance of turning attention from studying the possibilities provided by technology itself to the overall context of using the technology, forces us to strive for a better understanding of the social setting in which learning activities take place. The project will focus on developmental life cycles of collective activities in distant learning, emerging rules, norms and systems of mediational artifacts, as well as a social science perspective, namely a cultural – historical tradition (Leont’ev, 1978). The traditional classroom methods of teaching and learning have until now generally influenced the design of learning environments for distance education. A number of attempts to develop alternative approaches have been made recently. They include, for instance, Computer Supported Collaborative Learning (Koschman, 1996) and situated learning (Lave, Wenger, 1991). These approaches challenge us to find new technical and educational designs, more suitable to the new reality of education.

Project activities and challenges

In a study being conducted at the Department of Informatics, Umeå University, Sweden, mobile technologies are being used to address some of the above problems of distance education. More specifically, the aim of the study is to focus on how PDAs can support social context, how actors within social contexts can act and communicate more effectively with this technology, and how it will stimulate and support learning and collaboration. In our view, mobile technologies can significantly extend distance education, which is already powered with diverse technologies, such as stationary computers, laptops, and videoconference systems that provide a bridge over distant places and locations. As mobile technology more and more becomes an important ingredient of our ordinary lives, this kind of "carrying around" type of technology seems to support a more spontaneous manner of interaction between its users. The proliferation of SMS (short message service),
The reasons why PDAs can help solve the problems mentioned above and meet certain needs of distance education are as follows. First, they can provide the students with place-independent access to (some) course materials, such as papers, schedules, and lecture notes. Vast amount of traditional paper information can be stored in a handheld and carried around. It also provides an easy way to work off-line with the Web where the student can download the course web-site and update it when synchronizing the handheld with stationary computers. Second, they can help keeping in touch with fellow students when necessary an asking for immediate help when having a problem during individual studies, as well as sharing problems and findings with other students while working on group projects when being spatially separated from one another. Maintaining informal social contacts can also be one of the consequences of using wireless handhelds. Third, almost as important as the contacting fellow students is the possibility to contact the teacher. With other technologies, such as mobile phones it is sometimes difficult to do since teachers are often are unavailable on the phone, and do not want to be disrupted, or might be engaged in meetings with other students. Regular email is not flexible enough, since sending, replying, and receiving emails is only possible when one has an access to a desktop computer, which is often not the case for both students and teachers in decentralized education. Fourth, students that are spatially separated can be provided with the possibility to easier get notification information about what is going on within the course. Feelings of loneliness and alienation in the sense of "being away from where the action is" can be eliminated by "virtual" social practices of "mixing with the others" and "catching up on the local news". Checking with a message board or teleconference is an alternative to traditional practices and standards. Interaction during "distributed classes" is another interesting application for PDAs. These sessions have a limited range of interactions and the need for more possibilities for students to ask questions and participate in discussions is evident. Using a handheld device for asking questions and making comments during a telelearning session can be a solution because it can provide possibilities for more options for the students to contribute to their "distributed class" discussions. Finally, coordination in teacher teams can be enhanced, as well, when work needs to be tightly coordinated to avoid breakdowns.

Some of the problems described above can be solved by just using a mobile phone or an ordinary phone and computer. However, PDAs have a number of important advantages, which include the possibility to distribute resources between the handheld and a desktop computer and to use many versions of "regular" applications (e.g., ICQ), surfing the web, better input for sending SMS, exchanging graphics, and so forth.

The study is planned and to be performed on different groups of students engaged in distance education located in different places in Northern Sweden, during an extended period of time. We are planning to provide every member of the group with a personal PDA, in order to support their work. The study will employ ethnographical methods and techniques, that is, field studies, interaction analysis, and interviews. At the first phase of the project a pilot project is planned to be performed during this Spring that will point out some of the obstacles that we will need to be consider further before extending the study to a larger group. Potential support for actions and activities mediated by PDAs can be provided by the use of diverse types of existing software. Some of this software is widely used, and hopefully already constitutes a part of everyday environment and social life of our prospective participants. This technology is easy to carry around, and it can make it possible to keep in contact with fellow students and save time and effort during travelling back and forth between home and school. The challenge in formulating design implications for future use and development of mobile technology in distance education is an interesting and important issue. Finding new metaphors that can work as catalysts for new ideas and solutions can provide us with a better understanding of the impact of this technology on our daily lives. Hopefully, the work in progress reported in this paper can help find and shed some light on the issue of the social consequences of a widespread use of mobile technologies, as well as suggest solutions to some of those questions raised by the current trend towards mobile learning.

The study presented in the paper is being conducted within the framework of a project called “The Social Context of Collaborative Distance Learning: A Cultural-Historical perspective”, which is financially supported by the Bank of Sweden Tercentenary Foundation.

Abstract: by the light of the constructivist theoretical principles, the aim of this paper is to describe the phases of a teacher training model defined after the several training opportunities offered us from the "Developmental Plan of Educational Technologies" (1997/00) of the Ministry of Education – developed to provide teachers for tools and methodologies to support their educational activities based on ICT.

Theoretical Background

One of the most important objectives to reach in the teachers training concerning the use of Information Communication Technology (ICT) in classroom is to offer new knowledge on the use of the information tools and to guide them to plan, with critic and creative spirit, new and more efficient educational activities. We think that to introduce teachers to the correct use of ICT is to promote the acquiring of working skills such as in the cognitive apprenticeship. In other terms, the training activities that we carry out with teachers move from the assumption that is not important "to know" but to be able to transfer in practice the knowledge patrimony to define and carry out projects and products.

This fundamental change reflects a well known African proverb: "if a man is hungry, you can give him a fish, but is better if you teach him to fish". Paraphrasing Papert (1980) the aim of instruction is not to feed the people with a codify learning (the fish) but is to undertake to lead the individual to discover specific knowledges which he needs (to fish). For the constructivist assumptions this is the best way to acquire new concepts and to interiorise a learning methodology allowing people to became independent in its own cognitive processes.

This idea is well consolidate in the teachers' forma mentis, but what happens when the roles reverse and they became students? Often we think wrongly that because they are just holder of structured and experimented knowledge don't need spaces to reflex and to share the acquired concepts. So, to structure learning environment that allow to the course participants to accept and promote the inevitable comparison among different individual perspectives is one of the aim of the constructivism: the learning is not only a personal activity, but the result of a joint dimension of the interpretation of reality.

The Designed Model

Our objective is to define a teacher training model for using ICT which aims to:
- encourage mastery of multimedia and telematics, both the ability to understand and use the various tools as well as the acquisition of new and more efficient teaching/learning, communication and project management styles;
- improve the didactic organization regarding individual disciplines and also the acquisition of general skills.

The teacher training model that we have planned is subdivided into 5 phases as described below. The first begins with brainstorming (or brainwriting) activity using keywords such as multimedia, telematics, communication, net, collaborative learning, etc., and then the trainees construct basic definitions. More in detail, the participants are divided into two or more groups depending on the
numbers in the class, with the task of producing a definition based on the words associated with the keywords during the brainstorming session.

Next the individual groups read their definitions and discuss them with the others in order to distinguish similarities and differences. After this the trainer emphasizes that there isn't a right or wrong answer and all the trainees cooperate to produce a more exact final definition which is compared to the textbook definition. The same procedure is followed each time the trainer wishes to formalize the basic concepts necessary for the acquisition of more complex concepts.

The second phase is focused on the explanation of theoretical aspects underlying the introduction of ICT in everyday educational activities. This is followed by the consideration of the advantages and disadvantages linked to technological innovation in the school. Moreover, the course members are encouraged to reflect on the importance of reviewing their teaching methods to fully exploit the potentialities of ICT for didactic purposes. An other element of training is to discuss with teachers about the best practices to present them concrete and successfully models of use of ICT in classroo.

In order for the course participants to acquire increased awareness that the essential requirement for planning didactic units based on ICT is the extensive knowledge of these tools, the model includes a third phase during which trainees take on the role of evaluators. They are required to examine multimedia resources on CD-ROMs or on the Net. This activity is a valuable input for training teachers to make a critical examination of the technological and pedagogical aspects of the multimedia resources (Ottaviano et al. 1999) and of the WEB to plan didactic units. Later these teachers will be able to generalize this knowledge to other information tools.

Following the fourth phase in which the teachers are divided into work groups with the aim of simulating the planning of one or more didactic units based on the integrated use of ICT (Allegra et al. 2000). In this phase they are stimulated to put in practice problem solving strategies, coordination skills to mediate between different points of view, communicative skills, to carry out a series of events, to select suitable tools, etc. just as in real school situations. Teachers, thanks to the multimedia and telematics resources selected for them, must structured a didactic unit considering with the support of a scheme of the main steps of the didactic planning. The most important aspect that they have to consider is the choice of the right tool in relation to specific steps of the teaching/learning process. Furthermore, they are stimulated to reflect on the strategies to exploit the added value of each technological tool.

At the end, we have foreseen a fifth phase to evaluate the success of the training course, to this aim the course participants have to complete two evaluation forms. One of this regards the evaluation of the trainer and his method to teach, the second one is focused on the evaluation of each phase of course.

Advantages of the Approach

The results emerging from our experience show that the course parcipants consider interesting the activities focused on case study, problem solving and simulations of didactic planning because these are not aimed at memorising several definitions, but at interiorizing concepts and applying them into practice. Teachers in their evaluation appreciate this method of training because it allows them to capture their attention on the process in which they are directly involved, and it stimulates a more effective generalization of the learned concept toward the planning of didactic activity based on ICT in which they will be trainer in their turn. The didactic planning is an open and flexible operation of adaptation to the emergent necessities. "To experiment" the planning in the classroom is useful to clarify the contents on which focusing the attention, orienting themselves in the definition of the objectives and organizing the ideas respect to the materials and the procedures to be adopted from time to time.

Abstract: The Greek Ministry of Education implements a project concerning the training of 75,000 primary and secondary school teachers in ICT as an educational and professional tool over a three year period (2000-2003). This is a wide-range project, which has been designed to be completely decentralised as far as both the model and the methodology of training are concerned. Decisions about when to undertake the training, which delivery method and training provider to use are made by the schools, taking into account the local conditions and the training needs of their teaching staff. In addition to the training programmes the training process includes a lot of support activities, which will remain even after the project has been completed. This paper addresses the design and the implementation of the project.

1. Introduction

Central issue of the changes occurring in today's educational systems is the integration of Information and Communication Technologies (ICT) in subject teaching. The educational community has recognised the value of ICT as a teaching tool since the early 80's. However, in a world crossed by the information super-highways ICT is far more than just a teaching tool. ICT can perform as the vehicle for the reform of the educational strategies towards a student-oriented learning model, transferring part of the responsibility of the learning process to the students, implying at the same time new roles for the teachers and their classroom performance.

Today teaching has become more difficult, but also more important, since knowledge and learning are central issues in the information society. "The traditions and norms of the school, which earlier gave teachers unquestioned authority, are currently being questioned and in some aspects have been partially abandoned. Since teachers are not able to rely solely on tradition as a means of support, their personal qualifications are becoming increasingly important in determining how successful they can be in gaining the interest and participation of their pupils". (ItiS, Delegation for ICT in Schools, 2000). The students cannot be anymore passive objects of teaching, instead they must themselves seek and create their own stock of knowledge with interaction with others. In this change ICT can be a powerful tool for learning and as such promote the transition.

But in order ICT to be effectively integrated into teaching and learning, the teachers must have knowledge, skills and abilities (Wild, 1996) to make decisions about when, when not and how to use ICT in teaching particular subjects. Therefore, supporting teachers towards this direction is one of the most critical factors for successful implementation of these technologies in schools (Taylor, 1997). Helping teachers to integrate ICT in their teaching process is not mainly helping people operating machines. Rather, it is about supplying teachers with a powerful educational toolkit which can enhance their own pedagogical expertise and professional practice, redefining at the same time their profession's core and demands. Additionally, in the
social framework of learning, teachers' communication and collaboration with each other as well as with experts, is necessary for extending their knowledge and skills.

However, evolution in educational systems is a rather complicated process, apart from the potential of any technology, various parameters like cultural and ethical background, national curricula as well as student assessment methods, have to be taken into consideration.

The last four years the Greek Ministry of education has implemented an educational reform, which prescribes a change of focus in schools from teaching to learning and encourages the active participation of pupils in the teaching and learning process. Towards this target new and flexible curricula (Davis, 1998), capable to accommodate ICT based activities, have been developed and new educational material has been produced (books, CD-ROMs, Web sites). All schools will have Internet connection until the end of 2001 providing all teachers and students with e-mail addresses. Additionally, the schools' network is being established offering access to educational content and services over the Web and many pilot projects concerning school networks and educational software are implemented all over the country.

However ICT may contribute to educational development, only if teachers are able to utilise the new technology (Lawson & Comber, 1999). All true changes in schools must take place through the teachers, who are and will remain key figures in learning.

2. The project "Preparing Teachers of the Information Society"

Within this context the training of teachers in ICT is an issue of major importance for the Greek Ministry of Education. Therefore it proposed allocating a total of 100 million ECUs over a three years' period for ICT investments in schools. The goal is that by the end of 2003 75.000 teachers will have received training in the use of ICT in teaching and learning.

The Hellenic Pedagogical Institute (H.P.I.) was given the task of planning and implementing the project entitled "Preparing Teachers of the Information Society". This project is the largest and most comprehensive national investment programme ever to be made in the schools in Greece and offers the teachers training aimed primarily at acquainting them with the potential uses of ICT as an educational tool.

The main aim of "Preparing Teachers of the Information Society" is to raise the standard of pupils' achievements by increasing the expertise of teachers in the use of ICT in subject teaching. It is an ICT project as well as a school development project, which consists of the following components:

- In-service training for 75.000 teachers
- Establishment of a people's network which will support the training and will form learning communities which will remain active even after the end of the project.
- Establishment of local centres which will support the training process
- Creation of mechanisms for the accreditation of training
- State grants to improve the school's infrastructure and the school's accessibility to the Internet.

Also throughout the implementation of the project support will be given for administrative and organisational changes in schools, for the use of alternative teaching and evaluation methods and for the application of flexible curricula.

Basic design principles of the project

The project has been designed to be decentralised and there are opportunities to shape in-service training at the local level in accordance with the wishes and competence of the participating teachers. Decisions about when to undertake the training, which delivery method and training provider to use are made by the schools taking into account the local conditions and the training needs of their teaching staff. However the project's framework has been determined by the H.P.I., which produced the specifications' framework for the educational material as well as the training curriculum for all the training programmes.
The project offers flexible training programs as far as the content and the training model are concerned. Also quality assurance is provided placing mechanisms, which ensure that the ICT training is and will remain of the highest quality.

During the project active learning communities are being established across the country functioning as mutual help and self-learning centres. This “network of people” is a factor of major importance for the project’s success and will continue to influence the educational community after the end of the project.

Also, several support activities described below contribute to the successful implementation of the project. Local training support centres are established in each educational region in order to facilitate and co-ordinate the training process at the local level. The participating teachers are able to receive daily support by the H.P.I. through the Greek schools’ network operating at the Web. It is very important for the trainees to know that they can find help any time they need it during their training (Papadopoulos et al., 1999). All the trainees are provided with a PC and Internet connection for home use. These can be seen as a stimulus to the teachers, but above all as an essential tool in mastering ICT and exploiting its use in teaching. Teachers with their own computers can achieve the familiarity required for using a computer as a professional tool i.e. for administrative as well as educational purposes. Also, special measures are implemented for small isolated schools. Due to landscape peculiarities, too many isolated small schools -basically primary schools- exist in Greece, which are served by only one or two teachers. Especially for this kind of schools, a pilot training programme is going to operate, under the project’s framework.

**Basic principles of training**

By the end of the training the teachers should know

♦ When, when not, how and why ICT can be used in the process of teaching and learning
♦ How to choose, organise and use sources and means provided by the ICT in order to design and prepare effectively his/her teaching.

The purpose of training is to give teachers basic knowledge of ICT as an educational and professional tool. The training will focus on providing knowledge of and familiarity with the use of ICT in teaching but also developing the teachers’ grasp of how ICT is used in society at large.

Throughout the training process the pupil is a central issue. The whole training process focuses on persuading the teachers to use ICT for educational activities in the classroom (Underwood & Cavendish, 1996). The teachers are not trained only in order to support their own professional development or the ways they search for information and teaching resources but they are trained mainly in order to use ICT to enhance teaching and improve pupils’ achievements in a number of ways.

The training offered by the project is built up around the teacher team. “The reason is that past experience from in-service training in schools shows that the efforts of individuals alone are seldom capable of influencing the overall development of the school. It is difficult for an individual after completing a course to have a major impact on developing and changing working approaches in the school, primarily because there is a great deal of tradition and inertia built into many workplaces. On the other hand a group of colleagues, who participate together in an in-service training programme have a completely different range of opportunities to continue their learning and development “at work”. In such cases there are much better opportunities to bring about genuine change” (ItS, Delegation for ICT in Schools, 2000).

During the training process the participating teachers are expected to take great responsibility for their own training. Today and increasingly in the future, learning must be a lifelong process taking place in all the various places in which we live and work. In-service training is no longer a reward or solely a pleasure-oriented activity. The teachers themselves, and generally all the employees, will have to take personal responsibility and create the opportunities for their own professional development. For this reason “Preparing teachers of the Information Society” is implemented largely as “learning at work”.

---

1488
Implementation of the project

Prior to the actual implementation, the Hellenic Pedagogical Institute (H.P.I.) defined clearly and precisely the training courses, in which the trainees may participate, determined the training material's specifications and produced samples of original training material. Also it was determined how the accreditation of the knowledge and skills, acquired by the trainees during the training, will be performed.

The training process at each region is supported by the local training centres. These centres are equipped with state of the art laboratories as well as a frequently updated digital library of educational software titles and staffed with ICT experts and experienced teachers, who facilitate and co-ordinate the training process at a local level. Also these centres are in charge of the local facilitators and the school work groups co-ordination. Additionally, they have to maintain the local nodes of the Greek schools network.

Seminars are organised for school headteachers and local administrative heads responsible for education and training as well as for the facilitators (located at the local support training centres), who are going to co-ordinate and facilitate the group work in schools. The seminars are held by the H.P.I. in all the capital cities of the regions of the country with the contribution of the local Universities and municipalities.

The list with the approved training providers is published. The schools are free to choose the one they prefer according to their training needs. All the training centres have to meet a number of prerequisites concerning the training staff, the equipment and the services they can provide. The training providers can cover all the levels and models of training or just a part of them.

The four alternative training models offered are described in detail:

- In-school training, which includes face to face training performed either by a member of the school's teaching staff e.g. the IT teacher or an external trainer. The training content must meet the specifications published by the H.P.I. Wherever possible training takes place in the classroom or in the school computer lab, so that teachers can try things out as they learn.
- Training by the approved training providers, who have to follow the training curriculum produced by the H.P.I.. The training curriculum describes the targets of the training process and outlines the skills and abilities expected. It is for the training centres to decide the teaching methods and strategies in order to achieve the described targets.
- Self-learning which will addressed to teachers who already acquire basic ICT skills and experience in the use of ICT in the learning process and will include exploitation of the provided training material and participation in collaborative projects.
- Distance learning provided both by the training providers and the Pedagogical Institute making use of the teachers' training centre operating within the Greek schools network.

The schools determine how their staff will be trained. They are asked to fill an application form describing the training model and the resources required for the training. It is possible for a school to choose more than one training model according to the particular needs of its staff. It is also possible for a teacher to choose different training models for the various programmes he/she participates. Depending on the members of the staff seeking training and the chosen training model the schools receive a training fund to cover the training expenses and the actual training process begins.

The training programmes are structured in three levels:

- **Level 1: Training in generic ICT skills.**
  These training programmes intend to improve teachers self-confidence and knowledge as far as the new technologies are concerned. The curriculum of the programmes are designed in order to fulfil the particular needs of the Greek teachers. The training material and the activities designed derive from the schools' daily programme and the particular needs of teachers. The aim of these programmes is to acquaint the teachers with:
  a) the use of common computer applications (word processor, spreadsheet, browser, e-mail etc) b) basic
concepts of ICT c) the use of ICT tools for searching for information, for presenting and communicating ideas and for contributing to their professional development.

- **Level 2: Training in the use of ICT in subject teaching.**

During these training programmes teachers are expected to participate in activities relating to the use of ICT as a teaching tool. The curriculum of the programmes are structured over various activities. The activities include the development of lesson plans as well as the teaching process using educational software titles and common applications used in subject teaching. The effective use of ICT in the classroom implies new roles for the teachers, who are expected to act as facilitators of their students' approach to learning (Bickmore-Brand, 1996). In an attempt to promote and articulate new roles in teaching and learning process, during the implementation of the activities, teachers play the role of the student, having an expert as an instructor.

- **Level 3: Design and production of educational activities, lesson-plans and scenarios concerning ICT exploitation in classroom.**

These programmes concern teachers who feel confident in using ICT. In the framework of the programmes, work groups are established, with the active participation of both teachers and pupils, which will implement an interdisciplinary project. The programme encourages project themes, which are of interest to the local societies of the schools, in an attempt to bring schools in touch with the real world. Additionally, schools from remote locations collaborate using the facilities of GroupWare tools - in developing projects of common interest. In that way, the programmes are expected to perform as the kick off activity for the establishment and operation of the learning communities.

The general target of the above programmes is to provide the teachers the skills and abilities needed to evaluate ICT applications and resources and to be able to choose the appropriate one for teaching, assessment, school management as well as for self-learning and professional development. Additionally, teachers are expected to be able to determine the abilities required from their students in order to construct their knowledge model through the use of new technologies. The training is structured so as to be flexible and to accommodate for the needs and the existing knowledge of the teachers.

A pilot training programme is implemented concerning small isolated schools, which are supplied with special equipment and fast Internet lines, in order to be able to participate in on-line training programmes, using synchronous multimedia communication. The additional outcome expected from this pilot programme, is to bring the students and the local communities of these areas in touch with human and digital resources from all over the country, removing in that way their isolation barriers.

### 3. Evaluation of the project - Follow up activities

The evaluation of the project includes the following:

- Only approved training providers are allowed to deliver training. These providers had to demonstrate a track record of expertise and experience in providing successful training, advice and materials.
- The activity and performance of participants throughout the seminars and in the team should provide a basis for assessing successful completion of the in-service training programme and thus entitlement to a certificate (Hofman, 1996). The abilities and the skills developed by the teachers are going to be assessed through an assessment mechanism compatible with the European Union Initiatives.
- The educational material produced for the training process and during the implementation of the training programmes will be certified so as to become part of databases of educational material existing in the Greek schools network.
- A system to evaluate the overall success of the project by an independent organisation and the overall impact of the Government's ICT strategy.

The end target of the project is to establish active learning communities across the country, which will remain even after the "Preparing teachers of the Information Society" time limited mandate has been completed. This is one of the reasons why emphasis has been put on a decentralised approach in the project.

Within this context the implementation of follow-up activities is an issue of major importance.
In particular, the material and the educational activities produced by the trained teachers and their pupils are going to enrich the educational content provided by the Greek schools network functioning as reference in training material.

The support training centers at each region will establish connections with the schools and the local educational community, having the potential to encourage and contribute to initiatives and innovations undertaken by the schools.

The learning communities established by the project (including the trainees, the facilitators, the training providers) will exploit the collaborative opportunities provided by the Internet, aiming at the establishment of "a network of people", who will share common interests and will enrich and support the operation of "the Greek Web for Schools", an integrated learning environment (Papadopoulos et al., 2000), created by the HPI, over the WWW. These learning communities will support over the long term the teachers to effectively use ICT technologies in their daily work in schools in order to raise the standard of pupils' achievements and knowledge attainment.

Abstract: This paper presents the design and development considerations of GAIA, a curriculum-based, open-ended educational software, which is based on the use of multiple representations and direct manipulation, implemented through different software components. Additionally, it highlights the educational scenarios underlying the development of GAIA, as well as the use of three-dimensional representations in this context.

Description of GAIA

GAIA is a curriculum-based exploratory educational software using 3D building component. It is designed based on a number of educational scenarios that are implemented through seven well-known simulation experiments from the history of science, which are, in turn, realised through seven microworlds (Figure 1).

GAIA incorporates seven microworlds through which the student can (i) "travel" on the surface of the earth, (ii) conceptualise the orbits of satellites, (iii) study the earth's magnetic field (iv) calculate the earth’s radius, (v) experiment with atmospheric phenomena, (vi) travel inside earth, and (vii) study a model of a solar system. In GAIA, each microworld is designed according to specific educational scenarios, which encapsulate both the educational material that is to be presented, as well as the functionalities needed for each specific scenario. To this end, scenarios are constructed through a combination of different information, representation and interaction elements, and are designed to allow the educators to organise predefined activities that are presented to the students work sheets”. Each activity serves certain cognitive, learning, methodological and/or problem-solving goals, and is enriched with the techniques and guidelines, which can assist the activity’s integration into the educational practice of the school curriculum.

Exploratory Nature and Multiple Representations

GAIA aims to realise a constructivist learning environment, which facilitates active learning through experience. Throughout the learning process, the use of the exploratory software promotes experimentation and testing of multiple methods and techniques for the solution of a given problem. Thus, the software does not restrict the students to a unique and sequential path of problem solving steps, but promotes exploratory learning, problem solving and project-based learning (Papert 1980, DiSessa et al 1995).

Additionally, GAIA capitalises the pedagogical approach of multiple representations. A didactic concept can be represented through multiple ways that are chosen by the student depending on his or her cognitive background, learning style and learning path. Furthermore, each representation is supplementary to the other ones and includes only the necessary, according to its type, educational material, with which the user can interact. The use of multiple representations of information improves the perception and understanding of the taught concepts.

3D Components

GAIA adopts the component-based software engineering methodology. To this end, it defines one component for each representation, which is specified by the pedagogical needs of the educational scenarios. Component-based design provides a straightforward match between software components and representations, reusability of similar components in more than one microworld, tailorability and black-box implementation.
The development of the software has adopted the approach described in (Roschelle et al., 1999). Educators, who are involved in GAIA, define the functionality specifications for each representation. These specifications form the framework for the design of the software components. This process is iteratively followed, until a first draft of the specifications is finalised, and the components are prototyped. In addition, educators are continuously being involved in the development life-cycle, providing feedback for the educational “value” of the software components.

Furthermore, GAIA builds on recent advances in 3D technology, to provide three-dimensional representations. 3D offers a new set of advantages in representations issues and learning. The main characteristic of 3D is the ability to create “virtually real” worlds, where students can experiment in a more “na"

Objectives for GAIA supporting 3D representations are: (i) advanced conceptualisation of difficult scenarios, (ii) increased engagement of students, (iii) virtual experimenting, (iv) realistic view and free navigation, and (v) highly interactive environment.

Virtual Career Guidance Provision in Education

George Papas
Pedagogical Institute
Athens, Greece

and

Petros Stefaneas
National Technical University
Athens, Greece
petros@noc.ntua.gr

Abstract: Virtual career guidance – using distance education methods – can provide an educationally efficient and economically feasible way to support both students and counselors in the mutual interwoven role, thus improving the quality of careers' guidance provision. In this paper, we present a comprehensive account on educational and occupational issues pertinent to our "information technology era" and stress on the usefulness, for each student to be informed and exploit the virtual career guidance techniques, in preparing better his/her professional "route".

Introduction

Nowadays, easily accessible, up to date and reliable information, on educational and employment issues, is considered a fundamental prerequisite for successful counseling and career guidance services in education by career guidance counselors. On the other hand, counseling and career's guidance are both inseparable parts of every proper educational environment.

From the eighties (1980's) computers started to be involved in offering career guidance. That situation might be described in the following quote: "computers and more general Information Technology are being widely recognized as a potential and dynamic factor having to offer a lot, first in improving the quality of guidance and secondly it making more accessible to those who need it" (Papas, 1988).

Computer networks provide the potential for continuous access to information from a wide variety of sources. Hence, new opportunities and conditions are created for "opening up education" such as in open and distance learning systems for life long education. The schools' career guidance services - as well as the corresponding services in universities - have to be able to use and exploit all the new opportunities based on communication technologies. That way, the information horizon of students on education and employment issues will be remarkably widened and will remain up to date.

Nowadays, the communication technologies have started creating a "path" to allow career counselors to deliver their services by distance. Career counselors - using distance education methods - can use a variety of communication technologies to deliver different programs.

Social scientists and researchers try to find out the shape the labor market will have in a few years. Part of their written work - mainly in the form of papers - can be now be found in different web sites. Students should be able to have access even to this kind of information in order to form their career path with the assistance of their career advisors.

We consider that, in the long run, virtual career guidance will provide an economically feasible and efficient way to support both students and counselors in the mutual interwoven role, thus improving the quality of career guidance.

In this paper, we present a comprehensive reference to educational and occupational issues pertinent to our "information technology era" and stress the usefulness for each student in secondary or tertiary education to be informed and exploit the virtual career guidance techniques in preparing better his/her professional "route".
Knowledge of Educational and Occupational Issues

Emphasis must be placed by educationists so that students can be aware of and become familiar with the structure and different facets of the interconnected world of education, work and even leisure provision nowadays and of for the future trends.

The rapid changes in society and technology, the mobility of students through programs which allow exchange among different schools/universities and countries, e.g. European Union Countries and the flow of the work force among countries must be taken into account by the students.

The student must be aware that different educational experiences may be related to applied experiences in a specific field. The student must also be informed on: i) employability skills which are useful in seeking, finding and maintaining a job, and ii) on the existence of a wide variety of occupations that might be available to him/her.

It is wise for students to be informed that: "they can expect to change jobs about ten times and career fields three times in the course of their lives" (Employment and Education, 1989). Supporting the same view, Broughton (1996) states that: “our students will be expected to perform jobs in the future that have not been created or even conceived of today”.

Instructors and guidance counselors must provide students with clear understanding of career options and pathways in various sectors of the “globalized” economy where, for example, a sudden “imbalance” in Moscow’s stock exchange may affect violently and immediately stock exchanges of other countries and even more their economic situation.

Decision making and planning procedures are important components in the process of formulating a career plan consistent with students interests, skills, preferences and aptitudes. Students must be encouraged: “to develop skills in gathering materials from relevant sources both external and internal and to learn use the collected information in making informed and reasonable decisions. Another dimension considered is the concept of change, as it affects career planning” (Talavera, 1995).

Leisure time must be taken into account – by their career counselors - when students plan their career paths. It is wise for the student to be aware of the importance of leisure time for each individual’s personal fulfillment and well-being during his/her life span. There have been people who spend their life only working and who had put aside any involvement in recreation facilities. Part-time work and other “flexible” employment now, potentially creates, more time for leisure.

New Technologies and Changes in Work - The role of the school as “the mediator” of students’ career skills.

Recently, several scientists and authors have described the different facets of the technological evolution and of the consequent – so called – computer revolution which embraces and affects people, education, culture, places, systems of organization, the form of technology and the economy etc.

Nowadays, technology makes it possible to transfer almost “immediately” information, money and commercial transactions, property contracts etc through networking. Mortimore (1995) referring to effective schools stresses the usefulness of new technology in better learning and writes: «the ability to connect with other learners anywhere in the world, to use virtual reality to explore geographical, and historical phenomena and the opportunity to experience personal coaching through interactional multimedia packages must enhance the opportunity for better learning».

Factors of major importance in changing the nature of work and the structure of occupations is the comprehensive application, in the workplace: i) of advanced technologies, i.e., computers, microprocessors, fiber optics, satellites, etc., ii) the more sophisticated techniques in management strategies and iii) the consequent improvement in decision and policy making options.

Advanced technologies change the organization of work, its nature, the role of workers and consequently the new skills requirements to engage in work, specifically in those occupations which involve high technology or/and technology intensive processes.

At the end of the twentieth century a new «rough split» in the work force between those who can employment conditions and those who - more or less - can not has become evident. Rifkin (1996) expresses his reservations and fears, because of this situation, and declares that: «the rapid elimination of work opportunities resulting from technical innovation and corporate globalization is causing men and women everywhere to be worried about their future. The young are beginning to vent...
their frustration and rage in increasingly antisocial behavior while older workers seem resigned, feeling increasingly trapped by social forces over which they have little or no controls.

Knowledge and education are considered basic foundations of human resource development, economic development and the consequent better standard in the nation's competitiveness. At present and in the near future «the skills of schooling and learning and the skills of the workplace are increasingly complementary and overlapping» (Herr, 1995). This situation stresses that people with minimal training or capability of learning will face greater difficulties in finding and maintaining a job.

Many countries have started reforms and innovations in their educational system in order to make schooling more “career relevant”. Thus, they introduced courses on the principles of technology to help students to understand the effects of advanced technology in work places and more generally in the occupational structure. New skills – useful for the prevailing employment conditions – have been taught to the students. Skills for conflict resolution, skills to plan and prepare for work more systematically, skills for: problem solving, information retrieval, life long learning, etc. are examples of these skills.

Career recourse centers, using computer facilities, have been established in schools (USA, Canada, etc.). Partnership contacts between schools and the larger community, where schools are located, apprenticeship schemes etc. are some “facets” that a school offers its students as “mediator” of student career skills.

Virtual career guidance for students: different techniques and modes

Despite the importance that the education system gives to career guidance provision for students, the use - till now - of virtual career guidance is rather limited. This kind of guidance is used and based on communication technology. Virtual career guidance is expected to make available to the students the up to date information on career paths, new professions and predictions on the probable shape of the job market. It is expected to contribute to minimizing the discrimination, among students from different locations and backgrounds, provided they are interconnected.

To cope with the need of students for accurate and updated information virtual guidance can provide continuous access to career options for each student presenting diversified levels of maturity, having different educational and occupational interests. This kind of guidance should be compatible with educational, social and psychological concerns including: i) traditional guidance methodologies, objectives, tools and practices, ii) school dynamics and levels of interaction among staff and students; iii) relevant content and iv) needs for updated information. Hansen (1997) writes: “besides the changing life patterns in the Information Society, there are also changes in knowledge systems - in what we know and how we know it; with a growing body of literature in contemporary psychology on ways of knowing”.

Web based techniques - including search engines, data banks and multimedia applications - have been already applied by “on – line” carrier services. Examples of addresses of such internet sites – that may be used during carrier guidance sessions – are as follows:

- http://www.HeadHunter.NET
- http://www.hotmail.com
- http://colicon.com

EURES (http://europa.eu.int/comm/dg05/elm/eures/) is a European labor market network - started in 1994 – aiming at facilitating the mobility of workers in the European Economic Area. It links more than 450 euro - advisers - specialists in employment matters - throughout Europe. The last two years, more than 4 million citizens of the European Union have used the EURES services.

Similar techniques have been applied by Universities, see for example the Web site of Oxford Careers Guidance Service (http://www.careers.ox.ac.uk/mainpage.html). Also, other organizations offer similar services, see Prospects Web (http://www.prospects.csu.msm.ac.uk). External links to other Sites relevant to Careers Guidance on the World Wide Web can be found at http://www.unn.ac.uk/academic/hswe/careers/links.html.

Different Techniques
To design a virtual career guidance technique we have to take into account: i) users' needs (students and staff), ii) the availability of the telecommunication infrastructure, and iii) the expertise of the available staff. The information and communication systems that support virtual career guidance provide a very good paradigm of human-centered information systems. We now present some technological options for virtual career guidance.

I. Special search engines: Special World Wide Web (WWW) based search engines can be developed to allow intelligent browsing into companies profiles, job agencies, guidance offices, job offerings, etc. Intelligent browsing means that search engines should be able to make suggestions (by providing appropriate links) according to a student's profile and the current trends in the job market. Such engines should be used with the proper assistance of a specialized counselor(s). Student access should be limited to predefined links to avoid confusion and the overload of information.

II. Digital libraries - Data banks: The amount of information in digital form is growing explosively. Nowadays, libraries mainly in a digital form provide the necessary access for full exploitation and use of the available knowledge and information stored in the library files. So, libraries can be used - by potential users - more easily and more fully for information retrieval. In that way, information technologies provide the means for the search of information worldwide thus facilitating communication and connection among people.

III. Intranets - GroupWare applications using networks: Business simulation games as well as any relevant guidance games can be seen as examples of such GroupWare applications. They allow concurrent access to data by different students in a quick, simple and flexible way. A relational database (often object oriented) is "the heart" of each GroupWare application. In the case of career guidance applications they can contain electronic career paths, digital job profiles, etc. The counselor's advice can be provided to different student teams involved. Students can exchange information online and receive real-time feedback from the system. That way they can not only communicate with each other but also obtain automatic responses to their queries using the available data stored in the relational database. Various patterns of access to the GroupWare application are available, such as private (accessible only to its owner), group (accessible only to specified users) and global (available to all users).

IV. Virtual Guidance Rooms: A Virtual Guidance Room (VGR) can be a part of a well-organized counseling and guidance service. A VGR can use Tele- (and video) conferencing facilities as well as WWW based resources to support counselor's role. Access to videos can be gained via a video on demand server, while ISDN networks can be used to assist the guidance procedure. VGRs can then be connected through high-speed networks with a Regional Virtual Guidance Center. All these regional centers can be connected to a National one, which will be well supported with the latest available relevant resources. This structure is considered to be the most efficient - in technical and economic terms - since it will allow easy incorporation of local, regional and national educational and labor information to the existing information sites. These Internet sites will provide easily accessible and continuously updated resources in digital form (text, audio, video). Hence they will provide, if properly managed, the latest available information on career guidance.

All the above mentioned technological options, are new methods which have not been tested or compared widely. Hence, the relative research findings on the literature are very limited.

Modes for virtual career guidance

I. Autonomous individual guidance: This is a "guide yourself" approach. The student uses a Personal Computer (PC), possibly connected to the network. That way the student acquires new skills and starts the procedure for "searching" and "information retrieval". The student can also use traditional guidance materials like books, leaflets, videos, etc. The counselor is not necessary when using this mode.

II. Guidance with the assistance of a counselor: This is a kind of semi-autonomous guidance, where the student jointly with the counselor (who can be present really or virtually) can interact with the information system. The student - counselor relation is powerful. The counselor can administer a personality test or ask the student to write an assignment. Each aspect of this relation can be enriched with the use of information and communication technology. Even though computers and communication technology will
never replace the counselor, they can support some of the most crucial aspects of the student – counselor relation by providing fast and reliable access to information. Such aspects include presentations, questionnaires, access to student guides, etc.

III. GroupWare applications: This is based on advanced group communications. Individuals can interact, share material and experiences. Communication-oriented VGRs provide a characteristic technological application that supports a group-oriented counseling mode. The real challenge of this application, that is expected to be available in the near future, would be the integration of VGR operations with the functional requirements of group-based virtual guidance.

IV. Virtual guidance services: Students are allowed to participate, virtually, in career guidance sessions. Then, a student following a certain electronic path can search and exploit the available information. Options include virtual meetings with the counselors via teleconferencing, visits to the digital library (see case studies via video presentations, etc.) and electronic mail communication.

Concluding remarks

Any real change in society is expected to come through changes in the ways one learns and faces the different problems and situations. “To remodel a society, it is essential to influence the hearts and the Barlow and Robertson (1996) in their paper on Homogenization of Education.

One of the main targets, in our changing world, should be the familiarization of the new generation with the notion of continuous and unpredictable change. That way, they can act and operate as good “navigators”, in any “weather” and as reasonable decision makers use and rely on a set of relevant informations so they have access to through information retrieval techniques.

Nowadays, we have great progress in new information technologies and in their accelerated use within the educational system but mainly outside it. The new generation is the “favorable” and more dynamic learner, user and “explorer” of any kind of information through the worldwide networking – without “suffering” from any “barriers” that the formal education system might impose.

It is wise and efficient for the educational system to offer its students the means and modes for the exploitation and use of the new technologies in shaping better their future educational and occupational career route. This students’ expertise, acquired by means of the educational system, provides them with the knowledge on how they can be more efficient “shapers” of their future careers.

Abstract: Information Systems used in Education must take into account educational as well as technical aspects. Using educational information systems we must choose a balanced approach where: social, educational and technical aspects must participate in the "right mix", so that to meet the set requirement of the system in the prospect of having a positive summative evaluation.

Introduction

The accelerating use of Information Systems and more generally of Information Technology (IT), in each level and sector of education and training system - nowadays and in the future - reveals the need for development and use of optimization procedures. These are leading to improvement and positive exploitation of available modes and means and ultimately lead to the need for efficient management of the available resources to be used. A set of properties that must characterize an Information System, used in a specific environment, e.g. educational, creates a scientific interest to the end of revealing and tracing out the best "mixture", between requirements and management of resources so that an expectation of a better "fitting" is considered an attainable target.

Requirements Engineering

Requirements are properties that an information system should have in order to succeed in the organizational environment in which it will be used. In brief, requirements say what a system should do. According to Jirotka and Goguen (1994): "anecdotal evidence suggests that errors in requirements may amount for something like 50% of the total cost of debugging". Requirements capture and analysis specify the services that the system should provide and the constraints under which it must operate. It has been suggested by researchers that proper systems' requirements elicitation techniques should incorporate research methods from social sciences as well as methods which lie within the traditional computer science domain (J.F. Dumont & P. Stefaneas, 1996).

According to Davis (1990): "Requirements Engineering (RE) is the analysis, documentation and ongoing evolution of both: user needs and the external behavior of the system to be built". Requirements engineering is currently an active research field in the area of Information Systems. It is concerned to find out the future stage of the Information System and how the current one may change. It has to do with the proper prediction of Information Systems behavior. The main problem of Requirements engineer is to satisfy, at the same time, the needs of systems' designer and those of the user(s). Requirements engineer has first to gather information, then to consider various solutions and finally to suggest what kind of system should be designed in order to satisfy users' needs. All these stages are depended upon the available resources and the given technology. Efficient use of resources is considered to be taken into account in each stage of the requirements engineering procedure.

Educational research - according to Travers (1969) - is "an activity directed toward the development of an organized body of scientific knowledge about the events with which educators are concerned". Its aim is to discover general principles or interpretations of behavior that can be used to explain, control and predict events in educational situations; that is to create scientific theory. Research methods refer to the general strategy followed in collecting, manipulating and analyzing the data necessary for answering a specific question in an area of study. In general, four categories are used for classifying educational research. These are: experimental, ex post facto, descriptive and historical. Users' participation in RE process is considered to be absolutely crucial for its success. Various theoretical models have been suggested in the area of RE (see Eman, et. al., 1996).

Management of Resources

The degree expressing of how successful is an introducing procedure of a new information system in an educational setting (environment) is measured in terms of its usability, students and teachers satisfaction meeting
learning objectives and cost incurred, not only in economic terms. Systems of course are developed and used taking into account the available resources, in the specific environment. The "scarcity" problem of resources is considered to be one of the major issues to be taken into account and it consists of the so called "Project Manager's Dilemma" (Chatzoglou and Macaulay, 1995). Project Manager must develop the system in the domain of the available resources. The following three characteristics are considered vital and interrelated "components" in educational management: (1) Development and maintaining quality in procedure and outcomes, (2) Use of available recourses effectively, and (3) Establishing a strategic plan and an implementation schedule for the operation of the organization (institution).

Strategic planning is perhaps the most traditional view of how strategic decisions are made in organisations. The perspective indicates that strategy formulation is a distinctly intentional process involving a logical, rational, planned approach to the organisation and its environment. Further it implies that through the application of appropriate analytical and systematic techniques the "right" decision can be taken.

Information Systems In Education

Introducing a new information system in Education is a form of an organizational change. To overcome possible resistance and “inertia”, to such change is useful to “activate” and involve the potential users in, as many stages of development and introduction of the new system, as possible. The RE processes involves many stakeholder groups: policy makers, managers, educators, psychologists, students, etc. Each of those have their own viewpoints representing a particular perspective. So, it is necessary each type of requirements to be expressed and each viewpoint to be related to the other (Mullery, 1996).

A very important question, to be taken into account, is to which extend a system, an organization or more generally an environment can restrict or guide the requirements process and hence the whole systems' development life cycle. Another important question refers on dissemination of Information Systems within an organization and how this fits users' needs.

Requirements Engineering Techniques in Defining Requirements for Information Systems in Education

Information Systems used in Education must take into account educational as well as technical aspects. Using educational information systems we must choose a balanced approach where: social, educational and technical aspects must participate in the “right mix", so that to meet the set requirement of the system in the prospect of having a positive summative evaluation.

For such applications requirements must take into account theories of learning and cognition, the education system infrastructure, aims and objectives to be met and cost - benefits analysis aspects. The definition of the properties that an educational information system should have in order to succeed is considered crucial for the development of its life-cycle and the consequent applications.

Epilogue

Requirements Engineering – as we have seen – is concerned with needs (in the area of their interest), either of the "customer" (e.g. student) or/and of the designer trying to use the available resources as efficiently as possible. As, Macaulay (1996) writes: ....."RE is concerned with gathering information and considering possible options, and with identifying what should be designed in order to meet some perceived future need. Current systems will never be quite adequate for the future situation that the change will bring". So, a “balanced interwoven mix" taking into account: i) information system technology, ii) care for good management of available resources, iii) Deep knowledge of education – as a content and procedure – is expected to contribute to successful operation of the "system" in our case the most efficient use of Information Systems in Education.

Cooperative Interpretation of Technical Papers

Jose M Parente de Oliveira, Brazilian Institute for Air Navigation Services, Brazil; Clovis Torres Fernandes, Technological Institute of Aeronautics, Brazil; Fernando Masanori Ashikaga, Technological Institute of Aeronautics, Brazil

Support systems for learning through cooperative activities are becoming very popular, perhaps due to the growing need to form people with abilities to learn and work in groups. In learning settings, it is more and more necessary to share the form with others to see the knowledge, be it to obtain new knowledge, be it to observe the limits of a particular vision. Besides that, the construction of the knowledge possesses a strong social component.

A process of cooperative interpretation of technical papers in educational contexts is focused. Such a process has as educational goal the development of argument ability, the improvement of the capacity of interpreting technical papers and the meaningful learning of a paper content. However, without the aid of a support software, this process is subject to loss or misunderstanding of information, as well as to problems related to social aspects of the cooperative work.
Application of Virtual Reality to the periodic table for chemistry education

Abstract: We developed the VR program to be used to learn the periodic table in chemistry education. It is discussed how to develop the VR periodic table and what to learn through that. The VR program is developed using the 3D Webmaster program of Superscape. The students can receive the feedback according their action on the VR world. There are some chemical knowledge such as chemical elements, atomic radius, electron affinity, and ionization energy etc. The students could study interestingly and cooperatively the periodic table.

Introduction

As the computer is popularized in individual and society, it is using a many of area. In particular, there are many materials to learn a science knowledge using multimedia through computer. Many of them are web-based learning materials, which are developed by Java or Flash. Since the technology of the representation, storage, computation and communication in computer make progress, the environment of education is also developed.

Virtual Reality (VR) referred to ‘immersive Virtual Reality.’ In immersive VR, the user becomes fully immersed in an artificial, three-dimensional world that is completely generated by a computer (Steuer, 1992). It is also possible to define VR in terms of human experience, 'a real or simulated environment in which a perceiver experiences telepresence,' where telepresence can be described as the 'experience of presence in an environment by means of a communication medium.' (Riva, 1999). A key feature of VR is real-time interactivity, in that the computer is able to detect student input and instantaneously modify the virtual world (Seth 1999, Wylmarie, Robert 1999).

It is reported that using the VR simulation in chemistry education can increase student engagement in class, promote understanding of basic chemical principles, and augment laboratory experience (Christine 1996).

In this research, we develop the VR periodic table to grow up the attendance and interest of students in learning chemistry.

VR Periodic Table

The 3D models and objects are presented in the VR periodic table that is developed by 3D-Webmaster of Superscape, therefore the students easily recognize that. There are 4 push buttons on the left-down side in the screen (fig 1). Each of them is the electron affinity, ionization energy, atomic radius and reset. When the students push electron affinity button (fig 2), they can see the periodicity of electron affinity immediately. The knowledge of main
elements is also displayed as pushing those elements in periodic table and the discoverer, character, structure are presented on the other frame.

![Periodic Table of Elements]

Figure 1. Opening screen

![Periodicity of the electron affinity]

Figure 2. Periodicity of the electron affinity

![Periodicity of the ionization energy]

Figure 3. Periodicity of the ionization energy

**What To Learn**

Students in the level of middle or high school could learn chemical knowledge such as chemical elements, atomic radius, electron affinity, and ionization energy etc. through VR periodic table. Moreover, since the 3D models or objects are used in learning of chemical concepts, the students can feel the interest, and learn independently or cooperatively in learning situation.

Abstract: The aim of the present research was to study the role of the individual and shared mental models in the process of forming students' competent environmental decisions in synchronous CSCLE. An environmental role-play was carried out in the CVW learning environment with 12 groups of secondary school students. Their decision-making process was supported by additional web materials and a learning protocol. 27 science teachers conducted the formative evaluation of the teaching method and additional resources. The content analysis of log-files and students' post-questionnaire were used to investigate the role of individual and shared types of the mental models in forming competent decisions. Two different patterns of making group decisions in synchronous CSCLE were observed. It appeared that the decisions that formed on the basis of the shared mental model during students' discussion were more competent than the summation of decisions.

Introduction

During the process of making environmental judgements the decision-maker has to consider scientific knowledge, the aspects of legislation and economy but also ethical and moral issues to make competent decisions (Zandbergen & Petersen, 1995). A large amount of low-structured information available from different sources and a lack of experience inhibit the decision-making process of novice decision-makers. Competency in making environmental judgements is affected by the limitation of short-term memory that the decision-maker is capable to use actively during the different phases of the decision-making process. According to the phases of decision-making (Huitt, 1992; Ratcliffe, 1996) the decision-maker will initially generate a mental model of the problem, which is an abstract body of organized information, constructed using knowledge activated from long-term memory (Barker & Scraik, 1999; Jonassen, 1995). Secondly, different sources of information should be evaluated and an alternative problem scheme should be generated and compared with the initial mental model. The decision-maker has to judge the alternative schemes and make the decision. This process is affected by limited memory space. The short-term memory is described as having storage capacity of seven plus or minus two chunks of information for a relatively brief duration (Tulving, 1970; Hewett, 1995).

The memory-space of an individual decision-maker can be enlarged supporting it with the shared memory-space that forms during the collaborative decision-making activity. Collaborative team can form a shared mental model that is an average correlation among team members about how much each person knows (Kraut et al., 1999). Relying on the team members' different mental models a bigger number of relevant alternatives can be generated from the initial information. The shared memory-space would also help individual decision-makers to keep information in the short-term memory by peers' approval or disapproval of arguments. Therefore, collaborative team can evaluate alternative solutions more effectively than individual members and make a competent decision in a shorter time.
As a prediction of the present work it was supposed that environmental decision-making skills could be effectively taught by active learning methods in the synchronous computer supported collaborative learning environment (CSCLE). During collaborative learning the process of formation of shared mental model is recorded in the log files that support the visual rehearsal of information. The decision-making process can be scaffolded with additional materials on web pages, collaborative document-generating tools and learning protocols.

The Study

The aim of the present research was to develop an effective method promoting students' environmental decision-making skills in synchronous CSCLE. According to our hypothesis an environmental role-play in virtual environment as a teaching method could be applicable. The method of role-play has to be supported by different kind of scaffolding: the instructional scaffolding (learning protocols for the tutor) and the information-embedded scaffolding (web-based materials guiding different roles). The role of the individual and shared mental models and the role of different aspects of information in the process of formation of competent environmental decisions were investigated.

The study was carried out in the CVW environment (http://cvw.sourceforge.net/) that is applicable in collaborative activities in a distributed meeting situation. During a role-play the groups of users worked together in the different rooms of environment discussing the problem and jointly editing decision documents. Their learning was supported by additional web-materials and a learning protocol following the phases of decision-making (Huitt, 1992) that had to guide the chat-facilitator in tutoring the process of making environmental judgements.

A pilot study for the formative evaluation of the role-play was conducted with 27 science teachers as a part of an advanced in-service course on the usage of information technology in science classes. During the hands-on workshop they had an opportunity to participate in the role-play in CVW environment. A post-questionnaire and a semi-structured group interview were used to get teachers' opinions about the method. Their activities during the role-play were analyzed on the basis of log-files.

The application of collaborative role-play in CVW for teaching and investigating the mechanism of environmental decision-making process was carried out with 12 different classes of secondary school students (10-25 in each group). To study the role of the individual and shared mental models in forming competent decisions the content analysis of log-files (the comparison of decisions made in the different phases of decision making process) and the students' post-questionnaires were used. The consideration of information about different aspects of the problem (scientific, ethical, juridical and economical) was studied.

The aim of the environmental role-play activity was to oppose the role-groups representing different environmental knowledge, attitudes and values and to initiate the discussion for generating ideas, evaluating alternatives and implementing solutions. Supposedly this kind of role-play had to lead to the more competent environmental decisions compared with the individual viewpoints. The scheme of the collaborative role-play consisted of the following phases:

i) Students were divided into four role-groups that met in different rooms of the CVW. According to the learning protocol, the tutor introduced the tasks to students. In each room there was a link to the brief survey of the problem. Next, each student had to generate a note of his initial decision (an initial mental model), which could be used as a rehearsal material during the decision-making process when short-term memory might be overloaded.

ii) In the next phase of the activity each group was acquainted with their role and worked together in the separate virtual rooms using supplementary web-material about one certain aspect of the problem. According to the role of each group a limited amount of additional information was offered for making the initial judgement, because only some aspects of the problem were important from a specific viewpoint of the role. It enhanced the decision-making process of the role-groups. During small group discussion the learners of the same role had a possibility to restructure additional information. An expert decision of this role was formulated on the basis of the shared mental model of the group. They followed the instructions of the tutor and jointly edited a decision-document. The documents created by the role-groups were stored in their rooms and were available for all the group-members.

iii) Subsequently, the members of different role-groups moved to the different expert-rooms to discuss their preliminary judgements as experts and to find controversial issues in their previous decisions. Using the documents
generated in the role-rooms they discussed and evaluated the role decisions and made a final decision. The final documents were stored in the expert rooms.

iv) The evaluation phase of final decisions was jointly carried out in the conference-room, comparing and commenting on the final decisions of different expert-groups guided by the tutor.

Findings

The teachers’ group interview and the post-questionnaires and the students’ questionnaires exposed some factors that influenced the decision-making process in the synchronous CSCLE. The participants referred to the need to organize the leadership in teams and also difficulties in following the discussion while writing their opinions or creating the decision-document. The latter was one of the constraints that could have affected the teams’ decision-making process.

The analysis of the log files allowed to investigate the influence of additional materials to the decision-making process. It appeared that groups followed role-descriptions, examined additional materials and the presented information was taken into account while making decisions.

The content analysis of the log-files according to the types of students’ responses and the comparison of decisions in different steps of the role-play revealed two different patterns in making group decisions. Groups that concentrated on the discussion expressed a bigger number of arguments and decisions than the groups that organized their decision-making process plainly on comparing each other’s decision-documents. Due to the discussion a shared mental model for solving the problem was constructed in the former groups and the team-members were capable of drawing the final conclusion according to the decisions that were supported most of all. Conversely the teams that used the pattern of comparing each other’s decision-documents did not succeed in generating the shared mental model and forced their leader to make the final decision. Therefore, their group-decisions were strongly affected by the judgements supported by the leader.

These findings indicated the need to study the mechanisms that direct the teams in choosing one or another decision-making strategy to favor the pattern of discussion where a shared mental model is generated. During the discussion the team-members can develop wider and deeper mental models in shorter time than compared with an individual model. The decisions that formed on the basis of the shared mental model during the discussion were more competent than the summation of the individual decisions.

Abstract: Educators who are responsible for the creation, management, and administration of educational programs are central to the planning process. Research suggests that program planning is not driven by theoretical constructs, but rather by the personal experiences and beliefs of individual planners. This study explores how individuals who plan online programs perceive their roles. Planners' perceptions of their work are important because their perceptions direct their activities, and their activities guide a rapidly expanding segment of educational programs which are impacting a growing learner population. In order to study the perceptions of a geographically diverse group of individuals, this study observed the exchanges of the participants in an international online forum, the Distance Education Online Symposium (DEOS) during a 30-day period in 2000. The 286 messages exchanged in DEOS during the study's period were analyzed using the Constant Comparative Method. This analysis produced an organizational scheme which grouped the respondents perceptions into four categories.

Introduction

Online education is still in its beginning stages, and research describing what those who design, develop, teach, and administer online programs actually do is only beginning to emerge in the literature. Therefore, it may be useful to draw upon theory from related fields. This study utilized theories from traditional adult education program planning and models of adoption to compare and describe the perceptions online educators have about their work. The framework developed may be used as a basis of comparison for other populations of online educators, as a way of thinking about the professional development needs of those who work with online programs, and as a basis for future research.

A Review of the Literature

A number of authors in the field of adult education program planning argue that the actions of individuals who plan programs are guided not by theoretical models, but rather by their personal skills, interests, experience, and educational philosophy (Brookfield, 1986; Cervero, 1991; Darkenwald, 1982; Wilson, 1995). In the absence of research-based models of online program planning or evidence to suggest those who plan online programs work from theoretical constructs, this study begins with the assumption that the actions of online program planners are guided by the planner’s personal framework. Therefore, an investigation of planners’ activities through examining planners’ perceptions about their role and the work they perform is necessary.

While research from the field of adult education program planning suggests that investigation into the actual practice of online program planning needs to begin by examining the perceptions planners have about their work, models describing adoption of innovations provide a foundation for comparing the results of this
study. While there are several models describing the adoption process (such as the Paradoxical Disjunction Model (Cravener, 1999); the Model of Diffusion (Dooley, 1995); the Concerns-Based Adoption Model (Hall, Wallace, and Dossett, 1973) and (Hord, Rutherford, Huling-Austin, and Hall, 1987); and the Technology Acceptance Model (Wolski and Jackson, 1999)), most adoption models have their roots in Rogers (1962, 1965), work on adoption theory.

Roger's (1962) classic work on diffusion theory argues that adoption of an innovation is distributed along a normal, bell-shaped curve if plotted over time on a frequency basis. The first group to adopt an innovation is the “innovators,” and they are followed closely by the “early adopters”. The next group is the “early majority,” which is followed by the “late majority”. Finally, the “laggards” are the last group to adopt an innovation (for a variety of reasons). The innovator group -- those who are first to adopt a new technology -- are described as intrinsically motivated, self-taught, experimenters (Wertheimer and Zinga, 1997), who are comfortable with change, and attracted to challenges and risks (Hadley and Sheingold, 1993). When all or most of the members of the innovator category (those first to adopt a new technology) have adopted the innovation, it is referred to as the saturation point; and Geoghegan (1994) suggests that the saturation has been reached for innovators of instructional technology.

Building on Rogers' work is Hord, Rutherford, Huling-Austin, and Hall's (1987) Concerns-Based Adoption Model (CBAM). When confronted with a new challenge, technology, or process, CBAM argues that individuals undergoing change are focused on their own awareness (of the issue/need), desire for information, and personal concerns. That is, people undergoing change are going to be more concerned about gaining information about how the change will impact them personally. Once individuals have gained some experience with the innovation, they move away from the intense need for information and into stages focused on consequence, collaboration, and refocusing. How an individual perceives the innovation will determine how quickly the individual moves from initial inquiry to adoption.

Theories of program planning and adoption of innovations intersect at their mutual focus on the individual's personal perspective. How individuals perceive their program planning process has a direct impact on the resulting program. As program planners adopt the innovation of online technology, how they perceive these innovations influence their rate of adoption. As such, the design of this study focused on the perceptions of individuals responsible for planning online education programs in order to develop a framework to guide future inquiry. This design is briefly described in the following section.

Research Design

Two main issues shaped the design of this study. First, if one accepts the premise that program planners' actions are guided not by theoretical models but rather by their personal framework, then one should examine the actual practice of planners in order to discover the issues planners attend to. Second, as this study is concerned more with planners and less with the actual tasks of the planning process, one needs an unvarnished view of how planners perceive their work. Contributing to these issues is Rogers' (1995) position that innovators tend not to cluster around geographic centers but rather around others with similar interests. Therefore, an online community of practitioners was selected as the population for this study. Observation of an online group allowed the data to be collected without the respondents being influenced by the presence of a researcher, or what Goetz called the "Observer Effect" (1984). The population selected for this study was the participants of the Distance Education Online Symposium (DEOS), created in 1991 by Pennsylvania State University.

Data were collected during January 2000 and were analyzed using the Constant Comparative Method (CCM). As first described by Glaser (1967), CCM was applied in a rhythmic fashion which produced four themes or categories. These categories describe the issues the DEOS participants raised during the time period the study was conducted. These themes were compared to adoption models to produce an organizational scheme that describes the issues the members of DEOS addressed during January 2000. While the results of this study should not be generalized and applied to other populations or circumstances, they can serve as a basis of comparison for future research. A brief description of the findings as well as a discussion of how they relate to adoption models is addressed in the following section.

1510
Page 1460
Findings and Discussion

The analysis of the data produced an organizational scheme which grouped respondents' perceptions into four themes. Those groupings are: Comparison (between the online environment and the traditional classroom), Impact (of the online environment on the individual planner), Application (of the online environment to the individual planner’s discipline), and Improvement (how the planner can improve his/her discipline using online technology).

Comparison

The comparison theme is reflected in DEOS members’ messages which center on comparing familiar concepts and elements to the online environment. Data corresponding to this theme describe the online environment by comparing it to the traditional classroom, learners, and process. This is the largest theme, accounting for 34.8% of the entire dataset.

Building on Rogers’ (1962) work is Hord, et al’s (1987) Concerns-Based Adoption Model (CBAM), which argues that individuals will begin the adoption process by first becoming aware of alternatives and then gathering information about alternatives when confronted with a new challenge, technology, or process. This initial questioning stage is consistent with the theme of comparison in that the individual confronting a change will usually begin by gathering information --in this case, by comparing the online environment to a known environment. While the design of this study sought only to categorize the DEOS participants’ responses, comparing adoption models to these findings suggests this may be the first phase program planners would move through as they move their practice to an online environment.

Impact

Messages in this theme reflect a concern the respondent had about how the topic (of the message) would impact them on a personal level. This theme is the second-largest one, comprising 26.1% of the total dataset. While the messages in this theme address a range of topics, many of them reflect the respondent’s concern about the time involved, or required by, the topic of discussion. In other words, the messages in this theme reflect the respondents addressing how the topic of discussion would impact them personally by focusing on how much time was required to engage in a particular task.

The theme of how the online environment impacts the program planner personally is tied to Rogers’ (1995) work on diffusion models, and is not unusual when one sees this process through the lens of the program planner moving their practice into a new environment. Cravener (1999) explains this behavior, in part, through the Paradoxical Disjunction Model: “Paradoxically, the faculty rarely are interested in new technologies to support teaching and learning. The faculty are predominantly focused on psychosocial factors: personal affective issues and their need to meet institutional requirements for tenure” (p. 1). This idea can be seen in the respondents’ discussion of how the online environment impacts them as individuals.

Application

This theme is reflected in messages that explore the application of online programming in an individual’s professional practice. In other words, messages in this theme address the question, “How can I apply (the message topic) to my own practice?” Messages in this theme address a broad range of issues from topics dealing with organizational concerns to topics of professional development of an individual.

The application theme illustrates the environmental context --from the broadest organizational perspective, to the more narrow personal perspective, that shapes a program planner’s activities. Fullan (1991) describes the process of incorporating educational technology into practice as complex and multidimensional. Fullan writes that this sort of change requires the use of new or revised materials (curriculum, resources), the possibility of having to use new approaches to teaching (teaching strategies, approaches), and the possible alteration of beliefs (pedagogical assumptions and theories and underlying methods). These types of changes cut across the organizational environment and the individual’s personal beliefs and past experience. The theme
of application is seen again in the Concerns-Based Adoption Model (CBAM). Hord et al. (1987), showed that as individuals gain experience with an innovation, they move away from an intense need for information and into stages of consequence, collaboration, and refocusing. Individuals in these stages are focused on integrating the innovation into their personal practice. As individuals develop sufficient mastery of the innovation, they begin to expand their vision to address issues of improving their larger field of practice, which is reflected in the final theme of improvement.

**Improvement**

This theme is reflected in messages that explore how to expand or improve distance education as a discipline. Much of the discussion in this theme addressed broad issues, such as industry trends, purpose of distance education, and organizational change. Once program planners have successfully integrated online programming into their practice, they began to consider the larger context of their field. This need to share ideas and connect to a larger context is explained, in part, by Schein (1992), who writes:

> Once we have developed an integrated set of such assumptions, which might be called a thought world or mental map, we will be maximally comfortable with others who share the same set of assumptions and very uncomfortable and vulnerable in situations where different assumptions operate because we will not understand what is going on. (pgs. 22-23)

In other words, we are more comfortable with those who share our ideas and beliefs. Program planners who have integrated online programming into their practice will likely seek out these others by gravitating to groups who hold similar beliefs or work to educate their existing reference group.

**Recommendations**

Because the purpose of the study was to identify planners’ perceptions of their work, it did not test for relationships between the four themes of the organizational scheme. As such, future research should investigate not only the validity of the organizational scheme but the relationship between the themes as well. A comparison of this study’s findings with literature on models of innovation adoption suggests that online program planners may progress through the four themes as their practice evolves—a hypothesis for which there is little evidence to affirm or deny.

Additionally, a review of the literature related to planning adult education programs suggests the environment in which a program is created has a great deal of influence over its design and conduct. The concept of situated cognition states that learning is not just influenced by the environment but that learning is in fact shaped and defined by the context in which it occurs. Brown, Collins, and Duguid (1989) wrote that the learning situation “co-produces” knowledge, meaning that what is learned can not be neatly dissected from the context in which it was learned and how that knowledge is applied (1989, p. 32). The impact of the environment is similarly addressed in discussions of the planning process. Wilson and Cervero (1996) address the influence of the politics of power in the planning environment writing: “Any account of program planning must address both power and responsibility in order to be of any practical help in the every day world” (p. 9). Pennington and Green’s (1976) comparative analysis of 52 continuing education program planners found that the planner’s perspective and the environment in which they work had a much greater influence on the program produced than any theoretical construct. “Planning continuing professional education programs is a highly individualistic activity as the planner moves through the development process,” they write. “The decisions planners make to keep the program development process moving involve consideration of the environment in which they are operating, internal and external constraints and resources, and the possible outcome of any decisions” (p. 23). A review of adult education literature regarding the influence of the environment on the planning process suggests there is an interaction between a planner’s perception and the planning environment. However, as with a comparison to adoption models, there is no evidence to support or reject this hypothesis; thus further research needs to investigate the possibility of a connection between a planner’s perception and their environment.

This study began from the premise that discussions of online learning typically focus more on the learners and their experiences and less on the educators who create and work with the programs. As such, this
study took the position that educators' issues are the ones that have broader impact and greater implications. This is not to suggest that questions related to online learning are not important—they are critical. However, it was well beyond the scope of this study to consider the entire dynamic of the educator and online learner. Considering which part of the educator-learner dynamic to address, one part of the equation has to be considered first. Obviously, additional research needs to address the perceptions online learners have of their experience and how their perceptions influence their performance.

This study represents only one small step towards understanding the process of creating online programs. As the number of online programs grows, it becomes increasingly important to understand the process of creating, implementing, and administering these programs. How educators perceive their roles as online program planners is critical, as they are creating an ever-expanding number of online programs which are influencing a growing group of learners. Understanding more about the education process is critical because education changes people's lives.

Abstract: Laboratory micro enterprises of students are running in the Young Enterprise Europe educational program. This brief paper discusses how the results of the on-going FAIRWIS project can be used to improve the efficiency of these lab-enterprises and better accomplish their educational objectives. An example usage scenario of a student virtual fair and the architecture of the 3D information visualization module of FAIRWIS are introduced.

Web-based learning by doing for micro enterprises

A critical success factor for an industrialized country is to teach students the complexity of the economical world, by introducing them to entrepreneurial activities, hence to develop the future generation of managers. IGstudents Foundation (IGF) is the Italian member of Young Enterprise Europe (YEE), the organization that promotes managerial education in 19 European countries with over 600,000 participating students every year (see www.igstudents.it and www.young-enterprise-europe.com). IGF considers the enterprise as a means to improve the co-operation between educational and working environments, and to promote professional experiences to increase business know-how of young students. This mission is carried out through the creation and management of "laboratory" enterprises of students running in a protected environment, according to the "learning by doing" method. A lab-enterprise operates for a single year, develops (new or traditional) products/services, and grows within the global market, identifying actual development perspectives, internal management control systems and efficient communication techniques. Students manage their lab-enterprises in a realistic fashion: nominate a Board of Directors, study strategies to locate new markets and to sell products, keep books, draw up financial statements, and even pay taxes to IGF. Lab-enterprises are exhibitors in trade fairs and participate to competitions, these events allow the products promotion, and students compare themselves with other enterprises. The most important events are National Competitions, among winner labs selected in Local Competitions, national winners attend a European Competition. Several fairs are planned this year, located in dedicated areas of commercial centers, during these events the students show and sell products to visitors, that visit their stands mainly because are in the commercial center. Due to the increasing number of lab-enterprises this learning by doing approach is going to become very expensive and difficult to be implemented. This suggests a larger usage of ICT and Web-based educational modules (Pauselli, D'Atri, 2001). Preliminary experiences were specialized web sites and trainingsessions by videoconferencing systems. A second step, that is now under investigation, is the usage of virtual trade fair environments for remote training of IGF students in an interactive, synchronous and real time way.

Virtual trade fair environments for student training

FAIRWIS, an acronym for Trade Fair Web-based Information Services, is an on-going European research project (www.fairwis.net) that is developing a system to support real trade fair events and to promote virtual ones, by offering on-line services to organizers as well as a very large number of (local or remote) exhibitors and visitors. FAIRWIS services can be used for student virtual fairs, thus improving the efficiency of lab-enterprises by means of an integrated (virtual and real) exhibition marketplace (D'Atri, Pauselli, 2001). In fact an exhibitor of a student fair could virtually attend a related national real fair event, by showing products and services via a kiosk located in this venue, which simultaneously runs several remote student exhibitions. These virtual exhibitions could also be available on the Web, and be visible everywhere in the world, for longer period with respect to the student events. The visit to major national and international real trade fair events will also be possible. Hence, these fairs will be
learning and meeting opportunities and could evolve into stronger and effective relationships. In fact, a student may act both as visitor and as exhibitor, and can strongly increase and improve business contacts and knowledge about new related products/services. One of the main differences between FAIRWIS and similar services currently available on Web sites is that the latter have static data that it are difficult to update and to put on line in an appropriate format. FAIRWIS has a real time connection with an underlying database to guarantee coherence of data and up-to-date status. The presence of the database also give the possibilities to IGF students of easily generating new examples of Web fairs, by modifying the database contents and customizing a few data in the overall system, whose user interface is then automatically generated. However, presenting data on the Web in an understandable way requires a lot of work when they change dynamically, in particular it is difficult to modify the graphical layout without disorienting the users. An innovative feature of FAIRWIS refers to the generation of 2D/3D visualizations that are exploited to facilitate human-computer interaction. In the following we briefly illustrate the module that generates a database-driven 3D visualization environment based on VRML (ISO/IEC, 1997) and a RDBMS. The concepts that can define a formal basis for the implementation of such an architectural framework and its components are described in detail in (FAIRWIS, 2001).

Example scenario

Let us suppose users want to browse through a visually rich 3D virtual trade fair environment (compare to virtual gallery environment as described in Muller et Al., 1999) filled with, from their subjective point of view, more or less interesting stalls of various exhibitors. They want to look for a product or just review information about some exhibitors. They enter the system, and through an appropriate interface, provide the "search criteria" to the system for locating exhibitors and/or products. A 3D visually interactive presentation of a trade fair hall is then generated in an area of the screen. The selection of the exhibitors is based on the users' search criteria. In the displayed architectural topology of the trade fair, grounds and buildings are structured hierarchically and are therefore easy to navigate by selecting areas related to the different exhibitors, business sectors, and product categories. As the users move around in this virtual trade fair environment, they orient themselves with the help of so called “landmarks” and “signposts” inside the 3D environment. After a short spatial navigation, a trade hall entrance is reached. A label describes that the exhibitors located in this hall match a couple of search criteria defined earlier in the form based query construction dialogue by the user (e.g., a certain exhibitor and his products). Through the entrance, users proceed in the hall that contains only the exhibitors expected in this section of the trade fair. As the users navigate into the hall, they take their time to study the exhibitors positioned along the alleys of the trade fair hall. By clicking on one of the exhibitor stalls in the 3D environment, all information about the exhibitors stored in the database is displayed on a separate area of the screen together with a more detailed high-quality image of products and further meta-information like, e.g., pricing and sales conditions.

Architectural model for a database driven 3D visualization environment

The application aspects and the users' experience described above demand a set of different interactive information visualization functions to be supported by an overall technical architecture.
order to produce the actual data that matches the users’ request, the server translates user requests into a query to the database. The database system processes the query and returns the result. Now, the application server can use the retrieved data to construct the 3D scene with the help of some special server extension. The 3D scene is then sent to the VR browsing client and displayed properly. As the dynamically constructed 3D scene is interactively browsed (Hemmje, 1999), users can interact with certain objects of the surrounding environment, which, in turn, may need to get additional data from the database storage mechanism. If, for example, the user enters an area in which the data about exhibited products have not been incorporated yet, they have to be retrieved, downloaded, and integrated into the scene via the client runtime access mechanism. Furthermore, as soon as any data manipulation action is performed on the database storage mechanism, which affects the data visualized in the running 3D scene, an immediate notification of the client has to be performed to which the clients 3D environment can, in turn, react. The runtime communication and notification mechanisms do not necessarily have to go directly from the client system to the storage system. It is possible (and in many cases appropriate) to handle the communication through an additional middleware layer. The technical details of the system implementation are described in (FAIRWIS Consortium Deliverable2, 2001).

An Architecture of an Electronic Education Market Using XML-Standards

Jan M. Pawlowski, Markus Bick, Patrick Veith
Information Systems for Production and Operations Management, University of Essen, Germany
{jan.pawlowski|bick|veith}@wi-inf.uni-essen.de

Abstract: In this paper, we describe the conceptual architecture of an Electronic Education Market based on XML standard specifications for business processes and educational processes. This architecture supports the interoperability and portability of processes for educational companies and institutions, acting on the global marketplace of the WWW. The architecture is divided into two levels: Level 1 covers general trading transactions, whereas Level 2 covers specific educational transactions. We show how development and learning processes are supported, increasing the productivity of actors in educational processes.

Electronic Markets for Education
The Electronic Education Market (EEM) describes the interorganizational information systems for educational purposes (see Hamalainen, Whinston, & Vishik, 1996). Business transactions and educational processes are supported on different levels. On the one hand, trading processes for educational resources are supported. This includes the trade of educational products and services, such as courses, trainings, or information services. On the other hand, the design and development of educational materials are supported. The term Educational Mall is used synonymously to EEM.

An Architecture for Electronic Education Markets
In this section, we describe the architecture for an Electronic Education Market on two levels. First of all, we describe the use of general E-Commerce standards for the trade of products and services. These standards support general trade transactions, such as procurement, shipping, or billing. These trade functions can be used by E-Markets in general and were not specifically designed for educational purposes. Secondly, we show how educational transactions are supported. Examples of specific educational transactions are: concurrent design of educational resources, course retrieval, or handling of virtual courses.

EEM Architecture: Trade transactions
E-Markets in general cover both, the requirements of suppliers and their customer. Our example focuses on the negotiations between customer and supplier. These negotiations include the payment, terms of delivery, and product specifications. E-Markets add a different aspect to the traditional concepts as they have to incorporate the demands of Internet services. Especially the identification of trading partners and the security of Internet payment need more attention due to the anonymity of the medium Internet. Figure 1 shows a Use Case diagram with the processes involved in Level 1 of the architecture. This document focuses on the negotiations of payment and services between Educational Malls, its suppliers, and its customers. The main processes, exchanging data through standardized XML-documents, are registration, catalog handling, negotiations, ordering, and payment. Those transactions are performed using Electronic Business XML (ebXML), Electronic Commerce Modelling Language (ECML), and eCatalog XML (eCX) for the implementation of this layer. For further information see (EbXML, 2001, ECML, 1999).

Figure 1: Trading processes for an Electronic Education Market (Level 1)
EEM Architecture: Educational transactions

The second level (Level 2) of our architecture covers educational transactions. For developers, teachers, and learners the interoperability of learning environments and learning management systems is a critical success factor in the future. The trading processes are covered by level 1 of our architecture, on level 2 the following transactions are supported by the following standards:

- **Learning Object Metadata (LOM)** is a standard by the IEEE Learning Technology Standardization Committee (LTSC) to describe computer supported learning resources, such as courses, tools, multimedia objects (IEEE LTSC, 2001). **Computer Managed Instruction (CMI)** supports the interoperability of learning management systems. Different course types are administered, steered, and used by a central system. In our case, the administration is performed by a system provided by the EEM. The standard **Public and Private Information for Learners (PAPI)** contains information about actors in educational processes, such as personal data, user characteristics, or performance information. In our architecture, the learner model is controlled by the user who authorizes the use by the EEM and other systems. **Content Packaging** provides methods for the description, implementation and packaging of learning materials used independently of authoring system, platform, or system. **Question and Test Interoperability (QTI)** is a format for description, implementation, and transfer of performance monitoring of the learner (see IMS, 2001). The **Enterprise** specification provides an exchange format between learning systems and other information systems, such as HR systems. Finally, a **Quality Standard** defines the management and operative procedures in order to ensure the quality of learning systems used in the EEM. In our system, we use a standard based on ISO 9000:2000. The use of those standards for both, development and learning processes, is summarized in Figure 2.

![Figure 2: Educational processes for an Electronic Education Market (Level 2)](image)

Summary

In this paper, we presented an architecture of an Electronic Education Mall using XML-bindings of standard specifications. Our approach allows the integration of business functions by using standardized XML formats for data exchange between participating systems. This approach enables participants to significantly reduce transaction cost by the integration of their systems. For further information about this approach see (Pawlowski, Adelsberger, 2001).

Developing More Effective Access to Higher Education for People With Disabilities:  
A Case Study in the Design of Accessible Online Courseware

Abstract: Universities are under increasing pressure to recognise the rights to effective access of people with disabilities. The use of web based courses and resources presents an opportunity to broaden participation by offering flexible learning and independence, but also presents an additional challenge for the course developer when designing programs and developing courses. This paper discusses an evaluation of an online learning environment (WebCT) in practice at the University of New South Wales. Issues considered included compatibility with assistive technologies; structure, presentation and organisation of content and navigational elements; and the provision of alternative information for people with sensory, cognitive or physical disabilities. The results show that many barriers to accessibility can be overcome through the employment of learner centred design principles, and by taking advantage of the features provided by the learning environment. This paper will discuss the results of the evaluation, issues raised and potential solutions.

Introduction

In an atmosphere of growing demand for flexible provision to meet the educational needs of an increasingly diverse population, technology is now widely used in the provision of courses and resources. Online Learning Environments (OLEs) present the opportunity to exploit technology to create educational materials which are flexible, informative and accessible to individuals who may not otherwise be able to participate in Higher Education.

Institutions worldwide are adopting tools to enable academics themselves, rather than specialist technologists to develop courseware for use online. It is essential to encourage and empower academics to produce courseware which is accessible pedagogically, structurally and to users of adaptive technologies. The rationale for this project is to present a case study of best practice in the development of online courseware, which is accessible to people with a wide range of special needs. The particular package on which the study is based is WebCT.

Evaluation Methodology

To identify the issues and possible problems, an evaluation was carried out, with the consent of the designers concerned, of WebCT courses developed at UNSW. The process took a combined approach based upon:

- Extensive analysis by the researcher (Elaine Pearson) of WebCT courses at UNSW
- Discussion with and survey of WebCT Designers
Interviews with students and practical evaluation by students of the accessibility of courses using Assistive technologies

The evaluation was based on the guidelines provided by W3C “Web Content Accessibility Guidelines 1.0” and analysis of the courses using the Bobby (http://www.cast.org/bobby) validation tool. In addition, evaluation of a learning environment which takes account of the requirements of those with sensory and learning disabilities requires analysis of the structure, presentation, content and navigational aspects. For this the principles of learner centred courseware design were employed. A model of courseware design that combines content design, navigational design and visual design, and is informed at all stages by the learner model (Pearson and Green, 1999) is the one on which this evaluation is based.

Evaluation Results

The results of the evaluation can be divided into generic issues relating to the design of the courseware and issues relating specifically to the WebCT learning environment itself. The major problems encountered in courseware design included inconsistent and inappropriate use of icons or graphics; no text equivalents for graphics, figures or other illustrations; poor organisation of content which was originally intended for face to face delivery; the widespread use of PDF and other read only file formats for the presentation of text documents; text, abbreviations and unusual characters may not be correctly or accurately interpreted by screen reading software; the inappropriate use of tables; poor interface design and poor use of colours.

Whilst it is WebCT’s stated aim to be compliant with the W3C accessibility guidelines, some problems remain. There does not appear to be a text equivalent for some icons, headers and titles; the inappropriate use of tables; the overuse of frames; and the use of Applets and Java for the implementation of some of the interactive elements of WebCT, including chat windows, discussion groups and email.

Conclusion

The increasing use of the Web for teaching and learning provides an opportunity for inclusion of people with disabilities who may otherwise be prevented from full participation. However, it is important for developers of online courses to be aware of the difficulties that people with disabilities may face within such an environment. The danger is that the technologies designed to increase flexibility and participation could become a barrier in themselves. The adoption by UNSW of WebCT for the development of online courses has facilitated an analysis of accessibility problems within an active academic community and the development of a practical strategy for the design and development of online courses.

A blueprint for the design of accessible courseware has been produced that will enable academics developing online courses in WebCT to take account of the needs of students with particular needs. This in itself will result in learner centred courseware that is more accessible and more effective for all students. The move to online learning prompts academics to reconsider teaching and learning practices for all students, and although one cannot expect to meet the needs of all learners at all times, reasonable steps can be taken to ensure inclusive practice.

Technology at the Cutting Edge:  
A Large Scale Evaluation of the Effectiveness of Educational Resources

Abstract: The perceived effectiveness of traditional and computer-based educational resources, within the context of a single course in first year biology, was investigated within an action-research paradigm. The study examined the dynamic state of perceptions towards these resources by the major stakeholders involved (students, teaching staff and technical staff). A major focus of the research was the extent to which the computer-based resources were utilised, and the students' perceptions of the usefulness of these resources to their learning. The majority of students found the resources to be of use for their learning but some did not use them at all, even though they had access to the Internet, suggesting that the provision of on-line resources will not necessarily generate value-added learning.

Introduction

At The University of Sydney courses are still campus-based and students attend lectures and laboratory sessions in most weeks of the semester. In first year biology the development of educational multimedia to address the diversity of student characteristics, the ethnic/cultural sensitivities to animal dissections and specific learning difficulties has led to a focus on the use of computers in the learning process. This in turn has led to the development of an on-line virtual learning environment (http://fybio.bio.usyd.edu.au/vle/1.1/) enabling the students to access our resources anywhere/any time. The development of this resource is discussed in Peat, (2000). The current study examined one of the first year courses, Human Biology, which integrates a range of computer-based learning modules, on-line materials and communications strategies with more traditional learning resources such as lectures and practical sessions, designed to cater for a variety of learning styles. The purpose of this study was to provide both a reflective and analytical assessment of a broad range of learning resources integrated through web-based technology and determine their impact on student learning. A major focus of the evaluation was the extent to which the computer-based resources (educational multimedia and information technologies) made available to the students were utilised and the students' perception of their usefulness to their learning. To achieve this, an action research model was implemented with all stakeholders contributing to the collection of data to enable assessment of the learning environment from all perspectives.

Methodology

The research model adopted the Eclectic-Mixed-Methods-Pragmatic Paradigm (Phillips, et al., 2000) considered more capable of handling the complexity of modern society and technology with a focus on practical problems rather than issues, whilst acknowledging the weakness of current evaluation tools. The overall study was based on the dynamic state of the perceptions of the major stakeholders involved in the course, whilst this paper focuses on the students' perceptions of their use of educational multimedia and communications technologies within an integrated curriculum. The stakeholders included students (n=up to 800), lecturers (n=5), laboratory teaching staff (n=20), technical staff (n=3), and courseware developers (n=2). The target population of students is typically recent high school leavers enrolled in science-based degree programs. The student body has become increasingly diverse over the years, with respect to culture, academic achievements, literacy and science backgrounds as well as extra-curricular activities such as paid employment. The overall data collections
involved all stakeholders and data were collected at four separate intervals, using surveys, interviews and/or focus groups. Data from the preceding survey were used to design the subsequent instruments.

Results and Discussion

The results to be described in the conference presentation will focus on the major factors emerging from the research process and examine each of the following aspects:

- student use and perceptions of the Internet, access to on-line materials and views of communications technologies;
- student perceptions about using on-line tutorials in general; and
- student use (specifically) of virtual dissections versus real dissections.

Nearly all students in this course (99.5%) have access to a computer, with 98.5% of all students indicating access to the Internet (84% access at home), however there appears to be competition within the home for access to the Internet line (36.5% of students indicating competition from siblings or parents). Whilst general access to computers and the Internet is good, there is some concern within the student body about access to the biology resources for this course on the Internet due to technological reasons. It appears we can provide the resources but we need to be careful that we match them with student technological abilities and experiences.

The data show that 20% (200 in the cohort) of the students are not using the Internet as a resource for this course but of those that do use it 55% indicate it is useful but not extremely useful. The overall student use of email was high, with 97% of all students surveyed indicating some use (mostly non-course related), however only 10% of the entire cohort found email useful in supporting student learning in this course. Only 75% of students made use of the computer-based tutorials provided to support their learning, but the majority (91%) of those students that did use the materials found them useful. This reinforces the idea that within the student cohort there is a variety of learning styles, which require the provision of a diverse range of learning resources, both on-line and off-line. Oliver & Omari (2001) reported a similar lack of uptake of web-based teaching with 20% of students not comfortable with using the web as their learning environment. The reason for this lack of uptake needs to be investigated before putting a large proportion of teaching and learning resources on the web. From a curriculum development viewpoint it was important to gain an understanding on the relative usefulness of animal dissections and virtual dissections to student learning outcomes which would help inform the debate about the replacement of animal cadavers in student laboratories. Many of the students remarked on the usefulness of both the cadaver and the virtual dissection, indicating that the former was probably more useful for understanding structure and the latter for function, illustrating how different media can be used for different inputs/outcomes. The data, however, indicate that there is little difference between the two types of instruction.

Initial data from this study indicate that there are students who embrace educational multimedia and information and communications technologies and who will find these learning experiences valuable. However, there remains the issue that some students do not find them useful and this reinforces the need to offer a variety of materials on offer. It reminds us that we cannot use on-line as a replacement but we can use it effectively in the teaching program. It is important to remember that the student body requires a variety of learning experiences that not only include the new technologies in teaching and learning but also the more traditional resources. The outcomes reinforce the need to offer a variety of learning experiences that target different learning styles and enable a mix of off-campus and on-campus opportunities.

Maria, Regueras, Univ. of Valladolid, Spain;

TELEADAPT-SOCINF was an ADAPT project starting in January 1999 and finishing in October 2000, and co-funded by the European Social Fund, the regional government of Castilla y León and the Centre for the Telecommunication Development in Castilla y León (CEDETEL). In this project CEDETEL collaborated with the Institut für Technische Weiterbildung (ITW) and the Fachhochschule für Technik und Wirtschaft (FHTW).

The objective was to offer continuous training to the Small and Medium Sized Enterprises in the areas of Castilla y León in Spain and Berlin in Germany.

For this purpose we implemented a virtual learning space and several CDROM-supported hypermedias. The interdisciplinary group that worked in this project included technology experts, graphical designers, pedagogues, etc.

During nearly four months we run different groups of students, which gave us the opportunity to evaluate the materials and the telelearning experience itself. Most of the participants appreciated the advantages of this new methodology.
HURAA: An Interactive Web-Based Agent That Optimizes Information Retrieval in a Multi-media Environment

Abstract: The Computational Discourse Technologies Group is developing the Human Use Regulatory Affairs Advisor (HURAA). HURAA is a web-based information delivery and retrieval system that includes an animated agent that guides the user through six distinct learning trajectories. HURAA exhibits different patterns of interactions depending upon the trajectory the user selects. The knowledge base of the HURAA includes various documents on Institutional Review Boards taken from federal, civilian, and military sources. After a brief introduction and overview of the system, the six learning trajectories are described. The learning trajectories are as follows: (1) Historical Overview, (2) Lessons, (3) Explore Issues, (4) Explore Cases, (5) Making a Decision, and (6) Query Documents. Additional sections of the paper describe the other major components in the HURAA system.

Introduction

The Human Use Regulatory Affairs Advisor (HURAA) is being developed by an interdisciplinary team of cognitive psychologists, computer scientists, and engineers, who are affiliated with the Computational Discourse Technologies Group. HURAA is designed to help users learn the policies and regulations that pertain to using human subjects in research that is funded by the U.S. Department of Defense. The major components in HURAA include a multi-media interface, Dialog Advancer Networks, Learning Trajectories, Latent Semantic Analysis, and Sharable Courseware Object Reference Model (SCORM). The information in the HURAA database includes numerous military and historical documents that provide guidance about current policies to researchers, decision makers, military personnel, and civilian members of Institutional Review Boards (IRBs). Given that numerous persons must review a research protocol prior to its approval (e.g., DoD personnel, battalion commanders, or civilian IRB members), users are asked to specify their jurisdiction prior to the beginning of the interactive session.

Overview of HURAA

Once at the HURAA website, the user provides a user-name and password, and then selects from a list of user profile categories and purpose-of-visit options. Next the user views a brief Flash movie introduction that provides some historical information and describes the importance of the Belmont principles of beneficence, justice, and respect for persons participating in research. Some of history’s worst cases of human subject abuse, such as the Tuskegee syphilis study, the Willowbrook study, and Nazi concentration-camp research, are also highlighted in the introduction. After the introduction, the HURAA agent appears and describes how to navigate the interface and how to explore the various learning trajectories. The agent and the learning trajectory home page are presented in Figure 1. The six learning trajectories that users may choose to explore are as follows: (1) Historical Overview, (2) Lessons, (3) Explore Issues, (4) Explore Cases, (5) Making a Decision, and (6) Query Documents. Once the user selects a particular trajectory, the agent provides navigational guidance via synthesized speech and simple head movements. The user is free to switch learning trajectories at any time during the session. The interface also includes eight additional navigational and informational options that users can utilize at any time during the session (see Figure 1, Note: to view all eight options the user must use the scroll bar). Some of these options are a glossary search, links to other relevant websites, and a bibliography link.
The Components of HURAA

Dialog Advancer Networks

A Dialog Advancer Network (DAN) is a mechanism that manages the interactions that occur between a user and HURAA. A DAN allows the agent to micro-adapt each dialog move to the user's navigational choices. HURAA contains several DANs that include customized (i.e., trajectory-sensitive) pathways that are tailored to each of the six learning trajectories. A DAN includes a large number of potential pathways that terminate in a particular Advancer State. The Advancer States prevent navigational uncertainty of the user by including dialog moves that instruct the user what to do next. In earlier research, we found that conversation management is a particularly difficult task in automated tutoring sessions in the absence of a DAN (Person, Bautista, Kreuz, Graesser, & TRG, 2000).

Before the user selects a learning trajectory to explore, the agent relies on a generic DAN to help the user make choices. Specifically, the generic DAN provides the user with brief descriptions of the learning trajectories and navigational options when the user mouses over a particular option on the interface. For example, when the user mouses over the "Glossary" option (see Figure 1), the agent says, "Find the definition of a word." It should be noted that the agent, the learning trajectory options, and the other navigational options are constant features on the interface, and the user can select any of these options at any time.

Most of learning trajectories have distinct ways of presenting information to users; therefore, it was necessary to create several trajectory-sensitive DANs in order to provide the user maximal navigational guidance (e.g., Johnson, Rickel, & Lester, 2000). The generic DAN encourages the user to select one of the learning trajectory options, and once the user makes a selection, one of the trajectory-sensitive DANs takes over.
For the most part, the trajectory-sensitive DANs contain dialog moves that help the user navigate the information that is included on each page of a learning trajectory. For example, the agent may say something like, "To learn more about a particular issue, click on the corresponding bullet" or "You can search an original document by selecting the 'Ask Question' option on the bottom of the screen" or "You can review a relevant case study by selecting the 'Show Case' option." The system currently has approximately 700 pages through which the user can navigate.

The Six Learning Trajectories

Historical Overview. The first learning trajectory located directly under the agent is the Historical Overview trajectory (Note: The Introduction option is not a learning trajectory; this option allows users to here the Flash movie introduction again). When the user selects Historical Overview, a bulleted list of historical documents and information appears (e.g., the Nuremburg Code, the Declaration of Helsinki, and the Belmont Report). The DAN for this trajectory contains dialog moves delivered by the agent that inform the user as to what to do next. For example, the agent might say, "Learn more about the Belmont Report by clicking here." This trajectory is primarily an information delivery trajectory that helps the user learn about the historical events that led to the development of current policies and regulations regarding human subjects use.

Lessons. First-time users are encouraged to work through the Lessons trajectory first. This trajectory introduces the user to seven critical issues that are derived from the three major principles in the Belmont Report (Emanuel, Wendler, & Grady, 2000). When the user enters this trajectory, the agent tells the user to select Lesson 1. In Lesson 1, the user is introduced to the seven critical issues that all persons involved in human subjects research must know. After the user reads the seven critical issues, the agent instructs the user to select a specific historical case (i.e., Tuskegee Syphilis Study) to read. After the user reads the case, the user is presented information about how the seven critical issues were violated in the historical case. The agent then instructs the user to select the next lesson (Lesson 2). The user then reads about a particular case study and must identify which of the seven issues are problematic in the case. HURAA then provides the user with feedback on the issues that the user has selected or has failed to select. The Lessons trajectory contains two more lessons that continue in this manner: the user reads a case, the user selects the issues that are problematic, and the Advisor provides feedback to the user.

Explore Issues. When the user selects the Explore Issues option, HURAA presents a page containing bullets that correspond to the seven major issues discussed in the previous section. The information in the Explore Issues trajectory is presented to the user in a three-leveled hierarchy. The seven critical issues are presented at Level 1. Level 2 includes specific "Topics" related to each of the seven issues. Level 3 contains very specific "Points" related to the Level 2 “topics.” The agent guides the user’s navigation through the three information levels. In this trajectory, the user has options to view relevant case studies at Levels 1 and 2. The agent will remind the user of the “Show Case” option when an issue-related case is available. The agent also reminds the user of an “Ask Question” option by saying something like, "You can enter a question and search an original document at any time.”

Explore Cases. When the Explore Cases option is selected, bullets that correspond to ten controversial case studies are presented in the content window to the user. The agent instructs the user to, "Select a case study to read, and then test your knowledge of the seven critical issues by selecting the 'Test Your Knowledge' button at the end of the case." On the "Test Your Knowledge" page, the seven critical issues (see “Explore Issues” section) are presented to the user. The agent instructs the user to select the problematic issues for the case that the user just finished reading. Once the user makes the issue selections, HURAA provides feedback on the user’s selections. Correct responses are denoted with exclamation marks, and incorrect responses are highlighted in red and denoted with question marks. When users make errors (i.e., misses and false alarms), HURAA provides additional feedback when the user mouses over a particular problematic issue.

Making a Decision. This learning trajectory is designed to help users who need to make a decision about a particular research protocol. Once the user selects this trajectory, a bulleted list of nine distinct research areas appears in the content window. The nine research areas included in this trajectory are General Consequences, Basic Biomedical Research, Drug and Vaccine Trials, Radioactive Materials and X-rays, HIV/AIDS Studies, Human Genetic Research, Drug and Alcohol Studies, Behavioral and Epidemiological Research, and Training and Weapons
Development. The agent instructs the user to select the research area that most closely resembles the protocol under consideration. Users are then encouraged to explore the content related to the selected research area.

**Query Documents.** The final learning trajectory in the current version of HURAA is Query Documents. When this option is selected, the user is presented with a number of specific types of documents that are related to human subject use in research (e.g., the IRB Guidebook, Army regulations, Codes of Federal Regulations). The agent tells the user, “You can search any of these documents by clicking the box next to the document.” The user can search one and any combination of documents by entering a question in English. Once the search is completed, the agent says, “Look below the dialog box for the results of the search.”

**The Multi-Media Interface**

**The Flash Introduction.** Before the interactive session begins, the user views a Macromedia Flash Movie introduction. The Flash introduction is designed to accomplish the following: (1) reduce the volume of text the user has to read, (2) drive home the purpose of visiting the HURAA site, and (3) grab the user’s attention with an engaging presentation of historical information. It is delivered documentary style with striking graphics, bold text highlights, and a professional voice-over. Actual case photographs are used when available along with supplementary conceptual photos to create a dramatic effect.

**The Animated Agent.** Animated agents are beginning to appear on a number of websites and in web-based learning environments. The animated agent in HURAA is a female persona that remains on the screen throughout the interactive session. The agent was created in Curious Labs Poser 4.0 and is controlled by Microsoft Agent.

**Point and Query.** Within the Historical Overview and Explore Issues trajectories, a Point and Query (P & Q) option is available for most bullet options. By clicking on a question mark next to the bullet options, users are presented with a list of one to five questions that reiterate and expand upon the information available in the trajectories (see figure 2). The user clicks on any of the questions, and an answer for that question appears at the bottom of the screen. The P & Q option allows the user to quickly and easily ask the system sophisticated questions and receive accurate answers to those questions. Previous research (e.g., Graesser, Langston, & Baggett, 1993; Langston & Graesser, 1993) demonstrates that such interfaces are very usable and are very effective.

**Figure 2. Point and Query on Interface.**

---

1529

---

Page 1479
The Interactive Options. As mentioned earlier, there are six learning trajectory options on the interface and eight other informational options that are always available to the user (see Figure 1). Some of the learning trajectories are designed specifically to get users to actively engage with the content (i.e., Lessons and Explore Cases). Other learning trajectories present the user with hierarchically structured text, and users are encouraged by the agent to “drill down” through the content of the information. In addition, the agent frequently reminds the user of other exploration options. For example, the agent may remind the user to submit a question about the content or review a case study relevant to the issue or topic at hand.

The other eight informational options are provided directly below the six learning trajectory options on the interface. These options are as follows: (1) Glossary (2) Archives and Links, (3) Module Descriptions, (4) Replay Video, (5) Bibliography, (6) Systems Requirements, (7) Help, and (8) Log Out. When the user mouses over these options, the agent provides the user with brief descriptions. Users are free to select these options at any time during the session.

The remainder of the interface, basically the center and right side of the screen, is the content area. This is where all of the content-sensitive information is presented to the user when one of the six trajectory options is selected. There are two navigational options that are always available on this part of the interface, “Next,” and “Previous.” These options take the user to the next page or to the previous one; such buttons are standard on most web browsers.

Latent Semantic Analysis (LSA)

At any point during a learning session, the user may ask a natural language question about Institutional Review Board practices and procedures and DoD guidelines. This knowledge in HURAA is represented by LSA (Hu, Graesser, & TRG, 1998; Landauer, 1999; Landauer & Dumais, 1997; Landauer, Foltz, & Laham, 1998). LSA is a statistical procedure that compresses many text sources into a space of approximately 100 to 500 dimensions. The LSA text space in HURAA includes the texts from a variety of government, military, and civilian documents, plus a corpus of approximately 15,000 question-answer pairs. In most applications of LSA, a geometric cosine is computed to assess the conceptual similarity between any two sources of text. These cosine values range between 0 and 1 with higher values indicating more conceptual similarity. In HURAA, one text source is the user’s input (e.g., a specific issue, case, and/or a natural language query). The other text source is the LSA text space mentioned above. For example, when a user submits a question to HURAA, LSA is used to locate text segments from the particular documents that the user specifies (e.g., the IRB Guidebook, Army Regulations, etc.) that are most relevant to the user’s question. The five text segments with the highest conceptual overlap (LSA cosine value) are displayed for the user.

Sharable Courseware Object Reference Model (SCORM)

The information content in HURAA is organized to meet the requirements specified by the Sharable Content Object Reference Model (SCORM). SCORM is an attempt by the DoD’s Advanced Distributed Learning (ADL) Initiative to develop a standard model for representing on-line information that can be utilized by various information technologies. It is proposed that SCORM will transform education and training in the military. The goal of the ADL Initiative is to provide a reference model that will enable developers to reuse courseware materials and instructional components in multiple applications and environments, regardless of the tools used to create them. Minimally, this requires that the instructional content be separated from context-specific run-time constraints so that the material can be incorporated into other applications. SCORM defines a common interface and data schemes for reusable content units (see URL adlnet.org). In order for SCORM to work successfully, there must be a standard way to depict content and a standard way for content to communicate with a learning management system (LMS).

Currently, SCORM consists of three main specification sets. One is an XML-based specification set for representing content structures. This permits course content to be moved from one server/LMS to another. The second is a set of specifications relating to the run-time environment, including an API, content-to-LMS data model, and a content launch specification. The third is a specification for creating meta-data records for courses, contents, and raw media elements.

Using interactive comics for energy-education through the web

Katja Pesonen
katja.pesonen@tut.fi
Tampere University of Technology, Digital Media Institute
Department of Mathematics, Hypermedia Laboratory
P.O. Box 692, FIN-33101 TAMPERE, FINLAND

Abstract: This article introduces Energy!, which is a hypermedia based open learning environment accessible through the computer networks. Energy! is a product of a pilot project called Energy for Schools. The pilot project was organised in 2000 by the Hypermedia Laboratory of the Digital Media Institute, Tampere University of Technology. The target group of Energy! are the learners aged 13-18 studying energy issues. This article firstly describes the background to the Energy for Schools pilot. Secondly it presents the technical platform, A&O, which was used in Energy! The article goes on to introduce the Energy! learning environment; its pedagogical background, and its various content materials. Finally, the article reports the learning experiment and its main results. In conclusion an evaluation of the role of technology-based learning environments in energy-education is presented.

Background of the Energy for Schools pilot project

Energy for Schools was one of the pilot projects of the Open Learning Environment (OLE) project, organized by the Hypermedia Laboratory of the Digital Media Institute, Tampere University of Technology in Tampere, Finland. The OLE project is part of the national User-Oriented Information Technology USIX programme (1999-2002), and is principally funded by the National Technology Agency (TEKES) and a number of Finnish enterprises.

One central purpose in the OLE project is to produce a pedagogically sound and technically functional learning environment, called A&O. A&O supports user authentication and offers tools for data management facilities, hence the content material of Energy! was located there. A&O provided to the use of Energy! the communication and collaboration tools, and also user-friendly tools for producing hypermedia material. The content material of Energy was produced in a team. This consisted mainly of teachers and learners on the Degree Programme in Environmental Management. The graphic figures of the comics were drawn by a 16 year old learner.

Energy! is a product of co-operation between some teachers of the Tampere Region, representatives of the Tampere Energy Agency and researchers of the Hypermedia Laboratory. The Energy for Schools pilot project was funded by the Tampere Technology Centre Ltd and TEKES. The pilot project was finished at the end of January 2001, but the content material made during the pilot project is available on the web-pages of the Tampere Energy Agency at the address <http://www.hermia.fi/energia/energiaa/>.

A&O, the technical platform of Energy!

A&O <http://ao.tut.fi/demo> is an open learning environment accessible via computer networks, especially over the Internet. Thus A&O offers the learner an opportunity to study independent of time and place. It supports both self-paced and collaborative learning. A&O is open not only to various learners in schools and in universities but also to public and private organisations. It can be used in education with young as well as with mature learners, moreover A&O is an exploitable open learning environment for different content materials. It has been tested with content materials of advanced environmental and energy education, with matrix algebra at the University of Technology and with adults in the seamless service chain in health care. (Pesonen 2000, Pohjolainen et al. 2000.)

The main goal of the A&O learning environment is to be both pedagogically appropriate and technically functional. It has been designed on the basis of modern learning theories that emphasize the construction of new knowledge on the basis of previous knowledge, when the learners' active role and
collaboration with other learners are essential in the learning process. In addition to these, the learners’ intentions, meaningful learning context and transfer play an essential role in A&O. (Pohjolainen et al. 2000.) Constructivism is the central pedagogical idea of Energy!. Learners’ active role, construction of new knowledge, meaningful learning context and the transferrability of matters learned were the essential aspects in the process of developing content material for Energy!.

Energy! an interactive, open learning environment

The purpose of Energy!

The fundamental aim of the Energy for Schools pilot was to produce a web-based learning environment. The aim was increase learners’ awareness in energy matters. Another essential aim was to motivate learners to save energy in their daily routines. The aim was not only to enhance learners’ knowledge but also to encourage them to action. The studying atmosphere in the Energy! learning environment was to be positive and inspirational, not judgemental.

The format of the content material in the Energy! learning environment is comics, because they are closely connected to everyday situations and can therefore reach young people better than, for example, books. Gravett 1990 came to the conclusion that 40-50% of young people aged between 16 and 20 rarely read a book, but the majority of them read comics (Shelwood & Irving 1999, xiii). Energy matters are complex and multidimensional. They are a combination of values, beliefs, attitudes and choices. Therefore the dialogues between the comic figures are an excellent way to illustrate the different aspects and opinions in the energy matters in narrated comics. The greatest challenge in creating Energy! was to enable learners’ active role when studying energy matters. The dilemma was solved by creating an interactive learning environment in which learners could participate by considering, debating and making choices in energy matters. The choices the learners made directly influenced the continuation of the content material.

The pedagogical background

The pedagogical background of the Energy! learning environment is a combination of three ideas: learning with technology, comics in education and problem-based learning (PBL). This synthesis constitutes a context for interactive technology-based comics, and offers the learner an active role. The theories of learning with technology and problem-based learning emphasize the learner’s active role in the learning process. Thus these theories provide the most extensive pedagogical background for the Energy! learning environment. In general comics in education are criticized for putting a reader in the passive and uncritical role, but technology-based interactive comics can refute these critics. The technology-based interactive comics offer the learner an active role when using the content material. The learner is open to influences when he/she reads the comics, because there is always something between two panels, and the reader fills them with his/her imagination. This is the case in all reading, not even texts have only one correct interpretation. (Selwood & Irving 1999.)

Learning with technology

"Students learn from thinking... Technologies can foster and support learning...if they are used as tools and intellectual partners that help learners to think." Jonassen et.al. (1999,2) describe the role of the technology in the learning process. Learning with technology, not from technology, was the main idea in designing the Energy! -learning environment. Learners construct knowledge themselves in their learning processes, but technology can be a very useful tool to support those processes. Learning with technology is based on constructivism, which emphasises the activity of the learner in the learning process.

Learning with technology offers an opportunity to ascertain the different needs and interests of the learners. The technology-based learning environments open up the possibility to differentiate the content material to different users needs. Learners try to find the substance of the matter during the process of learning. Every learner structures knowledge on his/her personal experiences, which are not automatically replaced or transformed. Thus gaining the substantial knowledge from the information is a personal process. Therefore there are as many perspectives on the matter as there are persons considering it.
With the technology it is possible to simulate the real environment of the matter at hand in the learning situation. The simulated, familiar context motivates the learner and facilitates the adoption of new knowledge in the learning process. The transferability of the learned knowledge is easier when the context of learning is familiar. Understanding the substantial knowledge has an affiliation to the learner's wider social context in various ways. These aspects in learning with technology should help learners not only to recognize and solve the problems but should also guide them to critical thinking. (Jonassen et al. 1999, Kotilainen & Hankala 1999.) Understanding critical thinking helps learners to realize that there are various aspects to problems and not necessarily only one right answer.

Learning with technology empowers the interaction for the learner in various levels, which enables learners' interaction with peers, teachers, experts, tutors, mentors, computers etc. In the Energy! learning environment the technology offer learners more personal perspectives on content material with narrated comics. To be more precise the choices the learner makes in the material direct the following information in content material.

Comics in Education

Comics are visual storytelling; where texts and effects are added to bring more meaning to the visual story (Packalen & Odoi 1999, 8). The story plays the central role in comics, but the context must also be taken into account. The comics visualize the culture and wider social context of their audience, otherwise they may cause confusion for the reader. For example, energy education in Africa or in Scandinavia differ greatly from each other. On the other hand the comics from strange cultures can provoke readers'curiosity, for example school children are very enthusiastic about getting information on other cultures through comics as Packalén and Odoi (1999, 15) state. (Harrison 1981.)

Comics have been used effectively in education for decades. Already in 1913 "Mr Block" taught workers the message of industrial unionism (Selwood 1993, 41). In the classrooms comics are used to teach learners writing skills, awareness of value system, health education, relationships etc. The effectiveness of comics was compared to text, illustrated text and text with photos in educating preventive maintenance during the Second World War by the US Government. The best understanding was attained with comics. Much of the effectiveness of comics appears to ride on emotion. (Selwood 1993, 41.) Comics are an excellent way to visualize the communication and different aspects and attitudes. Comics connected to technology offer new possibilities; learners' affective, cognitive and psychomotor capacities can be supported by creating the learning environment with technology. (Alamäki 1999, 78).

Based on the facts presented on comics in education, narrated comics offer an excellent way to introduce different aspects of energy matters. In the comics the texts of the dialogues are short and thus excellent content material for technology-assisted learning. In addition dialogues offer more than the formal information and can therefore simultaneously include information about emotions and feelings.

Problem-based Learning (PBL)

Problem-based learning (PBL) is a way to think about knowledge, understanding and learning. Problem based learning supports the pedagogical idea of constructivism and especially the active learner with his/her ideas and perspectives. It supports the construction of knowledge from the learners own perspective. Problems and personally needed answers govern the construction process of the content material. Problem, disagreement or dissonance between new and previous knowledge in a certain context facilitates the process of problem solving. The primary idea of PBL is to find and use the core, essential information for problem solving. Problem-based learning supports the integration of disciplines in the problem solving processes, and thus presents a different aspect in processing the information if compared to many other learning theories. For example, when studying the greenhouse effect with PBL, studying is not limited to the facts of biology. Chemistry, geography etc. are integrated into the learning process. According to problem-based learning the process of studying should be investigative, critical, reflective and active. (Boud & Feletti et al. 1997.)

The Energy! learning environment includes the applied ideas of PBL. In it learners may independently retrieve the information needed through the link-words and get to know the theory of the themes. The construction of the content material originates in the target group's interests.
The content material of the Energy! learning environment

The content material of the Energy! web-based learning environment consists of five different areas: beginning, narrated comics, knowledge forum, hints for energy saving and conclusion. The style and the meaning of these areas differ greatly from each other.

![Image](image1.png)

**Picture 1.** First page of Energy! showing the comic figures acting in the narrated comics.

Picture 1 introduces the front page of the Energy! learning environment. The left side of the page introduces the areas of Energy! and is also for navigation. The picture on the front page illustrates the characters in the narrated comics. Every figure has different knowledge and attitude towards energy matters: One is very enlightened in energy matters, another is definitely not, one knows something but does not act like that, someone acts energy-friendly through being poor, someone wants to act better in energy matters, but does not know how. These aspects are represented in the dialogues of the narrated comics.

**The beginning**

At the beginning the learners are motivated to use the Energy! learning environment by testing their energy attitudes and behaviour with a ten-point scale. As a result of the test learners are stereotyped to one of the six comic figures. When the learner has finished the test he/she is informed with a portrait of his/her comic figure with the comment: "Your energy choices are closest to my choices!". Learners may read more about their figures if they are interested.

After the beginning using the Energy! learning environment may be guided precisely (by the teacher or the curriculum) or by the learners' own interests, which guide their learning processes. After the beginning the available content material consists of: knowledge forum, narrated comics on four topics and energy saving hints.

**The narrated comics**

The learners are guided to the energy issues by the dialogues of the narrated comics. In the dialogues six comic figures discuss energy matters, attitudes etc. The figures have different attitudes towards energy consumption. The narrated comics are about: clothing, food, leisure and traffic. All of them include: dialogues of the topic and link-words with more detailed information about the matter. Between the pages of the narrated comics there are the questions concerning learner’s knowledge and attitudes to energy matters (see Picture 2). After the answer the learner receives the reaction and the infobox with the specific information about the theme question. Studying with the comics requires activity on its part of the learner, because before getting
information or progressing in the comics, he/she has to make choices, complete groupworks etc. In the comics every theme is followed by the gallows game with which learners can test what they have learned about a certain topic. The gallows consist of the prompts of currently studied themes, terms and an area for the right answer.

![Image of the gallows game](image)

**Picture 2.** The page in narrated comics. At the end of the page there is a question which demands answer before the user can go forward.

**The knowledge forum, hints for saving energy and conclusion**

The knowledge forum of Energy! includes interesting background information on energy issues. It is divided into six levels: solar system, globe, society, individual, organic and miscellaneous level. All except the miscellaneous level, are on the aspects of a certain discipline. The miscellaneous level is an integration of the different disciplines. The style of the text in the knowledge forum is humorous and colloquial. At the end of every theory level there are some practical questions about the content of the level, but primarily the knowledge forum has the traditional text format.

The hints for saving energy is the most practical part of Energy!. Through the picture of the storehouse the learner can be given energy saving hints in different areas of life. The learner may choose the hints of interest by clicking the mouse on a picture. Finally, the learner finishes his/her studying with Energy! by testing his/her knowledge of energy matters in the conclusion. There is a ten-point test, but the questions put more emphasis on knowledge and its application than at the beginning.

**The learning experiment of the Energy! –learning environment**

The Energy! learning environment was tested with its audience during the national energy saving week October 9.-15. 2000 at schools in Tampere Region, Finland. The idea of the learning experiment was to find out how suitable the Energy! learning environment is for studying energy issues for learners 13 to 18 years of age. The main purpose of the learning experiment was to find answers to the following questions: How effective are the narrated comics in energy-education and how did the learners evaluate the material of the different themes in the Energy! environment. Would they use the same kind of learning environment for their studies also in the future. At the time the learning experiment was carried out the conclusion and the narrated comic about the leisure were under production, and are thus not evaluated in this article.

The learning experiment was organized in two secondary schools; Tammerkoski school in Tampere and in Moisio school in Ylöjärv. There were three teachers in each school who tested the Energy! learning environment with their students. The Ylöjärv teachers have had a very active role in the designing the Energy! learning environment. Data from the learning experiment were gathered mainly with semstructured questionnaires completed by the learners after the experiment. The experiences of the teachers were gathered.
with open questionnaires, and by informal interviews made by the researcher. The researchers’ participant observation also gave some understanding of the theme. (Borg & Gall 1989.)

Main results of the learning experiment

The Energy! learning environment was tested with 185 learners. The feedback of 167 learners is taken into account in the results. The learning experiment was carried out primarily during the national energy saving week, inclusive of some lessons during the following week. The time used for the learning experiment varied between the classes from one to five hours. The most common period for studying with Energy! was two or three hours. 60% of the learners in the learning experiment were girls. Almost all the learners were 13-15 years of age. As background knowledge the learners evaluated their awareness of energy matters to be quite poor, and they were not very interested in them.

After the learning experiment the learners evaluated the different parts of the Energy! learning environment with the same grades by which they are normally assessed by the teachers (scale 4-10). Highest grades (mean between 8.1-8.28) were given to the interactive comics; clothing, food and traffic. The interactive comics were liked mostly because of their questions and reactions to the answers.

"I wasn’t interested in the theme [traffic]; but the questions sort of tempted me to the comics."

"Using it [Energy!] is fun! I can test my knowledge and learn new things from the answers."

Learners both liked and disliked strongly the beginning of Energy!. Positive feedback was given because it connected students better to comics by giving them their "own figure". The beginning was criticized mainly of the technical problems in the use of it. The small number of alternative comic figures was criticized by the learners.

"Interesting. It was cool to get to know who am I like, but for a boy it’s not nice to be Ritu [the female character]."

The greatest need for improvement in Energy! was reported to be in the knowledge forum and in the hints for energy saving. Those were criticized for the passive role of the learner in them. In the knowledge forum there were only a few questions for learners after the theory levels and the energy saving hints were only for reading. A very typical comment on the knowledge forum was for example:

"Quite interesting, but there were not many possibilities to influence it [the form of the theory]."

The energy saving hints were improved after the learning experiment. The hints area introduced in this article is the improved version. The tested version of the energy saving hints included the same hints, but the style of the hints was plain text not a interactive picture as it is at present.

More than 85% of the learners who took part in the learning experiment evaluated Energy! to be suitable or very suitable for learning about energy issues. 70% of the learners estimated that they had learnt something about energy issues through the Energy! learning environment. 20% of the respondents learnt a lot or very much indeed about energy issues through Energy! in their own opinions. Learners estimated (80% of them) that the level of the information in the environment tested is appropriate for the users at their age.

Interactive comics as a form of the learning material were evaluated to be an excellent way to inform learners about energy saving. This was the opinion of 60% of the learners who took part to the learning experiment. 40% of the learners thought that the comics were adequate for explaining energy issues. Despite all the technical problems which appeared during the learning experiment three out of four learners would also like to use Energy! or the same kind on learning environments for their studies in the future.

The teachers explained their interest in using Energy! with their students with the integrational aspect to different disciplines and with the aspect of sustainable development in Energy!. Teachers felt that the use of the technology based learning environment changed the role of the teacher more to the role of expert, but also to the role of technical guide. They appreciated the variety of the themes, because they enabled learners to learn themes they were interested in. Teachers hoped for most improvement to the technical usability and to the instructions of Energy!

Conclusion

This article presented the Energy! learning environment, which was tested with the learning experiment described here. The results of the experiment and the researchers’ experiences show that interactive comics are a very appropriate form for material of the energy education. The technology-based learning environment
provided an opportunity for personal differentiation in the learning material. This supports different learners and different learning styles. The personal feedback which is offered to the learners in the interactive comics motivates and guides their learning processes, but there is still need for the learners’ own activity. Learners need active processing of the information and the activity depends mostly on the learners themselves. A very rational comment was given by a 14 year old learner about the Energy! learning environment:

"As a whole it's OK, but it [Energy!] is more suitable for those who are really interested in these themes."

Thus even if learning with technology deals with the problem of differentiating the education, how can we solve the problem between active and capable learners and those who are not motivated and thus manage under their level all the time? If the learners liked most the questions and their own chance to act and to influence the future of the environment, how can the authors of learning environments and content materials respond to the challenges? How can the games and learning environments be differentiated from each other in the future, or do they have to be differentiated at all? Are we moving faster towards edutainment, where the fundamental idea is that education should be fun?

Energy issues are a very challenging topic. They are closely connected to the values, beliefs and attitudes and therefore elicit strong opinions. The interactive comics provide a frame for the dialogue on energy issues, but the dialogue should be widened from the technology-based learning environment to real conversation and interaction between learners and other participants of the learning environment.

Online Education Practice: a Dual-Track Balancing Act

Mari Peté, Online Learning Centre, Technikon Natal, South Africa
mpete@umfolozi.ntech.ac.za

Abstract: Technikon Natal is a higher education contact institution in Durban, South Africa. In the last six years the Online Learning Centre has evolved bottom-up, driven by the contagious creative spirit of champion lecturers. Activities have grown to such an extent that it has become necessary for the institution's management to develop an institutional vision and model for online education.

This paper reflects upon trends and developments in this environment, from 1994 to 2000. It speaks of experiences and lessons learnt by online learning practitioners. It weighs up various issues in order to suggest a sustainable model for an institution that faces constraints commonly experienced by most higher education institutions in the developing world.

Introduction

Technikon Natal is a higher education contact institution in Durban, South Africa. In the last seven years online education has evolved bottom-up, driven by the contagious creative spirit of champion lecturers. By the end of the year 2000, activities had expanded organically to such an extent that it has become a priority for the organisation's management to take ownership of the practice. This ownership will allow a more clearly defined focus, enabling Technikon Natal to collaborate and compete with other institutions, in the context of preparing students for an e-commerce driven workplace.

This paper reflects upon trends and developments in the Online Learning Centre, from 1994 to 2000. It speaks of experiences and lessons learnt by online education practitioners. It weighs up various issues in order to suggest a sustainable model for an institution that faces constraints commonly experienced by all educational institutions in the developing world.

Technikon Natal is regarded a historically white institution. The transformation of the institution commenced during a transformation forum in 1994, the year of the country's first democratic elections. As a result of this process, 21% of the student population is presently white and the remaining 79% black.

During the time of transformation, the trend of academic development in the mainstream became prominent. Mainstreamed academic development implies a focus on the learner through academic staff development and curriculum development. Lecturers are taught to adapt their teaching techniques and the curriculum to suit a diverse student population. This approach is opposed to the voluntary, add-on, remedial student support model that existed previously during the apartheid years, where the curriculum and teaching techniques remained intact and “struggling” students were required to attend “extra” lessons conducted by tutors, outside of a course’s timetable.

Since South Africa became a democracy, the country’s educational policies have evolved towards a system of outcomes-based education (OBE), emphasising access, learner-centeredness and flexibility. All of these are facilitated with greater ease through the use of computer technologies.
Initial Implementation of Online Education through Ready-Made Courseware

During 1994 a pre-designed computer-assisted learning (CAL) system was purchased for the Education Development Centre (EDC), a student support department awkwardly placed outside the academic ambit of the institution. One staff member was appointed to install the PLATO online tutorial system in mathematics, physics, chemistry and English and to recruit users for the use of ready-made software.

Although there was no institutional vision for online education and no broad guidelines for implementation at the time, the CAL Centre's own long-term goal was to develop ways of introducing online learning in a sustainable way and to become a central academic support service for all faculties - the guiding consideration being, "how to extend the scope of involvement in the pedagogical use of online learning from the margins towards the centre of institutional practices" (Taylor 1998).

The challenges that the marginalized EDC faced when the CAL Centre became one of its subunits were: being a voluntary, add-on service (not timetabled); surviving on donor money; being placed outside the academic ambit; and carrying the stigma of "remedial education". In spite of these challenges, the CAL Centre currently functions as an independent unit known as the Online Learning Centre (OLC). It is centrally placed in the academic ambit, offering a range of services, has access to the institution's budget, and comprises of two academic staff members plus an administrator and a technician. In the main these successes can be ascribed to the systematic, research-based approach of a handful of adventurous, tenacious, lone-ranging practitioners.

Online education at the institution has now reached a point where top-down meets bottom-up: as mentioned previously, at the end of 2000 the academic management team showed an interest in making an institutional commitment in order to support lecturers in their practice. This point will be elaborated on at the end of the paper. However, at this point some guiding principles that have been used by this unit that has operated in the absence of an institutional vision for online education will be discussed:

From the start, the institutional climate posed challenges far greater than making the technology work. In the beginning stages lecturers' "remedial" approach to students with learning difficulties was still at the order of the day. It often occurred that lecturers sent individual students away to the EDC to get "extra help" in the student's "free time" for a particular academic problem. Single students would then work in isolation online, not knowing how to select relevant materials from a host of options, and losing motivation quickly.

Therefore it was necessary to keep a firm stance on implementation in the mainstream curriculum. This approach required a focus on working with lecturers and academic departments rather than with individual students. Lecturers have been required to be involved, following the process of online content review and selection (to customise various programmes suited to a variety of courses and learner needs); time-tabling sessions as part of students' formal programme; appointing subject facilitators to assist during these sessions; developing ancillary printed materials to link tutorials to lecture content; and giving credits for work completed to boost motivation.

As a result of this work method, the PLATO system is now extensively used for first year courses on campus. Student numbers have increased from an initial group of forty to close to two thousand. This proves that it is not only the design of educational software that determines quality of learning, but equally important is the way in which it is implemented.

The underlying pedagogy of the PLATO tutorials is mastery learning, which is particularly effective for the reinforcement of basic sub-skills, e.g. practising to do a chemistry titration or calculating vectors in physics (Bloom 1986). During 1994 we conducted a study with electronic engineering first year students who used PLATO maths. Results indicated that the PLATO intervention helped students to achieve outcomes that require the mastery of basic sub-skills. However, PLATO did not improve students' ability to solve problems that require the use of higher order thinking skills. Interviews with students revealed their need for balancing individual online tutorial work with constructivist-type activities such as follow-up group discussions, in order to make PLATO tutorials more relevant to lecture content.
The quotes below underline that first year students with no previous exposure to technology are empowered (and not alienated), if a learner-centred approach is used:

"PLATO doesn't become tired of explaining."
"It is that I am not afraid to do anything."
"I could never do calculations alone. PLATO gui

Although our DOS-based version of PLATO is now "old technology", it is still heavily in use after seven years.

In-House Courseware Development with a Focus on Staff Development

Since the initial implementation of commercially available educational software in 1994 at the institution, the need has arisen for the development of software in-house, in areas that are either not commercially available, or available but not quite fitting Technikon Natal's syllabus, or commercially available but not affordable. In order for two educational technologists to support fifty-five academic departments, a model of in-house courseware development with a focus on staff development has evolved.

As the unit has been a "lone ranging department" (Taylor 1998), staff has had to keep a focus in the absence of managerial input. This has had positive as well as negative implications. On the one hand we have had free reign to experiment and learn, pushing the boundaries of development and technology in our efforts to support lone ranging practitioners' innovations. On the other hand this has caused a scattered focus and an overloaded infrastructure, the unit being inundated with requests for involvement. Therefore, in grappling to regain focus and to find a suitable and sustainable model for online education, the OLC observed trends at other higher education institutions. The two main models that emerged seemed to be staff development and production.

Below is a summary of some of the benefits and drawbacks of both models.

<table>
<thead>
<tr>
<th>STAFF DEVELOPMENT UNIT</th>
<th>PRODUCTION UNIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lecturers are empowered if their skills are developed - it is a personal investment.</td>
<td>Good short-term solution (specialist developers can get something up and running quickly).</td>
</tr>
<tr>
<td>The lecturer is in control of the environment and owns process in the long run.</td>
<td>Specialist developers can develop sophisticated learning materials.</td>
</tr>
<tr>
<td>Long-term updates are more feasible.</td>
<td></td>
</tr>
<tr>
<td>The support department can function with skeleton staff, in the absence of managerial support.</td>
<td></td>
</tr>
</tbody>
</table>

Table 1: Benefits of staff development and production models

<table>
<thead>
<tr>
<th>STAFF DEVELOPMENT UNIT</th>
<th>PRODUCTION UNIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time constraints of lecturers to do development</td>
<td>A production unit requires a big infrastructure in order to develop projects for a range of departments.</td>
</tr>
<tr>
<td>If lecturers themselves do the development, it is not likely to be done on a sophisticated level (time constraints).</td>
<td>Cannot function in the absence of managerial support.</td>
</tr>
<tr>
<td></td>
<td>In the long term the lecturer is not in control of the environment - unable to take care of upgrades and updates.</td>
</tr>
<tr>
<td></td>
<td>Impractical for a production person to drop current projects to take care of updates a year or two down the line</td>
</tr>
</tbody>
</table>

Table 1: Drawbacks of staff development and production models
In hindsight it seems that keeping the focus on staff development and continually redirecting ownership to the lecturer since the early “PLATO” days of implementation, has been crucial for the creation of a sustainable climate. The greatest challenge has been developing software in collaboration with academics and, in the process, enabling them to remain in control of the process.

Orwig (1999) emphasises the importance of providing online practitioners (lecturers) with incentives and resources in order to get them involved, and rewards for successful practice. One of the most positive offshoots of the staff development model is that by gaining technological skills, a lecturer becomes more marketable. This personal investment is at least one incentive for getting involved, even if no formal institutional forms of recognition exist.

Another important focus in an attempt to cultivate a sustainable climate, has been to work with champions and to give these champions every opportunity to succeed, and to promote their work on and off campus. As a result, these champions become role models, mentors and, even, coaches to others further down the line.

Academic Staff Development Workshops

Since 1998 the centre has offered staff development workshops to all academic staff on campus. Web pedagogy has formed an important foundation for all workshops. Some topics at the time of writing are virtual classroom development, facilitation and management; website development and management; multimedia authoring and electronic presentations.

The quote below is a response commonly given by lecturers during feedback:

"Thank you for the relaxed, non-threatening environment in which this course is presented. It gave me the confidence to use the Net effectively and to apply its advantages to the classroom setting."

Lecturers are on the one hand keen to get involved, yet on the other hand many are hesitant since they have probably been intimidated somewhere along the line by those who claim to own the technology. Therefore we focus strongly during workshops on demystifying technology.

The following quote also indicates a common response:

"Many doors opened, but we need to step through now."

Once lecturers realise that they can master the technology, there is the realisation that stepping into practice is hard work, takes commitment and requires real support.

Development Tools

During training we have not focused so much on high-end bells and whistles, but rather on template-driven, “low-end” technologies that make it more feasible for lecturers to do the development (e.g. Toolbook Assistant; Microsoft Word and Microsoft Front Page for website development). As lecturers are able to create materials relatively quickly, there is more time to explore pedagogical issues, for example learning how to select media and development tools appropriately for a specific target group. Another important pedagogical skill is to learn how to facilitate actively online once electronic materials are developed, in order to prevent students from getting lost in cyberspace and to sustain online interaction and ensure that learning takes place.

Projects

The importance of faculty support of a lecturer’s project cannot be over-emphasised. Projects have stalled in spite of the enthusiasm and commitment of lecturers. Not only is this a waste of valuable resources, it is also
extremely demoralising for everyone who has poured time and energy into a project. We have therefore introduced detailed inter-departmental agreements, and in order to cope with the demand and to prioritise projects, only support subsidy-generating courses.

Below follow examples from the range of past and current online learning projects at the OLC:

The Pharmacology Project of the Community Nursing department is a CD ROM-based distance education multimedia project for registered nurses and midwives who are unable to travel to Technikon Natal. Through this project Fregona, Harris and Kruger (1999) have explored the provision of pharmacology training for rural community nurses and midwives in KwaZulu Natal.

The Operating Systems IV virtual classroom of the Computer Studies department is an example of constructivist learning on the World Wide Web. Fourth year learners construct a rich online resource every year through individual and collaborative projects. In this project the power structures of traditional education, including roles of lecturers and learners, are challenged (Pete & Khalili 1998).

The End-User Computing intranet site of the Computer Studies department is used to develop web browser literacy and information literacy amongst first year students, in preparation for projects such as Operating Systems IV (Khalili & Pete 2000).

The Thekwini Project of the Languages and Communication department is a virtual classroom on the World Wide Web that uses innovative techniques such as scavenger hunts to develop academic literacy skills and increase the motivation levels of second language students (McKenna 2000).

Online Open Learning for Contact Teaching

The range of projects listed above all fit in somewhere along the continuum of open learning. Online learning does not only belong to distance education. Where it is implemented in a previously traditionally taught contact course, open learning comes into play. For many of the courses above, lecturers have retained contact sessions with students. However, where these courses previously consisted of traditional transmission mode lectures only, there is now a balance of lectures, tutorials to touch base and make logistical arrangements and online sessions (that include access to materials and contact with lecturers and peers).

Conclusion: a Top-Down, Bottom-Up, Dual-Track Balancing Act

Taylor (1998) elaborates on Morrison’s (1996) idea that if thirty percent of lecturers in a given institution teach online, this indicates the critical mass that is required to extend online education towards the centre of institutional practice:

“…then the institution would undergo a paradigm change in its educational practices”.

In order to reach the critical mass, he proposes a dual-track approach, namely balancing innovation and appropriation – examining innovative lone ranging lecturers’ work methods and adapting and applying these to other courses. In this way an additional ten percent of “early adopters” can be gained. The challenge is to gain the last ten percent to achieve this critical mass:

“Institutions have to engage the attention of the unconverted rather than continue to focus on the easily or already converted. This identifies the target.” (Taylor 1998)

For the last seven years at the Online Learning Centre we have followed a dual-track approach, continuously balancing various aspects in order to gain and sustain the participation of the pioneers and the early adopters.
The recent commitment of our academic management team will enable the development of an institutional vision and a coordinated strategy. Issues that will be addressed by the newly founded Online Learning Committee include a survey to pool institutional resources; providing incentives, resources and rewards to motivate lecturers to practise, and a discussion of the existing intellectual property policy. It is hoped that these debates will shift online education from the margins towards the centre of Technikon Natal’s educational practice.

Instructional Strategies for the World Wide Web: Outline of a Taxonomy

JAN L. Plass AND ROBERT R. Whelan
New York University, ECT Program, USA jan.plass@nyu.edu, robert.Welan@eun.org

Abstract. Based on a review of the current instructional use of the WWW we outline a taxonomy that classifies web-based instructional strategies according to three categories: knowledge mode (from passive viewing of information to active construction of meaning), presentation mode (from text to virtual reality) and collaboration mode (from individual to open collaboration). We offer suggestions as to how this taxonomy can be used by instructional designers in order to evaluate existing online learning environments or to develop new instructional strategies that take advantage of the unique characteristics of the WWW.

With the introduction of a new medium, the question of how it can be used for instructional purposes is often very enthusiastically answered with claims that it will solve many of the existing problems of the educational system. Just as other media before it, the World Wide Web (WWW) has spawned great expectations of its potential for instructional use. In this paper, we briefly review currently used instructional strategies for the World Wide Web, using examples from the literature as well as a case example, a web-based graduate course on Instructional Systems Design (ISD). Based on this review of the instructional use of the WWW and rooted in a media attribute approach, we outline a taxonomy that classifies instructional strategies according to three categories: Knowledge Mode, Presentation Mode and Collaboration Mode. We offer suggestions as to how this taxonomy can be used by instructional designers in order to evaluate existing online learning environments and to develop new instructional strategies that take advantage of the unique characteristics of the WWW.

Instructional Strategies for the Internet and the World Wide Web

An instructional strategy can be seen as any method, application or adaptation of knowledge designed to serve the function of learning. Instructional strategies can range from the artistic or craft-based to highly systematic and structured approaches. For an instructional strategy to be regarded as effective, it is usually supported by an epistemology, a psychological or theoretical framework which endorses a certain approach to successful instruction, and by a structured design methodology which helps to guide the instructional designer through the creative process.

The Internet offers a range of services and tools that have been readily adapted for instructional purposes. Aside from 'first-generation' Internet tools such as FTP and Telnet, Finger and Gopher, the Internet is now an umbrella for a range of popular services such as newsgroups, BBS, chat, e-mail, and more recently, the World Wide Web. Each of these services has come to have instructional applications, although in some cases the instructional theory underlying their use is underspecified.

For example, instructional uses of the Internet include Newsgroups & Bulletin Board Systems, electronic message systems which allow users to leave their own messages and to view messages left by others. In instructional settings, they can be used to exchange information or as a collaborative tool for group study projects (Wiebe, Slovacek, Semrau, & Doyle-Nichols, 1993). Chat is real-time text-based communication between two or more users that can be used to exchange information and to provide a format for discussion of curriculum-related topics or conduct group work. Email is perhaps the most popular application used on the Internet and its original purpose was to provide basic communication, information exchange and collaborative research services. In an instructional context, it allows learners and educators to exchange information and references, obtain assignments, receive guidance or counseling from instructors or peers, share documents, participate in quizzes or asynchronous discussion on curriculum-related topics, and even make excuses about missed homework or absence (Poling, 1994; Monahan & Dharm, 1995). In addition, listserv can be used to broadcast e-mail messages to large groups of people, e.g. a class, school or an entire institution in an instant.

These applications and services can be described as instances of first-generation text-based Internet communication tools. Although their use began as early as the 1960's, wider acceptance did not begin in earnest until the mid-80's. A second generation of Internet usage involving hypermedia content – combining still and moving images integrated with audio and text-based information – became available for instructional purposes more
recently and continues to grow at a rapid rate.

Since the introduction of the Web Browser in 1993, researchers have suggested strategies for the instructional use of the WWW. For example, Hackbarth (1997), in a review of a collection of papers by Judi Harris, describes options for the integration of web-based learning into the curriculum, emphasizing the value of interpersonal exchanges, information collection, and problem-solving activities. By contrast, Bannan-Ritland, Harvey and Milheim (1998) offered a hierarchical framework of instructional activity types, listing the kinds of activities which the WWW can support: Simple 'one-way' information delivery, where a webpage is viewed; appended information delivery, with the use of supporting materials, media, resources, references, etc.; information delivery with synchronous or asynchronous online interaction and/or collaboration; structured information delivery such as integrated learning modules; the creation and manipulation of original information such as WWW sites; and immersive interaction in media-rich information spaces, perhaps with collaborative partners.

Three elements permeate across this hierarchy. First, knowledge representations are being formed, organized, presented, and structured in varying degrees of sophistication, usually to suit a given instructional objective. Second, the degree of activity and interactivity, the modes of presentation, can vary according to the way the Web is configured for a given instructional task. Thirdly, the affordances for collaboration and group communication are essential, in accordance with the software and tools available and the objectives in a given educational environment.

In a different example, Bonk and Reynolds (1996) outline a strategy to encourage “Learner-Centered Web Instruction for Higher-Order Thinking, Teamwork and Apprenticeship.” This three-prong strategy emphasizes the “Creative, Critical and Cooperative” aspects of learning. The authors list 10 kinds of activities, from online brainstorming, to role playing, creative writing, simulations and semantic webbing, to concept mapping, summarizing, case-based reasoning and categorization schemes, to various partner-based activities, conferencing, group investigations and gallery tours. Although the authors offer an open and flexible schema, we can notice three distinct elements: first, knowledge representation (what we refer to as the Knowledge Mode) are used to create, organize, and structure materials; second, differing Modes of Presentation are described to support access to and manipulation of information and media; and third, Collaboration Modes and communication brings learners together and allows them to exchange ideas in a variety of ways.

By contrast, Mioduser et al. (1999, 2000) outlined a 100-element taxonomy for classifying the structure and functionality of web-based learning environments, (1) including general descriptive elements, (2) elements addressing the underlying pedagogical-instructional model of the environment, (3) elements characterizing the knowledge and representation structure, and (4) elements to classify the types of communication which could take place there. The first category could be described as elementary metadata about the surveyed Websites, but the second category includes details about the instructional configuration of the Website (resources and their links), the instructional model (e.g. directed vs. open-ended), the instructional means (e.g., hypermedia, VR, modeling), the interaction type (browsing, interacting), as well as the cognitive processes elicited, locus of control, feedback, help functions and learning resources. The third category addresses the representational structure and means utilized by the site, and the type of knowledge and the navigation tools being used. The fourth category includes the types and means of communication tools used.

In this scheme, we find again that the elements fall into one or another of the three-dimensions outlined above. Knowledge is being represented in a specific mode, organized and created in varying degrees of complexity with various types of cognitive and organizational templates underlying it. Presentation Modes are used to provide access and exchange functions required by a given educational Website (for example hypermedia database access, VR exploration, complex information retrieval and processing or thematic index navigation). Finally, Collaboration and communication tools have an essential role in bringing learners together, be it for group tele-manipulation or synchronous chat.

Outline of a Taxonomy of Instructional Strategies for the WWW

The WWW is a medium where instructors can provide curriculum-integrated learning materials for students to engage in a wide variety of media-rich information discovery and collection, interpersonal exchange and complex problem solving. Nevertheless, some researchers have questioned the currently established theoretical basis and pedagogical use of the WWW as a medium (Windshitl, 1998; Doherty, 1998; Trilling & Hood, 1999; Mioduser, Nachmias, Lahav, & Oren, 2000) and have argued that future development of web-based instruction will require more clearly formulated strategies founded on firmer instructional-theory background. What is needed is a theoretical approach to instructional strategies for the WWW that includes a mechanism for its practical application
and assessment. In the following section, we situate instructional strategies in the context of Salmon's media attribute theory and outline a taxonomy of instructional strategies for the WWW that aims to address some of these unresolved issues.

Following media attribute theory as described by Salomon (1979), four classes of attributes have the potential of affecting learning with media: contents, symbol systems, technologies and social settings and situations. The content that a medium typically conveys does not seem to lend itself as a useful distinguishing factor for instructional strategies using the World Wide Web considering its seemingly unlimited breadth of information. The available symbol systems of the World Wide Web, on the other hand, describing the modes of appearance of information using sets of elements interrelated by syntax, combine the symbol systems of many other media and allow the representation of information in modes from text-based to multimedia to virtual reality immersion. Technological attributes are responsible for the availability and accessibility of information and the way learners can manipulate and interact with it. In this context, the World Wide Web combines the processing capabilities of the computer with the inherent communication capabilities of the Internet. Social settings and situations describe the social context of the medium's typical use but are usually only partially associated with the use of the medium. In the case of the World Wide Web, however, the social setting of its use can be described as individual, collaborative within a closed community, or collaborative within an open group of learners.

![Diagram of instructional strategies]

**Figure 1.** The three dimensions of instructional strategies for the WWW, comparing text-based e-mail, student-created multimedia-rich portfolios and simple synchronous chat.

In our review of the research literature on instructional strategies for the WWW, three dimensions emerge into which applications and adaptations of the WWW for instruction can be usefully categorized. These dimensions correspond very closely to the classes of media attributes described above. The first dimension relates to the epistemological approach taken to knowing and learning by describing how learning materials are organized, manipulated and created, see Fig. 1. This Knowledge Mode corresponds to the content and technology categories of media attributes, and describes the spectrum reaching from viewing information to the construction of meaning. The second dimension relates to the nature and complexity of the Presentation Mode that is used to represent information, from text-only to immersion in a virtual environment, which corresponds to the symbol system category of media attributes. The third dimension, Collaboration Mode, situates the instruction in a social setting and describes the level of interaction with other learners, such as individual work or collaboration, corresponding to the social settings and situations class of media attributes. In the following section, we demonstrate how this taxonomy can be applied to a case example.

**Case Example**

The case example for this paper is an online graduate course in Instructional Systems Design (ISD) developed by a team led by the first author at a large research university. The course had traditionally been delivered as classroom-based face-to-face instruction, but an increasing demand by students who had a long commute to the university or lived out-of-state prompted the discussion of offering an online section in addition to
the classroom section. The course was developed using the Instructional Design Process as described, for instance, by Rothwell & Kazanas (1997) with some modifications to accommodate the WWW as delivery platform. The design of the online instruction for the ISD course is based on a combined constructivist and cognitive approach. The constructivist perspective was expressed in the idea that meaningful and relevant authentic situations and settings help learners construct their own meaning. The cognitive perspective included the ideas that learners differ in the way they perceive and process information and how they interact with their environments and with other learners, and that these processes and interactions need to be understood and supported in order to facilitate learning. The features of the course can be described in two tightly related categories: Instruction and Communication.

Instruction. Instructional strategies of the ISD course include features outlining the objectives, the visualization of the design process that is being taught, and brief video-based advance organizer lectures by the instructor, discussing the context of the materials covered in each module and how they connect to other modules. To illustrate the course content with a practical example, a case study was employed that allowed learners to make the connection between the theoretical concepts discussed in the course and their practical application in a real-life situation. In addition, as a form of cognitive flexibility hypertext, students have access to a library of mini-cases that includes cases with different contexts for each of the phases described in the case study, see Fig. 2. These mini-cases allow learners to access materials that are relevant to their own life experience and that relate to the class projects they were working on. This feature also allows adding new cases to the library, enabling students to contribute to the learning process by submitting their own class projects as cases, thus sharing them with others.

Communication. The communication component, integrated with the course materials, allows for various forms of synchronous and asynchronous interaction among students, between students and instructor, and between students and the course materials. The telecommunications applications used for asynchronous interaction are email.
correspondence, a bulletin board with threaded discussions, a feature to upload assignments to the instructor, and an ice breaker activity to let students get to know one another in the beginning of the course, see Fig. 3. In addition, synchronous meetings were held throughout the semester, using desktop video conferencing and chat.

The interaction with the course materials includes features of individualized content for each student. For example, exercises with immediate feedback give students an opportunity to see if they have understood certain key concepts covered in the course. Another feature showed students how much progress they had made in working through the course modules, and which assignments they needed to submit and when. The instructional strategies used in this course and their categorization following the proposed taxonomy are shown in Fig. 4.

While the categories of the proposed taxonomy are value-differentiated, i.e., neither end of the spectrum is generally of a higher instructional value than the other, they do allow for a critical evaluation of the balance of the presentation modes, types of knowledge and social settings used in the application, with respect to the stated outcome of the instruction. In this case example, we notice that the strategies are well balanced in the knowledge dimension, providing instructional strategies that emphasize the acquisition of knowledge as well as facilitate the construction of meaning. The media dimension, however, shows an imbalance with a tendency to use text to convey the information for an instructional strategy. Research in individual differences in learners and their effect on multimedia learning has shown that different individuals prefer to learn with different modes of representing information (Plass, Chun, Mayer, & Leutner, 1998), and this should be reflected in this course web site. The social setting dimension shows a combination of individual activities and open as well as closed collaborations. In other words, the instructional strategies of the site combine individual learning with collaboration in various forms.

Discussion and Conclusion

The objective for this three-dimensional taxonomy for instructional strategies was to help instructional designers evaluate instructional strategies for existing sites and develop new instructional strategies that take advantage of the particular characteristics of the WWW. For the evaluation of the conceptual design of an instructional environment, one might find that a media-rich virtual environment that facilitates constructivist learning could be restricted to a single user, for example when trainee engineers use immersive VR to learn about the installation or functioning of a new technical component. On the other hand, one could design a discussion board that may fulfill basic collaboration and knowledge creation objectives with textual information only. It is therefore not implied either end of each of the dimensions of the taxonomy would lead to more effective instruction in a web environment. Instead, each dimension of the taxonomy can be individually, partially or fully reflected to varying degrees, as befits the instructional objectives. The taxonomy does allow, however, to identify if such objectives or requirements as the availability of collaboration features, the support of learners with different presentation modes of information, or the design of a constructivist learning environment, were indeed conceptually met.

Another use of the taxonomy is that an instructional designer can design a course based on instructional objectives by selecting, based on the taxonomy, the web-based application or service to facilitate an instructional strategy that supports the objective. Here, the taxonomy would allow defining, based on the instructional objectives and the learning theory informing the design of the environment, the characteristics of the instructional strategies to be used to facilitate the objectives with respect to the three dimensions of the taxonomy. Once these characteristics are defined, the actual instructional strategy that reflects these characteristics can be chosen. In fact, based on this taxonomy, new instructional strategies could be conceived that are unique to the WWW as delivery medium and that have not been used for other media before. Indeed, the taxonomy can be applied independently of the ever-evolving network infrastructure, so that further research could include, for instance, the use of broader bandwidth networks and more advanced computer hardware.

Windschitl (1998) has suggested new paths towards researching the social setting for web-based learning, including assessing the effects of collaboration and interaction in web-based learning. In terms of the other two elements of the taxonomy outlined above, relevant questions for further research relate to how online media and knowledge manipulation tools can best be used for instruction, how learners utilize them and how teachers can exploit them in learning environments and evaluate their use too. This could help to give the model a more practical application.

Abstract: If multimedia learning is to be successful, different sources of information need to be integrated into coherent mental representations. In many cases, however, the presentation and use of different sources of information does not result in the construction of appropriate mental representations. Starting from various potentials and problems of multimedia learning, the theory of structure-mapping is proposed as a framework which can be taken advantage of to design multimedia learning environments which systematically encourage and support the mental integration of multiple sources of information. A multimedia learning environment for statistics is described which has been implemented according to the design principles proposed.

Introduction

Multimedia learning environments commonly comprise different sources of information such as various linguistic as well as static and dynamic pictorial representations. In this context, it is frequently assumed that the (simultaneous) presentation of different and possibly complementary sources of information improves learning. During the last 10 years, however, psychological and educational research have collected extensive evidence that the presentation of different sources of information in multimedia learning environments might not only not improve but even impede learning. In many cases, the „obvious“ benefits of multimedia learning environments vanish in the moment serious evaluation takes place.

In current psychological and educational theories it is hypothesized that different sources of information are processed by different mental systems (e.g., Mayer, 1997; Paivio, 1986; Schnottz & Bannert, 1999). It is proposed that linguistic information is processed by a verbal system and pictorial information is processed by a visual system. The theories differ in their assumptions about the connections between the verbal and visual system.

According to Paivio’s (1986) dual coding theory, the construction of mental representations of linguistic information only takes place in the verbal system. The construction of mental representations of pictorial information, in contrast, takes place in the visual as well as in the verbal system. Mayer (1997) assumes that mental representations constructed by the verbal system are mapped to mental representations constructed by the visual system as well as the other way round. Schnottz and Bannert (1999) propose that mental representations of linguistic and pictorial information are integrated into a single mental model which corresponds to an analogous and modality-unspecific mental structure.
According to the theories of Mayer (1997) and Schnotz and Bannert (1999), successful learning in multimedia learning environments aims at the integration of linguistic and pictorial information into coherent mental representations. However, the presentation and use of different sources of information frequently does not result in the construction of appropriate mental representations. Up until now, it has remained an open question how the construction of coherent mental representations can adequately be supported in multimedia learning. In the following, various potentials and problems of learning with different sources of information are summarized. Afterwards, the theory of structure-mapping is proposed as a framework which can be taken advantage of to design multimedia learning environments which encourage and support the mental integration of multiple sources of information and to construct coherent mental representations. Finally, the multimedia learning environment VISUALSTAT for statistics is described. This learning environment has been implemented according to the design principles proposed.

### Potentials and Problems of Learning with Multiple Sources of Information

Potentially, multiple sources of information may improve learning in multimedia learning environments in various ways. For instance, different sources of information may be complementary, resulting in the construction of more complete mental representations of an application domain than a single source of information (e.g., Ainsworth, 1999). Furthermore, multiple sources of information may realize different conceptual perspectives on an application domain leading to the construction of multiple mental representations which can flexibly be used during problem solving, for example (e.g., Spiro & Jehng, 1990).

During the last 10 years, however, psychological as well as educational research demonstrated that the presentation of different sources of information in multimedia learning environments poses various problems to the students. Each source of information may rely on notations which are not familiar to the students. For instance, in many cases students are not able to identify visual and spatial structures in pictorial representations which would allow them to understand an application domain (e.g., Lowe, 1998). In other cases, students do not interpret the perceived visual and spatial structures conceptually (e.g., Weidenmann, 1994). Very often, such a lack of visual literacy is accompanied with illusions of understanding (e.g., Salomon, 1994). The need to process different sources of information poses additional challenges to the students. For example, the students have to process larger amounts of information and to direct their attention simultaneously to different information (e.g., Lowe, 1998). Very often, these requirements overburden the students' cognitive capabilities resulting in only little learning (e.g., Sweller, 1993, 1994).

One of the most severe problems, however, may be the finding that students frequently do not systematically relate different sources of information to each other (e.g., Ainsworth, Bibby & Wood, 1996; Anzai, 1991; Kozma et al., 1996; Lowe, 1998; Peeck, 1993). As a consequence, these students fail to integrate the information into coherent mental representations. Their mental representations about an application domain remain fragmentary and - especially - disjointed. During problem solving, for instance, these students very often switch back and forth between different mental representations of a posed problem without being able to determine which representation contributes in which ways to the problem's solution (e.g., Anzai, 1991).

Although the use of multiple sources of information has the potential to deepen understanding, their coordination and integration does not take place on its own.

### Facilitating the Integration of Multiple Sources of Information by Structure Mapping

We propose the theory of structure-mapping as a framework which can be taken advantage of to design multimedia learning environments which encourage and support the mental integration of different sources of information. Initially, Gentner (1983) modeled the construction of analogies between two application domains by means of structure-mapping. A structure is made up of objects and their attributes as well as relations between objects. According to Gentner's (1983) model, an analogy is constructed by (partially) mapping the mental structure which represents the familiar domain, named the base, onto the mental structure which represents the unfamiliar domain, named the target. In recent years, Gentner and Markman (1997) demonstrated how structure-mapping can be used to model how similarities among different objects are established.

We apply the model of structure-mapping as a means in order to encourage and support students to (1) externally relate different sources of information to each other and - as a consequence - to (2) mentally integrate the different
sources of information. In many cases, different sources of information in multimedia learning environments delineate structures which are (partially) related to each other. Because students rarely identify relevant structures and establish relations between them spontaneously, the model of structure-mapping can serve as a framework in order to guide the implementation of mechanisms into a multimedia learning environment which interactively and systematically (1) encourage the identification of structures relevant to an application domain and (2) support the construction of relations between the identified structures by (partially) mapping one structure onto the other.

In earlier research it has been demonstrated that students who actively relate different sources of information to each other construct more complete and more coherent mental representations of the application domain under scrutiny than students who do not (e.g., White, 1993). To know the relations between different sources of information also allows one to flexibly switch between them on the one hand and to integratively make use of them on the other hand during problem solving, for example (e.g., Anzai, 1991). Structure-mapping forms one means to guide the construction of such relations.

Figure 1. Different sources of information about the model and the methods underlying the one-way analysis of variance with two groups.

Supporting the Integration of Multiple Sources of Information in VISUALSTAT

VISUALSTAT is a multimedia learning environment for statistics for the social sciences in the World Wide Web (www.psychologie.uni-freiburg.de/visualstat/). It comprises different sources of information about various models and methods of statistics such as the general linear model, the method of least squares and the partition of the sum of squares. These models and methods underlie frequently applied procedures in statistics such as the t-test, the (one-way) analysis of variance and the (simple) linear regression (e.g., Hays, 1994). VISUALSTAT does not make up a complete and self-contained learning environment which is intended to be used instead of a textbook. It rather...
complements a textbook. While textbooks describe the considered models and methods almost always exclusively by means of text and algebraic equations, VISUALSTAT additionally visualizes them dynamically and interactively (see Figure 1). The dynamic and interactive visualizations draw a student’s attention to properties of the considered models and methods which frequently remain unrecognized or misunderstood in traditional statistics courses.

VISUALSTAT can be used in two different modes: (1) self-guided and (2) guided learning. The mode of self-guided learning aims at students who are already familiar with the dynamic and interactive visualizations in VISUALSTAT. These students are encouraged to take advantage of the different sources of information according to their own learning objectives and information needs.

The mode of guided learning aims at students who are unfamiliar with the dynamic and interactive visualizations. These students receive guidance according to the design principles described above. Firstly, in order to avoid cognitive overload, one visualization after the other is presented to the students.

Secondly, the students are encouraged to interactively and systematically map step by step components of the (familiar) textual and algebraic representations to components of the (unfamiliar) graphical representations in order to learn (see Figure 2): (1) which components make up the visualizations, (2) how the text, the algebraic equations and the visualizations are related to each other as well as (3) how the different visualizations are related to each other.

Every time a mapping is completed, the students are informed about the correctness of their mapping. If students repeatedly construct an incorrect mapping, the correct one is explained to them.

![Figure 2. Interactive mapping of components of textual and algebraic representations to components of graphical representations underlying the mean.](image)

**Discussion**

Although multimedia learning environments potentially may improve students’ learning in various ways, they also may impede learning. For instance, students frequently do not systematically relate different sources of information to each other in multimedia learning. As a consequence, their mental representations about an application domain remain fragmentary and disjointed.
In empirical studies which revealed these problems it is very often concluded that learning in multimedia learning environments needs to be supported (e.g., Ainsworth, Wood & Bibby, 1996; Peeck, 1993). However, until now, only a few measures have been proposed to support multimedia learning (e.g., Mayer, 1997; Sweller, 1993, 1994). The measures which have been proposed keep the students in perceptive and rather passive roles. They focus on how different sources of information should be presented to the students in order to facilitate the students’ learning (e.g., Mayer, 1997; Sweller, 1993, 1994).

In this paper, we proposed a form of support which places the students in active roles. It focuses on how the students’ mental processing of the presented information can systematically be encouraged and supported. Our proposal was based on the theory of structure-mapping (cf. Gentner, 1993). According this theory, two sources of information can be related to each other by (partially) mapping structures from one source of information onto structures in another source of information.

The multimedia environment VISUALSTAT was equipped with mechanisms which implement the proposed principles. In VISUALSTAT, the students are guided to relate different sources of information to each other by (1) identifying the relevant structures in the information presented and (2) constructing mappings between the identified structures. We are convinced that the activity of systematically relating different sources of information to each other will result in the construction of more complete and more coherent mental representations. Currently, we are designing an experimental study which will be conducted in order to formally evaluate the learning effects of the support mechanisms implemented in VISUALSTAT.

Changing Role of Teachers and Learners in Web-based Education

"Abstract:" The objective of this paper is to address the question of the changing conception of knowledge at present and the need for institutions of higher learning and educators to reconceptualize the notion of knowledge and learning in order to keep in line with the changes in the society. Furthermore, I will argue that it is necessary to develop teaching methodology that can function effectively in the new technologically-grounded paradigm that is evolving in the realm of the social and the economical on a global scale today. This paper is based on my experience in developing, designing and delivering a web-based Spanish Civilization course at the University of Arizona, Tucson.

Learning Environment
The Spanish Culture and Civilization course, Spanish 430 was taught during Summer Session I, 2000 at the University of Arizona, Tucson. It was unique in that it gave students the freedom to access class resources at any time, from any internet-connected computer in the world. Indeed, while many students in the Tucson area used the Web to read class materials, many others took part in class discussions and completed their assignments from Phoenix, Flagstaff, and Nogales, Arizona, San Diego and Los Angeles, California, and even from as far away as Spain and Italy. The course lessons were divided into three broad categories: La Tierra y El Pueblo, Poetas, and Pintores (The Land and People, Poets, and Painters, respectively). Each of these categories was divided into subsections where class readings, practice quizzes, and discussion topics could be found. All class readings included images, photos, maps, audio and video materials along with
text, and a dictionary feature that instantaneously provided word definitions at the click of a mouse.

One of the most innovative features of the course was a collaborative project. Students were required to form groups of three and read Spanish newspapers during the five-week period of the class, paying close attention to a particular news story and the manner it was presented in the Spanish news media. At the end of the course the groups presented their observations in the form of essays.

Student participation was facilitated principally through a section of the course called Mesa Redonda, but also through available chat rooms and e-mail. Mesa Redonda was a virtual round table where students were required to both post their thoughts on class lessons and read the postings of their classmates. During the five weeks of this course, there were over 500 postings. Students also had the option to use chat rooms to ask specific questions about class materials during the professor’s virtual office hours, or were able to have their technical questions addressed by the Technology Preceptor of the course. Chat rooms also provided for students who were in different areas of the world a means by which class readings and projects could be discussed in real-time. Students also made use of both the class e-mail system and their own e-mail accounts to discuss class topics and have their questions answered.

The designing, developing and delivering this experimental course presented me with several challenges and made me think about teaching and learning in the age of technology.

**Technology and teaching**

Technological innovation, the demands of global economy and the drive towards a cost-effective education are forcing educators, administrators and students alike to incorporate new and
innovative technologies into education. Consequently, the virtual-classroom has emerged as an alternative to the traditional classroom as well as conventional distance learning courses. However, the virtual-classroom is yet to realize its full potential. Teaching and learning in a virtual-classroom cannot be conceived as a simple enhancement of the delivery of customary text-based materials, nor should it be thought only as freedom on the part of learners to access materials outside the confines of physical classroom and text. Technologically-oriented education in its present state continues to rely on traditional pedagogy. This approach will be unable to cope with the new paradigm that is redefining the society in hitherto unknown ways. The challenge for educators is to evolve new methodologies wherein the concept of teaching and learning has to be thought anew.

Knowledge in Information Age

The technological innovations and societal changes over the last fifty years have profoundly transformed the concept and utility of knowledge. Jean-François Lyotard in his book The Postmodern Condition: A Report on Knowledge characterizes knowledge in the postindustrial age as "payment knowledge" and "investment knowledge" (Lyotard, 1984, p. 6). While the "payment knowledge" is "units of knowledge exchanged in daily maintenance" the "investment knowledge" is "dedicated to optimizing the performance of a project" (Lyotard, 1984, p. 6). However the educational institutions unaffected by changes in half a century—conceive knowledge as an end in itself. The academics envision the universities as places for pursuing whole body of human knowledge, therefore "research and the spread of learning are not justified by invoking a principle of usefulness" (Lyotard, 1984, p. 34). These two forms of conceptualizing knowledge today are the undercurrent of conflict witnessed between the communities and legislatures who demand greater accountability from academics on the one
hand, and the universities that defend their freedom on the other. Wedding Internet technology
and education as solution for this conflict is a losing preposition because these two groups views
of knowledge are radically different. The possible resolution lies in institutions of higher
learning reconceptualizing their idea of knowledge and its pursuit.

Teaching in classroom

Teaching in a traditional classroom takes place in a narrative framework: sender, receiver and
referent. The teacher is the sender who stands before a class and transmits information during
sixty minutes. The receivers are students who patiently wait for sixty minutes to pass, and the
textbook, a bound volume of knowledge, is the referent. This narrative model does not have an
inbuilt mechanism to foster teacher creativity and learner involvement. They are left largely to
the personal initiative of senders and receivers. The anecdotal experience of most of those who
went through colleges and universities demonstrates that they have had one or two teachers who
inspired them to learn and one or two courses where they really learned.

The dissonance teachers experience between teaching and learning in the classroom is the
reflection of the conflict between the two notions of knowledge I referred to earlier. The student
body that enters academia is drawn from a society affected by the technological changes. They
are exposed to a different form of information mapping and they process that information in a
different way. Television and videogames, major sources of information and interaction, are
episodic in nature, task-oriented and use-determined. However the narrative models of teaching
and learning ensue an accumulation of large body of knowledge whose goals and utility may or
may not be realized at a later date.
Challenges of a virtual-classroom

The Internet, so far, is the maximum achievement of the technological revolution. If web technologies are to be used in education, the concept of knowledge, how it is presented and for what purposes it is used has to be rethought. Without this reconceptualization of knowledge, publishing lessons and class notes on web with few added features such as note taking, search and visuals will be a mere translation of narrative model to Internet. Using the web as a delivery mechanism of traditional classes will be counterproductive because research has shown that students have not taken to reading on screens. Moreover, web learning eliminates the many benefits of live interaction in a classroom.

In a fixed classroom an innovative teacher responds immediately to evolving dynamics of the course through interaction with students and by evaluating students’ responses to the material and teaching style. However in the web-delivery such spontaneity is missing. The course cannot be redesigned or reoriented at such short notice. One potential solution is to incorporate as many scenarios as possible into course design and use the multimedia interactions. The teacher in a virtual-classroom has to forgo his or her role as transmitter of knowledge and become facilitator of learning. For this to occur the students have to be trained to play a new role, that is of active learner instead of passive listeners. My experience has taught me that both, the role of teacher and student have to be rethought and reengineered in adopting technology in education and creating virtual-classrooms.

Abstract: This article presents the advance of an inquiry project whose objective is the development of new cognitive tools that make possible the handling question of communication and cooperation on the Internet universe, where the pupil can be considered as an agent who can learn from the interaction with objects of the domain or other situated agents in remote points. The environment integrates collaborative learning, distance education and conceptual graphs, resulting in a tool that is actual been implemented.

1. Introduction

The collaborative learning on the basis of the distribution cognition theory, suggests that the knowledge is not an object acquired and possessed for the individuals, but it is inlaid in the social relations, in the identity of the apprentices, in the social conversations and speeches (Jonassen, 2000). The new applied technologies for distance education has taken the process of learning beyond the limits of the classroom. The Internet has been showed as a basic factor in the dimension processes of distance education, promoting the creation of computational communities directed to learning. In this context, of collaborative learning and distance education, is inserted the VEDA environment, a visual tool (graphical) for organizing and indexing the knowledge, based on conceptual graphs (semantic networks). Professors and pupils build the knowledge of a course domain, identifying concepts, constructing relations (connecting links between concepts), organizing ideas, reflecting the learning process and evaluating strong points (better assimilation) and weak (deficiencies) of the learning. The activities are carried through synchronous and/or asynchronous conferences, where the actions are visualized by all, identifying the author. They allow discussed about the domain on a collaborative form (argument, negotiation and explanation) objectifying the construction of the knowledge.

2. Indexing with Conceptual Graphs and Hypertext

The conceptual graphs (Sowa, 1984) provide a form to represent knowledge through the ontology (application domain) and logic (logical first-class). Following its formalism, we can represent graphical form in linear form and create a computational model. This computational model together with the features of hypertext, allows indexing the knowledge in HTML format. With canonical graphs it is possible to standardize the creation of conceptual graphs. Thus, we must follow the described steps in Table 1, for create activities:

<table>
<thead>
<tr>
<th>Step</th>
<th>Task</th>
<th>Module (Architecture)</th>
<th>Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Creation of an Ontology of concepts and relations. Insertion of axioms.</td>
<td>Ontology publisher</td>
<td>Obligator, synchronous and asynchronous conference.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Creation of canonical graphs</td>
<td>Canonical graph publisher</td>
<td>Synchronous and asynchronous conference</td>
</tr>
<tr>
<td>Step 3</td>

<td>Conceptual graph publisher</td>
<td>Synchronous and asynchronous conference</td>
</tr>
<tr>
<td>Step 4</td>
<td>Browser and query</td>
<td>Browser and query interface</td>
<td>Individual, synchronous conference</td>
</tr>
</tbody>
</table>

Tab. 1. Steps to create an activity.

We use the ontology publisher to create ontology of concepts and relations. The creation of an ontology also can be considered as an activity to be executed on the environment. Professors (specialists) and/or
pupils, congregate themselves in a conference about a determined subject. The axioms are created together with the definitions of concepts and relations. The creation of canonical graphs imposes restrictions to concepts and relations. The pupils can create URL for other pages HTML from the concepts and relations, generating a Web browsing for the environment. The query environment uses canonical formation rules for expansion and restriction. Thus, we can generalize or specify the knowledge for the information retrieval.

3. Architecture VEDA

The architecture has three general properties: visual environment of the knowledge, graphical form, allows to create and remove concepts, relations and arrows; collaborative learning environment, where synchronous and asynchronous conferences occurs to the resolution of an activity; Web environment, heterogeneous platform, where the only requirement for the equipment is to provide a Web browser. The architecture is divided in four main modules: Pre-processing. It has the function of assisting the execution of the management modules, as conversion of pre-defined formats. Conversion from GML (Graph Modeling Language) to CGIF (Conceptual Graph Interchange Format) and conversion of conceptual graphs from linear form to CGIF. Management. It receives formatted data from the Interfaces and execute functions pre-defined for edition, query and browser the environment. Moreover, they manage all the data communication for the conference. Act, also, in the processes of recording documents together with the repository module. The inference machine acts inside of this set to verify if canonical graphs and conceptual graphs are compatible, if concepts and relations follow the defined axioms and execute rules for restriction and expansion of conceptual graphs. Repository. It stores the documents involved on the conference. All the documents have HTML format. The involved documents are: conceptual graphs, literal chat, ontology and canonical graphs. Interface. It acts directly with the user. It's executed in Web browsers as Netscape and Internet Explorer. It has an applet Java to graphical view the data stored in the repositories.

4. Conclusion

The environment presents a tool that integrates collaborative learning and distance education, allowing the planning and accompaniment of the activities that assist the collaborative construction of the knowledge. In such a way, beyond the direct and indirect communication (synchronous and asynchronous), modules of planning and development activities, and perception of the participants actions are considered. The creation of conceptual graphs allows to a semantic mapping of the information, organizing the ideas. Its junction with hypertext, provides the indexing of knowledge and browsing Web pages. The use of the environment promotes the formation of a VEDA community to share knowledge.

Animated Agents for Language Conversation Training

Helmut Prendinger, Santi Saeyor, and Mitsuru Ishizuka

{helmut,santi,ishizuka}@miv.t.u-tokyo.jp

Abstract: Animated agents are cartoon-style characters that facilitate the learning process. We take an animated agent approach to improve English conversation skills of Japanese students. In particular, we use animated agents as conversational partners in interactive role-playing environments (theater, drama, and games). In order to engage the language student, animated agents feature believability-enhancing behaviors such as emotional responses and social competence.

Motivation

Recent years show a growing interest in animated agents to enhance learning in computer-based interactive learning environments (Johnson et al. 2000). Lester and colleagues (1999) promote animated pedagogical agents for their motivational role in the learning context, in addition to the possibility of increased learning effectiveness. In this empirical study, they show the affective impact of animated agents on students' learning experiences, that revealed the so-called persona effect: "[...] which is that the presence of a lifelike character in an interactive learning environment [...] can have a strong positive effect on student's perception of their learning experience."

Encouraged by those results, we recently started a project with the aim to employ animated characters for the pedagogical task of language training. Specifically, the animated agent approach will be used to improve English conversation skills of native speakers of Japanese. Serving a similar purpose, Native World (Oki Software), a commercial software tool, allows users to practice English by interacting with native English speakers displayed in video clips. Instead of preparing video clips for all possible dialogue moves, we believe that animated characters give more flexibility without sacrificing pedagogical effectiveness. Moreover, we envision client-side execution in a web browser as the learning environment.

In a typical conversation-training situation, the user interacts with one or more characters, and plays the role, e.g., of a customer in a virtual interactive coffee shop. The programmable interface of the Microsoft agent package is used to control and display the characters involved in the conversation. The animated characters available for this package are endowed with a variety of behaviors ('animations'), speech recognition, and a text-to-speech engine. To keep the students motivated, strong emphasis is put on the believability of the animated characters, by giving them rudimentary personalities, emotion expression, and social role awareness.

The next section describes our language conversation training system. We will introduce two kinds of agents, AIs and scripted non-player characters. After that, we conclude the paper.

Affective Agents as Conversational Partners

So far, we implemented three role-playing scenarios. In our interactive theater, the user may take the role of Rosencrantz, the companion of Guildenstern in Tom Stoppard's famous play. Our interactive drama offers the role of a customer in a virtual coffee shop. In line with the popularity of computer games, we also developed an interactive role-playing game, the Wumpus World. When first starting a session, the Microsoft Agent library is automatically downloaded, the only requirement is to run Microsoft's Internet Explorer 5.0 or newer.

Similar to game developers, we distinguish between AIs and scripted non-player characters. AIs are autonomous agents that serve as dramatically interesting conversational partners for the user. Scripted non-player characters, on the other hand, are scripted agents that simply run predefined scripts.

Autonomous Agents

It is widely accepted that animated characters with believable emotional and social behavior are an important contribution to make learning environments more enjoyable and fun for users. Hence, each character involved in a role-playing interaction with the user has its own mental model, and is able to reason about its affective state and the social context.
An agent's mental model contains different kinds of entities, including world knowledge (beliefs), affective states (emotions, moods, personality traits), and goals. Our affective reasoner derives from the influential 'cognitive appraisal for emotions' model of Ortony, Clore, and Collins, also known as the OCC model (Ortony et al. 1988). Here, emotions are seen as valenced reactions to events, other agents' actions, and objects, qualified by the agent's goals, standards, and preferences. The OCC model groups emotion types according to cognitive eliciting conditions. In total, twenty-two classes of eliciting conditions are identified and labeled by a word or phrase, such as 'joy', 'confirmed', or 'angry-at'. Emotional states, however, cannot be directly mapped to emotion expressing behavior, as emotional responses largely depend on an agent's personality and the social context in which the conversation is embedded. Thus, we place so-called social filter programs at the interface of the module that reasons about emotion (the affective reasoner) and the module that renders the emotional state to actual behavior. Basically, a social filter program consists of a set of rules that encode qualifying conditions for emotion expression. Emotions are then expressed in accordance with the vocal effects associated with Ekman's 'basic emotions'. E.g., if a character expresses the emotion 'happiness', its speech is typically faster, higher-pitched, and slightly louder. In effect, we achieve that characters react reasonably when interacting with the user, which makes them believable and even compelling conversational partners.

Prolog programs implement all reasoning related to conversation management and agents' mental models, i.e., affective and social reasoning. Jinni 2000 (BinNet Corp.) is used to communicate between Prolog code and the Java objects that control the agents through JavaScript code.

Scripted Agents

Some agents are not directly involved in the interaction with the user. Typically, those characters are used as 'background' characters, e.g., as visitors in a coffee shop whose conversation the language student can listen to. Scripted non-player characters possess all features of the AI characters (e.g., emotion expression) except for the reasoning component. Although conceptually easier than autonomous agents, it turned out to be very time consuming to control them with JavaScript. E.g., consider a dialogue between two characters that fulfills communicative functions related to initiation/termination of the conversation, turn-taking, and back-channel feedback. Even for a short episode, a prohibitively large number of 'requests' have to be set due to the inherently parallel nature of a conversation, e.g., one character is nodding while the other character is speaking.

Hence, we use an XML-style markup language called MPML that supports easy scripting of characters and easy integration of other media components (Ishizuka et al. 2000). MPML (Multi-modal Presentation Markup Language) was originally developed for the purpose of creating animated web-based presentations.

Conclusion

In general, we believe that animated agents offer enormous promise for interactive learning environments. Despite the early stage of animated agent research, it seems likely that this new generation of learning technologies will have a significant impact on web-based education and training. Although speech output sounds somewhat artificial and language understanding is highly restricted, animated agents behave in surprisingly lifelike ways. However, there is still a long way to go to make animated characters truly social and conversational. Also, we have to gain a better understanding of exactly which features make animated agents engaging as conversational partners or pedagogically effective as virtual tutors. We envision the animated agent approach as a new paradigm in computer-assisted (language) learning, and continuously strive to make this vision come true.

Abstract: In this paper, we present the architecture of a Web-based Intelligent Tutoring System (ITS) for teaching new information technologies (e.g. Internet). The system is addressed to high school teachers. It contains a variety of courses starting from introductory topics addressed to beginners and scaling up to more advanced topics. Its distinctive functionality is its ability to tailor the presentation of the educational topics to the users’ diverse needs. This is accomplished by using AI techniques to record each user’s learning model as well as the various pedagogical decisions. The teaching process is under the control of a hybrid expert system.

1 Introduction

Numerous computer-based systems have been used in education during the last decades. The first such systems were called Computer Aided Instruction (CAI) systems. Those systems were quite effective in helping learners. A major disadvantage, however, was the fact that they did not take into account the user’s knowledge level and skills. They were thus unable to adapt instruction to the individual’s needs. These drawbacks gave rise to a new generation of education systems known as Intelligent Tutoring Systems (ITSs). An attractive feature of these systems is their ability to adapt the presentation of the teaching material to the needs and abilities of the individual users (Aiello et al. 1993; Woolf 1992; Vassileva 1997; Stern & Woolf 1998; Brusilovsky, Kobsa & Vassileva 1998). This is achieved by using Artificial Intelligence techniques to represent the pedagogical decisions as well as information regarding each student. For these reasons, ITSs have become extremely popular during the last years and have been shown to be quite effective at increasing their users’ performance and motivation (Beck et al. 1996).

ITSs were usually developed as stand-alone systems. However, the emergence of the World Wide Web offers the potential for revolutionary changes in education at all levels. The Web gives an educational system such as an ITS, the chance to reach many real users. In this way, its functionality can be tested with numerous and diverse cases (Stern, Woolf & Kurose 1997).

In this paper, we describe the architecture of a Web-based ITS for teaching new information technologies (e.g. Internet). The system is addressed to high school teachers. It contains a number of courses starting from introductory concepts appropriate for beginners and scaling up to concepts for more advanced users. The system models the students’ knowledge state and abilities. Based on this information, the appropriate pedagogical strategy for teaching each individual user is selected. Moreover, the corresponding teaching material is chosen.

This paper is organized as follows. Section 2 presents an overview of the system’s architecture and afterwards describes in detail its component parts. Section 3 deals with implementation issues. Finally, Section 4 concludes.

2 System Description
During the last decade, computer technology has been introduced in many Greek high schools. A variety of computer-based systems have been used to support teaching activities, thus increasing the students' performance and motivation. Teachers are also provided with various generic tools facilitating the creation of educational applications. It is clear though that they needed some sort of training in new technologies. Teaching, however, people with quite different knowledge backgrounds may turn out to be a rather difficult task. Our Web-based system intends to cover this gap by offering a user-adapted framework for teaching new information technologies.

Conventional Web-based educational systems exhibit some special characteristics such as the following:

(i) They are addressed to people having different goals, interests and knowledge level.
(ii) The studying motives of the traditional teaching process due to the competition among the trainees and the direct contact with the tutor are missing.
(iii) The courses are static meaning that they do not adapt to the trainees’ needs.
(iv) The Web imposes restrictions on the users’ interaction with the system.
(v) The Web as an educational medium does not offer mechanisms of focusing the teaching process on specific pedagogical goals.

Our system is aiming to develop methods and tools dealing with the teletraining of persons with different traits and skills. The following figure (Fig. 1) depicts the basic architecture of the ITS. It consists of the following components:

(a) the domain knowledge containing the teaching material
(b) the user model which records information concerning the user
(c) the pedagogical model which encompasses knowledge regarding the various pedagogical decisions
(d) the user interface.

As shown in the figure, the domain knowledge and the pedagogical model are parts of an expert system aiming to control the teaching process. The remaining part of this section will elaborate on the system's key aspects.

![Figure 1: Architecture of the ITS](image)

2.1 Domain Knowledge

The domain knowledge contains the teaching material presented to the system’s users. The teaching material involves a variety of courses starting from introductory topics and scaling up to more advanced ones. The educational content of each course is distributed in sections, subsections and topics.
Each course unit is associated with a number of knowledge concepts. These can be either goal or prerequisite concepts. Prerequisite concepts are required to be known by the user in order to grasp the knowledge related to the goal concepts. The concepts are related to each other by describing each one's prerequisites and outcomes.

Each topic comprises a series of educational screens containing theory as well as examples. The examples assist the user in grasping the theory's key points. The number of presented examples depends on the user model. A user with high acquisition skills will be presented a small number of examples in contrast to a user with low such skills. The teaching material also contains various problems based on the examples. Each problem is associated with an explanation assisting the user in case of a wrong answer.

The course units are presented in a variety of ways, such as interactive simulations, hypertext, appropriate images and animations. This depends on the multimedia type the user prefers to interact with. These user preferences are part of the user model (section 2.2). To facilitate the selection of the material, each course unit is associated with attributes denoting which type of user preferences it corresponds to.

2.2 User Model

The user model records information concerning the user and regarding his/her knowledge state and traits (Beck et al. 1996; Anderson 1993). This information is vital for the system's operation according to the user's needs. However, such data may be difficult to gather because it is not easy to represent the user's knowledge abilities. Moreover, the nature of the Web imposes certain constraints on the system's perception of the user. For the time being, it is difficult and time-consuming to record every user action. Furthermore, it is clear that the user model should not contain unnecessary information so that the system will not be encumbered with useless interactions.

A user model used quite often in the past by other educational systems and which is used in our system is the overlay model (Carr & Goldstein 1977). In this model, the user's knowledge is considered to be a subset of the knowledge perceived by an expert in the learning field. Using this representation, the system presents the educational material to the user so that in the end his/her knowledge matches the expert's knowledge. A primary disadvantage of the overlay model is its inability to represent possible misconceptions from the user's part. For this reason, other learning models are often used such as the bug catalogue or its successor, the bug-parts-library.

The user model is based on the concepts associated with the course learning units. Further information modeled in the system concerns the user's acquisition and retention skills. Acquisition pertains to how fast a user learns new concepts. The system's response during its interaction with a user determines how high or low these skills are estimated to be. In addition, the user preferences regarding the multimedia type (e.g. text, images, and animations) of the course units is recorded. These preferences are recorded when the user obtains an account but he/she also has the option to change them during the teaching process.

Only registered users have access to the system. In this way, the system is able to record their knowledge state as well as their learning skills. A registered user identifies himself/herself to the system whenever logging on by giving a valid login name and password. An unregistered user must first submit to the system information about himself/herself (e.g. name, email address, multimedia type preferences) in order to obtain an account and access to the system's functionality.

2.3 Pedagogical Model

The pedagogical model represents the teaching process. It provides the knowledge infrastructure in order to tailor the presentation of the teaching material according to the information contained in the user model. The pedagogical model encompasses decisions involving the various teaching strategies. These strategies determine how a teaching course should be planned. Moreover, the pedagogical model possesses knowledge regarding the selection of the various course units according to the user's preferences.
2.4 Expert System

The pedagogical model and the domain knowledge are parts of an expert system controlling the teaching process. The expert system has an inference engine in order to make decisions based on the known facts. In addition, explanations concerning the solution of complex problems are provided.

Symbolic rules constitute a popular knowledge representation scheme used in the development of expert systems. The corresponding rules reflect an expert's knowledge in the field of educational software and they are elicited mainly through interviews. Rules exhibit a number of attractive features such as naturalness, modularity and ease of explanation. They are a typical approach to symbolic knowledge representation. One of their major drawbacks is that the interaction with the expert may turn out to be a bottleneck causing delays in the system's overall development.

During the last years, artificial neural networks are used quite often in the development of expert systems. Neural networks represent a totally different approach to the problem of knowledge representation known as connectionism (Gallant 1993). Some advantages of neural networks are their ability to obtain their knowledge from training examples (reducing the interaction with the experts), their high level of efficiency and their ability to represent complex and imprecise knowledge.

In our system, we adopt a hybrid approach integrating symbolic rules with neurocomputing (Hatzilygeroudis & Prentzas 2000). Our goal is to augment the corresponding advantages of these two knowledge representation formalisms and to simultaneously minimize their disadvantages. Other known hybrid approaches have proven to be quite effective (Medsker, 1994).

2.5 User Interface

The user interface is responsible for the system's interaction with the user. Due to the fact that it is a layer of the system that communicates directly with the user it should be carefully designed (Kommers, Grabinger, Dunlap 1996).

Primary aspects of the system's user interface are the following:
(a) Interactions, flow, or navigation between screens or other various parts of the system
(b) Interrelationships between messages within the system
(c) Screen designs and
(d) Messages to the user that keep him informed and grasp his/her interest. This feedback takes the following forms:
   (1) Status messages will be used to show progress of a task being performed.
   (2) Warning messages let the users know the consequences of the action to be performed.
   (3) Correctness feedback indicates whether an action or response is correct or not.
   (4) Navigational feedback shows the users where they are in the program. This is particularly important because the structure of the system will not be necessarily hierarchical.

We can distinguish two basic views as far as the users are concerned:
(i) General view: In the general view, the user can access all available teaching material by navigating through the sections, subsections and the topics of the application.
(ii) Administrator view: In the administrator view, the user can establish login names and passwords for the users of the system. Furthermore, the user can update the pedagogical model and the domain knowledge either by inserting new items or changing and removing existing ones.

Only the system's administrator has access to the administrator view. The general view is used by the trainees as well as by the administrator.

2.6 Offline Communication Among Users

The system provides an 'offline' way of communication among the system's users via an electronic bulletin board. The bulletin board is a shared location for posting and viewing electronic announcements in a simple text format. Each announcement contains its subject, its submission date, the author name and its body.
The user is able to send replies to announcements and replies to replies creating thus a chain of messages. Furthermore, he/she can sort all types of announcements according to their subject and submission date, "filter" the announcements he/she wants to view depending on their submission date. Additionally, the user sees which announcements were altered or posted later than the last time he/she logged on the system. The purpose of the bulletin board will be to increase the collaboration among the system users.

3 Implementation Aspects

The system is still under development and a prototype of it is on the way. The development of the system is based on the Microsoft Internet Information Server for Windows NT. The MS SQL Server is used to implement the databases containing the educational material and users' profiles. Active Server Pages and CGI scripts manipulate the information stored in the databases and dynamically produce the contents of the applications presented to the users.

4 Conclusions

In this paper, we describe the design of a Web-based Intelligent Tutoring System (ITS) for teaching new information technologies. The system is addressed to high school teachers. It will offer a variety of courses starting from introductory topics addressed to beginners and scaling up to more advanced topics. The system tailors the presentation of the teaching material to the diverse needs of its users. It consists of the following four components: the domain knowledge, the user model, the pedagogical model and the user interface. The domain knowledge contains the teaching material. The user model records information concerning the user's knowledge state and preferences. The pedagogical model encompasses the various pedagogical decisions regarding the planning of the course and the selection of the course units based on the user's preferences. Finally, the user interface is responsible for the interaction with the users trained in the specific teaching subject and with the system's administrator. A hybrid expert system incorporating the domain knowledge and the pedagogical model controls the teaching process.

The system will acquaint high school teachers with modern computer technologies by enriching their knowledge in education software. Its adaptability will make some kind of teaching possible without the assistance of a tutor. The Web's universality will enable many users to gain access to the system's operations and consequently, its functionality will be tested with numerous and diverse cases. Significant conclusions regarding the system's efficiency will thus be drawn. A future goal will be to use methods of Distributed Artificial Intelligence (Solomos & Avouris 1999) to achieve communication between our system and other intelligent systems with similar subject domains such as the adaptive hypermedia system described in (Papanikolaou, Magoulas, Grigoriadou 2000).

Students’ Use of the Internet as a Help to Write Essays

Burkhard Priemer, Lutz-Helmut Schön
Humboldt-Universität zu Berlin, Didaktik der Physik
Invalidenstr. 110
10115 Berlin, Germany
priemer@physik.hu-berlin.de, schoen@physik.hu-berlin.de

Abstract: An online survey addressing students and teachers was set up to get an insight into the use of the Internet for teaching purposes in Germany. Taking physics education as an example we are investigating students’ use of the WWW and the corresponding learning outcome in a school related setting. Students aged around 17 are asked to write an essay on a topic taken from the German curriculum. The only help provided is access to the WWW and a word processing program. By analyzing both the strategies of their work with the Internet and the gained knowledge, the main aim is to find correlations. The identification and description of effective strategies will lead to a better understanding of the students’ work with the WWW and hence can improve their Internet performance when using it as a help to learn.

Introduction

Supported by commercial companies, an education initiative of the German government follows the aim to get all schools in Germany connected to the WWW within the year 2001. The implementation of hard- and software is a requirement for computer assisted learning and teaching. Nevertheless didactical concepts are needed to accompany this investment. We are interested in the everyday use of the WWW for teaching physics in school and see its advantage more when used as a complementary tool than as a replacement of present learning phases. The WWW is suited to assist students’ work, for example, when they are writing an essay. By looking into students’ activities while working with the WWW and their gained knowledge we aim to draw conclusions that can support the practice of teaching. Our results, gained through physics education, can partially be transferred to other fields as well.

Results of the Online Survey

As a base of our main investigation an online survey was set up in 2000 addressing students and teachers who visit school related web sites (Priemer & Schön 2001). The goal was to get a first glance on their web activities. More than 300 users in eight weeks chose voluntarily a link that was set up for us on around 20 web pages to a questionnaire on our server. Knowing that this survey is not representative it gives nevertheless a helpful insight into students’ and teachers’ use of the Internet. Some of the results are:

1. We have many students who are novices in internet-use. In our investigation 80% of the survey participants have used the WWW 1 year or less on a regular basis. This result is confirmed by other surveys (see Feierabend & Klingler 2000). In addition, students rarely used the WWW for school related purposes but used it for entertainment.

2. Students have an uncritical confidence in the contents of web pages. Around 70% of our students completely or almost completely agreed that they take it for granted that the contents of web pages are correct no matter who the author is. Within the KIE project similar results were gathered, stating that students have the same confidence in statements of both famous scientists and anonymous persons (White 2000).

3. Orientation in the WWW seems to be no problem for students and is achieved fast. The appropriate selection of useful web sites raises problems for one third of our survey-students and teachers. Students are in general more satisfied with their Internet work than teachers. They very quickly seem to be happy with the search results they get as long as some keywords are included in the document and they more or less adapt their work to the gathered information and hence stop further investigations.
4. While students believe that the WWW by itself is a tool well suited for learning, teachers tend to rate the WWW more as a useful tool to collect material for non-computer-based teaching.

5. Students expressed their general wish that the Internet should be used in classes at school more often. Further they stated that teachers are often incompetent computer-users and do not perform teaching with the help of the Internet because of their lack of knowledge in that field. Teachers complain that they are not supported enough when using the Internet as a tool for teaching. They ask for didactical concepts, a better training, and better equipment.

Further Investigations

Based on these first results the main investigation will take a closer look into students’ use of the Internet and the corresponding learning outcomes. Students of age 17 will have the task to write an essay on a topic in physics. In this school related setting the only help provided to students will be access to the WWW and word processing programs. The evaluation will focus on both the identification of “Web-Work-Strategies” of the students and different aspects of the gathered domain specific knowledge. A correlation between strategies and knowledge can lead to a description of effective WWW user skills (see Unz & Hesse 1999). The identification of strategies will be achieved by analyzing log files and interviews. To find a measurable way of describing these strategies we will retrace the steps and web-moves of some students in case studies. By relating the content of the visited pages to the web activities, patterns or strategies can be differentiated (Choo, Detlor & Turnbull 2000). In addition a mathematical calculus based on graph theory will be set up to describe the path through the web in a more quantitative and objective way (Botafogo, Rivlin & Shneiderman 1992). The aim is to bring both approaches together in order to get an effective and efficient method of describing user activities.

Conclusions

By identifying effective strategies and knowing which strategies are likely to bring good results, we hope to gain an insight that helps students and teachers to use the WWW in an appropriate and effective way. Beside the academic interest the results can be used in three ways in practice: as an instruction for students and teachers, as a base for the optimization of web sites addressing students, and as a base for the development of a software help-tool.

Abstract: A reliable validated tool is being created to automatically screen students for learning disabilities, administered locally with minimal expert supervision, supported by a centralised data processing and evaluation system and a wide support network for students, educators, and parents. The component tasks address typical aspects of a learning disability profile. Development phases planned include software design and implementation (completed), pilot application for validation and tuning (underway), and final standardisation and widespread application in the school system. This project falls within the framework of an overarching integrated web-based environment for learning and support communities in the Greek educational system.

Learning disabilities in Greece

Despite a lack of official figures on the prevalence and characteristics of learning disabilities in Greece, a growing concern among relevant authorities has recently culminated in legislation addressing important relevant infrastructure issues within the general framework of persons with special educational needs. A significant increase in funding to support efforts in the domain of learning disabilities is anticipated in the context of the stated priorities of the Ministry of Education to combat functional illiteracy and reduce school drop-out rates. Substantial structural and material organisation will be required, including the creation of tools and materials for assessment and remediation. Currently, scant testing materials exist and most educational personnel are not adequately trained to administer or evaluate them. Moreover, regions far from urban centres are particularly disadvantaged with respect to availability of specialists.

Purpose, Scope and Context

The present project aims to develop a reliable validated tool for the automated screening of students for learning disabilities, to be administered locally with minimal expert supervision, supported by a centralised data processing and evaluation system and a wide support network for students, educators, and parents. The human network will be developed and structured over the platform developed by the Hellenic Pedagogical Institute (HPI), in the context of the project “Added Value Services in the Greek Web for Schools” (Papadopoulos et al, 2000). HPI will provide an integrated web-based environment to facilitate establishing and operating learning and support communities across Greece. The communities will bridge learning disabilities research centres (mainly in cities) to schools across the country. Interactions between special educators, teachers, and parents will help reduce social isolation related to learning disabilities. Participating teachers will be supported through web-based training courses to support efficient use of the screening tool and to found a virtual training and research centre, also introducing educators and parents to the benefits of information and communication technologies for educational needs.

Design of Test Components

The planned testing battery will apply accepted assessment methods and tasks using appropriate language-specific materials. As a first approach, for practical reasons of implementation and wide-ranging administration, the first grade of secondary education is selected for initial application and standardisation.
The motivation for the test components departs strongly from a typical diagnostic focus and instead emphasises practical screening efficiency over concerns regarding theory or comprehensiveness. The outcome of the test administration need not provide any theoretically coherent or practically comprehensive profile of the students but only a designation of status with respect to recommendation for referral to professional assessment. Therefore the implemented components address aspects of the learning disability profile likely to detect students in need of specific remedial or supplementary education. International experience (Gredler, 1999) with computerised screening tests indicates that a diversity of tested skills is common and perhaps most reliable. Relevant skills for screening purposes include aspects of the typical "dyslexic profile" for the particular linguistic setting as well as related cognitive and perceptual abilities. Practical constraints restrict the task space to tests admitting a mouse selection response, precluding oral responses. Thus many potentially useful tests, such as phonological awareness tests, cannot be considered.

In Greek the most prominent characteristics of reading disability (the most common recognised type of learning disability) include slow reading and poor spelling (Porpodas, 1999). Thus one test assesses reading speed, controlling for comprehension, via a timed reading task followed by picture matching to the text content. Another test assesses spelling ability in a selection task that requires detection and correction of misspelled words in context. A third test assesses isolated word spelling in a visual discrimination task in which the word matching a displayed picture must be selected among misspellings.

Commonly mentioned aspects of learning disability include difficulties with auditory processing (Ahissar et al, 2000). Three such tests are included: a tone detection task in a backward masking context, a pure tone frequency discrimination task, and a tone sequence reproduction task. The first test assesses temporal resolution and auditory integration intervals, the second test addresses spectral resolution with some taxing of auditory memory, and the third addresses auditory sequencing under severe time pressure.

Short-term memory (STM) is an important cognitive mechanism related to cognitive ability and linguistic ability and can be impaired in cases of learning disability (Swanson, 1994). This screening system includes two STM tests with a language flavour. One is a letter-span test, analogous to standard digit span tests but with consonants instead of digits. The second is a phonological memory task presenting a pseudoword of increasing complexity to be reproduced orthographically.

Implementation Planning

System development is planned over three phases. The first, already completed, includes the design and implementation of the eight screening test components on a multimedia development platform running on personal computers commonly available in secondary schools. The second phase, currently underway, includes pilot application of the testing battery in a representative sample of Greek students. The same students will be administered conventional testing to be independently classified as learning disabled or not. Analysis of the computerised testing battery results with respect to the conventional assessment will provide indices of validity and reliability for the test components, and a first attempt at standardisation. In the third phase, only tasks and content items correlating best with expert assessment will be retained. The trimmed battery will be administered on a large representative population of students to derive psychometric standardisation and reliability validation. The final outcome will be supplemented with informational materials for the educators and parents, detailed instructions and recommendations for using the system, and the aforementioned support network by the HPI. Centralised processing and evaluation of the test data will facilitate statistical analysis and further validation, allow research questions to be addressed regarding learning disabilities in Greece, and will greatly contribute to empirical information sharing among sites of implementation and coordination, including special educators, teachers, and parents.

On Effects of Information Technology on Learning

Zoran Putnik
Institute of Mathematics, Faculty of Science
University of Novi Sad, Yugoslavia
e-mail: putnik@unsim.im.ns.ac.yu

Abstract: Usage of computers in school and at home does not replace each other, it together shapes individual habit of using information technology throughout person's life. It become a meaningful tool in society in relationship with knowledge, with gaining knowledge, with processing it, with expressing it and with its usefulness. In this brief paper, I will try to raise a discussion on some of the basic concepts of technology usage. Also, I will try to combine those ideas with current, omnipresent trend of life-long learning.

1. Introduction

Currently, at all higher-educational institutions (and not only higher-educational), focus shifts towards life-long learning, in order to make natural and possible for everyone to refresh, adapt and arrange their knowledge to new circumstances, to creating new jobs, or just simply moving to another job. This rather naturally implies that information technology, with all of the advantages it brings, must play an important role in all aspects of education, regulations, curriculum or simply - in every subject in each school. Therefore, it is important that the “student” learns how to find knowledge, how to evaluate its significance and importance, how to adapt what is suitable, and how to make use of it when needed.

Although professors and their assistants are pretty much right in having an objective point in expressing their concerns about usage of information technology in schools - the fact is that computers are here to stay. They become important tools affecting lives of (almost) every subject of our society, one way or the other. Our students are our future, today computers and information technology in general play an important role in education, and there’s simply nothing even barely indicating that this trend will change in the future society, where our students are going to live and work. Therefore, the only logical conclusion arising from these facts is that teachers do have obligations towards their students and the whole society to use these tools in the field of education, so that students learn how to make meaningful use of computers in their future work and life [Putnik, 2001].

2. Problems And Concerns

Nowadays, teachers are introduced to computers and their usage in classroom, in their “finished” form - with pedagogical, psychological and methodical methods built-in into the program itself. So, it’s not only that the teachers are confronted with the new tools, they are also told how to change methods they have learnt and developed in their own way for years. “Programs and computers” are not asking teachers how they teach or what do they think are the best methods to enable students to learn - they are told how to teach. Even more erroneously, this is often done by computer specialists, or some other “experts” never involved in real-life teaching, those who have never taught themselves. In the best, but still refused situation, programs are created after consultation with the teachers who do not share the same opinion as to the pedagogical methods involved. In this position - it is easy to understand resistance of the teacher.

Teachers are facing more and more challenges and changes in their work - changes that many of them have not asked for and don’t like, changes for which some of them have difficulties in understanding the need. They have taught their classes for years and have been thoroughly successful, but now they are “forced” to use information technology in the classrooms. Still, huge majority of teachers are aware of one simple fact: by avoiding the use of computers in their classrooms they cannot at the same time make use of computer as an aid and a working tool. Beside, it is surely possible to recognize oneself in one of the following grades of information
technology usage. There are at least five easily distinguished levels of "integration of information technology into the classroom" [Martin, 1997]. Those are:

- **Familiarization**: minimal usage of technology, just up to the amount of "becoming acquainted" with it;
- **Utilization**: regular, everyday usage of technology - yet, without the real "commitment";
- **Integration**: full classroom utilization. Lecturers using information technology in this manner, would certainly be badly obstructed in their teaching without it;
- **Reorientation**: at this level, teachers are re-defining and re-thinking education to "obligatory" usage of information technology;
- **Evolution**: a process, currently happening at lots of (educational) places, revolving around problems and their solutions arising in educational and instructional institutions using information technology.

Teachers avoiding the use of computers in the classroom often have valid points for their avoidance. On the other hand - teachers have to look beyond just the subject they are teaching.

3. Resume

There is an obvious and urgent need for parents to be involved with their children's use of Internet. Also, help of parents is needed in young people rethinking that they "know all" about computers because of their use of them at home. Those who knew themselves to be "far from knowledgeable" in the field of information technology, are fairly ready to work and learn. Yet, the others resist because they are so sure of themselves that they do not take the time to learn. Still, if we let our students to use computers only at their homes, with friends and parents, or just at separately and specially designed computer classes, it is much less likely that they will later have the knowledge and possibility to properly choose when to use computers, and when to favor other methods. They will not be aware of the prospects, they will be denuded of advantages of making the most of what they are doing with the help of computers. The school has the significant role of creating situations, atmosphere and surroundings for students and pupil to get access to data, information, or in general knowledge, in such a way that they are able to make substantial use of them. They must learn how to search for information by themselves, get it and process it so that it is useful in their lives. So - usage of computers in school and at home does not replace each other, but together shape individual habit of using information technology throughout their lives. It becomes a meaningful tool in society in relationship with knowledge, with gaining knowledge, with processing it, with expressing it and with its usefulness.

Still, usage of computers and information technology in the classroom can not be applied blindly. It is very important to listen to teachers, and to help them find tools that not only suit their subjects, but also their teaching methods [Putnik, 2000]. Information technology will play a role in our future society at least as important as it does now. So, the key moment for success in a constantly changing environment to which we have to adjust our students is life-long learning, especially with the usage of computers.

The Technological Challenges In The Delivery At A Distance Of A Second Language Computer Mediated Program. What Can Technology Do For Us?

Nebojsa Radic, Univ. of Auckland, Aotearoa / New Zealand

The delivery and effective teaching of computer mediated language courses delivered at a distance is a challenge for both language teachers and technology experts. At Auckland we are trying to open widely the lines of communication.
"From DL POTS to DL PANS: The Advance Distributed Learning (ADL) Initiative"

G.A. Redding
Institute for Defense Analyses
Alexandria, Virginia, USA
Gredding@ida.org

Abstract: The President has signed an Executive Memorandum directing the National Economic Council to develop a Federal Plan and a National Strategy for using learning technologies to improve education and training and to lower costs. This vision ensures that its workforce will have "access to the highest quality education and training, tailored to needs, wherever and whenever it is required." Efforts to achieve these goals resulted in the Advanced Distributed Learning (ADL) Initiative. In developing ADL, it quickly became apparent that the guidelines and standards, implementing technologies, and learning objectives that serve DoD’s needs are almost identical to those of other public government agencies, the private sector, and academia. The four objectives of ADL are to: (1) exploit the Internet as a delivery medium; (2) reduce development cost and time through the use of Sharable Content Objects (SCOs); (3) develop collaborative relationships across industry, academia, and government agencies; and (4) explore new technologies for potential training applications. The ADL brings together the work of many sectors such as the IEEE, AICC, IMS, Ariadne, and the Dublin Core to develop a common technical framework. This presentation outlines "why ADL" and current activities within the ADL Initiative.

Introduction:

In November 1997, the White House’s Office of Science and Technology Policy and the US Department of Defense launched the Advanced Distributed Learning (ADL) Initiative. In an Executive Memorandum, the President directed the National Economic Council to develop a Federal Plan and a National Strategy for using learning technologies to improve education and training, and to lower costs. The public and private sectors’ shared vision is to ensure their workforces have "access to the highest quality education and training, that can be tailored to needs, and delivered cost effectively, anytime and anywhere." The ADL Initiative is designed to be a catalyst for joint public and private sector projects that advance the application of technology in education and training through the development of an ADL Sharable Content Object Reference Model (SCORM™).

This effort sought to leverage and accelerate emerging object-oriented databases and commercially available Internet technologies to better manage and deliver education and training products and services. With respect to management and delivery systems there have been wholesale infrastructure changes as organizations move from distance learning programs using “plain old telephone service” (POTS) to distributed learning environments using “powerful, advanced network solutions” (PANS). By better managing learning content using standardized meta-data tagging and expanding delivery options the ADL Initiative will ensure that learners will have “access to the highest quality education and training, tailored to needs, wherever and whenever it is required.”

In deference to “distance learning” wherein the instructor and the learner are physically separated by distance - but electronically connected by the Plain Old Telephone System (POTS) technologies - “distributed learning” in an ADL context, encompasses educational and training activities orchestrated via emerging information technologies. In the last 100 years, technology has revolutionized communication, transportation, healthcare, entertainment, and now education and training. There are compelling reasons to act now to establish a series of guidelines, including technical specifications and best practices, to enable the burgeoning e-Learning economy.

Prior to the 1970's technology, were predominately industrial, focusing on corporate automation: mass production, corporate control, more blue-collar jobs, factory-like schools, coupled with slow economic growth. In the 1980's - 1990's there was a transition to the "Information Age" and office automation was the order of the day. There was a growth in information workers with new job skills. The emphasis was on innovation, and this included increasing investments in putting technologies into schools. And now, in the 21st Century, the trends outline a networked economy engaged in global e-commerce. Corporations will be placing greater emphasis on knowledge workers, and increasing investments in human capital. By the end of 2001, 77% of companies will use their Intranet for training. By the end of 2002, half of all workforce training will be done through e-Learning. By the end of 2003, 40% of e-
Learning will be aimed at a company's external customers. And by 2005, $50B to be spent on e-Learning.
(Sources: ASTD, Gartner Group, US Bancorp Piper Jaffrey)

Finding a better way to manage emerging technologies and expanding networks has, for many, become an organizational imperative. By leveraging e-commerce models is it possible to revolutionize learning? Are there modern, efficient, and flexible alternatives that will be able to support personal networking so that a learner might be able to access resources anywhere and any time they're needed? Will just-in-time access to information, effecting personalized learning opportunities result in a higher retention? And will there be any returns on the monies, time, and effort that will be needed to bring any of this about?

To test these assertions an ADL strategy was developed to:

- pursue emerging network-based technologies;
- facilitate development of common standards;
- lower development costs;
- promote widespread collaboration that satisfies common needs;
- enhance performance with next-generation learning technologies; and
- work with industry to influence commercial-off-the-shelf product development.

By making learning software accessible, interoperable, durable, reusable, and affordable, the ADL initiative seeks to ensure that academic, business and government users of learning software gain the best possible value from the materials they purchase.

In order to facilitate this effort, specifications needed to be evaluated to enable an object-oriented learning environment. This was a top priority. Which universally accepted standards or standards might be applied to developing "powerful, advanced network solutions"? As it turns out, there are plenty of standards too many to choose from. Given the scope of the undertaking, four focus areas involving best practices were established:

- **Content Advocacy Group.** This group is developing functional requirements for education and training objects in subject matter using a collaborative process to identify and prioritize functional requirements and communicate them to ADL partners organized around learning content areas.
- **Business Market Group.** This group defines the business requirements for an efficient market in instructional systems, applications, and products focusing on identifying non-technical impediments to the growth of a market for object-based learning resources, recommending solutions and strategies for resolving these impediments.
- **Technical Working Group.** This group is seeking to identify technical requirements for software needed to cultivate the vigorous market for interoperable, reusable learning objects by identifying ways to ensure compatibility across platforms, enable instructional objects to communicate with each other, and resolve other technical issues learning management systems.
- **Research Priorities Group.** This group seeks to identify and describe issues related to human learning and performance. In addition to resource data assembled as part of the business marker group, this group is involved in multiple support areas such as authoring systems, knowledge representation, and attendant personnel support systems. Simply stated, is learning taking place? Can it be measured perhaps as performance-based outcomes? And how a learner's profile might be better managed?

**Background**

In January 2000, the Sharable Courseware Object – Reference Model (SCORM) Version 1.0 was published, providing a meta-data tagging specification. (NOTE: In Version 1.1, "content" replaced "courseware" in the acronym, signaling an emphasis on learning objects as opposed to courses.) The SCORM specification was designed, in part, to address the DoD's frustration with not being able to share distance learning courses among the different learning management systems deployed throughout the department. The SCORM document presents a framework for developing technical standards based on sets of specifications involving web-based learning technologies to enable content reuse, accessibility, durability, and interoperability. This framework references emerging standards from a variety of organizations focusing on web-based learning technologies. The ADL has collaborated with members of the IMS Global Learning Consortium, Inc. (IMS Project), Aviation Industry CBT Committee (AICC), the Dublin Core, ARIANDE, and Institute of Electrical and Electronics Engineers (IEEE) on
various parts of the SCORM. Accordingly, significant components of the ADL SCORM can be "harmonized" synchronized with developing industry practices as part of the seminal work of these groups. While the ADL’s SCORM defines a very specific so-called "content model", work from other groups is integrated into this model and adapted or extended to meet ADL requirements.

Subsequently, courseware developers in government, industry, and academia have been developing content and services and have gone through conformance testing against the SCORM. Simply stated, the first version of the SCORM was a set of technical specifications that apply to learning content and learning management systems. It defines a specific Application Program Interface (API), data models, and content launch mechanisms, as well as meta-data and course structure formats. It is not the intent of the ADL Initiative to set standards. Others are doing that, especially those involving network protocols and mark-up languages. Instead, in coordination with government agencies, industry groups, academia and other stakeholders, the ADL Initiative is creating guidelines for courseware development based on existing industry practices and standards that promote accessibility, interoperability, durability, and reusability of learning objects. The scope and detail of the guidelines will not be static; they will evolve and grow over time.

Validating the ADL Technical Architecture
A tough issue to deal with is picking the “correct” technology at the right time. There are legacy systems, systems being used here and now, emerging technologies, and the (volatile) future. For the most part, each of these builds on its predecessors. But as technology moves into areas of uncertainty involving operating systems and protocols, increasing attention needs to be paid to baseline architectures. If the technology is good, why throw it away? After all, telephone has been around for over 100 years. It has met the test of time and functionality - and it still meets most of the "-ilities".

Sharable courseware objects needed to meet our functional requirements must meet some criteria, which we loosely call our "-ilities". Among these "-ilities" five seem most important (though there are several other "-ilities").

- It must be possible to find needed and sharable content objects. They must be accessible. Basically, this means that there should be accepted and standard ways to store, find, and retrieve them.
- Once found, the objects should be usable. This means that they must be interoperable and portable across most, if not all, platforms, operating systems, browsers, and courseware tools.
- Once implemented, the object should continue to operate reliably. If the underlying platform, operating system, or browser is modified (for instance when a new version is released and installed), the object should continue to operate as before. It should be durable.
- The object should be reusable. Other platforms, operating systems, browsers, and courseware tools should be able to reuse, and perhaps even modify as needed, the original content object.
- Finally, this process must be affordable.

The core ADL Architecture Management Group (AGM), which includes technical representatives from government, industry, and academia developed a three phased approach to establishing an advanced distance learning architecture:

- **Phase I – Validate Technical Guidelines:** This phase began with the release of the first technical guidelines for creating object-based courseware. Participants in the project each contributed test applications that exercise various facets of courseware production within the draft (version 0.9) ADL guidelines and test objectives.
- **Phase II – Validate Courseware Development:** Following Phase I, the ADG AMG released version 1.0 Courseware Development Guidelines. During Phase II, participants created complete courses designed to fully exploit the full scope of the guidelines and to test for Phase II objectives.
- **Phase III – Validate Reusability:** During Phase III the interoperability of complex courseware components were fully exercised.

ADL Plugfest Goals
Three times in 2000 the ADL Co-Laboratory sponsored a Plugfest to bring together early adopters of the SCORM. The purpose of the ADL Plugfests is to establish a common test bed for experimenting with new object technologies that are purposely designed with these specific qualities using previously established guidelines. This presented early adopters a chance to create and demonstrate prototypical object components designed that could be launched
and tracked from multiple Learning Management Systems (LMSs). The Plugfests are intended to provide participants with a "fault tolerant" forum for explaining their experiences in migrating their products to follow SCORM guidelines and to present future product plans. First, the ADL Co-Lab offered a relatively safe environment for resolving glitches, and second there was ample peer review and lessons learned at the technical level.

Plugfest Overview
The first round of testing was in June 2000 at the ADL Co-Lab in Virginia, followed by application testing in August at the ADL Co-Lab at the University of Wisconsin and in November at the ADL Co-Lab in Orlando, Florida. ADL Co-Labs were established to promote collaboration in the research, development, demonstration, implementation, and evaluation of ADL technologies and products. Experience gained during the Plugfests is expected to inform the ongoing refinement of the SCORM specifications. The purpose of the ADL Plugfest program is to determine the feasibility of creating an object-based approach that is demonstrably accessible, interoperable, durable, and reusable in education and training domains. Thus, early adopters were invited to create prototypical object components designed to demonstrate these characteristics. These prototypes were each expected to be proofs of concept and experimental rather than complete applications. Plugfest attendees included:

- **Content developers** — brought small sharable "learning objects" that had been beta-tested with the SCORM specification. During the Plugfest, their content was "plugged" into as many LMSs as time permitted to demonstrate reusability. In some instances their content was combined with content from other participants.
- **LMS providers** — brought a beta-tested version conforming to the SCORM API. They were asked to provide their own content for at least some of their data models, or content from other Plugfest participants.
- **Repository developers** — demonstrated prototypical learning content repositories for SCORM-conformant content and media elements. They were invited to present concepts and demonstrate how others can import and then access SCORM content and media.
- **Authoring system vendors** — demonstrated how they were supporting the API and data model. Given the short time from the release of the SCORM Version 1.0, a few of the authoring system vendors were not able to demonstrate a conformant product, but they were encouraged to know how their authoring systems were being designed to support these critical elements.

Ground Rules for Participation
In order to achieve the objectives of the program, prospective participants met the following requirements:

1. **Test Project**: Participants must have a proposed courseware project that could be adapted to ADL technical guidelines either by conversion or through new work.
2. **Contribution to Library**: At the conclusion of each phase of the project, participants were encouraged to contribute components of their project for testing and re-use by other ADL project members.
3. **Lessons Learned**: Participants were asked to document their experiences for compilation by the ADL AMG and redistribution to other project members.
4. **Plugfest Participation**: Project members agreed to actively participate in each of the scheduled Plugfest activities on the agreed upon timetable.

People and organizations participating in the Plugfests were encouraged to make their intentions known early, as space was limited. Those who were not able to actively participate in the first Plugfest were encouraged to observe the proceedings, and schedule themselves for future Plugfests. Since the proceedings were posted on the ADL Home Page, there was additional opportunity to get involved – at a distance. Additionally, announcements for future Plugfests are posted at that site: www.adinet.org

Plugfest #1 – June 19-23, 2000
Approximately 225 representatives from over 90 organizations, comprising learning software developers and content providers from various sectors of the U.S. government, industry, and academia, actively participated in the Plugfest, which was hosted by the ADL Co-Laboratory in Alexandria, VA. This event brought together early adopters of the SCORM specification to experiment and demonstrate interoperability of content from many sources over multiple learning management systems and from separate organizations. Twelve vendors brought LMSs for conformance testing at the ADL Co-Lab, and 18 content developers brought content.

To varying degrees, all LMSs and content products conformed to the beta test suite based on the SCORM. Since this
was a first encounter for everyone – the testers in the lab and the participant products being tested – it was also an opportunity to sort out anomalies in both the test software and the course content packages. And there were numerous demonstrations of interoperability where “working code trumped all theory”. For the first time, content from different vendors’ LMSs was passed to other vendors’ systems without a hitch. Accomplishments included:

- For the first time: Real Code - Real Testing
- Learning content samples ran on multiple LMS systems!
- Tested LMS’s demonstrated the ability to run content from multiple vendors’ tools!
- Learning content from multiple samples were integrated into a common repository!
- Wide vendor support for SCORM
- The key standards bodies agreed to accelerate and continue to coordinate

**Plugfest #2 – August 2-3, 2000**
The Academic ADL Co-Lab at the University of Wisconsin in Madison serves as an academic testbed for moving ADL to the nation. It was been created through a unique partnership between the University of Wisconsin System, the Wisconsin Technical College System, the Department of Defense and the Department of Labor.

Unlike the First ADL Co-Laboratory Plugfest, which focused on beta testing of SCORM products, Plugfest #2 showcases the official release of the SCORM Version 1.0 test software and focuses on interoperability demonstrations among advanced early adopters of the SCORM. Demonstrations are planned to showcase SCORM implementation before educators. Plugfest sponsors and participates wanted to:

- Concentrate on content
- Demonstrate reusability and interoperability
- Expose and educate leaders and practitioners to ADL and the SCORM
- Introduce the Academic ADL Co-Lab, at the same time encouraging other academic partnerships through the Academic ADL Co-Laboratory

Plugfest #2 was a watershed event for the Academic ADL Co-Lab bringing together the nation’s higher education community, the private sector, standards groups, state and federal government, the national guard, and e-learning vendors, providing an opportunity for the lively exchange of ideas among the communities. Several LMS vendors were able to demonstrate functionality that was not technically possible as early as three week prior to the event. Using SCORM-compliant content, the LMSs were able to find and retrieve learning objects (actually “assignable units” or AUs that were completely disaggregated from their host course), manipulate those learning objects, and pass them on to another LMS. These retrievals were done “on the fly” effectively raising the bar significantly for LMS products.

**Plugfest #3 – November 27-30, 2000**
Plugfest #3, like the previous Plugfests, focused on the evolving functionality and increasing momentum of the SCORM set of specifications. Plugfest #3, sought to "push the envelope" by encouraging top-notch implementations of learning content. There were real time content development demonstrations, product showcases, technical exchanges and tutorials on specification development. Participants were invited to form multi-discipline teams for the purpose of designing and developing SCORM-conformant lesson modules using the latest authoring tools and LMSs.

Three additional Plugfests have been announced for 2001.

**Other Challenges**

As ADL programs evolve and are adapted, there will be applications not anticipated. Unintended outcomes – hopefully positive, are most certainly welcome. This short overview of the ADL Initiative illustrates a potential to radically change the landscape of education and training as it currently practiced. Content developers need to construct and deliver an intelligent, virtual environment where learners are allowed to experiment without interference, yet communicate and interact with instructors as they move through the learning process.

ADL brings together public and private sectors to develop a common technical framework based on several key...
elements, including widespread collaboration, common guidelines and specifications, network technologies, next generation learning technologies - all coupled with reusable content and object-based tools that are platform independent. As programs evolve and are adapted, there will be applications not anticipated. Unintended outcomes - hopefully positive, are most certainly welcome. This short presentation of the ADL Initiative illustrates a potential to radically change the landscape of education and training as it currently practiced.

The progress of the ADL Initiative has been noticed by other chartered organizations investigating the value and promise of the Internet as a viable learning enabler. A commission appointed in 1997 by President Clinton (the President's Commission of Advisors on Science and Technology) called for a rigorous empirical research program at a level equal to at least 0.5 percent of the nation's aggregate spending on K-12 education. The final report, The Power of the Internet for Learning: Moving from Promise to Practice, was presented to the President and Congress of the United States in December, 2000. (www.webcommission.org). The Report calls upon the Federal government to create a comprehensive research, development, and innovation framework for learning technology. In the body of the Report, the ADL Initiative was formally acknowledged.

One of the strengths of the ADL initiative has been the ability to work with those organizations most directly involved in developing applications and setting standards. There are several organizations and companies working on bits and pieces of learning technologies. Rather than trying to "consume the elephant" at one sitting, the ADL Team sought counsel from those that had been performing seminal research and evaluation. As consensus was achieved, those issues were codified and new issues were brought in. And as the SCORM progresses, each revision will hopefully be able to capture more of the learning technology landscape. The SCORM is more of a process than a product and future versions of the SCORM are already being laid out.

As previously described this series of Plugfest events provided ADL partners with the opportunity to synchronize the evolution and convergence of commercial authoring tools, LMSs and Web-based courses with the emerging open-architecture specification. Version 1.1 of the SCORM marked the end of the beta-testing phase of ADL and the beginning of the implementation phase. The specification has been widely vetted, updated and clarified, and is now deemed sufficiently stable to serve as the foundation for large-scale development of ADL tools and content. And more work is in progress. Concurrent with the release of the new specification is the establishment of a new process to "certify" compliance with the ADL SCORM specification. Version 1.2 will include content packaging profiles and a few new metadata tags, and version 1.3 will focus on content object repository profiles.

Now the ADL Initiative has another challenge before it as a result of its success. One day all of the "qualifiers" will disappear (distance learning, distributed learning, e-learning) as a distinction and the world will be left with an infinitely expanded idea of "learning." The ADL Initiative will continue to push forward with newer and more robust versions of SCORM, and will continue to work with all partners — the government, private industry and academia, to enable the creation of the future learning environment. The success of the ADL initiative will be measured by the extent to which:

- Consumers (learners) can acquire high-quality learning software less expensively than they do today;
- Producers of learning content are able to realize a higher return on their efforts; and
- Developers of learning support tools, services, and products are able to achieve a higher return on their investments.

In moving to powerful advanced network solutions, wired and wireless, all efforts would be geared to getting just the "Right Stuff" to the learner. Just the right CONTENT, to just the right PERSON, at just the right TIME, on just the right DEVICE, in just the right CONTEXT, and just the right WAY. That's the end game.
Cinemedia Astur: A Scalable Hypermedia Authoring Tool for the Development of Educational Artefacts

Jose Manuel Redondo, Univ. of Oviedo, Spain; Martin Gonzalez, Univ. of Oviedo, Spain; Benjamin Lopez, Univ. of Oviedo, Spain; Juan Ramon Perez, Univ. of Oviedo, Spain

CineMedia Astur is a powerful hypermedia scripting tool designed specially for multimedia collaborative development environments. In those environments, professionals coming from different disciplines (education, computing science, graphic design, etc.) have to share their knowledge using a common conceptual framework. Different experts conducted by the project’s director share a common workspace where they are able to include their designs drafts or ideas, sharing them with other users. The tool supports different kind of interactive objects and media (graphics, animations, video, etc.) and its functionality can be extended by mean of third party components which can be downloaded everywhere in Internet, as the unique constraint is that those components must be compliant with sun’s JavaBeans specification. CineMedia Astur supports the entire hypermedia development paradigm, even the evaluation stage as Cinemedia includes special tools for automatic remote testing of the navigation models of the generated applications.
Spontaneous Interaction between Kindergarten Children and Computers
A Case Study of the Project Discetech-Bimbotech.

S. Petazzi, I. Rega, A. Torrebrun, Discetech Staff Faculty of Engineering of Como, piazzale Gerbeto 6, 22100 Como, italy, spetazzi@komodo.ing.unico.it, irega@komodo.ing.unico.it, altorre@komodo.ing.unico.it

http://www.ing.unico.it/discetech

P. Paolini, Politecnico di Milano HOC (Hypermedia Open Center) DEI (Department of electronics and information) Piazza Leonardo da Vinci 32, 20133 Milano, paolo.paolini@polimi.it

Abstract The project Discetech, started in 1996, in Northern Italy, with the aim of experimenting the introduction of new technologies within the teaching-learning activities of high school classrooms. Since 1998, a similar project, Bimbotech, has been developed for initial classrooms (from 4 to 10 years old children). Several hundreds of experiments, involving several thousands of pupils, have been carried on by the teachers, previously instructed and assisted by the staff of the project. This brief paper briefly introduces the Discetech-Bimbotech project, and then closely examines one of the most interesting Bimbotech experiment's the organization the phases, the results and the lessons learned are analyzed. The last section describes how the work will proceed, in order to understand better some pedagogical issues, and how dissemination the experience to other classrooms and other teachers.

An overview of the project
The project DISCETECH started in 1996 in the City of Como, for the initiative of Politecnico di Milano, as an attempt to experiment new technologies for teaching and learning, within the Italian school System. Since 1997 the project also branched out in Lecc0 for the initiative of the Faculty of Engineering of the University of Lecce. and, since 2000 a new branch was opened in Milan too.

In the first phase, the project aims to give teachers basic ICT knowledge that can be used later on during their teaching activities. In the second phase teachers are asked to project and realize a didactical experience in the classroom in order to:

?? Discover useful strategies of using multimedia technologies in the didactical process;
?? Evaluate the efficiency of the above strategies regarding: content acquisition; knowledge skills acquisition (e.g. focusing and selecting information); behavior skills acquisition (e.g. cooperative skill and teacher-student communication).

Overall Discetech project has involved, so far, 430 teachers (some of them for more than 1 year) and more than 250 education projects have been developed, involving nearly 5000 students.

Spontaneous Interaction between children and computers

Environment
This experience has been carried on by one of the most active group of teachers of Bimbotech. The classes involved were two, one of 25 children, and the other one of 19 children, children were between 3 and 5 years old.

<table>

</table>

The overall aim of the experiment could be summarized as it follows:

a) To introduce the PC in the day by day class activities, promoting the self-interaction of children with the computer.

b) Let children consider the PC as a tool among the others that are daily used in the classroom.

c) Use of the PC for a special purpose, guided by the teacher.

Phase A: Spontaneous approach

Objectives
a) Let children have a first contact with the PC
b) Let children understand the function of the mouse, as a tactile interface with the computer.

data) Multimedia tools
The multimedia CDs used in the project were various and different from phase to phase. In the first phase the CD used was "Primi passi/prime lezioni". In the second phase the CD used was "La di più, Primi passi/prime lezioni 2".

Spaces and Time
At the beginning of the experiment the PC was settled in the classroom, in a quiet area. Two chairs in front of the PC protected the machine. This phase lasted 3 weeks; the PC could be used during moments of free playing.

Activity and Methodology
This phase focused on five years old children, divided in groups of five. The children already had a PC at home, or the usual leaders of the class, it followed an exchange of suggestions, tries and information. The teacher helped children only on demand (except if they accidentally quitted the CD).

Later on, the younger children (4 years old), interested in the PC could use it, but only with help of 5 years old children.

In the meantime 3 years old children could watch the older ones, if interested.

1 About 80 000 people, 50 km North of Milan, on the shores of the famous Como Lake.
2 The largest technical University in Italy, with Faculties of Engineering and Architecture.
3 A city, in the very southeast corner of Italy, of size comparable to Como.
4 The school is Scuola dell'Infanzia Salita Cappuccini - Circolo Como 8°. The teachers involved in the first two phases (formation and modelling) are Giordana Corbani, Luisella Verga, Gabriella Bonanomi, Cristina Di Giusti. One of them (Gabriella Bonanomi) is in charge of developing the project within the classes.
5 roughly translatable as "I know more. First steps/First lessons" published by Leader Family
Phase b: Self Interaction
Objectives
a) Develop the ability of surfing in a CD with a simple structure.

Multimedia Tools
In the second phase 5 CDs have been used, from the easier to the more difficult: "mire con la nonna" 6, "La lepre e la tartaruga" 7, "Sheila Rae la coraggiosa" 8, "L’Assedio al Castello" 9, "Darby il Drago" 10.

Spaces and Time
This phase lasted 8 weeks; the PC could be used during moments of replaying.

Activity and Methodology
The PC was powered on only on demand. The first three CDs were installed by the teacher and they could be surfed by groups of 4 to 5 children between 4 and 5 years old. Later on children could ask which CD they wanted to use. Children interacted autonomously between themselves and with the machine.

When children have deeply understood how to interact with the first three CDs or they have lost interest the teacher installed the fourth and the fifth CD. So in this phase 3 years old children were essentially observers.

- 5 years old children autonomously surfing: 12 / 75%
- 4 years old children autonomously surfing: 4 / 25%
- 3 years old children observing: 12 / 75%
- 4 years old children not autonomously surfing: 6 / 33%
- 3 years old children not observing: 8 / 50%

Phase c: Use of the PC for a special purpose
Objectives
a) Develop the ability of using software to create and print graphical pages.

Multimedia tools
In the third phase the following programs have been used: "Microsoft Plus Junior", "Microsoft Paint", "Corel Print House", and "Kid Pix Studio".

Spaces and Time
The last phase lasted 4 weeks and the PC was used when the class was split by activities.

Activity and Methodology
The teacher powered on the PC and children could use it in groups of 2 or 3. "Microsoft Plus Junior", "Microsoft Paint" were discovered by children autonomously or when asked, under the guidance of the teacher. During this phase two children (a 4 years old kid and a five years old one) were chosen as tutors by the others to solve problems and give suggestions (including how to quit the program and the PC). Only if they were not able to solve a problem the help of the teacher was asked. Children were able to print on their own from "Microsoft Plus Junior", but they needed help to print from "Paint".

- 4 years old children drawing and printing: 9 / 50%
- 4 years old children drawing: 7 / 40%
- 3 years old children drawing and printing: 7 / 35%
- 4 years old children drawing: 11 / 60%

The third software was used by the teacher who followed the request of the children, such as change size or colors to the images.

Results
At the end of the experiments above described, the staff asked the teachers to specify if they were satisfied and why. The following is the summary of their answers in the context of high level overall satisfaction.

A. Children, having the possibility to use the PC as one of the various tools located in different areas of the class, learnt to consider the machine as one of the other possible games or tools, to appreciate its possibilities and to know its limits rather than consider it as a mythical object.

B. The use of the computer was integrated in the usual activities of the children: children of 5 and 4 years old, guided by the teacher, were able to look for and create images and symbols used later in the creation of books, stories, games...

C. Approaching computers in groups, rather than as a "single", has given the children the possibility to develop relationships of cooperation. The first type of relationship was aiming at solving technical issues (e.g., how to use the mouse and to understand the meaning of the icons). Later relationships aimed at solving "strategy" issues, in order to achieve goals (e.g., how to win a specific game or how to pass to the next level) were developed.

D. The co-operation among children has been positive both for the already capable children, who learned to express their abilities, and for the less skilled ones, who learnt how to interact with the machine without a direct help of the teacher. The goals set for the first phase have been achieved by every child: everyone understood the function of the mouse, even if the ability in using changes from child to child according to the age, the previous experiences and the time of use.

E. A lot of children developed good (or very good) skills in surfing the CD's. Some children surfed autonomously, some others following the instructions of the classmates. Levels of intention were different: someone surfed randomly, some others knew what they wanted to search for. Some children, who were usually not able to pay attention for a long time, have improved their concentration skill, some children were much more interested than others in the use of the PC.

Abstract: Historically the technical centered approach was criticized because of its propensity to create technical objects without considering their future use. The user centered approach seeks for better understanding the users, their practice and the environment (including organization and institutional aspects) in order to take all these factors into account from the first stage of a tool design.

The design of the socio-technical system is itself a socio-technical activity, one of the important tasks of it being the organization of the involvement of users at each phase of the design project. This is a participatory approach to design. On a whole this approach can be considered as a research action, implying the constant follow-up of the design process and the progressive analysis of users needs, of changes in their work habits, of the occurred problems as well as different recommendations proposed by users.

The practical part of our article illustrates the concepts of participatory design approach that we applied to the design of the graphical web browser NESTOR. This tool helps to construct meaningful information from the "raw data" one's get access on the web.

Introduction

Any particular system development project takes place in a wider context of technology development in which human artifacts and human tasks co-evolve. The artifacts-in-use of current technology embody affordances and constraints for human activity; at the same time, the tasks people engage in embody requirements for further technology development. Understanding artifacts in terms of the scenarios of use they enable and obstruct makes it possible to more deliberately manage the co-evolution of tasks and artifacts. We explored a method for pushing the participatory activities further "upstream" in the design process, to the initial analysis of requirements.

In our research we adopted several principles shared by most participatory design practitioners (according to Computer Professionals for Social Responsibility):

Respect the users of technology, regardless of their status in the workplace, technical know-how. Consider every participant as an expert in what they do, whose opinion needs to be heard.

Recognize that users are an important source of innovation, the design ideas arise in collaboration with participants of different fields.
View a system not as a collection of software and hardware but as a network of people, practices and technology embedded in particular organizational contexts.

Treat problems that exist and arise in the workplace by or in collaboration with the concerned parties. Try to find concrete ways of improving the working conditions of users, for example, co-designing new opportunities for revealing creativity; increasing worker control over work content.

Be conscious of one’s own role in PD processes; try to be a “reflective practitioner.”

Our research is performed as part of a larger educational technology European project “Learning Network for Teachers (Learn-Net):” The project is coordinated by Bernadette Charrier from FUNDP (Les Facultés Notre-Dame de la Paix). A primary objective of the project was to construct the network allowing the share of education resources, than to develop and evaluate computer-based, collaborative learning tools and environments in support of teachers. Participants of the project include teachers, students and researchers from eight European universities, a high school, a research center and a distance learning department.

Case Study

We applied a participatory design approach to the development of a web browser and cartographer NESTOR. This tool allows to visualize the Web browsing and organize the gathered information on the graphical map, it pushes users to construct meaningful information. Different scenarios used as a source material in the participatory analysis were extracted from videotaped observations of students activities. We supplemented videotaped observations with other forms of data including notes taken during observations, videotaped interviews of student and teachers. In the interviews we asked students and teachers general, open-ended questions on collaboration, experimentation, and pedagogy. The interviewers were encouraged to elaborate their views and to take the discussion in any direction they wished. Classroom observations, interviews and artifacts were collected over a period of two years from four universities.

This approach allowed us to adapt the tool to the activity, to add functions necessary for the work as well as to develop another interfaces, such as cooperative synchronous work, according to suggestions and recommendations submitted by users.

We have learned that participatory design is far more involved than merely inviting users to a design meeting. The users must feel engaged. They must have effective access to relevant information. They must have status, power, and scope of action sufficient to allow them to take positions and contribute to decisions. We believed that several factors contributed to this favorable quality of participatory interaction. Users develop a greater sense of ownership of the analysis and design because the activities are grounded in authentic activities occurring in the user’s world. We think that our method successfully shifted power in the direction of the user. The users contributed to activities and decision-making from the very start, they were highly engaged by the analysis process and contributed significantly to the analysis results. We conclude that the method has a promise as a technique for evoking self-reflection and analysis in a participatory design approach.

Perspectives on Web-based Historical Audio

Dean Rehberger, Michigan State Univ., USA; Jerry Goldman, Northwestern Univ., USA; Steve Cohen, Tufts Univ., USA; Joyce Grant, Michigan State Univ., USA

The National Gallery of the Spoken Word (NGSW) is developing an on-line repository of spoken word collections. To do so, project is researching a number of technical and educational issues. The project team drawing on people from the humanities, library science, engineering and education) is working on creating a distributed system architecture based on the Open Archival Information System (OAIS) as well as best practices for watermarking, digitizing, and preserving spoken word resources as well as metadata schemas and interface design. While a number of search techniques work well for text, search techniques for very-large-scale databases do not yet exist for spoken materials. Participants in this project include researchers who are recognized leaders in the development of algorithms for searching using acoustic and linguistic models. In addition, the NGSW is developing an educator’s forum to establish best practices with historical audio on the web. The goal is to establish a set of activities and tools that will make digital audio repositories useful to students, educators and the curious public.
Development of Interactive, On-Line Cases in a Medical School: A Case Study in Pediatric Genetics

Abstract: The Web is increasingly becoming a platform of choice for delivering medical education. The representation of content on the Web takes a myriad forms, from image identification to complex, simulated cases. This paper is an attempt to explore instructional design issues that play a significant role in the development of effective case simulations. Ten rich, complex case simulations were developed using theories of metacognitive and motivation and empirical support from case based reasoning. Forty more will be added to the web site based on the evaluation data received from the current version. The authors conclude that the Web offers a potent, viable platform for the delivery of theoretically robust case simulations.

Introduction

According to the Association of American Medical Colleges Medical Student Objectives Project (http://www.aamc.org/meded/msop/report1.htm#Goals), a predominant goal of medical education is the development of clinical skills among students. These include reasoning deductively to solve clinical problems (medical decision making), and constructing appropriate management strategies for patients. Recently, an engagement with web based instruction has generated richly annotated web sites for the delivery of the medical curriculum. However, much of this content is focused on the Basic Sciences, with the relatively little attention allocated to objectives pertinent to the development of clinical skills.

Purpose

The purpose of this paper is to explore the design and development of interactive, case based learning environments to improve diagnostic reasoning among medical students completing their third and fourth year clinical rotations. The specific discipline utilized here is Pediatric Genetics. The following questions framed the foundation of this development:

- Can current empirical support for case based learning form an effective foundation for developing web based cases?
- What types of motivational and metacognitive strategies are compatible with the development of case based learning on the Web?
- Does the Web offer an adequate platform for active learning essential for simulated cases?

Methods

Phase I
Fifty case presentations on real patients were initially developed by a fourth year medical student, using html and javascript. Although the cases were successfully received by students, the interactivity lacked the following elements of effective instructional design:

- User friendly navigation
- Instructional strategies consistent with instructional goals
- Adaptability based on prior knowledge and experience
- Scaffolding structures to allow for support in retrieving diagnoses
- Extensive, meaningful feedback
- Effective metacognitive and motivational strategies
- An online evaluation

Phase II of the project describes how each of these concerns was addressed.

**Phase II**

Phase II began with rethinking the objectives in a more focused way in order to align instructional strategies with the objectives. A task analysis was performed to ascertain the flow of content and nature of interactivity. Instructional strategies that would promote metacognition and motivation were strategically placed. Feedback provided was rich in nature and used the capabilities of the web to capture and present group data. An online evaluation form was created to assess perceptions of learning via cases. This was accessible after each case was completed.

**Development Platform**

All cases were programmed in html and Cold Fusion, using an SQL database residing on the school server. Data was collected for each student for analysis.

**Results**

Ten cases have been programmed, and we have invited medical students and residents to use these cases and provide feedback. The remaining 40 cases will be developed after the evaluations have been completed.

**Discussion**

We now attempt to discuss questions posed in the introductory section. We found that empirically based guidelines could be extensively and usefully employed in the design of web based cases. This support was drawn from areas such as metacognition, novice-to-expert research, quality of feedback, and computer based simulations. Secondly, the Web allowed to manipulate and present collective information from students (such as pooled data on performance on cases). Consequently, the implementation of social motivational theory could be a part of the case feedback structure, unlike any other media. Finally, three forms of interactivity were employed: hypertextual access to information, prompted recognition and recall.

**Conclusion**

Simulated, online case based learning is a relatively new field of study in medical education. The online cases described above are an attempt to create authentic environments for learning, using empirical support and instructional design theory. The Web was found to be a powerful medium for the delivery of complex case simulations developed with effective instructional design principles and supporting theories. The ongoing evaluation of these cases will provide further feedback, on which further enhancements can be made.
Analytic Geometry on the Web

Abstract: The purpose of this paper is to show how to develop interactive didactical material on the web with a specific educative goal and structure. The idea is to develop the ability of the students to relate the geometric and algebraic properties. This relation becomes evident in Analytic Geometry. The software resources that are available make it easy to develop the material focusing in the concepts.

Background

Using the web to provide learning material for the students is increasing rapidly. In the recent past we worked in the computer's laboratory with interactive tools that gave the students the possibility of studying geometry in a dynamic environment Recently the same people that produced the PC-software gave the teachers a tool to translate their interactive sketches to Java applets. This new tool is a good way to develop material that can be used widely to learn geometry through the web.

Traditional ways of teaching geometry have not been effective. The approach usually used is through memorizing the canonical equation of a curve. The loci concept is very often forgotten and the students do not relate the coefficients in the equations with the geometric properties. This approach has proven to be highly inefficient because the student gets easily confused with the equation of, for example, an ellipse and a hyperbola. Also it is very difficult for the student to understand the variation of the form of the curve and the coefficients in the corresponding equation. Also, the student does not develop the algebra in a different context, which is more meaningful for him as compared to the algebraic manipulation alone.

In the classroom laboratory we used The Geometer's Sketchpad. This software is a tool that allows us to construct, in a classical way, geometric figures with ruler and compasses with the advantage that it is dynamical and one can do recursive programs and scripts for the constructions. This software is very simple yet it allows you to make sophisticated constructions. There is also the Geometrie Cabrie that is very similar. In fact, conceptually and the MS-DOS
version Geometrie Cabrie came out earlier. The Windows version of The Geometer's Sketchpad was available first.

The material

The approach used in the computer laboratory with the Geometer's Sketchpad allows the student to fully understand the loci concept dynamically. The problem is that not always we have the availability of a computer laboratory at school or there is not enough time to do all the exercises during classroom time.

Thus we are developing interactive sketches that show the geometric concepts such as loci and eccentricity, and help the student understand the relation between the form of the curve and the coefficients of the corresponding equation such as the lengths of the semi axes in an ellipse. For an ellipse it is possible to show how the eccentricity relates to the curve. The visualization is accompanied with a worksheet that leads the student to watch and think about the characteristics of the loci he or she is constructing. The difference with other Geometry interactive material found at the web is that ours has a structure that allows the student to explore one by one each of the relations for every one of the curves. This method was used in the classroom with worksheets that contain geometric constructions and associated questions that the student must answer while animating the construction. The intention of the questions is that the student can construct relations and concepts and make conclusions about them.

This way of working with the computers has been used by the authors for several years and has proved to be very efficient because it allows the instructor to answer the doubts of the students rather that being engaged in showing how to do the constructions with the software and it also keeps the students really working in the mathematics without distractions. Many of the negative reports in a computer classroom are related to students that engage themselves in reviewing their personal mails instead of paying attention to what is done in the class.

We are translating about thirty worksheets previously used in the PC-laboratory to Java applets. These worksheets include material from the line to the hyperbola allowing the student to explore many of the properties of the loci. It also lets the instructor explore the different geometric definitions of the loci. The translation from Geometer's Sketchpad to Java-applets is immediate. The worksheets are proving to be more difficult to translate because the approach at the PC laboratory is different to that used in a dynamic interactive construction that can only be moved or animated. To show the use of geometry in real life, each module includes an application of the concepts studied in the module. A link is also provided to resources on the history of geometry.

Research has demonstrated that social presence not only affects outcomes but also student, and possibly instructor, satisfaction with a course (Moore, Masterson, Christophel, and Shea, 1996). Teacher immediacy behaviors and the presence of others are especially important issues for those involved in delivering online education. This study explored the role of social presence in online learning environments and its relationship to students' perceptions of learning and satisfaction with the instructor.

The participants for this study were students who completed Empire State College’s (ESC) online learning courses in the spring of 2000 and completed the end of semester course survey (n=97). A basic correlational design was utilized.

This study found that students with high overall perceptions of social presence also scored high in terms of perceived learning and perceived satisfaction with the instructor. Students’ perceptions of social presence overall, moreover, contributed significantly to the predictor equation for students’ perceived learning overall. Gender accounted for some of the variability of students’ overall perception of social presence, while age and number of college credits earned did not account for any of the variability.

Implications of the study effect the design and instruction of online courses in terms of students' perceived learning and satisfaction with the instructor. Instructors need to be aware of the
impact that their immediacy behaviors and social presence or lack thereof may have on their students' satisfaction, motivation, and learning.

A PAD-Based Classroom Computer System

Adolfo Riera, José Vila, Senén Barro
Grupo de Sistemas Inteligentes
Universidad de Santiago de Compostela
España

Abstract: In this work we present an environment that aims to facilitate the presentation of multimedia content in the classroom. The principal innovation of this system with regard to other proposals is the use of a wireless-access interface implemented on a palm-top computer or PDA, an approach that has been successfully explored in other fields. For its development we presuppose that the classroom has a LAN connection to the Centre’s local network through which connection to the Internet is available. The system comprises a PC connected to the network, a video projector connected to the PC with VGA and RS-232 cables, and a wireless-network access point. Teachers are supplied with PDAs using a wireless connection, with which they log on to the Centre’s network. This system enables teachers to essentially carry out two functions from the PDA: to control the operation of the PC installed in the classroom by means of a virtual PDA and a keyboard emulation, and to control the operation of the projector.

Introduction

Throughout history different technological innovations have been incorporated into the teaching process, from the invention of paper and the printing press to the innovations that are currently striving to make headway in this field, such as multimedia materials. Nevertheless, the reticence of teaching staff to accept and incorporate technological innovations into their daily routine is well known, at least if they are not aware of the immediate and significant benefits for their activity, or how simple they are to use.

In this work we present an environment that aims to facilitate the presentation of multimedia content in the classroom. The principal innovation of this system with regard to other proposals [1] is the use of a wireless-access interface implemented on a palm-top computer or PDA, an approach that has been successfully explored in other fields [2].

Architecture Of The System

Figure 1 shows the architecture of the system. For its development we presuppose that the classroom has a LAN connection through which connection to the Internet is available. The system comprises a PC connected to the network, a video projector connected to the PC with VGA RS-232 cables, and a wireless-network access point. Teachers are supplied with PDAs using a wireless connection, with which they log on to the Centre’s network.

In our proposal we use a PC with an Intel Pentium III microprocessor running 500 MHz, the Windows 98 operating system, an NEC Multisync MT 1030G+ projector, a Compaq WL400 wireless network access point and a Compaq Pocket PC PDA [3], with the Windows CE operating system and a Compaq Wireless card-connection. Using this system we have developed a client-server (PDA-PC) application written in Java (JDK 1.3) [4,5].

This system enables teachers to essentially carry out two functions from the PDA:

a) to control the operation of the PC installed in the classroom by means of a virtual PDA, the operation of which is similar to that used by many laptop computers, and a keyboard emulation (java.awt.robot
class has been employed for both tools, enabling the server to launch events according to the orders
sent by the client through the communications socket [4]), which also allows mouse sensitivity to be
adjusted and different keyboard simulations to be selected.

b) to control the operation of the projector. This can be turned on and off, focused, zoomed in and out, etc.
(functions are obviously limited by the characteristics of the video projector itself). This task is carried
out with serial port communications between the PC and the projector, which are administrated using
Java Communication API classes [5] that need to be adapted the protocol that is specified by the
manufacter of the projector.

Figure 2a shows the principal screen of our application. Here we can see the keyboard emulator in the
upper section, the active area of the PDA in the centre, below the simulation of the three mouse buttons, and in
the lower section we find the control buttons. These allow the PDA to be connected to and disconnected from
the PC, the projector control window to be opened (shown in figure 2b) and application to be closed.

Discussion

The proposed system enables teachers to remotely control the PC and video projector in a practical
manner similar to how they would do so if they could physically use both systems. For example, they can access
the Internet or the PC in their offices to download a PowerPoint presentation, a Web page or a PFD file. They
can run the corresponding visual application, and they can even access their agendas to set exam dates, or
access their e-mail accounts to read questions posed by their students.

This system is only the first step in a much more ambitious project. The idea is to embrace teaching
using commercial applications as well as personal contributions and reduce the mobile equipment required by
teachers and students to as simple PDA. With this they will have access to didactic material, communication
tools, administration applications, etc.

Abstract: The CERN “Web University” is a European-wide project where distance audiences participate in seminars at CERN from their own countries. CERN is setting up a video-on-demand service and opening its lectures and seminars for people in the 20 member states using real-time network connections. The exact learning method depends on learners' needs; they can select live and/or networked based video-on-demand service. Live distance learning is achieved by using real-time, interactive videoconferencing over the broadband research network or by using real-time broadcasting over public Internet. Interactive sessions are carried out using a Web-based Virtual Room Videoconferencing System (VRVS) and broadcast using RealVideo from the CERN Webcast server. Furthermore, learning is independent of place and time as the slides used during lectures are integrated into the recordings of live sessions and stored on multimedia servers. The integration of the slides is done using SMIL or Sync-O-Matic 2000 software.

Introduction and goals

CERN (European Organization for Nuclear Research, http://cern.ch/) created the Education and Technology Transfer (ETT) Division in the beginning of 2000 and adopted a Finnish initiative, Web University (http://cern.ch/webuniversity). The Division is setting up a video-on-demand service and opening access to CERN lectures and seminars for distance learners in the 20 CERN member states using live network connections.

The CERN Web University is a European-wide pilot project where distance audiences participate in CERN seminars from their own countries. Partner countries include Finland, France, Holland, Italy and Slovakia (Rinta-Filppula 1999, Ruokamo & Pohjolainen 1999). Activities in Finland are part of the Finnish distance learning project "Open Learning Environment" (1999-2003). The Web University is based on the concept of a virtual university where distance participants communicate over networks by using applications such as multicast interactive videoconferencing, webcasting, video-on-demand, World Wide Web (Web) and email. The pilot uses national research networks, European-wide high speed Internet and public Internet.

Distance learners can participate in CERN seminars from their personal workstations or from suitably equipped conference rooms in their institutes. The method of learning depends on learners' needs; they can select live or networked based video-on-demand services. Live distance learning is achieved by using real-time, interactive videoconferencing over broadband research network based on Internet technology or by using live broadcasting over public Internet. Interactive sessions are organized by using the Web based Virtual Room Videoconferencing System (VRVS) and broadcast from the CERN Webcast server using RealVideo. In addition, the learning is independent of place and time because the slides used during the lecture have been integrated into the recording of the live session and stored on a server. The integration of the slides has been done using SMIL or Sync-O-Matic 2000 software. VRVS has been developed by Caltech in association with CERN and Sync-O-Matic by the University of Michigan in association with CERN.
The target audience are researchers and postgraduate students, but some courses in physics and information technology have also been offered to undergraduate students, journalists, general public and high school students. By using this technology researchers can keep up to date with fast changing fields of interest and the latest scientific discoveries from CERN may be immediately integrated into student curriculum (Rinta-Filppula & Korhonen, Rinta-Filppula 2000). Furthermore, selected CERN lecturers are also experimenting with the qualities of meaningful learning based on constructivistic theory (Jonassen, Ruokamo & Pohjolainen 1998).

Future plans

In the beginning of 2001, CERN decided to collect together all real-time transmissions, webcasts and digital recording activities into a new Division and record digitally all Academic Training lectures (about 100 hours/year) and Summer Student lectures (about 100 hours/year). At the same time, selected lectures will also be transmitted in real-time and with some interaction with the distance audience.

All digital recordings will be archived on the CERN Document Server (CDS) that is used to store all scientific documents at CERN. In addition, selected digital recordings will be automatically mirrored to servers in the member states right as soon as recordings are available. In the future, CERN will further develop recording technologies and practices in close collaboration with the member states.

eLearning today is the most important area of developing and training. In Hame Polytechnic eLearning is not only by offering courses on the Internet, it is totally new approach to combine technology, contents and skills in order to empower learners with a new ways of learning and grow. HAMK helps and provide support to enthusiastic staff and teachers in order to bring their new ideas of teaching into reality. This form of support includes technical and teacher training; financial; instructional design and development; and continuous research.
Combining Different Aims in a Portfolio System: a Web-based Portfolio and the Various Ways in which it can serve the Student

Abstract: A portfolio in a competency-driven curriculum can serve many functions. This article describes the essence of competency-driven learning and focusses on the role the portfolio can play in the formative and summative function of assessment. Important issues are validity and reliability. The implications of combining different functions for the design of an electronic portfolio will also be discussed. In the presentation the focus is on the design (including examples of student-portfolios) and the implementation procedure.

0 Introduction

A portfolio is an organised, goal-driven documentation of a student’s professional growth and achieved competence in the complex act of a profession. Although it is a collection of documents, a portfolio is tangible evidence of the wide range of knowledge, dispositions, and skills that a student possesses as a growing professional. Documents in the portfolio are self-selected, reflecting student’s individuality and autonomy (Campbell 2001). Portfolios can be used in different ways in education. In the literature on portfolios three main aims for the compilation of a portfolio are usually distinguished, resulting in three different types of portfolio (Wolf 1997):

1. To address evaluation requirements: assessment portfolio;
2. To advance professional growth: professional growth portfolio
3. To aid in employment searches: showcase portfolio

An additional emerging aim, which has recently gained much attention, is that of 'sharing knowledge', being part of learning community. The fourth function of the portfolio is the communication function. The function which is eventually assigned to the portfolio is closely linked to the educational concept existing within the institution and the way this is implemented at curriculum level. The specific functions which the portfolio has to fulfil determine its design and eventual method of implementation. This article will describe the function of a portfolio in a competency-based curriculum.

1 Educational Concept: Competency-based Learning.

For several years now forms of competency-based learning have been introduced into large sections of higher education in the Netherlands. This has involved different definitions of the concept of competencies. Elshout-Mohr (2000) describes competencies as follows: ‘In the Dutch context, competencies refer to attributes of individuals that enable them to handle complex professional tasks in an appropriate, process-
and product-oriented manner.' Other definitions go deeper into the 'attributes', Klarus (1998) for example refers to 'an individual's capabilities (cognitive and behavioural skills)' while others describe 'attributes' as 'attitude'. What all these definitions have in common is that students become acquainted with professional practice during their studies and learn to deal with professional situations of greater or lesser complexity.

Characteristics of competency-based learning are:

1. Realistic tasks. During the course students work on realistic tasks: study tasks and assignments have an explicit and demonstrable link to professional practice and competencies. Ideally products and tasks are commissioned directly from bodies in the professional field with students being responsible for delivering or implementing them. The main focus lies on developing the student's competencies. This means that education is demand-driven, the educational programme 'facilitated'.

2. Students are responsible for their own learning process. During the programme the responsibility of individual students increases: they become the manager of their own learning. The principle behind this is that the responsibility which the student has for providing particular services (see 1 above) will have a positive influence on the responsibility which is assumed for the learning process.

3. Assessment of students is based on competency levels rather than the testing of professional knowledge and skills: students prove that they can function at a certain level.

4. Students are addressed as starting professionals during their studies. Professional practice thus has a systematic place in the programme and is involved in the assessment of study results and student's competency development.

5. Learning organisation. Programmes are continually developing in response to the ever-changing and ever-increasing complexity of professional situations: an innovative attitude is expected of professional practitioners. Tutors (currently practising professionals) and students (future professionals) learn from and with each other.

The choice for competency-based learning has far-reaching consequences; it is not only the programme which will be renewed, but the whole organisation which will change (see further on this: Te Lintelo 1999, Mirande 2000, Terwindt 2000).

2 Competency-based Learning and the Portfolio

2.1 The Personal Growth Portfolio

The biggest change for students in competency-based education is having to assume greater responsibility for their learning process and providing evidence for this. The student is given responsibility for all phases in the learning process: orientation, planning, implementation and evaluation. Traditionally the student's input was restricted to the implementation phase. In the orientation phase (what has to be learnt?), the planning phase (which activities will need to be carried out to achieve this?) and the evaluation phase (has what had to be learnt actually been learnt?) the responsibility lay with the tutor. In a competency-based curriculum, the student takes or is given responsibility in every phase. This means that the programme becomes demand-driven instead of input-driven and has the role of facilitating the student's learning process. In competency-based education meta-cognitive knowledge and skills (including reflection) are essential skills for the student: students need to be able to analyse the strengths and weaknesses in their learning process and in their knowledge and skills. On the basis of this they have to make choices, formulate learning aims and monitor their own learning process. The portfolio is eminently suitable for supporting these processes. A portfolio in a competency-based curriculum is thus by necessity directed towards the student's development (professional growth portfolio: Wolf, 1997). The developmental aspect points in two directions: students record and monitor their own development as well as developing their meta-cognitive skills while working on the portfolio.

When the portfolio is used in this way it is much more than just a collection of selected work. Dochy et al (2000) cite research which shows that the learning experiences and strategies which students develop to work with the portfolio (collecting and analysing data, organising, interpreting, reflecting) are important skills in the concept of life-long learning. Through reflecting on the learning process, working in the
portfolio and receiving feedback, students develop meta-cognitive knowledge and skills. Research among teachers (Tanner, 2000 and van Tartwijk, 1998) indicates that compiling a portfolio stimulates systematic reflection on one's own educational practice because choices and considerations have to be made explicit. A condition for this is that a context is created in which the portfolio forms the impetus for discussion about one's method of work. For students this means that a portfolio must also fulfil a communicative function. At the Amsterdam Faculty of Education we are investigating in a longitudinal study the effects of the portfolio on the selfregulation by students.

An important condition for a personal growth portfolio is that students feel that they are the owners of their portfolios (Wade, 1996). A consequence of this is that the student must have a certain measure of freedom in the design and composition of their own portfolio and that the student can decide who has access to the various components in the portfolio.

In short a personal growth portfolio has the following functions:
1. Monitoring one's own learning processes and making visible growth and development in relation to the competencies;
2. Communication about choices, aims and learning processes;
3. Support for students in their reflection;
4. Registration of the student's individual curriculum. In a demand-driven programme students will inevitably be following a curriculum tailored to their own individual learning needs.

2.2 The Assessment Portfolio

The function of a portfolio in competency-based learning is not necessarily restricted to its role in students' development; it can also function in the assessment of students. Using the evidence collected in their portfolio students can show that they are competent at the level of a starting professional. This means that output feedback in the form of a one-dimensional score (for example pass/fail) is no longer sufficient, and that assessment and feedback must be directed at the way in which and the degree to which the student has developed. The assessment has a formative function here, this form of assessment steers the learning process and contributes to the student's development. Feedback (from peers, counsellors) must be directed at the strong and weak points in the student's functioning and support the reflection process. This assessment function can be completely fitted into the personal growth portfolio.

When it has to be assessed whether a student is competent at a certain level (for example, to decide whether a student is sufficiently competent to receive their diploma), the assessment has a summative function. What requirements need to be met for a portfolio to fulfil this summative function? In answering this question the issues of reliability and validity need to be considered. In the discussion about assessment portfolios it is generally held that assessment portfolios, unlike personal growth portfolios, should fulfil certain external quality demands to make reliable assessment of students possible. (Wolf, 1997). Assessment portfolios must be comparable; demands are made on the number and sort of artefacts which have to be included: in other words they have to be more or less standardised. But is this a justified demand? Is it in fact necessary for assessment portfolios to be similar and comparable and if so, to what extent? Or is it rather that in this new educational concept different demands need to be made of assessment and that so far we have adhered too much to old criteria in regard to standardisation and reliability in portfolio assessment?

Elshout-Mohr (2000) looks for new criteria and Table 1 gives a clear overview of three educational settings each with their own learning goals, learning arrangements and assessments. In the third column a description is given of the consequences of the different settings for assessment.

Table 1 Alignment of learning goals, learning arrangement and assessment

<table>
<thead>
<tr>
<th>Setting</th>
<th>Learning goals</th>
<th>Learning arrangement</th>
<th>Assessment</th>
</tr>
</thead>
</table>

1 Reliability means that the outcomes of assessment should not depend on accidental variables such as characteristics of the assessors. Validity means that assessment procedures should measure knowledge, skills and competences, which are relevant for the context in which the assessment takes place.
In the competence-oriented approach, the learning arrangements are based on the ideas that learning is situated in a professional context and that learners profit from learning episodes in which they participate, as novices, in professional work. Participation provides them with opportunities to construct their own views on the work and the profession, and to regulate their own learning. The right-hand column in Table 1 summarises how assessment procedures might stem from the same approaches to learning as the learning goals and learning arrangements. In setting 1 and 2 identical assessment criteria are used for all students. Elshout-Mohr argues that in setting 3 "congruence between the instructional setting and the assessment procedure can best be reached by employment of assessment criteria that are attuned to student's work and self-regulated learning. It is not fair to assess students by using standard tests and fixed criteria".

In fact what she says here is that in a competency-based curriculum, with a demand-driven programme where the student carries a great deal of responsibility, assessment needs to be 'demand-driven' as well. Not only the curriculum has to be tailored to the individual student, but also the assessment. The evidence presented by the student must of course fit within the general framework of the professional competencies; but every student gives these their own unique interpretation which can only be done full justice in a non-standardised assessment. Assessment criteria have to fit not only within the framework of the professional competencies but also be relevant to the learning process of each individual, self-directed student. Such an assessment wins in validity at the level of the learning process of the individual student. It is precisely in a demand-driven competency-based curriculum that validity has a higher priority than reliability (Klarus, 2000). How you collect the evidence, and the nature of the evidence, is not important as long as the portfolio is valid, up-to-date, authentic, dynamic, longitudinal, multidimensional, interactive and rich in evidence of competence (Dochy, 2000).

Programmes which are concerned with developing demand-driven, competency-based curricula struggle with the form of assessments and the role which portfolio can play in these. Van Tartwijk (2000) signals a tendency away from freedom in students' individual selection of material, structure and form towards a more structured portfolio in which attainment targets are used to direct a self-evaluation which is supported by material included in an appendix. The underlying motive here is the pressure from educational departments to increase the reliability of portfolio assessment and in this way also indirectly to increase their influence on the content of the curriculum. This emphasis on reliability above all else fits, we believe, within more traditional educational models. If the assessment demands a great many requirements which portfolios must fulfil, this means that students will eventually make portfolios which bear a strong resemblance to each other. There would be an unintended conformity in the program. These portfolios are reliable but not valid as far as the student's individual learning process is concerned. However, if, in a competency-based curriculum, the responsibility lies with the student there will be a wide variety of portfolios in which the assessors have to interpret whether a student has sufficient proof of competence or not. Elshout-Mohr (2000) suggests that the problem concerning reliability and assessment can probably not be solved at the level of content, but at the procedural level: a carefully planned and controlled assessment procedure, which of course would be identical for all. The portfolio can play a central role in such a procedure. The criteria and standards to which the content must conform are not part of the portfolio and can be reached in discussion between tutor and student and possibly also the assessor.
3 Design of the Portfolio: a Combination Portfolio

In the literature on portfolios an area of tension is signalled, also for students, between the formative and summative functions of a portfolio (Wolf, 1997 en van Tartwijk, 2000). Personal growth portfolios (formative) give a valid impression of the learning process at an individual student's level. This 'evidence' can also fulfil a function within a summative evaluation (see above). The area of tension for the student lies in the fact that that a personal growth portfolio demands an open attitude to learning and being vulnerable. Such an attitude is difficult to combine with the fact that the same portfolio will play a role at certain moments in the assessment of the student. The question is then how both functions of assessment (formative and summative) can be combined in one portfolio. In the Netherlands we have developed a portfolio design in teacher education institutions which is constructed so that it can fulfil both functions at the same time without difficulty. This format meets the following requirements:

- The ownership rests with the student; the student decides who has access to the various components of the portfolio;
- It offers space, freedom and creativity to the students; they decide how they will prove their competence and what is included in the portfolio;
- The portfolio fulfils a function in the communication among students themselves and between students and tutors.

A web-based portfolio is able to fulfil these requirements and unite various functions. Students collect evidence on their own web-page in the form of products, and feedback and reflection on these. This material is ordered around the professional competencies. From this developmental portfolio the student then makes a selection: what do I want to show my assessors which will prove as convincingly as possible that I meet the demands of the competencies? What we have here is in fact an assessment portfolio within a developmental portfolio, a portfolio with different layers. The student only has to show the selected assessment portfolio to the assessors. This means that we leave the ownership of the portfolio with the student. Only a digital portfolio allows this possibility. In our presentation we will show the design of the portfolio with examples and give a brief description of the implementation procedure.

The Online Learning Alchemist: Preventing Gold Turning Into Lead

Rod Sims
Learning Services, Deakin University, Australia
rsims@deakin.edu.au

Abstract: This paper addresses the creation of materials and resources for use in online learning, focusing on the new and emerging roles for teachers and learners in conjunction with developments in our understanding of the human-computer interface. As more educational providers adopt network-based technologies as delivery portals, the demand for skills in the creation of effective online resources is becoming critical. If we are to provide the learner with online resources that will enhance knowledge construction and the teacher with clear measures that these activities are effective, then we as resource developers must resurrect the role of what might be termed the online alchemist. Our first task is to ensure that new digital resources are not simply transferred from their original format but repurposed to ensure learner(s) accessing those resources are able to interact with both the content and their collaborative partners with new levels of flexibility and manipulation. We must transcend the too frequent use of technology as a means to replicate existing resources and conceptualise environments that engender new paradigms for teaching and learning. Our challenge remains to ensure the gold we have in effective teaching strategies and learning resources is not tarnished through ineffective applications within the online learning context. One strategy to achieve this is through proactive evaluation, a framework that integrates a set of factors and influences to better inform the development of online learning resources.

Introduction

The imperative for tertiary education providers to embrace online learning as the primary mode for access to teaching and learning resources has never been greater. While many practitioners are familiar with the issues and processes associated with the production of these materials, many institutions are demanding their creation without necessarily having staff competent in all aspects of the online paradigm. At the same time, research studies have demonstrated online environments to be both positive and negative in terms of effectiveness and achievement of outcomes (Franklin, Peat, Lewis & Sims, 2001). Given this environment, questions remain as to both the effectiveness and value of online learning and the available skill base to achieve institutional objectives. What benefits therefore do options for collaboration, conferencing and information-access provide the 21st century learner? In a recent presentation, Peter Goodyear (2000) proposed that:

The World Wide Web is the biggest disaster to hit technology-based learning since the introduction of the personal computer.

While his argument may not be so much anti online learning as a challenge to prove that computers actually benefit the teaching and learning process, the disaster articulated appears to reflect the frequent examples of online learning that are no more than colourful, often confused, digitised text. And why has this transpired? One reason is because it is now too easy to take existing, often print-based materials, and without so much as altering their look or feel place them into a web-page and market it as online learning. And if those responsible for the conversion to web-based delivery have limited skills in issues of learner-computer communication, then further problems can result in the effectiveness of these resources. It is not that the resources themselves are problematic. Rather it is the assumption that access by learners operating in the online environment will generate the same outcomes as those achieved in the classroom environment for which they were originally designed. Given this scenario, I argue that online learning can potentially be little more than a lead weight, limiting
learning opportunities and effectively destroying what were once useful, integrated classroom materials. To
dress the issues of skill deficiencies and digital replication, this paper identifies a series of factors critical to
the online development process, describing their critical components and the characteristics peculiar to the online
learning paradigm that influence the overall conceptualisation of effective teaching and learning resources.

Strategic Intent

One of the first questions we always ask our clients is “Why are you attempting to place these resources or
explicit answer, then it is likely that the
strategic intent or rationale for the product has not been defined succinctly. Without a clear understanding of the
purpose of the product and the stakeholders who have an investment and/or interest in its outcomes, the chances
of success are reduced. Within the context of the tertiary education environment, these stakeholders include the
administration, the faculty, the development group and most importantly the students. Without full commitment
to the concept from all stakeholders, even with the best intentions, effectiveness in terms of learning outcomes
being achieved may not be realised.

The critical issue is the extent to which the online component(s) being considered will add value to the overall
teaching and learning process. For example, if an institution decides to “go online” without allocating sufficient
funds to recreate materials so that they will be consistent with learner-computer communication, then the
decision could prove extremely costly with few, if any, positive educational outcomes. Indeed, anecdotal
feedback is suggesting a rebellion against online materials; for example, where online is seen to be an economic
solution used by institutions in response to government funding cutbacks and academic workload increases. In
some cases the intent has been to introduce online studies to reduce class contact time, resulting in student anger
and resentment for being short-changed, not to mention issues of quality.

Content

Many online projects have focused on the conversion of existing paper-based resources into their digital
equivalent, with a proliferation of unit outlines and study guides in either HTML or .PDF formats made available
for student access. But this is not online learning, and if portrayed as such then is a misrepresentation of the
capabilities and benefits of the technology. If content materials and learning activities are to be placed online,
then a significant level of thought must be placed on the very nature of the online medium and the underlying
implications for current practices of teaching and learning.

<table>
<thead>
<tr>
<th>STATIC &lt;-----------------------------------&gt; DYNAMIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Predetermined and Presented</td>
</tr>
<tr>
<td>Content defined and prescribed by the teacher, and does not change for one iteration of delivery.</td>
</tr>
</tbody>
</table>

Table 1(a): Influences Affecting Online Content

As shown by the influences identified in Table 1(a), the online environment caters for a range of content formats:
from predetermined static media to a dynamic state where content is sourced, repurposed, constructed and
enabled by and for all participants in the learning process. Between these two extremes are the more typical
options for delivery of course content in terms of resource material being contributed to by both the teacher and
the learner. It is important that this range of options is understood and that the implication for the discipline base
is considered. To fully exploit the online environment means having to reassess the overall approach to the
content, how it should be presented or accessed and the relationship between teacher and learner in that process. The components associated with the content must also be addressed by considering their interaction with the influences and their availability to the learning community. As detailed in Table 1(b), the issues to consider will have a significant impact on the role of the content and subject matter in the broader learning process. Underlying this notion is the understanding that content can no longer be seen as being "owned" by the teacher or discipline but rather as an information base that can be perceived and worked with in many different ways.

<table>
<thead>
<tr>
<th>COMPONENT</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>Structure Organisation &amp; Information</td>
<td>If adopting strategies that enable the dynamic construction of knowledge, traditional forms of information presentation may have to be modified.</td>

<td>To what extent can traditional norms for quality of presentation be maintained if a more dynamic approach to content is considered appropriate, and what impact might this have on roles in the development process?</td>
</tr>
<tr>
<td>Quality of Expression (language, grammar, image resolution)</td>
<td></td>
</tr>
</tbody>
</table>

Table 1(b): Online Content – Major Components

Learning Design

The term learning design is used instead of instructional design to emphasise the learner-centred environments online resources can provide. Taking this stance is particularly important because it forces designers to conceptualise the development process from the learner's perspective rather than that of the content. However this does not preclude developers from adopting an instructivist (I) or presentational strategy compared to a constructivist (C) or generative approach, but does require careful thinking about the learner and the options provided for interacting with the content and their learning partners.

<table>
<thead>
<tr>
<th>I &lt; ------ Pedagogy -------&gt; C</th>
<th>Learning Outcome</th>
<th>Resources (Media, Modes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Individual teachers and learners have different philosophies on the most appropriate ways that knowledge is gained and learning acquired. As online environments can be perceived as supporting the constructivist paradigm, adopting rigid instructivist strategies may degrade the overall effectiveness of the encounters experienced by the learners.</td>
<td>These options link learning strategy to outcome and affect each component of learning design: problem solving; declarative knowledge; concept learning; principle learning; procedural learning; cognitive strategies; attitude &amp; motivation and psychomotor (Smith &amp; Regan, 1999)</td>
<td>The ways in which media elements are used and extent to which they are accessible will influence the individual components of learning design.</td>
</tr>
</tbody>
</table>

Table 2(a): Influences Affecting Online Learning Design

As detailed in Table 2(a), the design of resources will be influenced by the pedagogy, outcome and resources considered appropriate for the task. When considered in terms of the specific components that are critical to the overall design task shown in Table 2(b), the complexity of addressing educational and technological elements of
the process are emphasised. Embarking on the design and development of resources for online environments requires new layers of thinking to be added to the well-established principles of course development.

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Prior Experience</td>
<td>Online learning is a new environment, and learners must have the requisite skills to effectively work within this paradigm.</td>
</tr>
<tr>
<td>Learning Styles</td>
<td>Does the provision of a range of media elements address the different motivational and perceptual styles of learners, and what impact will this set of options have on the overall development effort.</td>
</tr>
<tr>
<td>Learning Environment</td>
<td>The extent to which the environment is designed as a digital page or a virtual world will impact on the overall development effort (see Interface Design).</td>
</tr>
<tr>
<td>Pathways/Sequencing</td>
<td>The strategies for online learning can establish predefined pathways or enable students to explore and discover different facets of the content. Managing these options to minimise information overload becomes critical.</td>
</tr>
<tr>
<td>Outcomes</td>
<td>In providing an online environment, are the stakeholders providing for a range of outcomes or are the consistent with predefined objectives.</td>
</tr>
<tr>
<td>Assessment</td>
<td>Closely linked to outcomes, are new forms of assessment being considered for the online environment, such as collaborative understanding and concept formation.</td>
</tr>
<tr>
<td>Level of Learning</td>
<td>What impact might governmental standards have on the design - and do those standards influence or constrain the preferred modes of delivery within the online context?</td>
</tr>
</tbody>
</table>

Table 2(b): Online Learning Design – Major Components

Interface Design

The interface between learner and computer is one of the two most neglected aspects of online learning, the other being interactivity, as both are integral to successful and ongoing communication. As detailed in Table 3(a), the options available for on-line productions can range from the non-contextual through to the theatrical, where the learner is conceptualised as an active player in the overall learning process rather than a passive observer (Laurel, 1991; Sims, 2000).

Overall, the conceptualisation of the interface must consider the strategies employed to position the learner within the illusion of the virtual learning environment; the way in which representations, metaphors, icons are employed to support communication; how design decisions affect connectedness and interference within the learner-computer interface and the extent to which animations and sound effects impact on cognitive load and degradation of learning (Sweller, 1988). The associated components for Interface Design are identified in Table 3(b) and are linked explicitly to the elements of Learning Design, one area that can be neglected by developers new to the creation of online resources. To maximise the online learning experience it is not sufficient to apply rigorous educational design to content materials as the means by which that content (resource, activity, conference, reading) is presented to the learner will impact on its overall effectiveness.

| Non-Contextual <------------------> Contextual <------------------> Narrative <------------------> Theatrical |
|-------------------------------|---------------------------------|-----------------|-----------------|-----------------|
| Information Design           | Interaction Design              | Input/Output    | Navigation Design | Aesthetics |
| What procedures have been employed to ensure maximum communication of information? | Have the various interactivity options been catered for and communicated to the learner? | How clear are the options for entering and accessing content and responses? | Does moving between resources affect continuity of delivery or context? | How does the “look and feel” contribute to or detract from the communication experience? |

Table 3(a): Influences Affecting Interface Design
COMPONENT | Issues
--- | ---
User comfort - connectedness | Has appropriate usability testing determined the extent to which users are able to work with the resources and make the necessary connections between content elements?
User control | In what ways are users able to control the learning process and link the activities to their own learning requirements?
User centred | Supports content structure
| Has the interface been conceptualised to be consistent with the content structure while maintaining acceptable standards?
Supports learning design approach | Has the interface been designed to be consistent with the particular paradigm employed for the course?
Alignment of Mental Models | What strategies have been employed to ensure the mental model of the design group has been effectively communicated to the learner?
Customisation vs Individualisation | In what ways can the learner structure the environment to meet their own individual learner needs or preferences?

Table 3(b): Online Interface Design – Major Components

Interactivity

Interactivity is about successful communication and, in the context of online learning environments, one of the most crucial factors to address. As a component of the human-computer relationship or encounter (Sims, 2000; Sims, 2001), interactivity can include passive presentation, navigation, undirected exploration, directed involvement and specific manipulation. The extent to which these constructs of interactivity impact on the continuity of communication between learner and interface, content, other learners or other teachers is critical to the overall effectiveness of the experience and is inextricably linked to the factors and influences associated with content, learner design and interface design.

Student Support

Providing appropriate support for the learner cohort is even more critical in the online environment because in many instances they will be working independently in their preferred environment. Even though this environment may include collaborative work, the learner’s only medium of communication is the computer, and therefore support becomes critical to ensure their mental model is consistent with that of the other stakeholders in the process. In addition to the typical help systems, announcements and guides, recent research (Sims, 2000) has suggested that more explicit support is required to bring the learner into the online environment, especially by eliminating assumptions that learners will know what to do and why they are doing it.

Utility of Content

Within Australia, new digital copyright legislation and the proliferation of digital resources has provided new incentives to focus on the international standards for online learning environments. A crucial component of any development exercise therefore is to examine the extent to which content can be used in multiple environments (within and outside the product being developed), the means stakeholders might have to customise the materials and the interoperability between other learning objects in the wider curriculum.

Learner Outcomes

The final factor to consider relates to the ways in which outcomes have been successfully achieved. For example, measures of learning associated with both intra-curricula and extra-curricula activities; the level of learner satisfaction with the overall experience; the completion rates and the extent to which pass rates and grades are consistent with alternative delivery options. Overall the design effort needs to include items to enable a comparative analysis of student outcomes in relation to the overall development parameters.
Proactive Evaluation

The classification of factors and associated influences as discussed above provide the basis for a concept I refer to as proactive evaluation, developed in association with Graeme Dobbs and Tim Hand. The essence of this concept is that by first considering the complex interactions between educational design and online environments, designers and developers with new or limited skills in online learning will reduce the risk of producing poor-quality or ineffective materials as well as the likelihood of critical, negative evaluation. The ideas presented can be viewed as an extension to current practice in instructional or learning design, as many of the factors identified stem from that theoretical base. However, the underlying principles assume that the environment for which the development is being undertaken is not a traditional instructional setting, but an online world in which the traditional relationships between teacher, learner and content no longer always hold true. By applying the proactive evaluation concept, development teams will not only ensure all aspects of creating online learning resources and activities are addressed, but that subsequent formative and summative evaluation will be more rigorous and meaningful. In addition, the concept focuses the decision making process on the complex interaction between disciplinary content, learning outcomes and computer-based learning environments. By better understanding and addressing these relationships, more effective teaching and learning resources will be consistently produced.

Conclusion

In mid-1970, Donald Bitzer mesmerised an audience in Perth, Western Australia with a demonstration of the PLATO system. The capacity of computer-based technology to display combinations of media elements and respond meaningfully to user actions and manipulations was even then well established. Over the ensuing 25 years, the power and capability of the computer to support the learning process has often been lost in the maze of marketing publicity of technical gadgetry and wizardry, and has been maintained through the new wave of e-learning and online learning initiatives. Unfortunately, without the requisite skills, it has become all too easy to create web-based materials without understanding the underlying principles of online, interactive learning and rather than creating golden learning opportunities, many materials have been more leaden, with learning a confused labyrinth of information, links, colleagues and navigation. The factors and influences presented here, which are critical to online learning, have been expanded to provide a framework for the concept of proactive evaluation. By enabling development teams to address the critical issues associated with the creation of learning resources for delivery in an online environment we have a greater chance of ensuring our gold retains its lustre, and learners gain significant value from their online experiences.

Abstract: The Technology Serving Learning Institutes have provided instructional technology training to 60% of Southeast Missouri State University faculty since 1997, with most gains made since 1999. To prepare faculty for online course development, the Institutes were redesigned in 1999 to employ a flexible format based around a pedagogy course. The new format increased faculty participation in the Institutes, and fostered development of more course web pages, with greater sophistication than previously seen. Walk-in, phone, and e-mail faculty support continued beyond the Institutes in the Office of Instructional Technology (OIT). The OIT developed custom course management software, the Online Instructor Suite (OIS), which combined a manager, online calendar, online gradebook, online testing, and web page generator to meet instructor needs.

Introduction

Southeast Missouri State University is a regional four-year public university enrolling 8000 students. The University's Strategic Plan expresses Southeast's mission, with a focus on enhancing student learning through optimal use of information technology and development of "innovative applications of technology ... " with the ultimate goal of extending access to information technologies to faculty by providing training opportunities and support, and by extending distance learning opportunities via technology. These goals drove our efforts to provide instructional technology (IT) training and support to Southeast's faculty in the form of Technology Serving Learning (TSL) Institutes.

Early TSL Institutes

The Institutes originally followed a short course model, in which participants worked intensively over 5-8 days on topics such as PowerPoint 4.0, Authorware, and Web-Page Authoring. In Summer 1998 (S98), two-day "companion" courses were added to address specialized topics such as online testing and gradebook applications, leading on-line discussions effectively, and using video with Web pages and PowerPoint. Participants were to develop useful products, such as Websites or PowerPoint presentations, during or immediately after the Institutes. Deep immersion in the content would allow participants to return to the Departments as "experts" in the technology studied. We expected demand for the original Institute sessions to drop after the experts returned to the Departments.

What did we learn from the Institutes' first two years? The Institutes were quite popular. The hands-on nature maximized involvement in the design process, allowing participants to brainstorm with facilitators. Fears about turf issues and faculty resentment of IT spending were unfounded. However, the Institutes failed to leverage previous faculty experience, and they did not account for demands imposed on faculty by course content, accreditation agencies, and departmental resources. Faculty time commitment problems persisted, and despite efforts to impose balance, technical proficiency usually trumped pedagogical practices. We created few Departmental "experts"; but early participants did generate interest in the Institutes among colleagues. Finally, our intended focus
on product was imperfectly realized, with some participants failing to complete projects. Clearly, the Institutes required revision.

A New Format

The Institutes' popularity led us to offer Winter Institutes in January 1999 (W99). The W99 Institutes were not full-featured offerings; rather, they were teasers for the Summer Institutes and accommodations to faculty having scheduling difficulties. Fears of interfering with Spring semester preparations led us to organize W99 as single-day sessions. Nevertheless, we expected low enrollment in the three offerings. We were instead astonished to find demand so high that second sessions of each had to be hurriedly arranged. While length was the most noticeable change from S98 to W99, two concurrent improvements occurred: we completed the transition from Windows 3.1 to Windows 98 (necessary for FrontPage 98), and we began to teach CSTL-developed software (GradeA Gradebook).

Though not constrained by faculty's need to prepare for a semester's imminent beginning, we retained single-day sessions in Summer 1999 (S99) to allow faculty selection of programs maximally suited to individual needs. Modular design also allowed us to work around facilitators' schedule conflicts and more easily repeat high-demand sessions. To address concerns about the technology/pedagogy balance, we adopted a two-tier model, in which a mandatory pedagogy session was followed by choice of twelve applications sessions over three weeks. The pedagogy session, facilitated by OIT's Instructional Design Specialist, offered good composition practices that, while emphasizing Web pages, could be applied in any environment. The applications sessions practiced good pedagogy in specific software environments. A second custom-developed module (UTest, an on-line testing application) was introduced in S99.

We used the two-tier, single-day session model for all Institutes since S99. By hiring a PhD in Instructional Design in the OIT, we were able, for the first time, to present instructional design from a rigorous, theory-based perspective in Winter 2000 (W00). In Summer 2000 (S00) we increased the number of offerings of both pedagogically oriented and technically oriented sessions. Advanced instructional design and Web page development sessions were taught to attract veterans of previous Institutes. S00 also saw the first offering of an on-line session, "Teaching in the On-line Environment". The Winter 2001 Institutes focused on Web page development, with our custom OIS software serving as a course manager.

Results

A total of 251 faculty have attended the Institutes, nearly 60% of the faculty on campus. Most importantly, we saw a continuous increase in participants over the four Summer and three Winter Institutes. After large new participant enrollments in S97 and S98, the number stabilized at ~30 each in W99, S99, W00 and W01. We concluded from this pattern that, after attracting the early adopters in S97 and S98, faculty not prone to early adoption steadily joined the Institutes, as they observed successful IT implementations from previous Institutes. With new participant enrollment stable while overall enrollment climbed, veterans must have found enough value in the Institutes to return for more. We therefore conclude that we are winning over faculty to IT approaches to teaching and learning.

We also saw that our resources were expended efficiently. The cost/hour of instruction delivered to a participant fell ~50% from S97 to W01, due to more efficient technology (better copying/printing capabilities in the CSTL), self-written software (lower software license costs), and better organization (experience improved resource management). Recruitment cost declines also contributed to the overall drop in costs; we therefore argue that our increased enrollments did not result from expanded recruitment efforts. Indeed, faculty have recently begun to call far in advance of our recruitment cycle, requesting enrollment in whatever Institutes are offered! We apparently benefit from superb word-of-mouth advertising. Participants' PD stipends declined from $17/hr to $10/hr, convincing us that increased participation was not due to PD money "bribery".

Responding to our early disappointment with the lack of "expert" creation, we began in W99 to recruit participants from earlier Institutes to serve as facilitators. We believe that these faculty have become experts through self-confidence derived from having been selected to act as facilitators, and from greater care taken to learn the technology and pedagogy, knowing that they would be under the direct scrutiny of colleagues.

All Institute participants were asked to complete an evaluation instrument consisting of open-ended questions and questions seeking a response on a nine-point scale (9 = high). The instrument questioned interest, facilitator quality, content, pace, quality of the student helpers, effectiveness of the Institute, its usefulness, reasons
for taking the Institute, suggestions for future topics, and overall faculty satisfaction. Evaluations have been
generally very positive with typically an 80% response rate, and responses of 8.0 to 8.2. When rating effectiveness,
110 responses of "Effective", 36 "Somewhat effective", two "Somewhat ineffective", and one "Ineffective" were
recorded. The few complaints received focused on issues other than content, so we felt that we succeeded in making
the case that IT has an important place in college teaching.

The Institutes brought other improvements to campus, and especially to teaching and learning. Faculty
involvement in campus IT issues has increased greatly since the Institutes began. Attendance and presentations at
IT conferences has also significantly increased. We feel that Southeast has moved from the trailing edge of adoption
to the leading edge of development and implementation. Over 300 of 380 faculty have active IT server accounts;
over 500 course sections have web pages. Many faculty Web pages showed improvements in organization and
format; these pages also tended to appear in more easily navigable Websites than before. Finally, we have increased
the number of online courses (offered and under development) from zero to 60 in only two years! Southeast faculty,
almost all of whom have attended at least one Institute, developed all these courses. Importantly, sound instructional
technique is being included in course Web page development and pedagogy is taking on as strong a consideration as
the technology itself. We feel especially satisfied with this outcome, as the number of technically sound online
courses nationwide far exceeds the number of instructionally sound online courses. The emphasis on pedagogy in
online instruction is an important component of IT training and support at Southeast Missouri State University.

Future Plans

With new participants continuing to enroll, basic Institutes, such as PowerPoint, will remain in both
Summer and Winter sessions. Advanced topics (e.g., cascading style sheets, active server pages, Macromedia Flash),
and pedagogically-oriented Institutes (e.g., leading effective on-line discussions, teaching critical thinking on the
web, using the Socratic method in on-line teaching) will be developed to serve veterans desiring additional training
and to increase the focus on effective use of technology to enhance teaching and learning. Institutes to support on-
line course development, and additional selected Institutes offered entirely on-line are planned. Additional
components of OIS will be taught in sessions in the Summer 2001 Institute, including online calendar and online
conferencing software.
PERSONAL DIGITAL ASSISTANTS IN THE CLASSROOM: AN EXPERIENCE

PATRICIO RODRIGUEZ, MIGUEL NUSSBAUM, GUSTAVO ZURITA, RICARDO ROSAS AND FRANCISCA LAGOS

Abstract:
shown to be aseptic or “slow” in the adoption of new technologies. Personal Digital Assistant are low cost technology that permit individual use. Learning can be produced in a natural context (not in a computer room) using a specific language, video-game in our case, that allows both the children and the teachers to use the technology in an easier and more direct way. An experience with 263 children was carried out in Chile were it was shown through qualitative and quantitative results the success of the experience. The paper finishes addressing how wireless communication can be used in this environment to obtain social interaction and collaborative learning.

1. INTRODUCTION

1.1. Why computers in the schools?

The incorporation of computers in schools has allowed determining the effects of technology in the educational process. Studies indicate that this tool favors specific cognitive skills, time dedicated to the task, and student motivation for learning. Positive effects have been detected in reading speed (Krischer et al 94), in reading comprehension, an increase in visual vocabulary (Becnel 91, Rockman 93), and better performance in Algebra (Council 90). Also, attention span and concentration are favored by this computing tool.

The positive effects of the computing tool on learning are due to the fact that it personalizes learning to each student and presents contents in contexts not associated with school. The computer is an effective tool since it provides feedback, corrects without making emphasis on mistakes, frees children of the difficulties of interaction with adults, and finally, it is attractive for the student (Fitzgerald 91).

1.2. Problems with computers

1.2.1. Costs

However, the software and hardware technology needed to equip a classroom is still expensive for developing countries where the number of machines per school must be limited to 3, 6, or 9 and in exceptional cases, 30 (Hepp 99). For that reason, the effective usage that each child can make of them is still very low.

Complementary, the effective use of computers can be low due to operational reasons. Computers can lose their configurations due to system crashes or improper handling by the user, need system management and operating system training.

1.2.2. Lack of Software embedded with curriculum

While each school may have at least one computer, the acquisition of computers has not been matched by the development of educational software according to the objectives of traditional elementary education (Soloway 98). The existing software in this category is mostly in English, or it is not designed with formal ends, and there is no systematic effort to develop solutions that would satisfy the most basic needs of the curriculum of each country (Nussbaum et al. 99). So, it is more probable that the software installed on the machines is of general use – such as word processors or spreadsheets – than specific tools designed for learning.

The experience of the Chilean project Enlaces (Hepp 99) shows that teachers have greater appreciation for software that directly addresses their curricular objectives (regardless of how simple it is). They would like it to be closer to their methodological focus and in the Spanish language. This is very important because the issue of software simplicity has a direct impact on the platform that must be used to run the programs. Simpler software will require less associated hardware, and for that reason, cheaper technologies could be used that would allow for massive use.

---

1 This paper was partially funded by FONDECYT 1000520
1.2.3. **Difficulties in technology adoption**

In the United States (Mackenzie 99), 70% of teachers can be classified as aseptic or “slow” in the adoption of new technologies. Some of this is because they have received little support or opportunities and insufficient equipment. Others consciously resist. These “slow” adapters have little tolerance for change and are not very disposed to changing existing behaviors unless evidence exists that the efforts involved in the change will have results (Mackenzie 99). They demand a complete, finished product before accepting the idea. They demand a total solution that is friendly, complete, and with good foundations.

Other causes for resistance are the frustration involved in learning how to use the computer, lack of confidence about the effects on learning, the perception of the computer as a competitor for the children’s attention and as a risk in terms of the investment of time and effort that it implies, the fear of losing control or looking bad in front of the class, and the resistance to assuming new roles that this incorporation implies (Hurtado 97). To combat these fears, it is necessary to adequately train teachers for the use of technology. If this is not done, the feeling of lack of preparation for the use of the technology can become very high, even in developed countries (Mendels 99). Thus, the massive use of technology is not only made difficult by the low budget available to schools –a problem that does not only affect Latin America, but also the United States (Soloway 98)– but also by the difficulty of adoption for those who have to use it. However, the proportion of teachers who maintain a reticent attitude toward the introduction of computers in the school diminishes when they perceive positive results; they take an open, enthusiastic attitude toward its adoption (Núñez 96).

2. **AN EXPERIENCE WITH PDAS IN THE CLASSROOM**

2.3. **PDAs: Computer Technology at Lower Cost**

Today, technology offers new personal tools. The tendency is that each person will have a computer in his (or her) pocket to assist them with their work. Nowadays, electronic agendas, pocket PDAs, and even new cellular phones with additional functions are becoming more popular. The appearance of this technology has been more effective and lower cost than traditional technology. This opens an opportunity to explore new applications, especially in education.

PDAs\(^2\) are used in many different areas (business and entertainment, among others), some with more diligence than a PC. They can offer alternative technological possibilities in addition to their ergonomic and portability advantages (Yoshiyasu et al. 98). Also, users show great interest in mobile technology (wireless mobile web restricted with portable computers: Notebooks, PDAs, wearable computers) as assistants for their activities (Ammitava 99). However, few studies exist related to the incorporation of mobile technology in schools as a support tool for educational activities capable of generating similar results (Luff & Heath 1998).

2.4. **A computation tool Based on PDAs for the classroom**

2.4.1. **Key issues of the design**

Keeping in mind what was mentioned in Section 1, the idea arises to incorporate low cost personal technology that would permit individual attention for children. Learning would be produced in a natural context (not in a computer room, which breaks the learning context), using language that allows both the children and the teachers to use the technology in an easier and more direct way; they would forget that they are in front of a computing tool. Encountering this kind of language is a fundamental aspect for this kind of tool.

Ludic and motivational aspects determine the attitude of the students in front of the technology. Students prefer activities in which the educational content is presented in a game-like context, particularly when aspects like competition, time, and/or points present immediate and interesting challenges (Hubbard 91). The interest of the students in video games is so high that if we take advantage of it in the interest of education, we can create a great tool for learning and motivation (Baltra 90).

Several authors attribute great importance to games in the psychological and social development of people, especially children. There is a good deal of evidence of their measuring role in the socialization and learning processes (Bruner et al 76, Rogoff 93, Vygotski 79). According to Vygotski (Vygotski 79), games are the promoters of general development in children since they allow for teaching rules as well as investigating their own capacities and limitations. All this can later be extrapolated to real situations. In games, children generate their own spaces and opportunities that allow them to develop imagination, their symbolizing capacities (through the “as if”) and consequently develop abstract thinking skills as well as the comprehension and recognition of implicit rules that affect the game and reality. The child rehearses new activities and reflects on ideas without the pressure which frequently accompanies more formal attempts at learning (Bruner et al. 76, Rogoff 93).

\(^2\) Personal Digital Assistant, Hardware which supports mobile technology.
For this reason, the language of games seems to be the most appropriate to use in the implementation of technology. Such language allows children to learn without realizing it, forgetting that they are doing a “task” or that they are in a classroom. They can operate without the fear of making a mistake; all this changes the dynamic of traditional classes for both teacher and student.

2.4.2. Target Population and Tool description

In Latin America, there is a high rate of failure in the compliance with minimal educational objectives. In the case of Chile, the failure rate reaches close to 12% in the four years of general elementary education (GEE) (Nussbaum et al. 99). This means that a significant percentage of the children that finish 4 years of GEE do not know how to read nor do they possess basic mathematical concepts. In consequence, they represent the group at highest risk for later failures in school, given that they do not manage to adapt to the framework of formal education. The objective is to be able to assist in the education of the aforementioned population, supporting them through the use of a low-cost portable computing tool with educational games including basic mathematical concepts and beginning reading.

The educational tool (Nussbaum et al. 99) consists of a portable video game console, oriented toward children of 6 or 7 years of age. It contains 7 specially-designed educational video games which support the essential contents of the Spanish language as well as mathematics from first and second grade of elementary education. The tool does not require previous knowledge, which means that it is easy to use for both children and teachers as soon as it is turned on. Also, given that the equipment is basically a mini-computer, the video games are supplied with “intelligence” (an expert self-regulation system) which adjusts the difficulty levels of the games as the child uses the equipment.

In a first implementation, the Nintendo Gameboy platform was used because it is very popular and low cost. A cartridge was designed that contains the aforementioned software for the machine. In the future, other alternative platforms may be analyzed which comply with the requirements, may minimize cost, or integrate already existing personal technology.

Seven games were designed which cover mathematical and language contents:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Each game is associated with a story. For example, the game Magalu (Figs 1 y 2) consists of a little magician that must complete a bridge in order to get the magical objects that will make her a great Magician. Magalu must shoot magic at the correct blocks to make the bridge.

![Game Screenshots](image-url)
2.5. Experience

To study the behavior of the children in regards to the tool, it was decided that participating schools had heterogeneity in terms of socioeconomic level, type of administrative dependence, religious orientation, average age of first grade students, geographic location, and quantity of students per class. The decision was made to work with 263 first graders from six schools. The process began with training in order to form the teachers. Also, support material was given to the teachers, such as explanatory manuals, as well as charts of the games and how the PDA works.

The work with the establishments was divided into two large groups: those that received more support from the team and those that worked more independently. In the three establishments that worked with more support, implementation began with a periods of modeling in which representatives of the team presented the machine and games to the children. Also, the team asked the teachers for their semester schedule. According to these plans, a proposal was formulated so that each game would be used in parallel fashion with the presentation of the contents in formal classes. The other establishments had absolute liberty to decide which games to use and at what time. They did not have the modeling period previously mentioned.

2.6. Results

2.6.1. Management and Appropriation of the Tool By Students

Information was gathered through group interviews, surveys, and observation charts for the game sessions for analyzing the technology transfer. In general, all students showed themselves to be highly motivated by the tool and maintained a high level of attention and concentration during the game sessions. For that reason, thanks to a hand on experience, all of the children developed the necessary psychomotor skills.

The analysis of the collected information allows to conclude that the students’ technological transfer was not a difficult process. The students’ interest in the machine increased along with their commitment to take care of it, their capacity to handle it, and their motivation to use it as a learning resource.

2.6.2. Appropriation of Technological Innovation by the School System

The teachers evaluated the seminars given, indicating that enough tools were supplied for the implementation. The most useful thing for them was the given short training with the machine, followed by the game manuals and group discussions. Talks and simulations, however, were not considered to be of high utility for the implementation process.

The appropriation of the technological innovation process was studied more profoundly during the second semester of implementation. The purpose was to discover the importance of many aspects of the technology transfer. It must be noted that the characteristics of each establishment and of the teachers, significantly influence the characteristics of the processes of technological innovation that are developed in the classroom.

The observation in the schools revealed, in general, a good disposition toward incorporating technological tools in the classroom. As the teachers saw the children’s motivation with the tool, they began to get involved in the activities of the project and to work together with the coordinating team. In general, the teachers reported feeling comfortable using the tool. They pointed out the machine’s contributions to learning, its impact on the teacher-student relationship, and its contributions to the work of teaching.

2.6.3. Quantitative Results

Figure 3, shows how the use of the PDA influenced the voluntary attendance in the Hogar de Cristo school, with children involved with drugs and other social problems with an average age of 12 in first grade. Figure 4 shows the results in two schools where it can be seen the learning effect for children above and below the average, comparing them with a control group that didn't use the machines. Further results can be found at http://www.ing.puc.cl/sugoi/presentation
2.7. Introducing wireless technology to the Classroom

Once the first experience with PDAs was completed, the following question arose: Is it possible to obtain social interaction and collaborative learning with the help of mobile technology? Necessarily, this question implies incorporating communication capacities into the PDAs, such as those brought by Bluetooth technology.

Of the 12 basic models of collaborative interaction (Davidson & Worsham 92) that can be developed for the objectives and characteristics of the type of applications proposed here, the following is the most appropriate due to the type of interaction offered, number of participants it handles, type of collaborative objective it supports, and the collaborative learning formalisms it offers:

<table>
<thead>
<tr>
<th>Type of interaction:</th>
<th>Collaborative Group Learning to develop collaborative learning activities.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>3 to 5 participants, heterogeneously grouped for an academic activity that seeks a simple objective. The key elements (formalisms that have successful collaborative learning methods) for formal collaborative groups include positive interdependence, individual responsibility, group processing, social skills, and face-to-face interactions.</td>
</tr>
<tr>
<td>Model</td>
<td>In the model in Figure 5, the circles represent students, and the arrows indicate the interactions that can be achieved between the subjects, in order to achieve a collaborative environment.</td>
</tr>
<tr>
<td>Prescription</td>
<td>Utilized to intensely commit the student to the processing of necessary activities for learning and transfer. This model is adjusted to the formation of the groups, which could support collaborative learning activities in the same place (face-to-face) and at the same time (synchronous).</td>
</tr>
</tbody>
</table>

Figure 5 and 6: Models of Collaborative interactions with and without PDAs

Technological support is achieved by extending the previous model to the use of PDAs with bi-directional wireless communication, in this way forming a local mobile web (see Fig. 6). This new model allows the students to interact with their PDAs (rectangles in Fig. 6) as well as be able to interact face-to-face in a synchronous fashion. The PDAs send and process the information of the different groups formed during the collaborative activity.

Figure 7 shows the interface of 3 PDAs in a Mobile Computer Supported Collaborative Learning (CSCL) Mathematics application. Each PDA shows a number, and the objective is to sort the three numbers. Collaborators can move with their PDAs to verify the order of the numbers or to place PDAs in a given order they consider correct. When they finish this step, the child who has the lowest number in his or her PDA (or the highest depending if they should sort up or down) presses the button "juego". The rest of the collaborators consecutively press their button in their turn. If the sequence of the numbers has correctly been formed, the Mobile CSCL application communicates it to the collaborators through the wireless network. In case the sequence is incorrect, then the group is told that the answer is wrong (as it can be seen in Fig. 8). To indicate the collaborators the formation order, in the upper left an animation of a number that goes up or down, as it corresponds, is presented. For proceeding to another sequence of numbers, it is necessary that everybody agrees and that they press the button "si" (yes) in the moment that in each of their PDAs appears this option (Fig. 8). The sequences of numbers can be configured dynamically according to different factors, such as speed of answer, right responses, wrong responses, and so on.

Abstract: This paper reports on the development and evaluation of "WoundCare: An Interactive Learning Program for Health Professionals" (trial version). A key issue examined in this paper is the extent to which the learning activities incorporated in educational multimedia, such as WoundCare, promote deep rather than surface learning. Specific design features thought to facilitate and inhibit deep learning are identified. Modifications that could increase the learning effectiveness of WoundCare and other interactive multimedia programs are proposed.

Major goals and basic approach

The major goal of this project was to develop an interactive multimedia application that could be used by student nurses to enhance learning related to the assessment and treatment of people with wounds of various types. Specifically, the project aimed to develop an interactive multimedia application that could reduce the impact of problems associated with traditional methods typically used when teaching student nurses how to assess and treat people with wounds. The trial of "WoundCare: An Interactive Learning Program for Health Professionals" (trial version) has also led to a detailed examination of the educational value of the constitutive components of the program. In totality, the project consisted of an analysis of student needs and educational problems, the design and staged development of an interactive multimedia application, and, a comprehensive evaluation of the application and activities engaged in by students using the product in the context of learning.

Previous work

The impetus for developing WoundCare derived from contextual and practical difficulties associated with teaching wound assessment and management to student nurses using traditional methods. The major educational problem identified prior to this project was the ongoing difficulty nurse educators have representing clinical reality in university clinical nursing laboratories when teaching student nurses. Furthermore, it was recognised that use of WoundCare by student nurses had the potential to reduce the impact of practical problems including:

- und a bed or trolley to observe demonstrations;
- lecturers being unable to adequately supervise several sub groups of students practicing the clinical sment activities; and,
- inability to provide similar learning experiences to distance education students unless on campus residential campus computing facilities) was intended to improve students' cognitive, technical and psychological
y assert that it can be used to improve learning outcomes. Factors that may contribute to improved learning outcomes when interactive possibility of accommodating different learning styles

But, do learning outcomes always improve when interactive multimedia is used? Of course, the realistic answer to this question is ‘no’. It therefore becomes necessary to identify the features of interactive multimedia that consistently improve learning outcomes. Particularly important is whether a sequence of educational activities will stimulate deep rather than surface or shallow learning, i.e. thorough understanding rather than the capacity to recall isolated facts (Marton & Säljö 1976a, 1976b). Biggs (1999) argues that promoting deep learning rather than surface learning in tertiary education necessitates educational activities that require students to use both higher order and lower order learning activities. Table 1 presents Biggs’ classification of common university level learning activities.

Recent discourse related to interactive multimedia indicates that poor design will often stimulate shallow learning rather than deep learning. An interactive multimedia application that requires little more than clicking on a button to advance from one page to the next exhibits passive interactivity and promotes shallow learning (Sims, 1994). By contrast, an activity that requires the creation of multimedia demands deep learning (Tuovinen 2000). If interactive multimedia is to improve student learning it must be designed to encourage deep rather than shallow learning.

Materials developed

Early in the development process it was recognised that WoundCare could promote deep learning if it was designed appropriately. WoundCare consequently consists of a multimedia information resource (the InfoBase), Tutorials and a Case Study developed using the Authorware Attain (Macromedia Inc.) multimedia development application. Some screen dumps from the WoundCare application have been included in the Appendix.

The InfoBase included in WoundCare contained textual information, tables, diagrams and photographs for one hundred and eighty topics related to wound assessment and treatment. The topics cover skin anatomy and physiology, infection control, wound healing, assessment of people with wounds, wound status assessment, wound types, wound aetiology, wound healing inhibitors, wound cleansing, wound debridement, wound closure and wound dressing. It was intended that students use material included in the InfoBase to complete the Case Study and the Tutorials. Most of the keywords necessary to complete the Case Study were embedded in the textual material included in the InfoBase. The InfoBase information could also be used by students during relevant practical class activities, while preparing for examinations and caring for people with wounds during clinical fieldwork. While students could look up information in the InfoBase directly, such an activity in isolation from work on the Tutorials and Case Study was not expected to contribute significantly to deep learning.
study. It was anticipated that the structure provided by the objectives and topic listings would assist students to contextualise their study.

The four major sections of the Case Study included in WoundCare were intended to promote deep learning of clinical reality. The History section of the Case Study set the scene by presenting a brief case history and photographs of a wound attributed to the assessment data, which enabled them to specify diagnoses and treatments. The Case Study currently included in 'examining' the person with the wound and 'assessing' the wound itself. Students undertaking these activities had entered valid keywords in the relevant text entry fields in the Diagnosis section of the Case Study, the Case Study required students to identify appropriate treatments for controlling wound healing inhibitors, wound cleansing, wound deb whether the treatments specified were correct.

Validation

After ensuring that the operation of WoundCare was reliable, an educational evaluation of the program was conducted with student and peer reviewers. This paper presents a report derived from the students' evaluations

- determine whether use of WoundCare promoted deep learning rather than surface learning;
- identify features of WoundCare that contribute most to deep learning; and,
- identify that interfere with deep learning.

Sample

The sample for the trial of WoundCare was a convenience sample that included thirty five second year university pre registration nursing students who voluntarily consented to participate. There were thirty female

The sample for the trial of WoundCare was a convenience sample that included thirty five second year university pre registration nursing students who voluntarily consented to participate. There were thirty female major two part assignment related to wound assessment and management. Each student was also supplied with a copy of WoundCare on CD ROM and an instruction sheet. The software was also installed on computers located in the clinical nursing laboratories. It was anticipated that students would engage in activities intended to promote deep learning including self directed use of WoundCare (especially completion of the Tutorials and Case Study), preparation -Part A), and a small group multimedia creation activity -Part B). -trial

ta were extracted from written reviews submitted to satisfy requirements for Assignment-
questionnaires, diaries, post-trial questionnaires and diagnostic tests. Verbal data obtained from the written reviews of WoundCare (Assignment-Part A) and the open-ended items included in the initial questionnaire, diary and final questionnaire were thematically analysed. Particular attention was paid to classifying the student activities as they engaged with the multimedia according to the Biggs deep and surface learning categories shown in Table 1. Quantitative data derived from the initial questionnaire, diary and final questionnaire were analysed statistically.

Results and Discussion

The trial participants thought that the WoundCare program was relevant to them, registered nurses and other health care workers. The most common reasons for this were that the InfoBase included a large amount of clinically relevant information supported by photographs and other media, and that they could actively work through a clinically-oriented Case Study. Many participants felt the program was easy to use and the instructions and help available were adequate, but an equivalent number thought that WoundCare was either difficult to use or that there was insufficient direction (particularly for completion of the case study). Many participants thought the current navigation using permanent and temporary menus should be changed. Some participants indicated that navigation buttons and hypertext would be better. Some participants thought that it was important to be able to display InfoBase information in a separate window to the Tutorial or Case Study when they were trying to complete these activities. A large number of participants indicated that the interface could be enhanced dramatically by using different colors, borders or background image. It may be that the structural and cosmetic changes being suggested by participants would reduce observable split attention effects and decrease extraneous cognitive load thus maximising the working memory available for the specific learning task being undertaken (Sweller, van Merrienboer, & Paas 1998).

The problem of a computer program failing to recognise text entries is a difficulty frequently encountered when developing interactive multimedia. While the text-matching using wild characters feature of the multimedia authoring program, AuthorWare Attain (Macromedia, Inc.), helped improve recognition of student text entries, some students reported mismatches and an unacceptable number of unrecognised entries. Possible strategies for reducing mismatches and unrecognised entries include capturing student entries and updating the database of recognisable text entries. It may also be possible to improve the communication between the program and its user by including a clarification process when the computer is not sure of a user’s meaning.

The available qualitative and quantitative data highlight the difference between deep and surface learning and how simulation may be used to encourage engagement and deep learning. Detailed analysis of this data indicates that use of the InfoBase alone and completion of the Tutorials were not sufficiently challenging and therefore were not thought to contribute substantially to deep learning. This is supported by the suggestion by many students that the Tutorials should include review or test questions. Such suggestions also indicate a need to stimulate greater engagement with the program. Conversely, the Case Study, elicited the most intense mental engagement, motivation and presented the most formidable challenges for students using the program. It may be, however, that the Case Study was too demanding for some students, as several commented negatively on its level of difficulty, the time required to complete it, the lack of example questions, the lack of preparatory Case Studies or exercises, and the lack of realism. Consequently, both mechanisms included in WoundCare to promote deep learning, the Tutorials and the Case Study, could be improved.

The trial participants' views regarding the small group multimedia creation activity (Assignment-Part B) were varied. While many participants thought that the activity was too demanding, some indicated that it was an appropriate and enjoyable activity. The variable quality of submissions did, however, suggest that this task may have been too difficult for many student nurses.

Limitations

One major limitation of this evaluation was that the evaluation and teaching described here were carried out by the developer of WoundCare. Additional limiting factors associated with the lack of anonymity of participants are possible excessive student compliance and sample bias. It should also be noted that these factors and student workloads could have contributed to the attrition that was observed during the study-while 100% of participants completed the initial questionnaire and written review, only 22-35% of participants completed the logbook, final questionnaire and/or diagnostic test.
Future work and implications

The experience of developing and evaluating "WoundCare: An Interactive Learning Program for Health Professionals" has been a learning experience for all who have been involved in the project (1997-2000). It is easy to identify things that could have been done differently in order to expedite the development process or improve the end product. The student evaluation indicates that the current version of the WoundCare is robust, relatively easy to use, despite its identified limitations, and includes activities and material that can facilitate deep learning. From a developer's perspective WoundCare is relatively easy to expand and modify using the AuthorWare Attain (Macromedia Inc.) multimedia development environment. Nevertheless, the results of the evaluation reported here indicate that there are some significant problems that could inhibit deep learning.

Firstly, the student activities may not have led to deep learning because they were not sufficiently engaging. For example, WoundCare tutorials encouraged students to read InfoBase information but there were no questions to stimulate deep learning and give feedback to the learner. Thus if we examine Table 1, the tutorial activities and interactions should encourage more of the high demand mental processes in the first column.

Secondly, deep learning could have been impeded by design features that resulted in extraneous cognitive load, split-attention effects, reduced interaction effectiveness and reduced motivation (Sweller et al. 1998). For example, extracting, integrating and applying information derived from multiple places in the WoundCare InfoBase in order to complete the Case Study requires intensive use of available cognitive resources and is therefore very demanding (Chandler & Sweller 1992). The interactive Case Study was considered to be an appropriate type of challenge but may have been too cognitively demanding. Student progression through a series of increasingly difficult learning activities prior to attempting the existing Case Study may reduce the cognitive demands the activity currently requires.

Thirdly, the success or failure of multimedia in education may not be due to the inherent features of the program itself, rather to a creative or inappropriate use of the materials. For example, one of the student activities associated with the use of WoundCare by students was the specification of data for a new case study that could ultimately be incorporated into the program. As previously noted, this was a very demanding activity that again required students to extract, integrate and apply information derived from multiple places in the WoundCare InfoBase. Students could also use other sources of information if required. The activity associated with seeking and processing information in order to formulate case study data appropriate for an imaginary person with a particular wound and present an appropriate justification again required intensive use of cognitive resources (Tuovinen 2000). With hindsight, it may have been better to provide students with completion exercises, where part of the multimedia creation task had already been done and they needed to fill in the gaps (Paas 1992; Sweller 1999).

These problems reinforce the view that developers must give serious consideration to the level of processing expected of students when they participate in learning activities requiring the use of interactive multimedia. The results of this evaluation of WoundCare have established the need to:

- improve the aesthetic appearance;
- incorporate buttons and hyperlinks to make navigation more intuitive;
- develop and incorporate tutorial review questions and diagnostic tests;
- develop and incorporate additional case studies (with varying levels of difficulty);
- review feedback mechanisms and content; and,
- prepare additional InfoBase content and media.

Abstract: Multimedia, World Wide Web (WWW), video and telecommunications technologies, computer-based simulations, distance learning are a familiar sight in most schools. The aim of this paper is to propose an architecture of Advanced Data Broadcasting System (ADBS), an asymmetrical network system delivering data and interactive services at a high data rate to a large number of user stations via a direct broadcast satellite using the DVB/MPEG-2 standards. The core of this architecture is based on Digital Video Broadcast, which is a simple, turnkey solution for real time MPEG audio and video, which has the only streaming multimedia server that supports delivery to thousands of simultaneous users regardless of bandwidth requirements.

Why Satellite Technology for Tele-Education?

In a Tele-Education environment, the concept of virtual classroom is commonly used. This concept can be split in two different aspects: Real-Time Virtual Classroom (RTVC) and Deferred-Time Virtual Classroom (DTVC). The implementation of a virtual classroom could be done using satellite either as unique option or in combination with ISDN and Internet.

In the case of the RTVC, the most important part is the communication from the teacher to the learners. For this reason we need then high speed channels (around 2 Mbps) for the teacher, and slower ones (around 64 Kbps) for the learners. It is clearly an asymmetric communication, with a big information flow in one direction, and a small one in the return direction. Some possibilities to solve this kind of communication might be satellite, ISDN (Primary Access), ADSL, or a cable network. Concerning the DTVC, apart from several lectures of the teacher which might be solved as in the Real-time Virtual Classroom, the communication between the teacher and the learners is more symmetric, and, talking properly, the teacher becomes a tutor in this case. The functionality needed are e-mail, computer conferencing, maybe tools sharing and videoconference. This can be solved using Internet and a Basic Access of ISDN.

The nature of a large majority of current multimedia services is inherently point-to-multipoint. Today's explosion of new multimedia household and business applications is mainly asymmetric: distance learning (RTVC), web browsing, continuous broadcast streams, financial and sports news 'tickers', and weather forecasts, near-audio-on-demand, near-video-on-demand, software distribution. If these new applications are to be successfully implemented, the infrastructure deployment must be immediate, cost effective and on a large geographical scale. The terrestrial transmission channels have demonstrated their physical, and above all, economical limits for the provision of such services. With respect to the very reduced deployment of cable and ISDN lines, a satellite-based solution provides the possibility of deploying in a very short term and on a very large geographical basis these new business-oriented applications. In fact, a satellite-based solution solves the time and geographical constraints imposed by the emergence of these new applications and provides the most efficient way for data broadcasting delivery.

Advanced Data Broadcasting System (ADBS)

ADBS is an asymmetrical network system delivering data and interactive services at a high data rate to a large number of user stations via a direct broadcast satellite using the DVB/MPEG-2 standards. The ADBS system is based on Interactive Data Broadcasting System (IDBS) which uses the forward channel of a DVB system. ADBS offers a number of data applications based on Internet protocols such as TCP/IP, UDP/IP and HTTP. The ADBS software also provides a set of lower level functions for addressing/routing and higher level functions for
filtering/storing. ADBS supports unicast, multicast and broadcast applications. The return link is usually a telephone line plus modem to access an ISP (Internet Service Provider) of user’s choice.

ADBS supports several levels of conditional access, security and privacy. The basic mode of operation assumes that an end-user station receives data in a passive mode from the satellite channel addressed to it. Alternatively it may connect (through Internet) to the base station via SLIP or PPP link to its preferred ISP. Only authorized users may connect to the base station through Internet and operate in interactive mode (e.g. an on-line Web session).

They are served according to the scheduling strategies implemented by the system manager. Conditional access is implemented at the DVB transport level by conventional means, using smart cards or similar technology. In addition, every user station has a unique station identification (hardware address) which is used at link level for individual addressing of stations. The current implementation can deliver data at a rate of about 8 Mbps in SCPC (Single Channel Per Carrier) mode and/or at the full data rate of the transponder up to 40 Mbps in MCPC (Multiple Channel Per Carrier) mode.

The base station consists of a DVB uplink and a satellite router/server which are directly interconnected through the DVB gateway. It performs basic server tasks and delivers IP datagrams as a MPEG-2 data structure. The DVB uplink performs all necessary multiplexing, coding and modulation tasks for transmitting data over a direct broadcast satellite. The satellite router/server acts as a proxy using ADBS. At the system maintenance level, a set of utilities is provided for installation and configuration of the system, user management, access control, security and authentication functions, and scheduling policy. At the application level, ADBS provides support for Internet services. For instance, ADBS supports a set of multicast and broadcast applications and allows user interaction in an on-line and an off-line mode. Moreover, the proxy server provides a local cache for the requested data to increase the transmission efficiency (in terms of speed and delay).

The user equipment consists of a small-size satellite dish (e.g., 60 cm) and a DVB PC-board for processing the incoming satellite data. A standard Web browser such as Netscape or Microsoft Internet Explorer is used for interaction with the system. The DVB PC board performs demodulation, decoding and demultiplexing, reconstructs IP datagrams from the cells and routes internally to the appropriate applications. The end-user stations can access the base station in a number of ways, the telephone line/modem connection being the most popular; this connection, called the return link, is used for transmitting requests and control information only. The system can operate in one of three modes: fully interactive, partly interactive, and passive.

For fully interactive services, data is requested via the return link and retrieved over the satellite link (e.g. tele-education, Internet interactive services, Web site visits). For request-reply transaction services (e.g. the transmission of a large multimedia file), the return link is required for the transmission of the requests but can be released during the reply phase (e.g. distance learning, near-video-on-demand, software distribution). For passive-receive operations, data is filtered by the multicast or broadcast services from the local hard disk and no return link is therefore required (e.g. on-line newspapers/magazines, continuous broadcast streams, financial and sports news 'tickers', and weather forecasts).

Conclusions

In some ways, satellite technology has more promise than both DSL and cable modems. Its advantages are mobile access to remote areas and incredible speeds. Streaming technology via satellite delivers an advanced information system for distance education with a capacity to support traffic of voice, video and data, by interconnecting the LANs of several university centers.

Computer-mediated Communication in English Language Study

Irina Rozina, Rostov State Pedagogical Univ., Russia; Ronald Eckard, Western Kentucky Univ., USA;

This paper presents the authors’ two-year experience in conducting e-mail exchange distance learning project between the students of RSPU and WKU. The project is based on the research instrument of Professor J. R. Garrott “Cultural Values”. The project goal is to stimulate the Russian students’ study of English, rethink questions of language together with American students, introduce students to a new culture on a more informal level using computer-mediated communication.

To achieve the goal of improving students’ English proficiency (for the Russians) and learning how to use standard English to communicate with non-native speakers of English (for the Americans), the project has relied on e-correspondence. The project is carried out in four stages. Project authors have gathered the results of this effort.

Language learning by e-mail involves students with different native languages working together in order to learn about other cultures and lifestyles and English language itself.
Evaluation of Program Impact Based on Teacher Implementation and Student Performance

Laurie F. Ruberg
NASA Classroom of the Future Program
Center for Educational Technologies
Wheeling Jesuit University
United States
lruberg@cet.edu

Abstract
Twenty-one schools from the United States and Singapore participated in this evaluation of a high-school biology CD-ROM called BioBLAST®. Results include a summary of teacher descriptions of their curriculum-based justifications for using this software as well as a compilation of program features that teachers describe as facilitating successful implementation of new learning technologies. Analysis of teacher reports provides a profile of three types of strategies teachers used to implement the program. Analysis of student performance on pre/posttests shows how implementation strategies were associated with student gains in particular schools and classes. A comparison of student pre/posttest scores one year later with previous pre/posttest results suggests that changes in implementation strategies, teacher incentives, or a decrease in support services had a direct impact on student performance. Students with a wide range of prior knowledge were able to use the software and show performance gains appropriate to their knowledge level and experience.

Introduction
This report examines technology implementation decisions made by teachers in the context of a particular multimedia high school biology software program called BioBLAST®, a computer-based, multimedia, learning environment for high school biology classes. This study examines the relationship between teacher implementation strategy and student performance. The software program described in this investigation was designed to help teachers address both NSES goals. Based on these goals, a scenario was created for a problem-based learning environment that put students in the role of NASA Advanced Life Support researchers. Student teams are challenged to use the software tools and resources to accomplish their goal: Design and test a plant-based life support system that can support a crew of six for at least three years without re-supply.

Reports from national commissions, disciplinary groups, researchers, employers, faculty, and students repeat the call for instructional innovations in science, mathematics, engineering, and technology (SMET) education. Across all these reports Springer, Stanne, and Donovan (1999, p. 22) find a consistent recommendation for a shift in emphasis from teaching to learning and greater use of, “active, collaborative, small-group work inside and outside the classroom.” The National Science Education Standards (NSES, 1996) recommends that teachers move away from methods of direct instruction to an inquiry-based approach to teaching. The report further recommends that teachers use alternative approaches to improving student learning that address both the method of instruction and the need to identify the content being addressed. Instruction should be student-centered rather than teacher-directed, and classroom curricula should be linked to real scientific issues and events (NSES, 1996).

An evaluation study by Cook, Habib, Phillips, Settersten, Shagle, and Degirmencioglu (1999) reports that gains in student achievement were associated with schools that have a focused academic articulation of goals for student achievement. This finding is consistent with research by Phillips (1997) and Lipsitz, Mizell, Jackson, and Austin (1997) who report that student performance improvements are most closely related to academic focus and less tied to social climate issues. Cook, et al., (1999) acknowledge that the results of their evaluation study are limited by the fact that program implementation fell short at nearly
all of the schools included in the study. They suggest that ways to improve and understand program implementation are greatly needed in order to understand student change.

This study examined teacher implementation strategies by adapting the issues addressed by Cook et al. (1999) and Kerr (1999) to the context of high school science teachers involved as lead teachers in the field testing of the BioBLAST software. The following research questions are examined in this study.

1. What were the academic and pedagogical goals that teachers described as their curriculum justification for using this software?
2. What strategies for implementing the software were reported by teachers?
3. How were implementation strategies expressed in student performance as evidenced in the pre/posttest scores? Are these student performance measures consistent with teacher reports?
4. What does the comparison of teacher implementation strategies and student performance during the different periods of the program cycle suggest regarding classroom application of this curriculum supplement?

Method

BioBLAST was developed by the NASA Classroom of the Future in collaboration with the National Aeronautics and Space Administration (NASA) Advanced Life Support research program. The virtual reality interface of the CD-ROM draws students into a futuristic, problem-solving scenario that is situated in a simulated, lunar research facility. In the virtual lunar base environment, students use graphical simulation tools and resources to prepare for their mission goal: to design and test a model for a plant-based, life-support system that can sustain a crew of six for three years. Along with the goal of helping teachers move to an inquiry-based approach to teaching, a secondary goal of this program is for students to have access to current life science research in the process of investigating a legitimate problem.

The data collection techniques include teacher surveys, observations of teachers and students in their classroom environment, interviews with teachers, pre/posttests, and student and teacher reports. Twenty-one high schools from urban, suburban, and rural areas of the United States and Singapore participated in the classroom testing of this software. The school applications were self-selected in all but two cases. The specific schools included were selected from the group of applications based on geographic distribution, access to technology required to run software, and level of interest in learning alternative teaching techniques as expressed by teachers in their personal essays.

This study compares teacher implementation strategies with student performance during the final stage of the formative evaluation cycle (beta testing) with student performance during the pre-publication cycle when professional development support for teachers was no longer available. Participants differed in the location and level of technology available at their school and in the level of administrative support for implementation of curriculum-related instructional technology. This analysis of student outcomes based on comparison of pre/posttest scores involves a subset of the larger group who fully implemented the program and returned the completed pre/posttest materials. Table 1 provides a summary description of schools involved in the larger and subset groups.

Results

The following questions were examined in analysis of the data collected from teachers reports, surveys and interviews; student reports, pre/posttests, and surveys; and observation of on site and off site implementations of the program.

1. What were the academic and pedagogical goals that teachers described as their curriculum justification for using this software?

Many teachers described their use of BioBLAST software as offering an opportunity to change their methods of teaching to incorporate use of technology within the context of instruction and to include
more cooperative learning group activities. Moving to group work was cited by one third of the teachers as a greater challenge to their teaching practice than incorporating the new technology. Teachers also reported that Internet access and at least class email accounts accessible within the classroom were an important technology component of this program. These communication resources allowed students to ask questions to NASA experts and find current resources on the Web. Teachers commented that students were drawn into the QuickTime virtual reality interfaces since many video games that are popular among teenagers use this kind of interface. The “BaBS” culminating simulation was captivating to nearly all students and was the students most favorite aspect of the BioBLAST program. Students also responded favorably to the scenario link with current NASA research and laboratory exercises that had real connections with NASA experiments.

A summary of program features that teachers reported as most important to them in selecting new resources to adopt and implement is provided in Table 2. An important feature that emerges from this summary is that teachers want software/technology tools that will support their curriculum goals and help them grow. Teachers report changes in their teaching position, restructuring of existing course, the creation of new courses, and the implementation of alternative scheduling at their school based on experiences with the BioBLAST program as a “test-case” technology-integration program.

</tr>
</tbody>
</table>
2. What strategies for implementing the program were reported by teachers?
Teachers used the laboratory and computer-based investigations provided by the software development team and incorporated these materials into their academic grading system. Teachers adapted the suggested sequence outlined by the project development team to suit the needs of their students, their school curriculum guidelines, and the time they had available in their course schedule. Teachers selected implementation strategies based on topics and scientific inquiry process skills that they believed their students most needed to address. The software development group suggested that teachers view their implementation of the software as having four phases much like the four phases of the problem based learning approach to teaching. The four phases of BioBLAST were presented to teachers as: Phase 1, Orientation to the problem; Phase 2, Research and analysis of the sub-units of the problem; Phase 3, the Mission in which the sub-units are integrated and combined for testing possible solutions to the problem; and Phase 4, the Report in which students present a summary of data collected, data analysis, results of initial testing, and recommendations for solutions and continued research.

Based on analysis of teacher reports, surveys, documentation of email communications, and observation of teachers in their classroom, we found that teachers implemented the software in three distinct ways. The “Lab” group focused most of their time on skill-building activities and one or more of the laboratory activities. This group allowed their students to interact with introductory materials and structured exercises embedded within the software simulation programs. Teachers using this implementation style reported that their students did not have science content and process skills required for the more advanced activities. The “Simulator” group completed the Orientation, Research, and Mission phases of the program. This group allocated at least three class periods (45 minutes each) for their students to complete the "BaBS" model building simulation in which previous plant, human, and resource recycling research is compiled and integrated and tested. The format and assessment of the Report phase were more open-ended than previous activities, and this may be why some teachers did not implement this phase. The group called the “Researcher” group completed all four phases of the project and had their students complete a project report as their culminating activity for the program.

3. How were implementation strategies expressed in student performance as evidenced in the pre/posttest scores? Are these student performance measures consistent with teacher reports?
Not all teachers submitted pre/posttest results. Teacher surveys and reports were required, but pre/posttests were not. A small percentage of the Lab group submitted their pre/posttest results, and teachers reported that they did not feel that they gave their students the full benefit of the program because they did not use the simulations. The entire Simulator group and all but one of the Researcher group submitted their students’ pre/posttests for evaluation.

The pre/posttest consisted of 16 questions, seven of which were multiple choice, the others requiring short answer and one concept-mapping responses. Analysis of pre/posttest scores on the seven multiple-choice questions indicates that student performance was significantly improved in all but two cases. The paired T-test analysis shows huge gains in nine of the eleven cases. Table 2 provides a summary of the main effect of the T-test score for each school. In one of the cases where student scores overall did not improve, the student pretest scores were already nearly perfect on the multiple choice test questions. In the other case, student scores improved, but this improvement was only significant on one question, and not all seven or on overall score. Teacher reports from the eleven participating schools expressed confidence that the program helped them successfully implement new teaching practices that incorporated student-centered and inquiry-based approaches to learning. Below are a few excerpts of teacher observations about student learning from the software program.

- “BioBLAST made student learning more meaningful; students are beginning to show more proficiency in their use of technology; the simulations encourage student thinking because they have to ask themselves why did they only survive that long, what happened?”
Later in the [biology] course, students would reference what they saw in BioBLAST as a reference for other bio curriculum activities; BioBLAST seemed to provide a good transfer, a good bridge, and a solid base for students to refer back to...

"Students were frustrated by the technology, but were also engaged by it...[through the use of this program] I accomplished the goal of incorporating more math, graphing, and research skill-building into student work; working in teams was most challenging, but in some cases most rewarding for students."

A doctoral research study (Cain, 2000) was conducted during the alpha testing of the software that analyzed student group discussions while using the Mission Phase simulation. One of the questions examined in this research study was "In what ways did the content knowledge change after the initial phase of the simulation-based learning activity?" Based on his analysis of the data, Cain reported improvements in student content knowledge in both early and later trials with the simulation. Six out of the sixteen content areas in which Cain noted deficiencies in early trials improved with continued use of the simulator. Improvements in content knowledge, similar to those noted by Cain (2000), was also evidenced in student pre/posttest scores in the following areas: [Question 2] how plants obtain nitrogen; [Question 5] understanding of the interdependence of plants and animals; [Question 8] graph interpretation of physical science concept; [Question 9] experimental design for plant science investigation; and [Question 12] in-depth understanding of human and plant respiration and photosynthesis.

4. What does the comparison of teacher implementation strategies and student performance during the different periods of the program cycle suggest regarding classroom application of this curriculum supplement?

As Table 3 shows, teacher implementation during the Beta testing process was more successful than their implementation in the later year when there was minimal support and no in-service workshop provided. During the Beta testing, teachers received a small stipend to cover the cost of their reporting, administering, and handling of evaluation materials. Teachers also attended a 5-day off-site workshop the summer before the Beta testing in the classroom began. Weekly updates regarding the project were emailed to teachers during the beta testing, and teachers were encouraged to contact project team members if they had questions or needed assistance.

As reported in the research study by Cain (2000) and supported by analysis of teacher surveys and reports, student learning improved and continued through continued use of the simulators. Later implementations of the program may not spend the same amount of time preparing the students for effective use of the simulators and may not allow time for continued trials, analysis, and comparisons of simulator trials. In
addition to the professional development and incentive programs, giving students two to four separate
sessions to use the simulators, analyze results, make modifications, and compare outcomes is a necessary
interactive process for effective use of the simulations. More research is needed to identify what support
or feature associated with the beta testing is most critical to facilitating the most successful, long-term
implementation success. Since the number of pre- and posttests available for analysis were greatly
reduced, it is difficult to conclude whether the trend found in the two cases documented was consistent
across all implementations.

Discussion
What generalizations can be made regarding ways to improve program implementation? Can effective
implementation strategies improve student achievement? Student performance improvements were
statistically significant in all but two cases. The indication of reduced (although still demonstrating
statistically significant improvement) student achievement in the pre-release (post-beta) test group
reflects the time-sensitive nature of program implementation. The list of program features that teachers
report facilitates successful software implementation (see Table 2) suggests that if any one of these
eleven factors changes, the implementation strategy may be curtailed or disrupted. Teacher reports and
survey data indicates that teachers want a clear set of recommendations for an activity sequence, time to
allocate for each activity, and suggestions for effective use of the simulators with student groups to
support their implementation strategies. This information was not available during formative evaluation,
but can be made available on the Web site to new teachers using the program.

Several interesting observations from this research suggest ways in which software and other learning
environment technology tools can motivate and engage students who have previously shown little or no
interest in a given course. Analysis of student performance from the pre/posttest scores showed that
software implementation that included use of the simulators exhibited gains for groups that were weak in
fundamental content as well as for groups that were ready for more advanced concepts. By allowing
multiple ways to implement the software, students with a wide range of prior knowledge were able to use
the software and show performance gains appropriate to their knowledge level and experience.

Filling RL/IT Gap with International Curricula

Nina Rubina, Federal Univ. Computer Network of Russia RUNNet, Russia; Yury Kirchin, St.Petersburg State Institute of Fine Mechanics and Optics, Russia

After several years of constantly increasing enthusiasm in IT area it becomes more and more evident that these expectations were seriously overestimated, there are signs of disillusionment and even some recession. Having solved tremendous technical problems of performance and connectivity the IT has not contributed enough for tackling Real Life (RL) tasks. Cause-to-effect analysis undertaken on the basis of creating and using IT objects as well as solving managerial tasks for the passed decade discovers logical gap between RL and IT spaces being of totally different nature and internal logistics, the gap preventing to directly extend logical framework of RL task down through IT layers or vice versa to launch IT formal logic up-through RL situations. Being observed in Russia, Europe, America, Africa - the problem seems to be completely international and rather timely. We call to discussion of experience for establishing new university curricula in the pointed area.
Teaching Veterinary Physiology by means of Multimedia

Peter Rudas, Veterinary Faculty Budapest Hungary, Hungary

Veterinary Physiology is a basic science subject taught in 150 lecture hours and in adjoining 60 hours of lab work plus a Directed Self Education block. The course is given in three languages (English, German and Hungarian). The high number of students and the aim to foster independent and self-paced learning forced us to develop a multimedia environment for our teaching. First the entire theoretical material was made available in multimedia format (P. Rudas “Veterinary Physiology, a multimedia resource for teaching, learning and self-testing”, Mezogazda Publ. House, 1998) and then parts of the lab work was replaced by multimedia type of work (Virtual Physiology Series by Thieme Vlg, Germany). Mid-term tests and the final exam is also based on CBT. Analysis of comparative test results and interviews with the students show that the average score increased by 12% (between 1998-2000) but the attitude of students is unchanged (30% likes multimedia methods, 30% accepts it as an improvement, 40% would prefer traditional methods).
Architectural Concept for an Integrated Learning Platform Using Learning Object Metadata

Abstract: In the context of inhouse qualification different teaching methods are used at DaimlerChrysler AG. Apart from classical teaching methods, efforts towards a global online training system are currently in progress. In this paper the subsystems of the framework currently under development as well as the motivation, the goals and the first steps of their integration into a global system are presented. This system shall offer a Web-based access to courses and learning materials for different user categories (e.g. student, teacher, personnel staff and authors) and provide interfaces for administration, maintenance, and composition of courses and their media, as well as for the administration of users, resources, qualification and certifications.

1 Introduction

1.1 Motivation

Currently, the area of "online training" constantly gains importance. The shortening innovation cycles within the technical area and the progressive globalization requires the permanent training of employees. This trend requires the availability of detailed technical information, didactically edited training courses and materials for training purposes for the different target groups often long before the introduction of the individual products onto the market. The applied teaching methods already evolved from the classical methods of self-studies with printed media and face-to-face training. The use of "new media" such as training videos, TV transmissions, computer-assisted learning (a.k.a. computer based training, CBT) and teleseminars is increasing. Since the availability of the inter-/intranet, web-based training (WBT) is used as an asynchronous teaching method also. If WBT training courses are extended by synchronous components (Teletutoring), then we are talking about internet based teleseminars (distance learning, DL). In an organization, in which teaching methods are used separately at present to a large extent, an integrated concept is desirable. An integrated system provides central access to learning resources and supports reuse of learning objects in various ways.

1.2 Context and Requirements

Different teaching methods are used for training within the DaimlerChrysler AG at the moment. These cover self-studies using printed media, face-to-face training, CBTs, training videos and a teleseminar system based on a European-wide satellite TV signal with ISDN back channel for interaction. Additionally, a business TV channel called DCTV (DaimlerChrysler television) is broadcasted throughout the company, which offers current information on the enterprise and its products and services. An education management system (EMS) for the administration of teaching materials (printed media, WBTs, CBTs etc.), resources (e.g. classrooms and their equipment) and user information (their personal data, curricula and learning goals, their participation in training supplies, their test results and learning history etc.) is currently under development and evaluation. A media storage and retrieval system (called "media server") provides central administration, handling and playback of media objects and their associated metadata. New CBT applications are currently developed with web deployment in mind, in order to be offered as online WBTs as well.
For the integration of the learning material on the content level, the use of metadata is essential. At present a suitable metadata set is selected and refined. This selection is based on widely-known standard approaches like IEEE LTSC LOM, DCMI Dublin Core, IMS Metadata, ADL SCORM and so on.

One of the determining requirements of the architecture of the total system (apart from the functional requirements) is the extensive use of commercial standard software in order to reduce the costs as well as to increase the expandability and the scalability of the system. The latter points are particularly achieved by the use of "open" standards and systems.

2 Architecture

The architecture enables the user to select and book/consume suitable training resources. The system should support the user in the selection of the appropriate material in order to fill his individual information gaps. The system enable teachers and managers to arrange curricula from a workstation and assign it to user groups. The participation in the courses and the success in the individual tests and questionnaires are stored in the user profile and should serve to monitor the individual learning progress. Authors of learning material should be able to use the administrative interface of the media server in order to add new media and to combine content to new units. They are supported by the possibility to search the entire stock of media by different methods (categories, glossary etc.).

The architecture is based on a three tier software architecture, i.e. the separation in user interface, process management and data management layer as a guideline for the system design. The system is partitioned in several front-end and back-end components like the media server, the WBT playout and tracking system, distance learning components and the user, ressources and qualification management system, as well as further components necessary for the integration.

The integration of the content in terms of individual media objects is carried out by the use of suitable metadata. This data about the media data does not only enable an identification and contains further information about the object, but it models likewise the relationship with other media objects and enables the classification into an educational context. Therefore, they represent a central starting point for search, administration, composition and creation of course sections and complete courses. As mentioned above, the suitability of LOM (learning objects metadata, (see LOM 2000) as a data basis for the selection of the individual data elements is evaluated at the moment. Furthermore, the different possibilities to generate metadata about learning objects automatically as well as the semi-automatic assignation of metadata, for example by categorization, are of special interest.

3 Current Status and Further Work

Currently, the media server consists of several subsystems (HTTP/video/Real/RDBMS), which are integrated by a content management system (Informix Media360) supporting the definition and assignment of metadata sets. The content management system provides backend interfaces for integration with the other components of the whole system. At the moment, the media server is customized and filled with media and the appropriate learning object metadata sets. The use of Saba EMS (education management system, www.saba.com) is intended for the implementation of the user, qualification, courses and resources administration. For the implementation of the DL functionalities, especially online tutoring and virtual classroom, products will be evaluated in more detail in the near future. Users of the system access courses through SABA, while content is originating from the media server. Content modules communicate user interaction data (tracking information) to SABA using AICC standards. The "dynamic" search and composition of course materials using metadata is planned in a further step.

Computing learning in secondary schools in Spain: some implications related to gender

Esther Ruiz Ben
Institut für Informatik und Gesellschaft (Abt.I)
Albert-Ludwigs Universität Freiburg
Germany
esruizben@hotmail.com

Abstract: In this study we examine the gender gap in computer attitudes, ownership and experience on a sample of 425 secondary students from four different schools in Madrid. Differences between girls from co-educational schools and girls from schools with a female majority were also considered. Significant differences were found between girls and boys from coeducational schools, favorable for this last group in respect to concepts about computers and self-confidence in using them. Also between girls from coeducational schools and girls from schools with a female majority were found significant differences, favorable to the last group regarding their interest in computers and their concepts about them.

Introduction

Women’s tendency to choose traditionally female stereotyped studies and especially their distance to scientific and technological disciplines is one of the main reasons for the gender gap in qualifications limiting women’s perspectives in the labor market. Health professions, education and social and behavioral science are the fields that women mostly study; on the other hand, women tend to avoid industrial and engineering fields (Carrasco et al., 1997).

In Spain, the male presence in scientific and technical studies remains predominant although is not so noticeable as in other western countries. Concretely the average of women in Informatics accounts for 25% (OECD, 2000). In the secondary education the tendency toward gender segregation in study and professional choices is already shown (Gaviria Soto, 1993). While the institutional support to the introduction of information technologies in schools has been very important in the past years, few studies have examined the students’ subjective value and expectations of success on computing and the factors linked to them (such as the perception of the motivation from the parents to learn about computing or of parents’ and friends’ gender stereotypes related to computing).

The literature about the gender gap in computing in secondary schools have revealed that males dominate its ownership and use and consequently their deeper experience determinates their more positive attitudes toward computers. In some cases, boys’ computer experience serves as an orientation for university study choices, making their decisions clearer in contrast to those of girls. In the educational context several studies have shown that the masculine image of computing exists within the schools as well as outside. The gender stereotypes related to computing that boys and girls acquire through the socialization process, through social experiences with significant others in the family, in interaction with teachers and peer groups are manifested in learning processes. The computer use of boys and girls with different family members reflects gender behavior patterns in the socialization process within the family context, in which the perception of parents’ motivation to learn about computing also plays an important role (Shashaani, 1993). Several studies have paid special attention to the interaction process in the class during informatic courses. The supposed neutrality of co-educative schools was questioned on the basis of the results of these researches, that confirmed gender stereotyped patterns in the interactions processes within co-educative classrooms, particularly in informatic courses (Jones & Clarke, 1995). The different teachers’ behavior with boys and girls in this context, the lack of feminine role models in computing and the unbalanced experience on computing between both sexes, determined by the deeper extracurricular boys’ computer use, influence girls’ attitudes toward computers and
Considering this survey of the research literature, and on the basis of the Eccles' et al. model of Achievement-Related Choices (1994), we have designed this study from a social psychological perspective to examine the gender gap in computing subjective value and expectations of success, ownership and experience and the intention of choosing computer sciences as profession on a sample of 425 secondary students from four different schools in Madrid. Differences between girls from coeducational schools and girls from schools with a female majority were also considered. It was hypothesized that boys would show more positive subjective value (interest and concepts about computers and their use) and expectations of success regarding computing (self-confidence) and would have more experience with computers than girls from coeducational schools. Girls from schools with a female majority's tendency regarding these aspects would be similar to boys.

The participants were 274 female and 151 male students who attended four schools in Madrid (1996): two public co-educative schools (one of them with a female teacher for informatics), one private co-educative school and one private school with a majority of girls (85%). The students age range is between 14 and 17 years old. The students were asked to complete a questionnaire during school time, under the supervision of their class teachers. The survey questionnaire consisted on seven sections related to the following areas: demographic information, relationship to the parents, informatic as professional vocation, gender stereotypes associated to computers, perception of parents, teachers and peers attitudes toward computers, perception of parents' and teachers' support to learn computing, computer experience and use, attitudes toward computers.

**Findings**

The results of this research support the hypothesis that there are significant differences in computer attitudes and experience between girls and boys in co-educational schools as well as between girls in the two types of schools considered, based on a sample of secondary students in Spain. Males were more interested in computers than were females in co-educational schools, had more self-confidence in working with computers, and their concepts about computers were also more positive. Nevertheless, girls reported a positive self-confidence in respect to computer use despite their lack of interest on it. Boys have more positive concepts about computers than girls, particularly in respect to the importance of computer skills for getting a job and the usefulness of computers for making labor tasks easier. However, boys and girls tend to agree with the general utility of computers in daily life. In our research we found that girls expressed a lower perceived ability to use computers and to learn about them than boys. That is, the subjective task value of the implication of computer tasks is more positive for boys than for girls. The cost value is also different for boys and girls in our study, since girls find computers not so enjoyable as boys and expressed a greater fear and insecurity of using computers. Table 1 below shows these results.

| Table 1. Attitudes toward Computers: Boys and Girls in co-educative schools (means) |
|---------------------------------|----------------|-------------|-----|
| Interest in computers           | 2.93           | 3.37        | 6.52|
| Self-confidence                 | 4.25           | 4.73        | 4.62|
| Concepts about computers        | 3.78           | 4.05        | 3.73|
| Concepts about using computers  | 3.56           | 3.68        | 1.43|

p< 0.05; p< 0.01***; p< 0.001***

Girls from the school with female majority were significantly more interested on computers and showed more positive concepts about computers than girls from co-educative schools expressing a higher agreement with the importance of computer skills for getting a job and the usefulness of computer for facilitating work tasks (Table 2).

| Table 2. Attitudes toward Computers: Girls in schools with female majority and Girls in co-educative schools |
|---------------------------------------------------------------|----------------|-------------|-----|
| Interest in computers                                       | 2.93           | 3.37        | 6.52|
| Self-confidence                                              | 4.25           | 4.73        | 4.62|
| Concepts about computers                                    | 3.78           | 4.05        | 3.73|
| Concepts about using computers                               | 3.56           | 3.68        | 1.43|

1643

Page 1593
Significant differences were found with respect to computer ownership and experience outside school. More boys than girls have and use a computer outside school and use it more than girls for programming, playing computer games and using internet. But no significant differences were found between both groups in regard to the computer use for word-processing. In our research, boys used the computer mainly for playing computer games whereas girls used it for word-processing. In our study girls from the co-educational school with a female computer teacher showed the highest scores in the sub-scales related to interest and self-confidence in using computers of the three groups of girls in coeducational schools. Therefore, since female computer teachers could serve as a role model for girls to improve their interest in computing, hiring on female teachers in this discipline should be also considered. Since girls in the female majority educational context showed more interest in computing more positive concepts about than those of girls in the co-educational context, experiences in single-sex groups for girls in spanish secondary schools should be considered as an alternative to resolve the gender-based unbalance in computing in this educational level. The experience differences in computing between both sexes should serve as a basis for group formation. Thus, boys and girls with same experience level could further be grouped together in a positive co-educational environment.

Email: Heli.Ruokamo@urova.fi

Abstract: This article examines the Solver Learning Environment and anchored instruction on mathematical word problem-solving. To collect data, a teaching experiment was arranged in 1996 at the Kaukajarvi School in the city of Tampere, Finland. The participants of the study (N=66) were fifteen years old. Several tests were arranged to measure the mathematical word problem-solving skills of the pupils and to evaluate their mathematical abilities. The pupils’ attitudes towards mathematics, mathematical word problem-solving, information technology, and the environment used in the teaching experiment were also measured. In this paper, we present some ideas and the pupils’ attitudes towards the anchored instruction utilised in the Solver Learning Environment.

Introduction

The main aim of the study was to examine the connection between different learning environments and the development of the problem-solving skills of pupils at different levels of mathematical abilities. The study compared the development of the problem-solving skills achieved in the technology-based Solver Learning Environment with a learning environment of conventional pencil-and-paper tasks. During the teaching experiment, data was collected on Solver’s suitability to develop pupils’ problem-solving skills at different levels of mathematical abilities. A group of mathematics teachers at the Kaukajarvi School prepared mathematical word problems and their model solutions for the Solver Learning Environment in co-operation with the author. Solver was produced as part the Nääsnetti Project of Multimedia Services of Alexpress Ltd., which is part of the Aamulehti Group Ltd. The Nä Multimedia Project was a part of the Finnish Multimedia Programme (FMP). (Ruokamo-Saari 1996a, 1996b, 1997, Ruokamo 2000a, 2000b, a, b.)

The participants in the study were ninth graders (N=66). Empirical group comparison methods were used in the study. During the teaching experiment, group A studied mathematical word problem-solving in the technology-based Solver Learning Environment (Solver Group). Group B studied the same material with conventional teaching methods, using only pencil-and-paper. The control group did not take part in the problem-solving lessons; they just participated in the tests. The contents of the Solver Learning Environment were designed to take a contextual approach and transfer into account: the word problems were connected to real life situations and thus to the real world. Problem solving was through collaboration and the view of learning was “moderate” constructivistic (Reusser 1991a). Solver was designed to support the activity and reflection of the pupils. (Ruokamo-Saari 1996a, 1996b, 1997, Ruokamo 2000a, 2000b, a, b.) This article describes the Solver Learning Environment, and discusses the ideas and pupils’ attitudes towards anchored instruction on mathematical word problem-solving.

The Solver Learning Environment for Solving Mathematical Word Problems

Solver is a technology-based learning environment that includes different presentation forms of hypermedia (e.g. hypertext, graphics, animation, sound, video) and network properties, social interaction, physical learning activities and mental thinking processes in a learning situation (Ruokamo-Saari 1996a, 1996b; Ruokamo & Pohjolainen 1998).

Solver was used to study the connection between the level of the pupils’ mathematical abilities and development of their problem-solving skills (Ruokamo-Saari 1997). It is designed based on the HERON, ANIMATE, and Jasper programs. HERON is a computer-based program developed by Reusser et. al. for word problem-solving (see Reusser 1988, 1991a, 1991b, Staub et. al. 1994; Reusser 1993, 1995). ANIMATE is developed.

In the Solver Learning Environment, the properties of on-line and off-line hypermedia are connected. The on-line part is designed to be used via the Internet and the off-line, local part is programmed with the Multimedia ToolBook 3.0. Figure 1 presents the user interface for the Solver Learning Environment (in Finnish): an on-line HTML document and motivating video for the "Home Party" problem series is seen on the left and an off-line ToolBook application and an empty solution space is on the right. (Ruokamo & Pohjolainen 1998; Ruokamo 2000a, 2000b, a, b.)

Figure 1: The user interface of Solver and the motivating video for the "Home Party" problem series

Videos, problem tasks, hints, model solutions, and a bulletin board were programmed using HTML, so that these could easily be distributed via a network, and they could later be updated. A situational and contextual approach was adapted in creating the problem situations. The topics that were chosen for the word problems were based on pupil inquiry: the pupils were asked about the real life problems that they would like to solve. Video material was produced to introduce the problem situations to the pupils and to motivate them to solve the problems. Six different series of problems connected to real life problem situations were developed. The problem series were as follows: A) "Camps", B) "Rabbit Minttu", C) "Course in Computing", D) "Sport Quiz", E) "Home Party", and (Ruokamo 2000a, a, b.)

At the beginning of problem solving, the pupils familiarised themselves with the problem situation by watching the motivating video. Following this, they read the problem text very carefully. Below is a transcription of the task 1 for the Home Party problem series:

"Susanna arranged to have a home party with her sister Johanna. They served punch to their guests, for which their parents had given them permission to use their 10% home wine, if the girls diluted it to 2%. The girls said that diluting the wine to the correct amount wasn’t easy at first. They had practised with a glass that held 2 dl of home wine. The girls poured the wine into the punch and added the required lemonade to the bowl to dilute the drink to 2%. How much diluted punch did the girls get with one glass of home wine?"
The problem text could include links. By activating these links, the pupils could obtain definitions, rules, formulas, and other information about the subject. If a problem was too complex to solve, they could select the hint tool to obtain tips on how to construct the solution. When constructing the solutions, the pupils might ask one another for hints in problematic situations. Using the bulletin board, the pupils were able to discuss problem-solving processes with other pupils. Based on these conversations, they could further develop their own constructions. The pupils solved word problems by constructing solution trees with cognitive tools. This process resulted in solving the problem posed in the text. In the Solver Learning Environment, the model solution for a given mathematical problem was presented systematically, and the pupils were assumed to discover the solution procedure. The pupils' solutions were saved for later analysis. (See Ruokamo & Pohjolainen 1998; Ruokamo 2000a, a, b.)

Solver did not tutor pupils in the problem-solving process unless it was asked for help or hints. This property was thought to be suitable for especially the better problem-solvers who did not necessarily need any tutoring but were able to conduct autonomous and original problem-solving. Tutoring was designed to meet the needs of those pupils who had difficulties in problem solving. It was also important that pupils had the chance to notice by themselves the possible mistakes they made during problem solving. When pupils asked for a hint during the solution process, Solver tried to find a so-called context sensitive hint related to the pupils' situation in their solution. If the pupils' way of constructing the solution was very original and Solver could not help them, it asked the pupils to try to find support from other pupils via the bulletin board. (Ruokamo & Pohjolainen 1998; Ruokamo 2000a, 2000b, a, b.)

The user could start modelling in any situation and move on to an open solution space. In principle, pupils were able to construct the entire solution without tutoring until the final stage, where Solver asked the pupils to evaluate the final equation (see Fig 2.).

Figure 2: Task 1 of the "Home Party" problem series, titles, solution tree and the request to give final result for the problem.

After checking the results, the pupils could see a representation of the model solution and could compare it with their own solution. Even if the solutions were not similar, they could be correct. All the pupils' solutions were saved to files, so that the problem-solving processes could be examined and compared later. The new solutions proposed by the pupils could later be used as examples of alternative ways to construct solutions. (Ruokamo & Pohjolainen 1998; Ruokamo 2000a, 2000b, a, b.)
Some Ideas of Anchored Instruction

The Cognition and Technology Group at Vanderbilt (1993) has examined anchored instruction. The anchored instruction approach represents an attempt to help pupils actively become committed to learning by anchor instruction in interesting, complex and realistic problem-solving environments (cf. contextual and situational approach). These environments are designed for the type of thinking that helps pupils to develop the general skills and attitudes that are helpful in effective problem solving and help them to learn specific concepts and principles. The group (Cognition and Technology Group at Vanderbilt 1993) has carried out experimental surveys in multimedia learning environments for scientific problem-solving. They have utilised videos and computer technology to recreate various experiences that could be realised by real scientists. They thought that pupils were able to respect scientists in this way, and that they were able to experience actual scientific working process, not just to see final product of the process. Pupils should be able to see science (and mathematics) as an important part of their everyday life, and be able to pay attention to scientific activity in their communities. The group was willing to improve the pupils’ skills to solve the problems that helped them to understand the relations between knowledge and theory. Based on the results achieved by the group, multimedia learning environments could be effective in increasing special, content based knowledge. (Ruokamo 2000a.)

Hmelo et al. (1993) have carried out a longitudinal study into the effects of anchored instruction on mathematical problem solving transfer. Based on the results of their study, anchored instruction leads to the total control of the initial problem. Pupils who had participated in teaching were able to transfer their understanding and qualitative reasoning ability to a new problem. (Ruokamo 2000a.)

Pupils’ Attitudes towards Anchored Instruction on Mathematical Word Problem-Solving

In this study, several attitude tests were arranged. The pupils’ attitudes were very positive towards mathematical word problems. The majority of pupils agreed that “Real life mathematical word problems are useful” (45 %, N = 65) and “I solve real life word problems with pleasure” (34 %, N = 65) (in other words, the claim is well founded). Forty-two per cent of the pupils agreed that “Problem-solving was meaningful because the mathematical word problems were connected to everyday life” (the claim is well founded). Thirty-two per cent of the pupils who studied in the Solver Learning Environment and 52 per cent of the pupils who studied with pencil-and-paper made this choice. Almost one third (27 %) of the pupils in the Solver Learning Environment totally agreed with this statement (even considered the claim as very well founded); at the same time, this percentage for the pencil-and-paper group was just 10. Pupils in the Solver group were more satisfied with the fact that problems were connected to everyday life – the motivating videos that introduced problem situations might have a positive effect on their opinions. Almost half the pupils (49 %), and the majority of pupils in both groups – 57 per cent of the pencil-and-paper group, and 41 per cent of the Solver group – made the choice that the statement “Mathematical word problems were somehow connected to my own life” was to some degree well founded. (Ruokamo 2000a.)

Forty-seven per cent of the pupils agreed (to some degree well founded) that “The tasks in the problem series have been interesting” – over 50 per cent of the pencil-and-paper group and 41 per cent of the Solver group made this selection. Thirty-seven per cent of the pupils agreed (to some degree well founded) that “The themes in the problem series have been interesting” – the majority of the pupils in both groups made this choice – 43 per cent of the pencil-and-paper group and 32 per cent of the Solver group. Thirty-seven per cent of the pupils thought that the statement “In my opinion mathematical word problems are useful” was somewhat well founded. (Ruokamo 2000a.)

The Attitudes of the Pupils towards Anchored Instruction in the Solver Group

In the Solver group (N=21), 38 per cent of the pupils thought that “I became interested in solving the problem tasks because of the video that introduced the problem situation” was well founded. Four pupils thought that the videos were Solver’s best properties. The majority of the pupils (35 per cent, N = 20) thought that the claim “It was useful that when solving tasks, that during each of the lessons all the tasks in one problem series were connected to the same situation and theme” was very well founded. Thirty per cent thought that it was extremely well founded and the same percentage thought that it was somewhat well founded. Almost half the pupils (48 %) thought that “The videos made it easier for me to understand the problem” was somewhat well founded. Forty per cent of the pupils (N = 20) thought that “The hints in the Solver Learning Environment helped my progress with problem-solving” was somewhat well founded, but two pupils thought that Solver’s worst property was that there was no use for the hints. The pupils thought that the videos were motivating and they were very satisfied with Solver’s contextuality and situationality. (Ruokamo 2000a.)
The pupils who studied in the Solver Learning Environment were asked for their point of view on what was the most interesting problem series. Their opinions divided as follows: Home Party was the most interesting problem series (43 %), the Course in Computing was the second (24 %), Rabbit Minttu was the third (19 %), and the Sport Quiz (14 %) was the fourth. None of the pupils selected Camps or Family Travel Costs as one of the most interesting problem series. To the question "What was the best in the Solver Learning Environment?" some of the pupils answered as follows:

- "It was different from math lessons. Solver helped in some tasks."
- "It was different from the ordinary study of maths and it was funny and interesting."
- "It was a good change to the ordinary math lessons. It was very different. A very fine thing."
- "We get to learn new mathematical program on the computer. Some of the tasks were interesting."

Based on the results of the study, there was a connection between the pupils’ gender and their attitudes towards the Solver Learning Environment: girls reacted more positively towards the Solver’s situational model as a tool for problem-solving, and to the contextuality of the Solver Learning Environment. According to the variance analysis, there was a statistically significant difference between the pupils’ gender and their interests towards a series of tasks (F = 13.349, p = .002, Eta^2 = 0.413). Gender affected interest in all six series of tasks. The interests of the pupils divided as follows: eight girls and just one boy thought that Home Party was the most interesting series of tasks. All the pupils who thought that the Course in Computing was the most interesting problem series were boys – there were five of them. Two girls and two boys selected Rabbit Minttu as the most interesting problem series. Two boys and one girl selected Sport Quiz as the most interesting problem series. No one thought that Camp or Family Travel Costs was one of the most interesting problem series. (Ruokamo 2000a).

Conclusions

This paper describes the Solver Learning Environment developed as a part of the study dealing with mathematical abilities and development of mathematical word problem-solving skills. Several attitude tests were organised as a part of the teaching experiment to gather data of pupils’ attitudes towards mathematics, mathematical word problem-solving, information technology, and environments used in the teaching experiment. This paper presents some ideas and pupils’ attitudes towards anchored instruction on mathematical word problem-solving. The conclusion may be reached that pupils’ attitudes were fairly positive towards anchored instruction on mathematical word problem-solving.

ABSTRACT: The EnterTech™ Project is a collaborative effort of Texas business, education, and community organizations to develop a job skills training program specific to entry-level manufacturing positions in technology industries critical to the Texas economy. Its goal is to effect change by creating a job training program that is based on industry needs, that can be delivered to large numbers of people, and that teaches transferable skills and knowledge through simulated work environments.

Demonstration And Report

The EnterTech Project is the development of a support model including a unique, realistic, interactive approach to training designed to provide employers with employees that are (1) ready for entry-level positions in technology and related supply and service industries; (2) equipped to solve work-related problems and add value to their workplace; and (3) prepared to continue improving their skills and education. The Governor of the State of Texas is providing funding to support the project. The IC² Institute, The University of Texas at Austin facilitates the project for a coalition of more than 70 employers, community-based organizations, educators and policy makers. Targeted learners are high school and college students, dislocated workers, incumbent workers, recipients of public assistance, and unemployed or underemployed people. http://www.utexas.edu/depts/ic2/et/report.html

The Training Program

EnterTech is web-based training for people who want to enter and succeed in the technology workforce although the skills are transferable to other industries. The learner acts as an employee with peers and supervisors in a virtual technology company. This web-based company is part of an integrated learning environment that also includes a personal planner, institution and instructor's guide, group activities, and interactions with the instructor.

The employer-validated competencies are based on actual on-the-job observations, and in-put from entry-level workers. Competencies include understanding an employer's needs and expectations, developing good workplace habits and ethics, utilizing available resources, managing time, communicating well, reasoning mathematically, solving problems and on-going learning. While these skills are taught by performing actual entry-level tasks in the virtual technology company, the skills are transferable to other industries also. In addition to workplace tasks, the learners solve problems relating to their personal lives, such as transportation issues and child care issues, as they impact the workplace. Learners utilize local resources to solve these problems.
Outcomes

1. Creation of a virtual technology company on-line with the learner as an employee in the virtual company.
2. Learning in a virtual work setting such that the learner gets a "feel" of a technology company.
3. Delivery of knowledge, skills, and abilities in a virtual work setting with problem solving scenarios relating to work as well as addressing problems where the learner's personal life impacts work.
4. Expansion and contraction of the length of the training program driven by the learner's successful completion of module post-tests facilitated by (a) tracking the learner's progress and (b) directing each learner to new training materials based on the individual's appropriate skill level.
5. Experience by learner with word processing, spreadsheet applications, and email.
6. Availability of information and web links to community resources to assist the learner in understanding how to create support networks at home and at work.
7. Creation of a results-oriented portfolio with problem-solving and assessment results, and actual work examples with levels of skills achieved by the learner upon completion.

Example EnterTech Pilot Sites

Capital Area Training Foundation (Austin, Texas)

Instructor: Frieda Gress, Program Coordinator, Telecommunity Partnership Initiative
EnterTech is offered to adult learners in an evening continuing education environment. The Capital Area Training Foundation is a non-profit, industry-led organization that brings educators and employers together to create a quality workforce and to prepare all students for lifelong learning and career success. EnterTech is offered as part of their Telecommunity Partnership Initiative, a program offering free computer skills training, community access, and job-seeking assistance for adults in the evenings at Travis High School in Southeast Austin.

Kyle Family Learning and Career Center (Kyle, Texas)

The Kyle Family Learning and Career Center offers EnterTech in conjunction with adult basic education, GED preparation, and computer skills training curricula. The Center is one of the programs of Community Action Inc. of San Marcos, Texas. A bonus feature to this rural organization is co-housing with a workforce development center to create a one-stop center for social services, training and employment referrals.

Near Northside Partners Council (Fort Worth, Texas)

The Near Northside Partners Council (NNPC) is incorporating EnterTech with its Neighborhood Jobs Initiative to connect Fort Worth inner-city residents to jobs in growth sectors offering better pay and benefits. Unlike many urban, inner-city neighborhoods, their main employment issue is not one of unemployment but of underemployment. The majority of residents work in low-skill, low-wage jobs. NNPC seeks to enable better job placements. Their long-term goal is to evolve into an organization that emphasizes job retention and advancement in the labor market.

McAllen ISD - Options in Education High School (McAllen, Texas)

EnterTech was offered as a supplement to business and marketing coursework to sophomores, juniors and seniors within an alternative high school setting. Options in Education High School is an alternative educational program that recognizes the unique learning and motivational needs of students and provides a flexible, student-centered learning environment which empowers them to achieve their full potential as lifelong learners. The diverse grouping at Options consists of high school students from who are not experiencing success in traditional settings.
eLearning, Teaching and Training: a First Look at Principles, Issues and Implications

Malcolm Ryan, School of Post Compulsory Education and Training, University of Greenwich, UK.
m.ryan@gre.ac.uk

Lynda Hall, School of Post Compulsory Education and Training, University of Greenwich, UK.
l.hall@gre.ac.uk

Abstract: Although it has yet to make a major impact on education and training in the UK, interest in eLearning is growing. The means exist to create Virtual Learning Environments (VLEs) but if these are to become widespread in Higher Education then a “cultural shift” will be needed - a shift away from a focus on teaching to a greater focus on learning. This raises a number of issues - including the attitudes and perceptions of a number of stakeholders - and has implications for institutions, the curriculum, staff and students. These implications are explored in this article and point to a need for institutions to review current policies and practice if they wish to maximise the potential of eLearning.

The Context of Change

Changes in society are occurring on a global scale resulting in “a mass higher education system that is reassessing its learning and teaching practices and exploiting the use of communication and information technologies.” (Maier and Warren; 2000) A further consequence of these changes is that our clients (students) are demanding more flexible modes of study, just-in-time training, work-based learning and accreditation of prior experiential learning (APEL) whilst world-wide government initiatives continue to promote the concept of life-long learning. We are also told that Higher Education Institutions (HEIs) wishing to exploit technology effectively need “a clear and shared understanding of a wide range of issues - pedagogical, infra-structural and organizational.” (Barblan and Fayant; 2000)

Many companies and large organisations also realise that they must continue to train employees if they are to remain competitive. Modern and dynamic companies no longer view training simply as a cost but as an investment, linked to their ability to be both profitable and successful. However, traditional training methods tend to be very time consuming and are not particularly responsive to individual needs.

In addition to these changes, we have witnessed an unexpected and exponential growth and interest in the Internet and in the World Wide Web (WWW) in particular. Alongside eMail, eBanking, eCommerce and eShopping we now have eLearning and Teaching (ELT). eLearning is attractive to the corporate market “because it promises better use of time, accelerated learning, global reach, fast pace and accountability.” (Cross, 2000)

What is eLearning?

In a very short space of time definitions of eLearning have mushroomed. These include, “the convergence of learning and networks and the new Economy,” (Cross, 2000) and “the use of network technology to design, deliver, select, administer, and extend learning.” (Masie, 2000) Goodyear (2000) is clear that eLearning is not just the equivalent of eCommerce or of learning on the Web but asserts that it is, “the systematic use of networked multimedia computer technologies to;

- empower learners,
- improve learning,
- connect learners to people and resources supportive of their needs, and
- integrate learning, performance, individual and organisational goals.”
He suggests that eLearning is essentially dependent upon, and shaped by, three enabling technologies; the infrastructure of the Internet, the presentational capabilities of modern multimedia computers and the information sharing tools and protocols of the world wide web (WWW).

Already, there are claims being made for eLearning and its ability to revolutionise education and training. Citing Cross (2000), legitimate eLearning is more likely to:

- focus on the needs of the learner, not the trainer or institution,
- take advantage of the net: real-time, 24/7, anywhere, anytime
- bring people together to collaborate and learn
- personalize, often by combining 'learning objects' on the fly
- offer more than one learning method
- incorporate administrative functions such as registration, payment ... monitoring learner progress, testing, and maintaining records.

So, whilst it is still a relatively new concept, currently eLearning appears to be characterised by the exploitation of Web based technologies to create learning materials and for course delivery, accessed via a browser with some form of on-line learner support

Implementing eLearning

To facilitate eLearning, a Virtual Learning Environment (VLE) is usually employed containing four main elements:

1. courseware – self study learning materials, simulations, multi-media components
2. supporting materials – reference materials such as articles, case studies, books, World Wide Web links
3. on-line assessment – both formative and summative tests, quizzes and assignments
4. on-line support – via e-mail, Computer Mediated Communication (CMC), chat rooms, bulletin boards.

At one level such an environment can be the extension of an existing Intranet (Fig. 1) that will usually contain three of the above components.

![Diagram of Intranet](image)

**Figure 1 - Elements of an Intranet (based upon a figure in FEFC, 1998)**
The missing element, on-line support, is often provided by e-mail or some form of bulletin board. As an interim arrangement this may work satisfactorily but a true VLE will integrate these functions fully and provide more sophisticated support, tracking and assessment tools.

**Issues**

Whilst the use of Virtual Learning Environments can provide a much enhanced ‘distance learning experience’ (Ryan, 1997) and reach new markets, there are also some drawbacks. Many of these can be partially addressed through training and support (Rogers, 2000) but unless a student has frequent and regular access to the technology and the necessary range of skills to exploit it, then they are likely to have an unsatisfactory learning experience. It is questionable, for example, whether all subjects can be delivered satisfactorily at all levels, to all students. It is relatively difficult at this time to provide the kind of ‘hands-on’ experiences via the Internet that may be gained in a science laboratory, engineering workshop or training kitchen. It is relatively easy on the other hand to present content-laden subjects and conceptual ideas via the Internet but, for the moment, many kinds of social interaction are probably still best experienced in face-to-face classrooms. Some commentators recommend a mixture of more traditional and eLearning approaches that acknowledge the diverse range of learning styles and subject matter in order to achieve maximum effectiveness.

A major area of concern reported by many researchers and practitioners (Ben-Jacob et al, 2000; Laurillard, 1995; Rogers, 2000; Ryan, 2000; Smith and Hardaker, 2000) is cultural shift. This ‘shift’ has a number of facets, some more tangible than others, but can be broadly described as a move away from teacher-centred, didactic exposition to a more resource-based, immersive and learner-centred environment. It would be dangerous to assume that all students will welcome this shift of emphasis away from teaching towards learning. Whilst many have responded positively to the use of ICT and VLEs in particular, (Birbeck, 2000; Smith and Hardaker, 2000) there are those who are sceptical and believe that flexible learning approaches are an abrogation of responsibility by the teacher. (Halsall, R. et al, 1998) It is certainly our experience (Ryan and Woodward, 1998) that more is expected of students and tutors operating virtually than within a traditional distance regime and this does not always suit all participants. It is important to introduce students (and staff) to this new way (culture) of learning and teaching, including how to learn (and teach) within a virtual learning environment.

The design of VLEs tends to promote the concept of a community of learners and opens up possibilities for networking, peer interaction and collaboration at a level not often seen in traditional classrooms. (Barajas, 2000) Interaction is at the heart of learning with ICT and the skills and attitudes required to make most effective use of VLEs are likely to be distinctly different to those normally operating within a traditional higher education institution. (Ben-Jacob, 2000; Rogers, 2000)

In turn, this cultural shift raises a number of issues for both students and tutors including:

- perceptions of learning and teaching
- attitudes towards being ‘required’ to learn as well as being taught
- the ICT skills required to operate efficiently
- ownership and control of learning and teaching
- the respective roles and relationships between stakeholders

No matter how far down the eLearning road one travels, the above issues (and others) will need to be considered and appropriate strategies developed for meeting the needs of users. Of paramount importance is the issue of staff development. “Academic staff development in the pedagogical applications of new technologies is fundamental to the transformation of teaching and learning ...” (Sprat et al, 2000)

**Implications**

Given the issues raised above, any institution or training organisation would be advised to review its current policies and practices if it is to maximise the potential of eLearning. There is a wealth of material in the public domain that outlines good practice and indicates what steps need to be taken to replicate that practice and address issues and potential problems. What follows is not an exhaustive list but is intended to provide a starting
point for considering the large number of factors that will impact on all stakeholders engaged in eLearning and Teaching (ELT).

Institutional

As suggested by Barblan and Fayant (2000), an audit of current practice across the organisation with regard to the use of ICT and learning, teaching and training strategies is a good place to begin the review process. Part of this review should include an ICT staff audit to establish levels of competence. This will provide a substantial amount of information about current operating practices and also give some insights into the prevailing culture. It is quite likely, for example, that an organisation familiar with more traditional teaching and training strategies will need to develop a new vision for the future which is student (client) rather than teacher or institution-led and this information will be helpful in developing an ELT policy. It will also be necessary to establish and maintain a stable telecommunications/networking infrastructure that will be future-proof. For eLearning to be as significant as on-campus provision there needs to be a greater emphasis on (and more resources devoted to) ICT infrastructure. The initial costs of ELT are high and financial resources will need to be committed to on-going development and maintenance.

Rome was not built in a day and any organisation intending to move into the eLearning world should consider developing short, medium and long-term plans for the implementation of ELT. Incremental change is far more likely to produce the required shift in culture than a full-frontal onslaught. It may be helpful, and promote a greater sense of ownership, if individual schools, faculties and departments are charged with incorporating ELT in all future strategic plans.

It is well known that the exploitation of ICT in learning, teaching and training requires a multi-disciplinary approach. Establishing a centre of expertise, if one does not already exist, which can become a one-stop shop for all matters relating to ELT would enable the range of expertise necessary to make most effective use of the technology accessible to the majority of stakeholders.

Although major software houses make wide ranging claims for their products it is acknowledged by practitioners that no one tool will deliver everything necessary for a fully functional VLE. It is better to identify and establish an eToolkit (a range of tools) that will deliver the organisation’s policy on ELT rather than trying to use a ‘hammer to drive a screw’. This toolkit may be based on one of the major VLE platforms such as Lotus LearningSpace or WebCT but should also include a number of specific tools for web audio and video streaming. This will allow a greater range of learning, teaching and training strategies to be employed within the virtual learning environment.

Although an ICT audit of staff may reveal them to be competent users they are still likely to require additional support to enable them to more fully exploit the potential of the selected eTools. It is advisable to provide a comprehensive staff development programme ranging from awareness raising to the design, development and exploitation of VLEs and the ELT toolkit. Alongside this provision there should be a range of user-support mechanisms both on and off campus for hardware, software, authoring and design. Consideration should be given to strategies that encourage greater collaboration/co-operation between schools and departments so that expertise is shared for the common good. One approach to providing on-going support and leadership might be the appointment of school/department-based ELT experts from amongst the ‘ranks’ to act as consultants and co-ordinators at a local level. Teaching and training within a VLE often occurs outside of ‘normal’ working hours. Tele-working is a legitimate method of operation and institutions may need to review staff contracts in the light of requirements for more flexible use of time - e.g. a longer teaching year, evening and weekend work.

In addition to the above, institutions will also have to develop an eLibrary, a comprehensive range of e-student support services and ensure that there are safeguards in place and a fallback position to support students when the technology fails. It may also be necessary to review regulations governing registration, assessment and accreditation to provide greater client orientation (flexibility) that facilitates just-in-time training and life-long learning. Some organisations will be better equipped than others to embrace these changes but whatever their position in the global market place everyone will benefit if future ICT developments in learning and teaching are grounded in sound educational practice, documented, evaluated and published.
Curriculum

The traditional offerings of universities and training organisations will need to be reviewed in the light of the changing market-place with its greater emphasis on, 'just-in-time' training, life-long learning, work-based training, mentoring and key skills. There is a worldwide shift towards more consumerism in education and training with its associated increase in client-centred content and greater involvement of the student/trainee (consumer) in determining outcomes and methods of assessment. To ensure that products are accessible and appeal to a worldwide audience institutions will have to conduct more in-depth market research. The delivery of these new curricula will have to become more flexible in terms of time and place with students operating outside of 'normal' university semesters.

Because eLearning is still in its infancy there are as yet no identified or established models to inform curriculum development. Some exist with regard to the use of ICT generally and computer mediated communication (CMC) in particular (e.g. Mason, 1998; Ryan, 1997). The articulation of such models will be helpful in the medium to long term and avoid much duplication of effort whilst building upon what we already know about the impact of ICT on learning and teaching.

One major difference between ICT-based and traditional learning, especially at a distance, has been the collaborative nature of much of the interaction and the extent to which the peer group supports one another and uses the tutor as a facilitator rather than a content-expert. Combined with market forces this shift in emphasis, from teaching to learning, may well lead to the greater involvement of a range of stakeholders (students, employers, industry, and the community) in the development of new courses and programmes.

An added bonus of working within a VLE is that students must make effective use of a range of ICT tools that can result in the acquisition and development of essential and transferable key skills. Programmes of study that are delivered within VLEs must ensure that there are opportunities within the curriculum to acquire and develop these skills or some students (those who enter with the skills) will have an unfair advantage over those who do not possess them.

Research has shown that novel ways of learning and teaching are possible when we employ ICT tools. What we have learnt about the use of these tools and the opportunities they provide should be fully exploited within VLEs so that the widest possible range of learning, teaching and training facilities are made available.

Students

Much of what has been said about the curriculum will impact directly upon students. Institutions should consider the likely impact that technology will have on students and be prepared to raise their awareness of the differences between traditional and eLearning and Teaching. Many students, for a variety of reasons, may have had limited exposure to the full range of ICT tools. Some students may have had limited access to the technology and only a minority are likely to have experienced operating within a virtual environment. If eLearning is to be successful then institutions must consider how students will gain regular and frequent access to appropriate technology, which may include home access via cable and satellite television and personal computer/communications devices such as laptops, handheld computers and WAP phones.

Alongside the traditional skills and abilities of students such as reading, writing, speaking and processing information it will be necessary for them to acquire and develop additional skills to fully exploit ELT. These will include using a wide range of ICT tools, time management and reflection both on and in action. For some students used to operating in isolation within a traditional distance context, they will also need to learn to collaborate and support their peers. Students may also need to modify their expectations of the tutor especially if they perceive them as being the 'sage on the stage' as they in turn adapt to their new role as 'guide on the side'.

Because eLearning is so technology-dependent, it is essential that there are clearly established lines of communication and support to ensure that students are not disadvantaged in the event of technology failure. It may be necessary to provide a full range of support mechanisms accessible 24 hours a day, 7 days a week to make most effective use of ELT. Within most UK universities this would be considered as an unusually high level of 'customer care'. However, with changed expectations about the learning and teaching processes and the
role of the technology, it is likely that new ways of thinking about how we perceive students and how they perceive teachers will need to be adopted.

Staff

Perhaps the greatest first step for academic staff and trainers will be the need for an increased awareness of the cultural shift from learning to teaching alongside embracing what technology has to offer. Staff development may help to facilitate aspects of this shift but there will need to be a fundamental belief in these new ways of working if they are to impact significantly on current practices. Training in the use of a range of ICT tools and their appropriate exploitation is but a small part of the overall staff development package that will need to be on offer and willingly embraced.

If full use is to be made of the novel opportunities provided by the technology then teachers and trainers will require time to translate existing and develop new courses for delivery within a VLE. Scholarship is more critical within an ELT environment (where expectations about currency are higher) and tutors will need time to undertake appropriate research to identify current and relevant resources to ensure those materials are always up-to-date. It is probably the case that most UK academics already have access to a dedicated computer, which will be essential if they are to exploit ELT effectively. There may also be a need to review timetabling to ensure greater cost-effective and efficient use of academics engaging in both traditional and ELT. Consideration may need to be given to alternative methods of allocating tutors to students e.g. case-loading. Terms and conditions of employment are different across the world but many UK HEIs operate on the basis of ‘contact’ hours. Such a basis for allocating time is probably inappropriate within a VLE and staff must be willing to be involved in a review of contracts with regard to working outside of ‘normal’ institutional hours, days and semesters.

The same need that students have for technical and user support will also apply to staff if they are going to be able to function effectively at all times. Additionally, it will be necessary to provide effective and efficient administrative support both centrally and locally to ensure an effective VLE.

Concluding Remarks

This paper has attempted to begin the process of raising awareness to the emerging nature and concept of eLearning and some of the issues and implications for learning, teaching and training within a virtual learning environment.

If eLearning is to be successful then it will be important for everyone involved to recognise and prepare for the cultural shift that underlies this revolution in learning, teaching and training. We should be wary of thinking of this new concept from a purely technological stance, a mistake made by many of the innovators and early adopters of ICT in learning and teaching. Instead, we should be guided by the outcomes of research and evaluation, which propose that we exploit the unique qualities of these technologies to enable new and diverse ways of supporting learning and always ensuring ‘fitness for purpose’. (Laurillard, 1995)

Change does not mean turning our backs on tried, tested and successful models of learning and teaching. To jump on the technological bandwagon and try to deliver everything via the web would be a mistake. Web technologies are still evolving. They are in their infancy and whilst great strides have been made over recent years they probably have a long way to go before they mature – if indeed they ever do before we are overwhelmed by the next technological breakthrough!

The degree to which an institution is able to prepare all participants for this shift of emphasis and address the issues and concerns of all parties will inevitably determine the success of any project, including that of a virtual university. Staff development will be a major contributor to addressing these issues for tutors, alongside ongoing support and development by key personnel. Steps must also be taken to ensure that students are supported through this transition from traditional to virtual learning and teaching or institutions risk losing their share of the growing eLearning market. In a virtual learning world there must be some compelling reason for a student to be persuaded to undertake a course of study at one institution rather than another.

Die Neue Lehre: An On-line Course in Schenkerian Analysis

Jennifer Sadoff
Center for Schenkerian Studies
University of North Texas
United States
Jen_Bsn@hotmail.com

Abstract: The interactive nature of music classes at the university level have traditionally necessitated a face-to-face learning environment. New digital technology and the increasing acceptance and use of the internet have made it possible to create effective interactive, multi-media activities for students to access and utilize on-line. In the music discipline, computers have been used effectively to augment undergraduate courses, providing computer-assisted drills and delivery of facts and knowledge mostly for music history and appreciation, and elementary music theory and aural skills. With the opportunity to connect professor to student using the internet, other more advanced courses may now be offered to remote students. Here a course in Schenkerian Analysis, an advanced type of graphic music analysis, developed by Austrian music theorist, Heinrich Schenker (1868-1935), has been adapted for the web using WebCT, a platform for delivering courses on-line. Noteworthy are the innovative method for displaying the Schenkerian graphs, employing notation software, Music Press, the animations which manipulate the graphs, and the unique opportunity for students in other counties to interact with top Schenkerian scholars at the University of North Texas.

Introduction

Heinrich Schenker (1868-1935) was an Austrian music theorist who developed a method of analyzing music in terms of structural levels and their relationship to one another (foreground, middleground, and background). Since most of the authorities on Schenkerian analysis reside in America, a course had been proposed to expose students in other countries to this unique form of analysis. The pedagogy of Schenkerian analysis itself is complex. It is generally agreed that a teacher or facilitator is necessary in order for students to grasp the basic concepts and graphing techniques. Previously, such interaction has been difficult in any but a face-to-face arrangement with students, but with the distance learning options presently available via the Internet and related technologies, more advanced courses that require direct interaction with a teacher are now possible. Through this project I have developed a distributed learning course to teach Schenkerian analysis to students anywhere in the world.

With the proliferation of Schenkerian theory in the US, Great Britain, Israel, Finland, for increasingly mainland Europe in the past quarter century, the pedagogy of Schenkerian analysis has become an important issue. Schenker himself was suspicious of textbooks with their tendency for artificial codification and over-simplification; rather, he recognized that his "New Teaching" ("Die neue Lehre") - as he and his students referred to it - would require a different, more "organic" pedagogical approach that was both personal and yet accessible to a wide audience.

New digital technologies have made it possible to disseminate Schenker's pedagogical approach, not through textbooks, but by adapting interactive techniques of Web-based instruction. In practice, Schenker's "new teaching" was as organic as his theory itself - and as novel in the connections it sought to draw between the individuated disciplines of theory, musicology, composition, and performance. The interactive and multi-media components of Web-based instruction enable us to realize Schenker's own pedagogical approach to instruction in Schenkerian analysis.

I have created an online course with a variety of components to make learning Schenkerian analysis possible. The webpage, created for use with WebCT version 3.0 (Web Course Tools), a platform for distributed learning courses, contains Schenkerian graphs with explanation and study questions by celebrated Schenkerian scholar, Dr. Timothy Jackson, professor of music theory at the University of North Texas. I have set his original graphs using a graphic notation program called Music Press, and then converted them to web-ready graphics files of unparalleled superior visual quality. Students learn about basic graphing techniques through musical examples, and they practice applying these techniques in their assignments with interactive activities created using Flash software.
Assignments are begun with initial guidance from the instructor, and then scanned in and sent to the instructor as email attachments or faxed. The instructor posts the graphs in the public forum with critiques, and the class is encouraged to participate in a virtual discussion in periodic scheduled “chat” events. There are also pre-recorded videos of the instructor explaining certain concepts, and students are able to communicate with the instructor through WebCT-unique email. Grade evaluation is based on class participation, that is comments posted and assignments submitted, as well as an individual research and analysis paper presented at the end of the term. Students also complete timed multiple-choice quizzes which are graded automatically using WebCT software, emphasizing time-on-task qualifications, as well as immediate feedback, two crucial elements to the mastery of a new technique. Each of these components add to the student’s progress in the field of Schenkerian analysis.

**Project Goals**

The main goal of this project is to provide training, unencumbered by restrictions of time and space, in Schenkerian analysis to anyone unable to come to our campus.

**Course Objectives**

1. The students will create Schenkerian style graphs for the purpose of analyzing and interpreting music.
2. Students will recognize and describe the work of Heinrich Schenker, commentaries on his work, and recent field work in the area of Schenkerian thought.
3. Students will be able to apply analytical elements of Schenkerian thought to the literature of the established musical canon, and critically evaluate Schenkerian graphs.

**Web Site Content (WebCT)**

- Syllabus
- Interactive class calendar
- Interactive assignments
- “Hands-on” activities
- Real-time net chat “events” and bulletin board postings
- Schenkerian graphs made with Music Press converted to PDF format

**Figure 1: Example of a Schenkerian Graph**

![Example of a Schenkerian Graph](image)
Course Procedures

- Students register online for the class through UNT according to the normal Center for Distributed Learning registration process.
- Net chat “events” are scheduled; students’ graphs will be scanned in, posted, and discussed with students and professor in real-time and with bulletin board postings.
- Students send homework assignments to professor via fax, sent as saved PDF files in email as attachments, or in the mail.
- Professor posts assignments online with critiques for the whole class to see and posts his own graph with explanation.

Conclusion

There are two primary reasons for creating a distributed-learning course for Schenkerian analysis. It allows people in remote locations, who may not normally have the opportunity to do so, to learn Schenkerian analysis, and local students have the option of working at their own pace, and access to Schenkerian graphs and course materials anytime, day or night, from any computer that has an Internet connection.
Abstract With the spread of low-priced computer, almost all students of our university own a laptop computer and bring it into the classes. In this situation, it is getting more required that how students can smoothly integrate their laptop with the existing university facilities such as CALL and computer laboratory. This paper describes three tools for system integration, which provide user integration of data, actions, and operation among different applications and computers. This integration allows user to use more than one computer as if they were unified as one system.

Introduction

With the spread of low-priced computer, in our university ownership of computer is obligatory for all students. Since this obligation started, students have always brought their own computer into university, placed it by the side of computer of computer laboratory, and done their work, operating two computers at the same time. In this situation, it is getting more required that how students can smoothly integrate their own computer with those of computer lab, even if the two computers differ in OS (operating system), and do their work efficiently. However actually intending to do so, various problems arise such as the inconvenient exchange of data by difference in OS, a double operation of mice and keyboards by using two computers, unsynchronized execution of software working on different computers etc. Therefore we propose three support tools for system integration, which were designed for users who operate more than one computer simultaneously. Final goals of our tools are four types of system integration as follows:

1. to smooth the way of data exchange among different OS computers without using FTP and file share. (Integration of Data)
2. to operate all computers, which user is using, with only one mouse and one keyboard. (Integration of Device)
3. to use some application software on different computers simultaneously, connecting one application with another. (Integration of Software)
4. to control operations of different OS computers with simple script. (Integration of operation)

Tools for System Integration

Universal Clipboard
Universal Clipboard allows user to exchange data easily among some different OS computers without using FTP and file share. This system is implemented in JAVA RMI and consists of one server and some clients, which are working on more than one computer.

Find Commander
Find Commander provides user automatic flow control among Java applications with simple script. This system consists of one server and some clients (See. Fig.1), and the exchanging data is sent to the clients via the server. By using Java reflection class FindCommander can firstly detect methods from the given application programs, execute them, write data, and operate their buttons without changing any Java programs, in accordance with user’s script program. The script program can control the actions of applications and transfer the data from one application to another applications on the remote computer. FindCommander realizes the integration of Java applications, which are working on several computers.

ExMouse -- Unified mouse and keyboard operation
ExMouse enables user to operate more than one computer with only one keyboard and one mouse, even if input devices are for different operating system. This system consists of two components as shown in Fig.2:
MouseControl and ExMouse. These components are connected by Java socket interface. MouseControl detects the actions of the mouse and keyboard, and ExMouse operates the mouse and keyboard by using Java Robot class. Clipboards of both computers can exchange some data with simple command such as "set remote / get remote". Since the actions of mouse and keyboard can be also recorded, user can replay them any time. Moreover user can put some MemoTags to the recorded actions on the screen and can replay the recorded actions by pushing on the MemoTags.

Applications

There are many possibilities of using the three tools in working and learning environments. In order to make use of resources more efficiently, learners can integrate their own laptop to the computers of CALL and computer lab as shown in Fig.4. By using ExMouse learners can operate the learning materials and WWW browser of Computer 2 with the mouse and keyboard of Computer 1. Finding a new word and useful expressions in the materials and WWW, learners can easily transfer such texts from the Computer2 to their laptop of Computer1 with three simple operations: Copy, Get remote, and Paste. Moreover, the function of event recorder allows learners to transfer data and to look up dictionary automatically. Learners can put the MemoTags at any place on the screen and take notes on them. Teacher can also give learners some instructions by using MemoTags. MemoTags can be also used as the start button for the recorded action sequences.

Conclusion

In this paper, three kinds of support tools for system integration were introduced. These tools facilitate integration of data, operation, and action among different applications and computers. Since they are written in Java, integration is also realized among different operating systems. This integration is particularly useful for constructing working and learning environment, and moreover for using more than one computers and many application programs.

Abstract: This paper describes a web-based laboratory system and courseware for potential energy experiments. It reports results which students achieved operating the system through the LAN at a local public university. The system utilizes experimental apparatus and courseware written in the HTML language to conduct various scientific experiments through the Internet. This system, called the WWLab system, allows learners to conduct live experiments using a robot arm. Surveyed afterwards, all 15 students involved in testing the system expressed interest, and concluded that the WWLab was useful for independent studies. However, we have found that lag time before screen display of live experimental work is long, approximately 20 seconds. So, in order to avoid entry of redundant commands during lag time, we plan to display complementary explanations of experiments, instead of command screens.

1. Introduction

As use of the Internet increases, so does the use of the Internet for teaching and research purposes. On-line teaching using the Internet used to consist mainly of communication from teachers to learners, namely, in one direction only. However, learners could deepen their understanding especially in the field of science by performing experiments themselves via the Internet. Therefore, Saisho et al. (1998, 1999) proposed the World Wide Laboratory (WWLab) system in which learners could operate experimental apparatus through the Web, and have been developing it on an experimental basis as described in this paper.

We have developed experimental apparatus and courseware written in HTML language for scientific experiments on the WWLab system. In this paper, we describe the system and courseware designed for potential energy experiments using the system.

2. Outline of the WWLab

The WWLab, shown in Figure 1, consists of a Web server machine, a video camera and experimental apparatus including a robot arm. The web server machine controls the video camera and the robot arm. We have developed a few experimental apparatus, such as a refractive index (Saisho et al. 1998), for this system.

At first, a learner opens our courseware using an Internet browser, such as Netscape Navigator or Internet Explorer. After the learner reads about the courseware, the learner may conduct live experiments, which are actually done in real time using the robot arm. At the same time, the learner can both observe the live experiment by video image transmissions and control directions of the video camera on our courseware. In addition, we provide a pre-recorded experiment which may be viewed as a movie file in advance.

In this system, anyone can freely access our courseware through the Web. However, if many learners try to work simultaneously, operation of the live experiment and the video camera is disrupted. Therefore, we have developed a scheme that enables only one learner at a time to operate the live experiment and the video camera via the WWLab system. Yet learners other than the one operating the apparatus can see the state of the live experiment and replay the recorded experiment through the Web at any time.

![Figure 1: WWLab System](image-url)
3. Software configuration for the WWLab system

The WWLab's software configuration consists of control software and courseware. Additionally, we use RealServer and RealProducer (RealNetworks, Inc.) to broadcast the live experiment for learners. Learners need RealPlayer (RealNetworks, Inc.) to observe various aspects of the live and the recorded experiments.

3.1 Control software for the WWLab system

In this system, control software is a set of programs to operate the video camera and to control the robot arm for live experiments. The program for operating the video camera is on a Web server, and it functions to change camera angles (tilt & pan) and the size of the video image (zoom). The program for operating the robot arm is also on the Web server. It consists of several commands, including the open-close command for robot finger movement which coordinates the positions of the fingertips. It is necessary to write special programs for each experiment.

3.2 Courseware for potential energy experiments

Courseware is on the Web server machine and is written in the HTML language. The courseware on potential energy consists of (1) an experimental overview section (an explanation for the potential energy of an object with a figure); (2) a section of an image of the experimental apparatus and an experimental method: A ball is rolled from the upper end of a track, to collide with a wooden block placed on the lower part of the track. The potential energy of the ball is determined by the measuring a distance that the ball moves the block; (3) a section of instructions for three kinds of experiments: (a) the comparison of small and large metal balls (b) the comparison of the same size of metal balls (c) the comparison of plastic and metal balls; and (4) a section of instructions for an operation of the video camera.

In addition to a video view of the live experiment, there are video views of pre-recorded experiments. Learners can replay the pre-recorded experiment if their live experiment fails, or if learners want to determine whether their live experiment was successful.

4. Experiment

We used Personal Web Server (Microsoft, Inc.) as software on the web server. Fifteen students from the Prefectural University of Kumamoto tried to operate the system using the LAN at the university. All students were interested in this system, and agreed to use it for independent studies. Their comments are as follows:

(1) It was interesting that a learner could operate the experimental apparatus by oneself, and observe the state of the live experiment using the video camera.

(2) A learner can use this system as a review of a class.

(3) After a learner took out one of the instructions for the live experiment, the time until the screen of the live experiment began to work was long.

(4) Connections with the Web server machine did not work well when more than a few students tried to access the recorded file of the experiment at the same time.

5. Discussion

We discovered a problem with this system, which is that the response time from the Web server machine is long, approximately 20 seconds. We guess that one cause of the problem is the web server. We currently use Personal Web Server software, but have found that its processing function is not satisfactory because it serves only basic functions. We expect to achieve functional improvements by changing from Personal Web Server to Windows NT server (Microsoft, Inc.).

Though it may be reduced, the problem of lag time will not disappear, because much of the response time is required to encode image data and move it to client computers. It is counter-productive for the learner to get bored by the same screen, or to click the control buttons again and again. As alternatives during lag time, we plan to display complementary explanations of the experiment. We expect alternatives displays to avoid entry of redundant commands.

6. Conclusion

In this paper, we have presented an outline of the WWlab system and courseware for experiments in potential energy, and confirmed operation of the system on a LAN. What developments remain to be seen are as follows:

(1) ways to use this system from outside the university;

(2) additional functions that learners can use for communication with each other by audio or keyboard input;

(3) applications of our system for actual learners; and

(4) developments of other experimental apparatus and courseware of experiments.

Some Educational Approaches Using Multimedia Technologies

Nicoletta Sala
University of Italian Switzerland
nsala @ arch.unisi.ch

Abstract: Multimedia technologies can modify the learning environment. This paper describes the results of three different experiences which involve the use of multimedia technologies in cognitive and educational processes (in High Schools and in Universities). First experience is an example of the application of multimedia technologies in the didactic path to help the students to reach the educational and cognitive goals. The computer plays a central role in this process. These courses of Mathematics, named Mathematical thought (first year) and Computer Graphics and New Media (fourth year), are presented as 20 lectures, given weekly throughout the academic year. We have used some multimedia technologies (e.g. CD-ROM, computer-aided design (CAD) tools, scientific documentaries, educational hypermedia, Virtual Reality, Internet sites) in support to the traditional educational tools (overhead projector or blackboard) to introduce the interconnections between Mathematics, Arts and Architecture. During the use of the new technologies we have noted that the hypermedia facilitate the application and transfer of complex knowledge to new situations. Such cognitive flexibility requires the representation of knowledge along multiple rather than single conceptual dimensions. Hypertext facilitates this cognitive flexibility because it allows a topic to be explored in multiple ways using a number of different concepts or themes. It is possible to identify the existence of a similarity between navigation in the real world and navigation in a virtual world (Calvi, 1997; Sala, 1999). We have used some educational hypertexts because we have noted that hypertext supports the connection of ideas (Brown, 2000). In fact, the use of hypertext-linked documents (and reference links) allows the readers to jump from content to content (idea to idea, at the whim of the reader). The comparison between statistical results on then learning rate using traditional methods and multimedia technologies will be available in the next future.

1. Multimedia technologies to support the traditional educational methods

At the Academy of Architecture of Mendrisio (University of Italian Switzerland) there are two courses of Mathematics (first and fourth year) that use the multimedia technologies in the didactic path to help the students to reach the educational and cognitive goals. The computer plays a central role in this process. These courses of Mathematics, named Mathematical thought (first year) and Computer Graphics and New Media (fourth year), are presented as 20 lectures, given weekly throughout the academic year. We have used some multimedia technologies (e.g. CD-ROM, computer-aided design (CAD) tools, scientific documentaries, educational hypermedia, Virtual Reality, Internet sites) in support to the traditional educational tools (overhead projector or blackboard) to introduce the interconnections between Mathematics, Arts and Architecture. During the use of the new technologies we have noted that the hypermedia facilitate the application and transfer of complex knowledge to new situations. Such cognitive flexibility requires the representation of knowledge along multiple rather than single conceptual dimensions. Hypertext facilitates this cognitive flexibility because it allows a topic to be explored in multiple ways using a number of different concepts or themes. It is possible to identify the existence of a similarity between navigation in the real world and navigation in a virtual world (Calvi, 1997; Sala, 1999). We have used some educational hypertexts because we have noted that hypertext supports the connection of ideas (Brown, 2000). In fact, the use of hypertext-linked documents (and reference links) allows the readers to jump from content to content (idea to idea, at the whim of the reader). The comparison between statistical results on then learning rate using traditional methods and multimedia technologies will be available in the next future.

2. Multimedia technologies in substitution to the traditional educational methods

Prof. Umberto Pisani (Department of Electronic - Politecnico of Torino, Italy) has reorganized his course of Electronic Measurements, based on lectures and successive laboratory practice, using multimedia tools which combine two different learning phases: a theoretical phase, and a practice phase in a single tutorial stage self-managed by the student (Sala, 1999). This project was inside to the important Italian Distance Learning Project named "Nettuno". The project's goal was to develop a new approach in the Laboratory of Electronic Measurements where the students could carry out a pre-training activity outside the laboratory and possibly at home; each student could thus individually adapt the learning rate to his own capabilities. After this pre-training phase, students who enter the laboratory require reduced assistance and less time to complete the training activity. In these activities the author was an expert subject matter. The multimedia modules have been developed to expose students to a comprehensive range of electronic instruments and basic measurements techniques, and to allow students to give practice on the particular instrument whose front panel is simulated on the monitor and the behaviour is emulated by computer. This multimedia course, oriented to defined objectives of knowledge, is structured on a set of modules each containing a particular topic or instrument in form of a self-contained multimedia presentation. Each module has been developed using Multimedia Toolbox™ (with the aid of several thesis students), and contains different media (e.g., animation techniques, digital television camera images, audio supports, etc.). Each module includes several tests to verify the level of the acquired knowledge on the educational objectives and lesson subjects. Examinations include the laboratory quizzes by multiple choices, some simple projects (which could require few data processing), some puzzles (where student must rebuild an instrument block diagram or measurement procedures). In all exercises, the data are randomly selected to always generate new projects entry points. The test results are stored into a database file, which can be processed by an external DBMS program with the possibility to extract statistical indicators on the class by DBMS query. Virtual instruments are implemented in the multimedia packages (developed in the VisualBasic™ environment...
with the exception of a minor part written in Microsoft C++™, in order to allow simple simulations of the real instruments during the self-training phase. For example, when learning the spectrum analyser, the student, after setting a particular input signal, can evaluate the effects of different instrument configurations on the simulated screen. The idea is to design a laboratory that is simultaneously and remotely accessible to several students, who concurrently share the same instrumentation, but not necessarily the same experiment. The instrumentation is accessible in a sort of time sharing process, which is managed by a server and transparent to the user.

3. Multimedia technologies in a constructivist environment

Hypertext is considered by many researchers to facilitate human learning. Hypertext also mimics the way the brain works, by association. In educational process the students generally realized hypertexts or hypermedia on topics which they know (multimedia authoring). Their teachers control and give them all information to include in hypertext. Using this approach the role of the students is passive, because they transfer, on digital support, information furnished by the teachers. For this reason we have thought to control two groups of students that have researched, selected information, and produced an hypermedia on the Neural Networks (a subject which they didn't know before). The project "Learning by Doing and Creating" (LCD) has been developed in the Laboratory of System and Techniques of Transmission (3 hours in the week throughout the school year) in a high school (it is a technical institute) in Italy (specialization course in Information Technologies). We have controlled two different samples of students. The first sample (school year 1997 - 98), was composed from 15 students (aged 18 - 20), second group (school year 1998/99) was composed from 14 students (aged 18 - 20). We have proposed to the students a multiple choices test, before to start the project, to control their knowledge on the Neural Networks. The statistical analyses of the test have demonstrated that the students didn't know this subject. For this reason they were a reliable sample to study this "Learning by Doing" approach. After the students have created the hypermedia using the HTML language (with Java-Script procedures). In the final part of this educational research we have controlled the knowledge on Neural Networks of my students using multiple choices test, and we have proposed to the students a test to evaluate my contribution (e.g., information on my interaction with the classroom, my contribution to the project, and so forth). Results of this analysis have been encouraging, because 64% of the first sample and 75% of the second students have achieved the educational goals (Bloom's taxonomy), and our contribution to the project has been well evaluated. In the months of October and November, school year 1999/2000, we have chosen another sample of 15 students to explain the Neural Networks using the traditional educational methods (some lectures using blackboard and overhead projector). We have dedicated to this phase ten hours. Afterwards we have controlled the students' learning rate using a multiple choice test (the same of the other two samples), and we have compared the statistical data of the three different samples. It has been necessary to evaluate the effectiveness of the "Learning by Doing and Creating" (LCD) approach.

4. Conclusions

The use of multimedia solutions in degree level courses or in college has proved to be effective in several different fields. In the courses of Mathematics at the Academy of Architecture of Mendrisio the use of the multimedia technologies have allowed to study in depth the platonic solids, to apply to isometry and the perspective, to observe the fractal forms, to manipulate some virtual objects (e.g. virtual fullerenes or platonic solids). The solution designed by the Politecnico of Torino, for the Electronic Measurement course, is an example of an integrated solution in which the theoretical part is made available through a hypermedia and the laboratory part can be carried out by accessing real instruments through a network connection. This solution can reduce the training cost on the electronic instrumentation. Third our experience is an example of "Learning by Doing" environment where some students build an educational hypermedia and they learn while build it; it is also cooperative environment. The final comparisons between the three samples have permitted to determine some important considerations on the use of the new media in a constructivist approach. In particular way, in the active role of the students. Some researchers have emphasized the active role learners must play in order to learn in hypertext-based learning environments (Spiro & Jehng, 1990). This approach is in agreement with Seymour Papert that says "Better learning will not come from finding better ways for the teacher to instruct but from giving the learner better opportunities to construct" (Papert, 1990, p.3). The students exhibited strong motivation in this multimedia development, and this is encouraging for the future application of multimedia technologies in educational process. Finally, it is important to remember that the teacher must be a facilitator in this cooperative learning environment, and not to fall into the trap of letting students totally "construct" their knowledge on their own. The teacher is still a very important resource and the computer is also a resource that will be used to help students in the acquisition of knowledge.

Learning with Multimedia Technologies: some examples

Nicoletta Sala, University of Italian Switzerland,

This work presents the results of three different educational experiences, which involve High Schools and Universities, where the multimedia technologies play a central role.

First experience is an example of the application of multimedia technologies to support the traditional educational methods. It has been developed for a first-year and a fourth-year undergraduate courses of Mathematics at the Academy of Architecture of Mendrisio, University of Italian Switzerland (Switzerland).

Second activity is an example where the multimedia technologies substitute the traditional tools (e.g. overhead projector or the blackboard) in the field of computer based training. Multimedia modules have been developed for a distance course to introduce the electronic instrumentation and the measurement techniques. Virtual instruments are implemented in order to allow simple simulations of the real instruments during the self-training phase. A client-server system has been designed in order to allow the students to operate on a remote laboratory for experimental training.

Third activity is an example of the use of the multimedia technologies to develop a new learning environment which uses the constructivist approach and the cooperative learning in a High School (a technical Institute in Italy).
Differences in Learning with Multimedia vs Non-Multimedia Presentation Formats

Abstract: There is indication that Computer Supported Collaborative Learning (CSCL) and accompanied inquiry-based pedagogical practices can enhance student learning. The aim of this study is to experiment CSCL and inquiry-based approach in real classroom situations and to analyse students' approaches in inquiry process in terms of cognitive and motivational engagement. Two elementary school classes participated in the study. The one of them was lower elementary school class (21 students, age 10-11) who participated in CSCL inquiry in natural science and the other was upper elementary school class (18 students, age 13-14) who participated in CSCL inquiry in literature. The data consists of students' written computer notes, students' interviews, video-reported motivational orientations. The results indicate the possibilities of enhancing students learning in literature and in natural sciences by CSCL inquiries. However, the results also reveal failings in students' inquiries, e.g. dominance of superficial approach to inquiry.

Introduction

Computer Supported Collaborative Learning (CSCL) combines learning theoretical approaches that emphasise the meaning of individual knowledge processing and views that highlight the meaning of collaborative discourse in knowledge acquisition (Koschmann, 1996). CSCL seems to be one of the promising innovations to improve teaching and learning with advanced communication technology (Järvelä, Hakkarainen, Lipponen & Lehtinen, 2000). CSCL tools are usually accompanied with inquiry based pedagogical approaches to fulfil the ideas of individual and collaborative settings of learning (Roschelle & Pea, 1999). By participating in inquiries students can reach models from expert working cultures and learn in apprenticeship like manner (Glaser, 1991; Roschelle, 1996). Through inquiries students can improve their understanding of both the content and the scientific practices, which are essential skills for lifelong learning (Hakkarainen, 1998).

There is indication that CSCL can support students' learning cognitively by helping them to structure their activity and to reflect their actions in metalevel (Scardamalia & Bereiter, 1993). CSCL has also potentials in providing tools for organising, representing and visualising knowledge (e.g. Pea, Tinker, Linn, Means, Bransford, Roschelle, Hsi, Brophy, & Songer, 1999; Rochelle & Pea, 1999). Furthermore, by means of technology CSCL applications can offer embedded process supports and multiple resources for student learning (e.g Barron, Swartz, Vye, Moore, Petrosino,
Zech, Bransford, & CTGV, 1998; Lin, Hmelo, Kinzer & Secules, 1999). In addition to cognitive benefits of CSCL, it is suggested that technology supported social interaction and collaborative learning could lead students to engage themselves in novel forms of knowledge construction (Koschmann, 1996; Dede, 1998). Successful collaboration involves mutual engagement and effort to solve problems together with collaborating participants (Dillenbourg, 1999). Collaborative learning situations afford multiple opportunities for students to create rich representations of problems and apply a variety of problem-solving strategies (Barron, 2000). CSCL can be a powerful tool in creating learning communities where students have a chance to collaboratively make representations, develop explanations of the subject studied and analyse knowledge (Scardamalia & Bereiter, 1993). Above cognitive and social potentials of CSCL, there is also indication of possible benefits to student motivation that it may offer. A study by Järvelä (1996) and Rahikainen, Järvelä & Salovaara (2000) suggest that CSCL might restructure elementary school students’ motivational orientation among non-task-oriented students.

There are, however, at least two caveats in implementation of technology-supported inquiry-based learning. First, there is a need for complementary empirical evidence of benefits of CSCL and inquiry-based activities. Many of the studies conducted in CSCL settings are based on short period of data collection and are implemented outside of real classroom situations. There are only few reports of broader dissemination of these novel practices (Roschelle & Pea, 1999). It is evident that more precise evidence of learning processes that involved in CSCL and inquiry situations is needed. For example, according to Rochelle & Pea (1999) collaborative processes are overemphasized, generalized, and their technology-specific features are not explicates enough. Second, CSCL practices need to be developed concurrently with pedagogical approaches so that technology, classroom activities and learning culture mutually support each other (Edelson, Gordin & Pea, 1999). It should be noted that students may not benefit from CSCL if they are not accustomed in the practices of new learning culture produced by CSCL and inquiry-based activities (Hakkarainen, Järvelä, Lipponen & Lehtinen, 1998).

Aims of the study

This work was motivated by a challenge to experiment CSCL and inquiry-based approach in real classroom situations and gather longitudinal experience in implementing collaborative inquiry culture to classroom. The aim is to examine students’ approaches in CSCL-based inquiry process in terms of cognitive and motivational engagement.

Procedures and method

The study was participated by two elementary school classrooms. One of them was lower elementary classroom (n=21) where CSCL and inquiry-based approach was used in natural science lessons. The other was upper elementary classroom (n=18) where CSCL was used in literature lessons. Pedagogical approach in both classrooms was inquiry-based. Topics for learning projects were derived from general curriculum of science and literature. Basically, each class participated on 4-8 weeks learning projects three times. Students had project lessons 2-3 times a week. Teachers supported students’ inquiries by instructing them when needed and presenting supporting activities.

CSCL tools, CSILE (Computer Supported Intentional Learning Environment) (Scardamalia & Bereiter, 1994), its’ further developed version KnowledgeForum (http://csile.oise.utoronto.ca/) were used to help students to conduct their own investigations and to create forums for social knowledge construction. The environments support students’ learning by providing tools for inquiry-based activities, discussion and knowledge production. Basically, they consist of empty hypermedia databases in which the students produce the contents. Student present their own research questions, intuitive working theories and new knowledge in the form of textual, graphical and discussion notes. The basic assumption is that all notes are open to the other members of learning community and all students have equal possibilities to participate to the activity. The applications contain tools for producing, storing, seeking, classifying and linking knowledge by text and graphic processing and discussion tools. Student learning is supported cognitively by helping them to articulate, explore and structure knowledge. Applications also include tools for generating discussion on the topics and possibilities for commenting each other’s notes so that students, teachers and experts can collaboratively work with knowledge.

Student learning was examined by gathering data in general level by self-report questionnaires of student motivation, learning strategies and self-regulation. More specific data from CSCL situations consisted of on-line...
interceptions, databases of students' postings and video recordings. The following table (Table 1.) presents an overview of the data collection in both experimental classrooms.

Table 1. Data collection in experimental classrooms during the project.

Student self-reports that included several sub scales were analysed in order to reveal students' general motivational tendencies (Niemivirta, 1996). Following a pattern-oriented approach in studying individual differences in motivation, the students in both studies were grouped by using a K-means cluster analysis into four different groups emphasising different goal orientation, means-ends beliefs and learning strategy use.

Students' actual situational behaviours were examined by database, interviews and video analyses. The content of databases was analysed according to principles of content analysis (Chi, 1997). The categories were based on earlier studies conducted in CSCL settings (e.g. Lipponen & Hakkarainen, 1997; Lipponen, 2000). The videotaped lessons were analysed by drawing a time-line diagram with on-task and off-task dimensions and interaction phases with the teacher and the other students (Rahikainen et al., 1999). This procedure enabled to make a profile of different students' activities as well as to see what were the patterns that formed the whole learning process. Videos were also used to provide authentic case examples of students' situation-specific behaviours during inquiry-based CSCL activities. The interviews were used to provide students' own situation-specific interpretations. Interview transcripts were also analysed by content analyses although the categories were based on motivational and self-regulatory constructs. In the following results are reported by integrating evidence derived from different analyses.

**Results – Development of inquiry-based CSCL culture**

**Students' cognitive approaches in the process of inquiry**

The results indicate slight dominance of superficial approach to inquiry especially among the upper elementary school students. Literature class students produced, in all, 367 notes with an average 20.39 (SD = 9.38) notes per student. On the contrary, in the natural science class all students participated to some extent and produced, in all, 662 notes with an average 31.52 (SD = 10.22) notes per a student. The quality of driving question that students phrase in the beginning of inquiry process is crucial to learning (see Hakkarainen, 1998). Particularly in literature class the driving questions that students formulated in the beginning of the learning projects were not complex enough to generate deep inquiries. The results derived from upper elementary school literature class show that 79.6% of the research questions were fact-oriented and only 20.4% of the questions were explanation seeking in nature. Accordingly, information that students wrote to the literature databases in order to provide an answer to research question failed in its purpose in terms of coherency, quality or information value. Only 8.7% of the noted labelled as new knowledge were student-generated explanations that presented a conceptually coherent explanation related to the research question. 91.3% of the inquiry notes included surface-level information. In science class, the quality of the information posted was slightly deeper: 51% of the questions were explanation oriented. In both classes there were, however, substantial individual differences in the participation rates. In science five students were the most active participants in the class, and wrote 41 to 51 notes, whereas the most non-active participant wrote only 15 notes. In literature most there were only four students who wrote over 30 notes and two most non-active students who wrote only 8 notes. Reasons for uneven participation can be examined by looking students' motivational profiles.

Students motivational approaches in CSCL-based inquiries

The results indicate that students' self-reported preference for certain type of motivational orientation clearly corresponded to their actual engagement in a novel learning environment. This is seen for example in video analyses from lower elementary school biology class. A selection of the videotapes was analysed by drawing a time-line diagram with on-task-off-task dimensions (Rahikainen, 1999). The results show that the learning oriented students' off-tasks periods were minor and they generally involved in progressive knowledge building process. There were two major findings concerning the non-learning oriented students. Firstly, a part of the non-learning oriented students indicated progressive motivation: episodes of high task-involvement and progressive knowledge building processes. However, the other non-learning oriented students created only few meaningful notes and their motivational coping was regressive. The video-data showed that the non-learning oriented students had difficulties to cope with the demands of a knowledge building procedure. However, it was possible to notice that even the extreme cases of non-learning oriented students accepted the working procedures involved in progressive inquiry, even if it was extremely slowly. That is to say that there is minor indication that working with CSCL project may cause qualitative changes in students' motivational interpretations. The novel instructional setting seemed to encourage some students to abandon behavioral patterns that might be expected in basis of their self-reported motivational orientation. There were students who presented clearly different strategic patterns of inquiry and engagement on knowledge construction discussion in different projects. The interview data provides possible explanations for students' context specific motivational coping behaviours. Students expressed factors that may have cause qualitative modifications in their motivational and cognitive approaches in different projects. These were such as task interest, cognitive demands of the environment (e.g. demands for self-regulative actions), and novel cognitive possibilities provided by the CSCL environments (distributed knowledge building processes) and a change of a classroom culture.

The potentials of collaborative knowledge construction discussion

Whereas the student inquiry notes referred to superficial engagement on inquiry the results indicate evident benefits of the collaborative knowledge construction discussion. Almost 69% of the students' comments were relevant to the inquiry process in science class. In literature class 88.4% of the comments were related to the content of the learning. Students evidently developed practices of commenting each other's work and thereby developed collaborative knowledge building practices. Furthermore, the interviews indicate that students were aware of the possible benefits of collaborative work. The following excerpt presents an example of this.

INT: Could you please describe how did you work with other students in this project?
STU: Well, we commented each other's work in CSILE.
INT: Why was that?
STU: They provided me some new ideas.
INT: What kind of ideas?
STU: Well, for example some suggestions what I could do next.

The analysis of the computer notes collected from the projects showed that there were some unique discussions in databases in which students asked questions from each other and collaboratively created explanations of the phenomena under investigation. The following excerpt from the upper elementary literature class presents an example of students' collaborative knowledge construction activity in the CSILE environment.

ANNA: Where does time come from?
ANTTI: It comes from a clock!!!!
HEIDI Time comes from sun.
ANTTI: As far as I know sun is not in a clock!!! What do you mean by saying that time comes from sun? It would mean that when the sun explodes the time stops.
LAURA: How is it possible that the sun would explode?
ANNA: How does the time come from the sun? Why? Does it not come from a clock? If the time does not come from a clock, where does it come from? How does the time come to the clock? From the sun or from where?
HEIDI:- People make clocks. Don't ask me how, ask a clockmaker. Let's assume that all the clocks on the earth would be broken. Does the time stop? No.
HEIDI: When the earth goes one time around the sun, it is a year. When the moon goes one time around the earth, it is a month. When the earth rotates once around its axis, it is a day. Do you understand? The time does not come from a clock, time is only measured by a clock.

ANNA: The most common conception is that time comes from a clock. But how does the time come to the clock? From the sun, I was told. Log time ago the calendar was developed and it is still used. I think that the calendar can be explained like this: The earth goes around the sun once and it is a year. The moon goes around the earth once and it is a month. When the earth rotates once around its axis, it is a day. It become clear to me that the exact length of a moon year is 354 3/8 days. It corresponds so called full rotation of the sun from a spring equinox to another spring equinox. The almost recurrence of natural phenomena creates a base for calendar and thereby so-called astronomic chronology is developed. --- But would the time stop if the sun would explode. Let’s assume that time comes from a clock. If all clocks on the earth would be broken at once, would the time stop? NO. Time can’t stop.

Progressive discourse, which comes from science tradition, can be seen as a core of knowledge building (e.g. Chan, Burtis & Bereiter, 1997). This example illustrated how the students participating in this study collaboratively processed an explanation of time, constructed a representation and advanced in explaining the phenomena. Building knowledge requires the students to consciously confront their previous knowledge and the possible misconceptions, and develop more coherent and examined explanations by considering the new evidence presented in the learning situation. Bereiter (2001) sees that scientific progress is not a matter of getting closer to the truth but a matter of improving existing knowledge. As characteristic to progressive discourse, the students mutually advanced in understanding and reflected upon the problem openly. The overall focus of the progressive discourse is on pursuing understanding and on seeing knowledge as problematic and something that needs to be explained.

Conclusions

The results of this study indicate the possibilities of enhancing students learning in literature and in natural sciences by CSCL inquiries. The research is in progress, but it can be stated that students need help in planning and conducting their own CSCL inquiries. Students should be advised to consider the information value and objectivity of the data or information that they use in their inquiries and to construct more coherent explanations to their inquiry questions. It is also evident that inquiry based approaches should be tailored specifically by considering the nature of the subject matter. Inquiry-based learning is generally considered to be an appropriate way of learning science, and it is frequently used in studying physics, chemistry or biology. However, there are not so many studies in which the inquiry-based learning would have been used in teaching social sciences or humanities, such as literature. From a curricular point of view, the challenge seems to be in finding meaningful connections between subject matter specific curriculum and inquiry practices that create possibilities to students to get close to expert working cultures. In next phases of this study it is essential to examine students long-term adaptation to the pedagogical culture of CSCL.

Chan, C.,

Anthropology 491: Teaching an on-line laboratory course.

Abstract

This paper presents a review of an upper division class on archaeological stone tool analysis. The goal of the course is to recreate the objectives, resources, and outcomes required of a typical laboratory analysis class, but in a completely on-line context. The on-line class components include syllabus, supporting material, specific lessons (with goals, objectives, and projects), and links to on-line research. Students access quizzes and exams, chatrooms, and bulletin boards, and are required to submit the results of their analyses, including data tables and digital images on-line to the instructor. The “text” for the class is a CD-ROM, Digital Stones. Compelling elements of the class are (1) the attempt to create a laboratory class on-line that will be available to any student around the world and (2) the invitation to recognized experts in the field to discuss their research live with the students in chatrooms. Problems encountered during the initial offering of the class included: working with the university bureaucracy, overestimating the students’ self-discipline and motivation, time zone differences between Idaho and our international students and invited guests, and the computer literacy of both the students and guests.

Introduction

This paper presents a review of Anthropology 491, an archaeological stone tool analysis class for upper undergraduates and graduate students. The goal of the course is to recreate the objectives, resources, and outcomes required of a typical laboratory analysis class, but to do so in a completely on-line context. The “text” for the class is a CD-ROM, Digital Stones (Lohse and Sammons, 1998), in which the analytical system, terminology, and history of research are presented in a multibranching format. Line drawings, digital photographs, microscopic views, and videos provide visual references for the text. Portions of the CD-ROM have been converted to HTML format so that they may be viewed over the World Wide Web. The on-line course includes syllabus, supporting material, specific lessons (with goals, objectives, and projects), and links to relevant on-line articles and research. Most of these are available to anyone. Registered students may also access the quizzes and exams, chatrooms, and bulletin boards; these students are also required to submit the results of their analyses, including data tables and digital images on-line to the instructor. Compelling elements of the class are (1) the attempt to create a laboratory class on-line that will be available to any student around the world and (2) the invitation to recognized experts in the field to discuss their research live with the students in chatrooms. Experts from England, the United States, and Australia came into the chatroom for two-hours sessions with the students. Problems encountered during the initial offering of the class included: working with the university bureaucracy, overestimating the students’ self-discipline and motivation, time zone differences between Idaho and our international students and invited guests, and the computer literacy of both the students and guests.

Overview of Anthropology 491

Many universities are offering on-line archaeology courses as part of national and international trends to deliver instruction over the Internet. Most of these courses supplement traditional lecture or laboratory instruction with syllabi, class notes,
exercises, assigned readings, chatrooms, and email contact with the instruction. While these classes make effective use of electronic resources, their primary role is to support traditional classroom instruction, rather than to replace it. Virtual classrooms allow students to use their own initiative, proceed at their own pace, and to move through the content as quickly as their own motivation and the academic infrastructure will allow.

In Anthropology 491, many of the supporting elements of a web class were present: syllabi, lessons, exercises, assignments, readings, and links. Because this is a laboratory analysis class, however, there were significant differences between this and other web-supplemented classes. First, the students’ text was the Digital Stones CD-ROM, which demonstrated the concepts, terms, and research of stone tool analysis through text, images, and video. Secondly, recognized experts in the field of archaeological stone tool analysis were invited to discuss their research with the students. Researchers from England, the United States, and Australia joined us and the students for two-hour sessions in the chatroom. Prior to the chats, the researchers also linked us to, or allowed us to post, their current research. Some of this research represented work-in-progress, and so our students had the unique opportunity to review and discuss leading edge research with the researchers themselves. Finally, a third unique element of the class was the assessment of the students’ mastery of the concepts. Two forms of assessment were used. On-line quizzes and examinations were required, using WebCT’s course tools. Students were also required to create and use stone tools at their home sites, perform certain analyses (described and outlined on both the CD and the course lessons), and then post the results of their analyses as data and images back to the instructor.

Instructional Issues

The creation of the Digital Stones CD incorporated several issues, including instructional design, content, authoring, and dissemination. Digital Stones was designed in accordance with standard procedures of instructional design (Kemp, et al., 1996). Instructional design model encompass many steps, including assessing the needs and characteristics of the learners, identifying specific tasks which the learners must perform, stating the objectives of the instruction, sequencing the instruction, and evaluation.

The pedagogical issues faced during the creation of Digital Stones have been fully described in a paper presented at the Computer Applications in Archaeology conference (Lohse and Sammons 1999). The impetus for creating the CD was our assessment of our learners, their needs, the learning context, and our own needs to train competent stone tool analysts in an environment which had limited facilities for students to perform replicative experiments. Therefore, we determined to create a multimedia, multibranching resource that would allow students to review the analytical system (Lohse, 1998) while simultaneously encountering terms and visual examples of the analytical variables. For example, if the analytical system required a student to identify “polish” on a stone tool (which may indicate that the tool has been used to scrape soft leather), then the CD allows the student to click on the “polish” field of the data table, read the definition, and zoom in on macro and micro views of polish.

The pedagogical issues influenced our design decisions, including the development of different topical sections, the choice between line drawings or digital images, the number and look of buttons or hyperlinks, and the use of fonts, animation,
sound, and movies. And, in the dynamic process which is multimedia development, authoring issues influenced and were influenced by the design decisions. For example, Macromedia Director 6.5, in which the CD was created, did not support hypertexting and we had to devise a way around the problem. Our solution was to color code words or figure references in the text to signal the user that more information could be found in the Glossary or Figures buttons. These buttons opened new windows, such as the Glossary window, through which the user could scroll until the desired information was located. This was an awkward but workable compromise to the lack of hypertext ability (hypertext is easier to create in the current version, Macromedia Director 8.0).

The choice of Macromedia Director as our authoring tool also influenced delivery of Digital Stones, especially its conversion to a web-based format. Although current versions of Director will convert to a Shockwave movie or other web format more easily, at the time, conversion would have required more time and resources than were available. Therefore, for Anthropology 491, the Digital Stones CD was required as a separate text, rather than made available on-line.

Anthropology 491 was designed as an advanced, in-depth overview of research in stone tool manufacture and use. Theory and method were integrated into a hands-on approach that emphasized completion of projects, data compilation and synthesis. Course structure included a front-end menu with links to the introduction, suggested reading lists, lesson plans, hands-on exercises, chatrooms, bulletin boards, exams, email (to the instructor and the web wizard), the glossary, and lists of upcoming conferences.

Formative Evaluation

Anthropology 491 in its first year was a success on many levels. Several problems were encountered which must be resolved before the class can be offered to off-campus students consistently. An early problem was dealing with the University bureaucracy. Like many institutions just extending into electronic offerings, the University was not equipped to deal with normal functions (such as student registration) outside of its normal range. Off-campus students were required to pay several fees (including out-of-state tuition) even though they were not using University facilities for the class. Additionally, the University only registers students at the beginning of each semester. Although an online course theoretically is set to the student’s pace, beginning with the student’s interest and ending with their completion of course requirements, the University is set up for courses to begin and end with the semester. It was extremely difficult to register students who wished to enter the class after the semester’s starting date.

The students themselves posed several problems. Some did not have the requisite computer literacy to navigate through the course requirements easily. Several weeks at the beginning were spent in remediation; a better solution would have been to require computer literacy as a prerequisite. A second problem was a universal one with students: their tendency to leave things to the last minute. For some students, “at their own pace” meant that all assignments would be completed during the last week of class. The solution we have determined will be to require certain assignments at certain times.

However, most aspects of the class were very successful. The WebCT program provided us with an environment that allowed students to access the class materials,
quizzes, chats, and email easily. Quizzes and tests could be taken without involving a proctor or assistant.

The chatroom, once the students mastered the technique, was the most successful and important elements of the class. Several stone tool analysts, known throughout the archaeological world for their research in stone tool manufacture and use, agreed to participate in the chatroom with the students. These researchers logged on to the chat from England, the United States and Australia, with a different researcher joining us each week. Their current research (published and unpublished) was posted or linked to the Anthropology 491 site for the students to read prior to the chat. Once both students and guests were comfortable using the chatroom, several excellent discussions ensued. The gracious participation of these researchers was a unique resource for our students: it took very little of the experts time, yet allowed them to share their knowledge with students who ordinarily would not have had this opportunity.

Abstract. This paper presents EM², a tool for managing educational meta-data. EM² facilitates, through a user-friendly graphical user interface, the creation of new, and the modification of existing XML-based educational meta-data files, which can be based on any specification/standard, or user-defined set of educational meta-data.

Introduction

The rapid evolution of information and telecommunication technologies facilitate mouse-click access to enormous knowledge repositories and educational resources, unconstrained from time, location, etc. The full exploitation of this mass body of knowledge - which is continuously and exponentially expanding - is being, however, limited by a number of barriers, including the difficulty in describing, classifying and maintaining these knowledge sources in such a way that they can be searched, identified and retrieved in an "educationally efficient and effective way" (Karagiannidis, et al, 2001; Wiley 2000).

In this context, a number of international efforts have been initiated during the past few years, aiming to define educational meta-data sets for the common description of educational resources. These specifications and standards include fields that are considered necessary for the description of educational resources - such as the type of the resource (i.e. whether it is an experiment, simulation, questionnaire, assessment, etc), the target learner age, difficulty level, estimated learning time, etc - as opposed to "general purpose" meta-data specifications and standards (e.g. the Dublin Core, http://purl.org/dc), or those that have been developed for different fields of knowledge (e.g. geo-spatial meta-data standards, http://badger.state.wi.us/agencies/wlb/scx/metatool/mtools.htm). The most well-known educational meta-data specifications are produced by organisations and committees such as the IEEE LTSC (Learning Technologies Standardisation Committee, http://ltsc.ieee.org), the IMS (Instructional Management Systems Project, http://www.imscopy.org), the CEN/ISSS LTW (Learning Technologies Workshop, http://www.cenorm.be/ isss/Workshop/l/Default.htm), ARIADNE (Alliance Remote Instructional Authoring and Distribution Networks for Europe, http://aria.dne.unil.ch/ Metadada), etc (Bacsich et al, 1999; Bourda & Helier, 2000).

At the same time, a number of software tools are being developed for the effective and efficient management of educational meta-data. Meta-data Editors is one such category, including tools which are mainly used for the creation of new meta-data files. Meta-data editors usually provide a graphical user interface for entering values in the meta-data fields, and save meta-data files in different formats; examples of meta-data editors include the Reggie Meta-Data Editor, the Dublin Core Meta-data Editor Template, the META Builder, the DIF-Writing Tool, etc. Meta-data Generators is another category of educational meta-data management tools, which can automatically create meta-data files for selected educational resources. The automatic generation of meta-data is usually based on the frequency of different words in an educational resource, or in the heading of the resource, etc; examples of meta-data generators include DC-dot, Klarity Software Program, etc; more information on meta-data editors and meta-data generators can be found at http://www.ifla.org/II/metadada.htm. Finally, there a number of tools which can support several different features which fall into more than one of the above categories - one example tool that falls in this category is the Intral en tool - http://www.interleaf.com (Day, 1999; Greenberg, 2000). These tools can, in principle, employ different formats for the representation of educational meta-data, however, the most common format that emerges as a standard in this field is the XML format - http://www.w3.org/XML/.
This paper presents EM², a tool for management educational meta-data files. The EM² tool can be used by educational content authors, to describe their content so that it can be easily searched and retrieved; by tutors, to describe a pool of educational resources, as well as their relationships, so that their students can easily search and retrieve them; by publishers, to describe their educational resources (including copyright and cost), so that they can be easily be searched and retrieved by their customers; by Vertical Learning Portal (VLP) administrators, for describing the educational resources including in the VLP, so that it can be effectively retrieved by VLP users; etc.

The next section presents the functionality of the EM² tool, and exemplifies its use by the above main target user categories.

The EM² Tool

The EM² tool facilitates the creation of new, and the modification of existing XML-based educational meta-data files, through a user-friendly, graphical user interface. The initial screen of the EM² tool is shown in Figure 1, and the description of the EM² functionality is provided in the following paragraphs.

Figure 1: EM² initial screen

Creation of new Meta-Data Files

For each educational resource, the user can create a new educational meta-data XML file for describing its content. For example, an author of an educational resource (e.g. a textbook) can use the EM² tool for creating an XML meta-data file which describes this book, and upload it on a public repository, so that learners can search, identify and retrieve it. The author can define which is the content of the book, the date of publication, the target learners, level of difficulty, etc.
EM² enables the user to define / select the educational meta-data set that will be used for the description of the educational resource. Currently, EM² supports IEEE LOM as the default specification, which appears to be the most widely adopted specification. In addition, EM² supports the IMS Learning Resource Meta-Data Specification (basically identical to IEEE LOM, categorising elements into “Core” and “Standard Extension Library”), and the Dublin Core Element Set (which, as mentioned earlier, is more generic, and applicable to different domains).

Subsequently, the user can enter values in the fields of the selected meta-data set. EM² presents at the left-hand side of the screen the tree representation of the selected meta-data set. For each meta-data field, EM² uses a different visual notation (colour, fonts, highlighting, etc), depending on whether the respective field belongs to the core or the extended set of the IMS specification, and whether the user has already inserted values in the respective field. Similarly, at the right-hand side of the screen the respective fields of the meta-data set are displayed (see Figure 2).

![Figure 2: EM² tree representation of educational meta-data](image)

**Modification of Existing Meta-Data Files**

Along the same lines, the user can modify an existing educational meta-data XML file, which has either been created through EM², or by any other educational meta-data management tool. After the user specifies a filename, the same representation described above is being displayed, and the user can modify the meta-data set, as well as the respective values, and then save the modified file. For example, after authors have created meta-data files for describing their content, the on-line publisher of this material can modify the description of each educational resource, adding, for example, information about cost, copyright issues, etc.
Modification of Meta-Data Set

In both of the above cases, the user can also define a new educational meta-data set. In particular, the user can add new fields in each node of the meta-data set, or remove existing fields. Subsequently, the user can save the modified educational meta-data set with a different name, so that it can be used in subsequent phases.

For example, the content administrator of a Vertical Knowledge Portal which is targeted to a specific country can add a new meta-data field, describing the specific secondary level grade of the respective National Curriculum that the resource is appropriate for. Then, the administrator can specify the range of values that are valid for this field (e.g. for the Greek National Curriculum, grade 1-6), and subsequently save the modified set of educational meta-data with a different name for future use.

Additional Features

EM² provides a set of additional features which aim to assist the user in the management of meta-data files, as well as improve the interaction with the system, including:

(i) expand/collapse meta-data set tree: the user can expand the tree representing the meta-data set and make all nodes and leaves visible, or select that only "level 1" nodes are visible

(ii) add/remove field: the user can add a new, or remove an existing field in the meta-data set; for these specific cases, EM² requires that the user confirms these actions, since they modify the meta-data set that is used for the description of the educational resource (e.g., it may result in the file not being "IEEE LOM-compliant" anymore)

(iii) view values: for the fields that are included in standard educational meta-data sets (e.g. the IEEE LOM), EM² displays the list of proposed values that are appropriate for this field, when available; for example, the IEEE LOM specification proposes that the value for the "difficulty level" field is in the range 0-4; the EM² tool displays these values so that the user can select among them

(iv) define default language: the user can define the default language that is to be used for the description of all meta-data fields

(v) options: the user can select and modify a number of attributes of the visual presentation of the tool, such as the general look-and-feel (selecting between standard windows and Java look-and-feel), the visual characteristics of the different fields of the meta-data set (e.g. how the core elements of the IMS specification should be displayed, etc)

Discussion and Conclusions

Educational meta-data can significantly improve the effectiveness and efficiency of the description, search and retrieval of educational resources available at the Internet, and educational meta-data management tools are, in turn attracting considerable attention worldwide.

This paper has presented EM², an educational meta-data management environment, which facilitates, through a user-friendly graphical user interface, the creation of new, and the modification of existing XML-based educational meta-data files. EM² also enables the user to define alternative educational meta-data sets, thus the tool can be easily customised and used with different meta-data sets which could emerge in the future.

EM² facilitates the creation of educational meta-data files, which can describe the educational resources available from educational organisations, educational content providers, etc, so that these resources can be easily described, searched and retrieved either by "general-purpose" search engines, or by dedicated educational applications.

The EM² tool will be used by a number of European R&D Projects in the field of Learning Technologies for Education and Training. It has been developed within the context of the IST No 12503 Project "KOD - Knowledge on Demand" for the description of the educational resources, so that the KOD system can determine which resources are appropriate for a specific learner. In addition, EM² will be used by the 3DE “Design, Development, and Delivery Electronic Environment for Educational MultiMedia” IST project (www.3deproject.com). The 3DE project aims to develop a methodology for the design, building and delivery of courses which can be customised to the needs of different learners; again, EM² will be used for
the description of educational resources, so that it can be determined whether each resource is suitable to be included in the course developed for a specific learner.

Our current and future work in this field involve a number of extensions to the EM² tool. Our aim is that EM² will form the basis for the development of an integrated educational meta-data management environment, which will provide added-value services for the management and administration of Vertical Learning Portals (VLPs). This environment will support a number of features which are considered necessary for educational meta-data management, apart from the creation of new and modification of existing educational meta-data files, including:

(i) validation of meta-data information
(ii) creation of new meta-data specifications for specific requirements (e.g. extending existing specifications for including additional fields which are necessary for a specific application)
(iii) support of different meta-data technologies, i.e. managing educational meta-data files which have been created by different tools
(iv) mapping of educational meta-data files between different specifications/standards
(v) manipulation of sets of educational meta-data files; for example, supporting the task of inserting a value for the “author” field to many educational meta-data files together; or to modify the description of a set of educational meta-data files, e.g. the files which include the same value for the “author” field; etc.

To this end, we have already proposed a architecture for supporting the above features (Papaioannou, et al, 2001), and we are currently working on the implementation of this architecture towards the development of a full educational meta-data management environment.

Acknowledgements

The work presented in this paper was partially financially supported by European Commission under the IST No 12503 Project “KOD - Knowledge on Demand” (http://www.kodweb.org, http://kod.iti.gr) through the Information Society Technologies Programme (IST).

More information about the EM² tool can be found at http://em2.iti.gr.

This programme offers a systematic approach both to the impact of Information and Communication Technologies (ICT) on the different social spheres and to the global transformations which occur alongside the current emergence of an information and knowledge society.
Learner Led Learning: The case of Business-to-Business Marketing

Sicco santema, delft Univ. of Technology, the Netherlands; Ralph Genang, Delft Univ. of Technology, The Netherlands

In this case study we described the process of getting to a digital classroom around the B2B-marketing classes within the Delft University of Technology.

Experiences upto 2000:
1. Interaction with the teacher via E-Mail outside the classroom
2. Integration of video in the classroom
3. Use of real media (including first life course on the internet in the Netherlands)
4. Division of the book into 100 bodies of knowledge, each supported by video, text, PowerPoint, links to other universities etc.
5. Generate questions
6. Change FAQ lists into FGA list (and use them)

All steps truly improved the learning results and the learning habits of learners.

SYSTEMATIC PLANNING FOR ONLINE TEACHING TO SUPPORT FACULTY'S NEW ROLE

Rowena Santiago, California State University San Bernardino, USA

Faculty faces many questions and issues as they embark to do online teaching. Faculty development centers are also faced with the task of supporting faculty's new role as online teachers. To address these issues, the Teaching Resource Center (TRC) of California State University San Bernardino (CSUSB) developed an overall plan that identifies the major steps involved in course development as applied to online teaching. This systematic and holistic plan serves both as the map and the glue that holds the various phases and players together. It can be a useful tool to both individual faculty and a faculty development center. This presentation will feature this systematic plan and will also summarize, in the form of a checklist, the instructional and non-instructional issues that need to be addressed to do online teaching. Finally, it will present results of a survey that evaluated faculty and student experiences with online courses.
Abstract: Computer-supported cooperative learning (CSCL) environments arise as one of the most powerful Internet-based applications. Moreover, CSCL holds many-sided features, and its classroom use faces problems. To solve reported problems, we built a model of cooperation, expressed as process patterns and we have developed a pedagogical and computational infrastructure to support project-based cooperative learning. In this paper, the assessment in CSCL environment is discussed, in order to establish the appropriate background to describe the procedures presented in the infrastructure.

Introduction

In the last few years, the Internet has become the most up-to-date way of structuring innovative educational settings. In this scenario, Computer-Supported Cooperative Learning (CSCL) has experienced rapid growth. The analysis of CSCL area shows that there are few references to individual and group assessment in this kind of environment. Moreover, to assess students' performance is an important component of the learning process. The primary purpose of assessment is to improve the student's learning (Taylor and Maor, 2000). Practices, in agreement with learning goals, curriculum, instruction, and the students' knowledge level, should be employed to provide information about goal achievement and students' progress. Good educators assess the student progress through such methods as structured and informal observation and interviews, projects, tasks, tests and experiments. In face-to-face approaches, assessing students is not an easy task. In computer-based environments, it is even more complex. Traditional apparatus, such as mastering learning and criterion-referenced measurement, do not seem to be good approaches for assessing students in CSCL environments. The mastery of learning is a systematic approach to instruction based on students' performance on a pre-specified criterion level in a given unit of instruction before moving to the next unit. Cooperative learning settings usually do not deal with a rigid unit of instruction. Criterion-referenced measurements are techniques for determining the mastery of learning a pre-specified content. Not always are the intended goals in virtual environments closely related with the achievement of individual mastery of specified contents.

Dochy (1992, in www.1) proposed an assessment model initially conceptualized for distance education, but it can also be suitable for assessment in CSCL environments. The model aims at integrating formal and informal assessment, and learning. It comes in five steps: (1) learners start by stating their learning goals; (2) learners prior knowledge state is estimated; (3) after having taken a pre-test, learning goals can be redefined; (4) learners can begin with the appropriate learning tasks; and (5) during the learning process, learners frequently take tests to check learning progress in order to see if additional guidance is needed, and to determine subsequent learning tasks.
The model suggests that cooperative learning tasks carried out on CSCL environments can be enhanced via formative assessment. This assessment is conducted during learning activities to appraise the students' learning progress, to identify goals, which have not been met, and to ascertain whether students have enough prior knowledge to cope with subsequent stages of a particular learning subject.

On the other hand, many educators have embraced Internet communication tools like listservs, e-mail, newsgroups, and real-time chat programs for their apparent potential to enhance, record and assess traditional classroom activities. Specifically, the use of these tools is believed to enrich the three major activities of all teachers: to counsel students individually, to deliver information, and to encourage classroom discussion. (Bennett, 2000). Online assessment became a promised and a controversial point. Although the most common uses of online technologies are for communication and assignment submission via email, there is an increasing adoption of structured online assessment processes (O'Reilly, 2000). These include group discussions to support individual assignment preparation, collaboration in a common project or presentation, peer-review and self-review, and problem-based approaches to cases and scenarios, to name just a few.

We designed a pedagogical and computational infrastructure in the domain of cooperative project-based learning, starting from the hypothesis that CSCL environment designers do not know how to handle the educational domain and teachers do not know how to handle computational technologies. Moreover, they need a flexible environment, allowing them to figure out different cooperative projects according to their pedagogical viewpoint, concerning individual student and group specific characteristics. The infrastructure offers a cooperative work environment and a tool framework. Within the cooperative environment, teachers can define cooperative educational processes, and students can carry out group activities supported by tailored tools. From this background, the article aims at describing how students' assessment is understood and supported in our infrastructure. With this purpose, the next section discusses the assessment process in CSCL environments. Section 3 describes our infrastructure and outlines its assessment procedures and instruments. The last section presents the conclusions and future works.

Assessment in an Infrastructure for Cooperative Project-based Learning Environments

The infrastructure was designed to allow teachers to determine the main aspects involved in cooperative teaching and learning activities. Therefore, we first determine a domain for carrying on cooperative tasks - the domain of cooperative project-based learning. Next, we modeled cooperation. The model embraces problems and their solutions in the form of a system of process and design patterns. According to our model, the main issues involved in cooperation are mediated by Culture, Stimulus and learning Context, which in turn depend on the available Technology. Culture, Stimulus and Context strongly stress the educational Objectives and the collaborative Process. Learning Theories, Previous Knowledge, Cultural Aspects and Collaboration Forms influence the educational Objective. A Collaborative Process is related to Activities, Roles, Coordination, Group Memory, Awareness and Learning Assessment. For details, see Santoro, Borges e Santos (2000a, 2000b). The model works as a repository of software components and theoretical and practice guidelines. The system of patterns provided useful requirements to the development of the infrastructure components (Fig. 1). It embodies a cooperative environment, a project database, a reference library, support for students' assessment and a framework of tools. The cooperative environment is the student and teacher's workplace, and is the starting point for planning and executing project activities. The environment is based on a client-server architecture, which accesses two centralized databases. The server side is represented by the Project Server, which activates secondary servers, and maintains the project database, composed of documents related to the projects, and the reference library, composed of consulting documents. The secondary servers are responsible for the services available within the infrastructure.

The Process Server is responsible for the execution of the process, working as a kind of workflow machine. An editing tool is necessary to design the cooperation processes. The tool adopts symbols and conventions that might represent all process important components: activities, roles, agents, flow, rules, descriptions, and how these components are linked. The process server interprets the symbols, discharges the execution of the process in the beginning of the project, and maintains status and important information about the activities. The adopted conventions agree with the infrastructure requirements: they create conditions for the teacher to define cooperative educational situations. The Document Servers establish connections with the tools that make use of a document and treat the multiple events generated within the environment, according to a client request.
The Agent Server manages people and teams registration and maintains information on the active user sessions. The Agent Server manages people and teams registration and maintains information on the active user sessions. The Tool Server maintains the registration of the tools and of the active servers within the environment. The Assessment Server disposes services of gathering information about the work process, and features for building assessment instruments of learning. The Searcher Server accomplishes the connection with the Library of References, offering services to search documents requested by the users.

![Fig 1 - Infrastructure for Computer-Supported Cooperative Project-Based Learning Environments](image)

The client side is represented by the applications "User Session Managers", whose functions are: (1) to connect the user to the main server and the secondary servers; (2) to provide the status of the project; (3) to manage personal information; and (4) to activate tools, according to the process that is being executed. There are also available groupware tools to support the accomplishment of activities defined in the process. The tools establish connections with document servers related to the activities through which they were invoked. The Database of Projects stores the information about the process of the projects. The Library of References is a multimedia database that stores documents of any type (images, HTML pages, finished projects), which can be consulted by groups during the project. Several types of projects can be developed in the context of the cooperative environment, indicating the need of different tools to support their activities. Thus, the infrastructure must be flexible enough to allow the increment of new services (servers) and new groupware tools (client applications) to be added to the infrastructure context. The Tools Framework allows the development of both the server and the client applications.

Designing the Assessment Server considered the main assessment problems found in CSCL environment context and reported solutions. Problems and solutions were comprised in three process patterns: Process of Educational Assessment, Individual Assessment and Group Assessment. The first pattern, Process of Educational Assessment, defines a learning assessing process and its stages. Generally, the starting point to define an assessment process is the choice of a learning approach and its underlying theory. Based on it, teachers describe the learning goals and design their pedagogical strategies, which will result in specific tasks. After that, they can plan the assessment procedures, comprising goals, strategies and tasks. If the teacher understands that the better strategy to achieve learning goals is the cooperative learning approach, he/she must define specific procedures to assess both individuals and group performance and attitudes.

The two other patterns, Individual Assessment and Group Assessment, point to the need for some kind of assessing procedures. The infrastructure provides facilities to support both the qualitative and the quantitative assessment approach along all stages of the cooperative project development. Even when the learning goal is to improve social behaviors, some procedures and instruments to assess individual progress must be designed. According to Constructivist theory, each student builds his personal knowledge, bringing his own perspectives to the learning...
activity. Standardized tests do not allow teachers to assess student perspective. Individualized tests or tasks can better reflect the personal development. In a Socio-Cultural-based environment, both knowledge acquisition and social attitude improvement are relevant outcomes. Some kind of qualitative instrument must assess the group’s progress. Structured observations and interviews can give appropriate data to ensure the group’s progress. It is important to keep records of each student’s participation in cooperative tasks and his contribution to find the solutions. The analysis of data files of group interactions working with the Internet communication tools can offer relevant information to teachers. In addition, CSCL environments could provide an electronic space where teachers store their comments and notes about the individual and group behavior and progress. Self and peer assessment can be proposed when students are mature enough to carry on their own assessing. Teachers must also assess the group as a single entity, observing both academic outcomes and social behavior. Several kinds of instruments can give support to the assessment process, such as group reports, group testing, formal or informal observations, and interviews. Groups can assess their own work, in their peer assessment approach. These issues are reported in patterns format, as shown below.

**PATTERN NAME: PROCESS OF EDUCATIONAL ASSESSMENT**

**Problem:** How to define an assessment process in CSCL context and relate it to an underlying learning theory?

**Context:** Assessment is a process to verify the extent of CSCL experiences and make sure they are actually producing the desirable effects. Educational goals (the concepts and abilities taught and the designed activities) are part of the context.

**Forces:** The assessment process starts with the definition of program goals. In other words, its main aim is to determine to what degree the desirable goals are actually being accomplished. It is directly related to proposed educational activities, and consequently to the learning theory they are based on. In the view of a social-cultural and constructivist theory, it is not possible to evaluate the knowledge construction disassociated from the process, which enable it. Therefore, assessment should be continuous and allow the teacher to identify and create zones of proximal development. In the constructivist educational space, processes are even more relevant than products. Qualitative assessment should go beyond the quantitative assessment, without disregarding it though.

**Solution:** The assessment process of learning in a cooperative environment can be defined in four steps:

- Educational goals can be used as a first step to the definition of items to be evaluated, including the learning of the cooperation process itself. To map the relationship between the educational goals and the validation variables we can use some method for knowledge representation.

- The next step is to identify situations, which allow the students to manifest their expected behavior as derived from the educational goals. These situations should occur during the entire working process developed within the environmental context. The environment should provide means for tutor intervention anytime he decides that this is necessary for the assessment purposes. These interventions should be inserted in the activity development and should be used according to the need of each group member.

- The instruments for assessment should be examined. It can either use those already available or develop them. These instruments should be capable of collecting, storing and analyzing the data about the progress of each member and of the group as a whole.

- The definition of quantitative and qualitative measures, which represent the result of the assessment. For qualitative measures, we can use a set of concepts aimed to represent the student progress, such as: cognition, social relationships, participation, argumentation capability, criticism and creativeness.

**Related patterns:** Individual Assessment and Group Assessment.

**Known uses:** Studies in the educational area (Tyler, 1974), identified classical methods for the assessment process, establishing a direct relation to educational goals. Some computer-supported learning environments adopt these methods, either in part or as a whole. They developed specific solutions to help the representation of goals and supporting tools in some of the stages of these methods (Leite & Omar, 1999; Tarouco & Hack, 1999).

Fig. 2 - Example of a Conceptual Pattern

Assessment solutions were expressed as **conceptual guidelines**, **services** and **templates**. **Conceptual guidelines** provide theoretical principles, practical guiding and help about how solutions can be implemented. **Services** are available in a special Assessment Server, allowing services of gathering data concerned with the cooperation process. It also associates teacher's comments to documents produced by a group, and to certain events related to the activities, modeling and presenting assessment results through specific reports.
Teachers use the Process Server (see Fig.1) that works as a workflow machine, to design and propose a process for the cooperative project development. During an activity operation, students use some kind of tool, which has also been previously defined to assist them. Using educational groupware tools, students exchange messages, contribute to other members work through comments and annotations; and teachers can grade students' participation and contributions. The tool sends all the information about the interaction process to the Assessment Server, which stores and creates a kind of activity log. There are specific reports to format and present this information to the learning evaluators.

![Diagram](image)

Fig. 3 - Representation of the Information Gathering in the Infrastructure

New services can be attached to the Assessment Server aiming at giving teachers personal support. Besides the server, the infrastructure also presents templates for the main assessment apparatus described in the patterns. Templates are empty structures previously defined, where details can be changed and adapted to specific situations. The apparatus both for quantitative and qualitative analysis is summarized below.

**QUANTITATIVE INSTRUMENTS**

The goals of the Individual Assessment are to verify each student’s progress, according to his/her own profile. In this case, the template generates tests that may include questions and exercises prepared by the teachers. Any test can be associated to a specific student and project activity. Teachers can program tests that can be presented to students at any moment of the process.

- **QUESTIONNAIRES AND INTERVIEWS** - there is a template that teachers can use to build questionnaires and interviews. It can be useful to evaluate how people feel about the work process and then compare it with the generated products. They are also useful to evaluate the background knowledge and group interests.

- **SELF-ASSESSING** - this template produces a questionnaire of self-assessing organized by topics. Teachers or students can be responsible for the creation of the structure of topics to be appraised.

- **GROUP EXAMS** - according to the assessment issue defined in the patterns, it is important to dispose some kind of group exams, since the work context is the cooperative approach. Teacher can compose a three step cooperative test: (i) students receive the test carry on a discussion about the questions, using a special tool to support the discussion; (ii) students answer the questions in group and send the results to the teacher; (iii) each student evaluates the group’s result as a whole (members participation, contributions and identification of difficulties about some topic). Two templates are available: one to generate a group test that can be accessed by each group member, and the other to generate the assessment of the group results that is individually accessed by all members of the group.

**QUALITATIVE INSTRUMENTS**

- **OBSERVATIONS ABOUT THE INTERACTIONS DURING THE WORK PROCESS** - this is a template that helps to format and present information gathered during the work process as described in Fig. 1. Teachers can determine how to organize the messages and contributions of the students per activity/ per process stage / per some kind of pre-defined structure (type of message, contribution content). Thus, they can better analyze the collected data.

- **ANNOTATIONS OR STRUCTURED COMMENTS** - this template also helps to format and present information gathered during the work process as described in Figure 1. It is possible for the teacher to insert structured comments or
annotations on the students' work or even add grades for specific events in a project. This is done within the context of the tool usage, which is associated to the project activities. The template gathers and organizes these specific comments/grades and generates a report with this information. The possibility of group members to evaluate the accomplished tasks and their members, according to their participation and cooperation in the project, is an important aspect in cooperative settings. Teachers and teamwork can use the questionnaires and interviews to address this requirement.

Conclusions

The process of assessment usually requires a higher level of analysis than merely performance measuring task. Teachers should collect information about student performance, as the data allow them to determine the students' levels of achievement, evaluate the effectiveness of instruction, and identify topics that require additional support (Miller, 1999). The assessment of students' progress is an important aspect of the teacher's role, since its process is many-sided. All faces of the process show that the assessment cannot be done in an automatic or electronic way. Apart of the learning environment, students' assessment is a teacher's job. In our infrastructure, the assessment of individuals and groups belongs to the teacher, but it also offers additional kinds of support to continuous assessment of each student and of the whole group.

Up to now, we have just finished the implementation of environment prototype. To verify the infrastructure behavior, the next step is to start a real collaborative environment, tailored to the undergraduate Science Computer students' needs. Experimental findings will provide useful guides to refine some components of the infrastructure, including the Assessment Server.

Abstract: In this paper we bring up some thoughts over a virtual environment generated in the Virtual World (Cibercidade-Sitecria/LEC-UFRGS/OEA) - Community coupling based on the epistemology of enchantment, where each participant (teacher, student and researcher) is an observer, an investigator, a learner in charge of constituting this space. Our analyses are based on the experience of two groups of students and teachers at the elementary level from public schools in Porto Alegre/RS and Novo Hamburgo/RS. The initial data collected indicate the constitution of a space of distinction by a living together. We “photographed” two moments where we analysed different manners of acting/"dwelling" (in) this space so as to create these distinctions. This process of self-organization makes us think of the emergence of a hybrid phenomenon, of the creation of an artifice a blend of human nature, culture and technique.

In fairy tales, the characters may be animals, plants and other inanimate beings, they have voice, will, attitude, desire... Enchanting has to do with this, to give voice and action to the object. It is the eyes of the observer that considers the object a live entity, a dynamic one, that transforms and is transformed by and in the interaction.

For the utter dreamer, nature is only the dream that may more attentively be studied - the dream that lasts enough so we find rules, laws, that perhaps each other person dreams is ours, or the world of our inner dreams has people dream ours, or the world of our inner dreams has, had we time and abilities for this science of /shadow/. Nature is not real anymore; it is more vivid than dreams. Nature is the dream that all souls dream together. (Pessoa, 1999)

But how would be the building of this dream, this enchantment in a virtual world of Internet? We invite the reader to travel with us in this adventure of thoughts and questioning from the establishment of a community...

Once upon a time...

The Virtual World: A Scenery To Be Enchanted

The virtual worlds, as informational devices, have a reticular and fluid space, in which the user is considered an explorer who will inhabit that environment. It could be the explorer him/herself, as an navigator or
his/her representative, an avatar who obeys his/her commands. It is "a digital reserve of sensorial and informational virtualities which are updated only in the interaction with human beings" (Levy, 1999).

Depending on the devices employed, this updating may be more or less interactive, unpredictable, leaving a variable share to the initiatives of those who immerse in it. The virtual worlds can be enriched if inhabited collectively. It becomes, in this case, a meeting point and a communication means between its participants. The virtual world of which we speak here is the Cibercidade-Sitecria (or, in English, Cybercity-Sitecria) - http://oea.psico.ufrgs.br/sitecria.

Initially, this space was created to facilitate the interaction for the active learning of students. Its creation is based on the fractalized idea, in which the teacher being trained via telematics, who is developing shared projects, taking part on the construction of the virtual community with his/her peers, also watches the students in the same process of cooperative learning. Consequently, the teacher can observe, apply, experience, reflect the various forms of interaction and building of knowledge in the development of cooperative projects in Distance Learning - DL - with other students and teachers, thus improving his/her development and contributing to the building of students' knowledge.

Its layout has been developed on a metaphor: the city. Initially, it is necessary that the user register, accepting to be a dweller of Cibercidade-Sitecria and soon the user is invited to help us unveil a "Great Mistery". This is the way we found to create in the user the need to interact in this space, an initial challenge.

This virtual world contains some "social institutions": the city hall, a post office, the assembly hall, a news/communications site, an art studio, a sports area and a bookstore. These sub-environments are mainly based on the users' interaction, i.e., they are updated, rebuilt, reconfigured at each interaction. Each inhabitant receives a personal mailbox, a notebook for personal notes and a space for publishing anything. Initially this set of resources was named house-kit, as it was our plan to offer the possibility that each participant build his/her own "house" homepage.

In that manner, the "starters"\(^1\) tried to offer the most interactive possibilities, in a fun and enjoyable way, based on three pillars:
- a design that gives students the possibility of feeling invited to take part on the building of a virtual community, exchanging experiences and giving priority to interactions which favor relationship cooperation and autonomy in them;
- systematic synchronous communications sites such as IRC and ICQ and asynchronous such as e-mail, forms and discussion lists.
- sites/moments in which students may participate on challenges made up by other students, teachers and researchers as well as building them themselves;

It might be said that Cybercity-Sitecria is a kind of 'skin', a scenery that will have its dynamics managed by the community itself. What dynamics can emerge from the interactions of the participants with this virtual world?

\(^1\) We used, 'starters' or 'world engineers' from Levy (1999) referring to the developers of Cyibercity-Sitecria in the sense of not being the authors of a finished work, but of a world that is in essence, unfinished.
and between them? What is missing for this world to be enchanted and become an environment upon which a community can be built? The participants\(^2\) and their interactions, of course!

**Bewitching**

The epistemology of enchantment (Chrislieb, 1994) seems to be a trail to travel over in this study:

> "Once the object is considered to be able to have its own qualities, and it is allowed that it behaves according to its will, then it is possible to interact with it (...) What the subject did was to bewitch the object: the subject put a spell on people, animals and things around so that they are converted into live entities. " (Chrislieb in: Montiero, 1994, pg. 25)

In that manner, the objectivity necessarily is secondary. It means that in the experience, we cannot distinguish between illusion and perception. The experience is a condition characteristic of the observer and this is the reason why a group of observers cannot make such distinction either (Maturana, 1999). A single reality is not considered, but the possibility of several distinctive realities and distinguished by the view/action of the observer. If we consider each participant an observer, a curious investigator of the "world's mysteries", a scientific researcher, we could say that each of them is also responsible for the enchantment. All - teachers, students, researchers - are learners.

Thus, the object is alive, dynamic and collective, it stops being MINE (the researchers') and becomes OURS (the collective of participants of the community). It is a digital virtual community being constituted. A community is alive and there is no way to study it without somehow modifying it.

Even in the making of science, all that happens is produced by the observer in his/her praxis of living as primary condition, and any explanation results secondary. Every explanation - including the scientific one - is a generative mechanism that originates the experience by explaining with the use of other experiences different from that which is being explained (Maturana, 1999).

> "(...) A thorough analysis shows that science does not know 'bare facts', as the facts that we acknowledge are already seen from a certain point of view, being, as a consequence, essentially ideative. If that is so, science history will be so complex, chaotic, permeated by mistakes and diverse as much as the ideas within it (...) Each person will read the words in his/her own way and according to the tradition to which this person is affiliated" (Feyerabend, 1989, pg.34)

Making science, as living, is a continuous process of transformation of the researched object and of the researcher him/herself. It is a constant process of deconstructing oneself, as if going back to childhood, in which it is necessary to confess our ignorance, to start studying science from its very beginning, its genesis. It is also a process of enchantment, as a life experience and passionate one.

> "[a scientist] began as a child, as childhood comes before adulthood in every man, including the primitive. As for knowing what the scientist takes from his/her first years, it is not a collection of innate ideas, once there are trials and errors in both cases, but a constructive power, and among us someone came up and said that a physicist of genius is a man who knew how to preserve the creativity proper of his childhood instead of losing it at school " (Piaget & Garcia, 1982, pg. 64)

It is in this trial of deconstructing a perspective to build another that we see the need of this enchantment which allows a dialogue at the same moment when the object makes itself come to existence. And it appears that there is no other way for us. We can only build it as the creative process is occurring, because it is in the means where we are moving:

> "Facing the individual's reality and facing the reality of systemic institutions, it appears then a reality that is not within the individuals and institutions... not even in groups, but it is embodied in a third nature, not quantifiable and impeccably real, made of communication... This is the third reality, the one of the means, of the intersubjectivity" (Chrislieb in: Montiero, 1994, pg.51)

**The Enchantment: Beginning of a Self-Organization**

\(^2\) Participants in the sense given by Levy (1999) for the 'explorers' of the virtual world, that will not just build the viable, multiple, unexpected sense, but also the order of operation and the form of appropriation.
According to our conception of virtual environment, it is only with the very interactions of participants with
the virtual world and between each other that it is possible that a dynamics of functioning emerges.

This virtual (digital) environment builds itself in the interaction between subjects-subjects and subjects-
objects, it changes as interactions occur, as the participants engage on cognitive activity. It is updated at every
action/operation and its virtuality is changed at every questioning. In the same manner, the subjects are transformed
in/by the interaction. There are no strict limits between what is means, object and subject. A virtual environment
under the constructivist perspective, it is constituted mainly by the relations that occur in it. It is in living together,
through the interactions, questionings, actions/operations that this world is being built/inhabited. It is a space of
distinction by a living together of a community.

This collective object, enchanted, will only remain enchanted while we, observers, consider it to be in
movement, what Maturana names drift. It means that every moment is a different moment, that will be determined
by the history of interactions that occur, but, at the same time, always being updated in its structures. At each
moment, one happening, one experience.

The virtual community constitutes itself in the gathering around centers of common interests, about the
cooperative learning, about open processes of collaboration. (Shaw, 1995; Levy, 1999). The construction of social
ties occurs much more over affinities of interests, knowledge, mutual projects, in a cooperation or exchange process
than over relations or geographical proximity, institutional affiliations or power relations (which does not mean that
they do not exist).

In this sense, the process of constituting virtual communities can give us elements to reflect about how our
social relations in and out of the cyberspace have been changed and change intellectual technologies.

"virtual communities perform de facto a true updating (in the sense of creation of an
effective contact) of human groups that were only potentials before the appearance of the
cyberspace. The expression current community would be, essentially, much more adequate to
describe the phenomena of collective communication in the cyberspace than virtual
community" (Levy, 1999, pg 130)

From this perspective, the community becomes active in its own development process, and it is possible to
say that it develops its own dynamics of functioning, it organizes itself. This Collective Intelligence is updated more
as a problems section than as a solution, more as a "way of accomplishment of mankind that the universal digital
network fortunately favors, without us knowing a priori to which direction and to which results the organizations
that put their intellectual resources in synergy tend to". (Levy, 1999)

This participants-virtual world imbrication makes us ask, which are the borders between subjects and
objects, human and techniques? Would it be, then, the appearance of a hybrid phenomenon, the creation of an
artifice, mix of human nature (?), culture and technique, as tells us Pedro (1998).

Let us see some "photographs", of moments that can make us think over the possibilities of "dwelling"3 the
Cybercidade-Sitecria, of constituting the community and, who knows, think of the construction of an artifice?

A Moment: A Way To Occupy Space

Our explorers are part of a group of students of a public municipal school of Porto Alegre/RS, with ages
ranging between 10 and 14 years old.

As soon as they accessed Cybercidade-Sitecria, these participants tried to occupy the space in a way that
had not been thought of (at least in the beginning of the process) by the starters of this virtual world.

We could say that most of the children were more worried in “occupying” the space verifying that sub-
environments were not being offered and they considered important in a city: “Hey... there are no trees in this
town!”; “That’s true... it’s missing a soccer field for us to play”; “There’s no cemetery either. Where are people

Henceforth, each one started planning how to implement his/her own sub-environment.

It was at this point that they realized that cemeteries, garages, video rental places in the cyberspace cannot
be the same as in the real world.

---

3 We understand dwelling here in the sense of "feeling at home", to be at ease, to appropriate space, in opposition to
the notion of settling down, to take root somewhere.
Another question then arose: building spaces that could be interesting and useful for the other classmates. They started looking for solutions to these questions: "I can put one of those to fill up [forms], asking what the problem of his car is. Then, I analyze its problem, and I answer how to fix it... and then I send it back!"; "We could make a park with many trees and with information on each one. Then people will know how to plant, what kind of climate it likes, if it likes water, things like that..." and so on.

This way of interacting with Cibercidade-Sitecria established a dynamics that disturbed and "forced" the environment to change, as the proposed initial challenges in each sub-environment, at least at this moment, were not the focus of main interest of these explorers.

Proposing new public, collective areas was not in the initial proposal. But it became the guidance of this virtual world, together with the interaction between inhabitants. The individual - virtual world coupling occurred in this manner at this moment with these participants. Would we be able to say that this newly constituted system points to a clue of a self-organization process?

And how was this disturbance taken? Each inhabitant now had the possibility of proposing his/her way of living in the virtual world - his/her project on Cibercidade-Sitecria - and to contribute that from this environment emerged a community. The initial conception of "house-kit" was considered individualistic and the option was the living collectively.

In order to make the environment adapt itself to the proposal of the participants, some changes and transformations were made. Four other sites were created: the Moon Corner, the Space Corner, the Mountain Corner and the Ocean Corner. These sites are available so the explorers can choose where they want to develop their projects.

So, as interactions occur, social relations that change and are changed by the virtual world appear. It is in this hybridization that we see the possibility of indicating an area for living together.

Another Moment: How To Interact

We see this space as a domain of differentiations created from the experiences that occur so that the community constitutes itself and changes its own space.

In that manner, in another moment, another group of participants chose to use the interaction sites of the Cibercidade-Sitecria. In this group, there were students and teachers of a municipal public school of Novo Hamburgo/RS, aged between 8 and 11.

These participants are still, most of them, oriented by their domains of daily habits. It means that the messages exchanged are related to their daily life and is directed to other inhabitants who they already know physically (party invitations, poetries and jokes about physical characteristics of each other, etc.)

"Hi, you, Taliba, skinny guy. If you don't eat you disappear, alright?"
"Baby please send this message to Taliba. Hey taliba you are too ugly, what about a plastic surgery?"
"Little girl, you are really cool"
A POEM!
I DON'T GIVE YOU A ROSE BECAUSE
IT'S FULL OF THORNS BUT I GIVE YOU
MY HEART WHICH IS FILLED WITH LOVE"

The community is delimiting their space through this construction and the interactions between its participants. In this "photograph" of the dynamics, differentiations have not yet been made. When we talk about differentiations, we refer to the distinctions that will be built with relation to the cyberspace in general and related to the other domains of existence that each participant is part of.
In this case, the domain of daily life existence still is the predominant regarding the life in the Cybercity. The individual dimension still prevails, there is no notion of insertion in a collective of participants: a great number of messages have explicitly a private notion and have an idea that nobody else has access besides the receiver him/herself. It is clear this dynamics for the site of preferential interaction: the Post Office, as there is still the possibility of sending personal messages.

The Enchanted World

The world will be enchanted whenever it is possible to update it. Whenever it is updated, new differentiations will be made and the community constitutes its space of living together. We could even say that a new domain is created for its participants, a digital domain. The "digital life" does not eliminate the other domains of existence. Very much on the contrary, it can enlarge and change its ways of occupying the non-digital world... and vice-versa. How to analyse, for instance, the different moments in the cognitive development or the different ages of the participants? Are they aspects of the domain of existence that interfere in the way that each one bewitches the virtual world in which they interact?

This process of self-organization by which the community builds itself is autopoïèsis in the sense that it is because of its own inner dynamics that the domain will be built; it is a system that produces itself.

In this sense, one of the ideas that permeates “behind” all our thoughts is that any knowledge is built from the interaction of the subjects with the objects (whatever it is, “things” or people), and both will be built from that point. It is a process that happens in this intergame of the subjective as the objective reality. And, we could even say, an artifice is created, because it is a result and resulting of a process of hybridization of subjects/objects, of the human/technical.

With this epistemologic concept, its construction has to be dynamic and in process. The end here cannot be “... and they lived happily ever after”. Like nature dreamt by Fernando Pessoa, though, every moment is time for virtual, digital, all kinds of enchantments. What is important is to experience and share this experience... it is to create environments for living together.

Literature References

This work is a proposal of an Integrated Hypermedia Environment for the development and management of distance education courses. The environment is composed by modules which are fully integrated. All modules are managed by a unique interface manager. These modules use different technologies, like palmtop programming (for Palm Pilot handhelds), multimedia data synchronization and databases. The main objective of this environment is to make instructors able to create and manage online courses, using the most advanced technologies available. The system is based on templates, which make it very easy to use by non-experts. The environment is composed of three modules. The WebCourse module is a hierarchical web-based tool for the creation and management of courses carried via the Web. It is composed by three submodules, which are interconnected: WebCourse Instructor, WebCourse Teacher Assistant and WebCourse Student. Each one of these modules has specific tools and are integrated on the system.
Teacher Guidance to Digital Lectures

Freimut Bodendorf & Manfred Schertler
Department of Information Systems
University of Erlangen-Nuremberg
Germany
bodendorf@wiso.uni-erlangen.de, schertler@wiso.uni-erlangen.de

Abstract: An innovative approach is introduced that guides teachers to modern ways of teaching with new media technology. The basic idea is to integrate teachers into the production process of a particular kind of teachware, which provides digital lectures in a virtual learning environment. So far, most of the teachers are rather passive presenters of knowledge. They are filmed giving lectures in front of real students. The outlined approach forces teachers to play a more active role while learning to teach by using an electronic environment. One major aim is to teach teachers how to use new technologies during their lectures and to promote didactical effectiveness of teaching with new media.

Lecture on Demand

The basic idea of lecture on demand (LoD) is to provide the students with lecture content at any time and any place. This is done by recording video and audio streams of lectures, editing the recordings, and linking additional teaching resources (slides, annotations, diagrams, animations, questions, exercises, tests, ...) to the lecture video. These teaching resources together with recorded lectures build up the LoDs offered to the students via a LoD server. The first step of the LoD authoring process is to record and digitize the lecture given by the teacher. The digital video material is combined with additional teaching resources such as presentation slides, graphics, diagrams or animations to display complex or dynamic content. Hyperlinks to Websites give direct access to external information and are suitable for illustrative examples. FAQ sites and annotations offer help in difficult situations. Quizzes and tests are integrated to enrich the LoD with interactive elements. The LoD authoring tool allows to create quizzes including different types of questions, such as multiple choice, true-or-false or technical term questions. The students access the LoD packages via a web browser. The screen is divided into two frames. The left frame shows the video stream and the main control panel including a list-box of time-links to additional resources. When the video stream reaches a timing specified in the list-box the corresponding resource is displayed in the right frame. On the other hand if a resource is selected from the list, the video stream is positioned to the corresponding minute and second.

Teaching in Lecture-on-Demand-Scenarios

There are different ways a teacher can participate in the production process of a LoD package depending on how positive he/she is about using educational technology. Common and least straining for the teacher is the passive role of simply teaching in front of a class and being recorded by the LoD producers. This type of LoD teaching is more likely to motivate sceptical teachers, whose attitude towards using new media technology during their lessons is rather reluctant. Nevertheless, even having a passive role in the production process of a certain piece of LoD teachware there are at least two positive effects. First, the teaching material (e.g. blackboard drawings, overhead transparencies) has to be transformed into digital form. Either the teacher transforms his material by himself or at least uses content that is easy to digitize. Second, within a LoD teaching scenario the teacher has to be aware of teaching in front of a camera. Another position is given by the enthusiastic kind of teacher who is eager to bring all sorts of technical enrichment into his or her classes. These teachers are used to experiment with information technology as soon as new developments take place. The support they need is not in a technological or didactical scope. They usually just need more manpower to realize all their ideas. But even without direct support the results of their endeavors are raising in quality every time they create a new LoD package simply by habit formation. The most interesting group is the 'in between' teacher. This teacher is interested in new ways of teaching, but he or she is rather conservative in extending the own style of teaching by using electronic media.
Training Program "Teaching With Media"

During the past five years more than 60 LoD packages have been produced. A development team consisting of up to four members cared about the whole production process. Teachers kept their hands off the technical realization of the electronic teachware. Apparently one major cause of substantial didactical and pedagogical deficiencies is the insufficient integration of teachers in the design, preparation, and implementation of electronic lectures. As a result a training program is being developed to make teachers ready to meet the challenges of high-tech education environments. Each teacher’s attitude towards media-teaching needs particular assistance. To achieve this a single teacher is assigned to a selected level within the program (reluctant teacher to level ‘novice’, ‘in between’ teacher to level ‘advanced’, enthusiastic teacher to level ‘expert’). One cycle of the program consists of four steps. In each of these steps certain tasks can be handed over to the teacher.

Table 1: Steps and Levels of the Media-Teaching Training Program

<table>
<thead>
<tr>
<th>Media Preparation</th>
<th>Level ‘Novice’</th>
<th>Level ‘Advanced’</th>
<th>Level ‘Expert’</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use content that is easy to digitize</td>
<td>N/A</td>
<td>Transform own analogous content into digital form</td>
<td>Create digital content using enhanced digital options</td>
</tr>
<tr>
<td>Course Draft Creation</td>
<td>N/A</td>
<td>Divide content into well-defined topics</td>
<td>Adjust course draft to teachware storyboard</td>
</tr>
<tr>
<td>Teaching</td>

<td>N/A</td>
<td>Adjust teaching style to LoD production</td>
</tr>
<tr>
<td>LoD-Authoring</td>
<td>N/A</td>
<td>N/A</td>
<td>Perform complete authoring process</td>
</tr>
</tbody>
</table>

In order to illustrate these steps and levels the following example describes a fictitious teacher, whose lectures are transformed into LoD-packages, using the teaching-with-media training program. This teacher doesn’t use any digital content so far. He makes his presentations with chalk and blackboard most of the time. His curriculum is rather flexible, he tends to go into detail spontaneously. The training program might look like as follows: Instead of using chalk and blackboard a liveboard is made available to the teacher. The liveboard is connected to a computer so that every annotation is digitally recorded. The teacher doesn’t change his course draft and his teaching style (1st level cycle). The teacher designs an own set of digital content using standard presentation tools (e.g. MS PowerPoint™). On the one hand this accelerates the media preparation sub-process within the LoD authoring process. On the other hand while creating his course draft the teacher is motivated to define clear sections which can be used to structure the LoD package later in the authoring process (2nd level cycle). Getting used to digital content creation the teacher extends his efforts to multiple visualization forms, like animations, audio sequences, video sequences (plus slow/fast motion), simulations, etc. As he learns how to author a LoD package he modifies his course draft accordingly. Likewise he adapts to teach in front of the camera and to address his 'virtual' learning community. Finally he performs the LoD authoring process completely by himself. At the time when he decides to use a desktop camera to record himself he is not even depending on the camera team any more (3rd level cycle). After each particular training cycle the teacher has to decide whether he is ready to perform the tasks belonging to the next level of the training program or not. In the latter case he might want to repeat the tasks of the current program level in a new cycle before going on with the next level.

Conclusion

The challenge of teaching within media rich environments is often reduced to technical problems. Pedagogical and didactical aspects evoke interest only as far as the learners are concerned. As a result many teachers are not prepared for a paradigm shift claimed by theoretical and technical visions of future education. One way to meet these requirements are training programs like the one described in this paper. By performing a whole program of training cycles definite improvements in quality can be reached, for example: mature, clear and well-structured visualizations of teaching material (media preparation), clusters referring to particular topics in content and structure (creating course draft), straightforward, focussed and media supported lectures (teaching), complete, content-driven and multifarious enriched lecture-on-demand-packages (LoD-authoring), over-all sensitization for the whole LoD-production process and the impact of each teacher’s action on this process.

The research on lecture on demand scenarios is part of a research project supported by the DFN-Verein (Association for Promoting a German Research Network) called "Teleteaching/Telelearning Reference Systems and Service Center within the German Research Broadband Network".

Abstract: This paper looks at the design of an Online Learning environment focusing on the collaborative aspects, both from an educator's viewpoint and from a student's viewpoint. The design is based on socially constructed needs with flexibility as main concern.

Introduction

In times of financial restrictions, the demand for more efficiency and effectiveness in the Higher Education system is often connected to the potential of tele-supported university teaching. Whereas it is becoming more popular to use the Internet as the technical platform for the distribution of on-line study offers, a lot of surveys, (self-) descriptions, reports, etc., promote the thesis of almost unlimited possibilities in education that just have to be implemented. Frequently, a positive view is held which pushes the discussion of problematic areas of (interactive) on-line offers into the background. The gain in relation to the effort for development and realisation is seldom mentioned.

At the Institute of Law and Computer Sciences (Institut für Rechtsinformatik) of the Saarland University (Universität des Saarlandes), international on-line courses on the Internet have been offered regularly since 1996 (http://seminar.jura.uni-sb.de). The didactic concept is communication-oriented and is based to a vast extent on discussions and group work via the exchange of electronic messages through the WWW. Technical specialities, like an extensive media integration (e.g. audio/video), were not incorporated and the programming was reduced to a necessary minimum. Nonetheless, a vast investment of time during the development and the realisation of such on-line courses had to be noticed mainly due to organisational and support activities.

Implementation

Submitted works and responses of the participants show that it is a valuable course. The rising acceptance hints to the fact that the people value the advantages of studying independently of time and place and they appreciate the communication-oriented approach where participants have to be actively involved and are taken care of daily. Experience also shows that it is necessary to count in the economic factor as well. If one wants to try to simulate all-important elements of conventional teaching in a virtual environment, then new requirements have to be followed:
- the development and implementation of a course with specific didactic concept is usually more work intensive than in ordinary courses. Details have to be prepared before the course, the sequence and interaction have to be planned completely.
- the teaching concept has to come with a technical realisation concept, which makes forward planning and test runs necessary.
the organisation is extensive: processing of requests, collection of participants data, log-in and user identification distribution and updating data require much more time. The support of participants is done around the clock, even on weekends and cannot be seen to be an inadequate relation to that of conventional seminars. With the number of messages reading and answering them exceeds the time available for conventional courses including office hours. It is noticeable that the students have higher expectation in their support than usually, the reasons still have to be empirically researched. Technical, didactic, and content developments require the delegation of assignments which creates new dependencies and requires a lot of co-ordination efforts. Although high international participation lifts the quality level, limitation of participant numbers has to be considered, and the question of where to find additional resources has to reconsidered. Since the course offer is not limited to students of the particular university, sharing of cost with the other has to be discussed. Whereas this is already done in other countries, the German university system does not offer the necessary legal base for such actions yet.

A reasonable conclusion of this is that there currently are a need for integrative concepts for the implementation of open and distance learning via IT in Higher Education that can demonstrate a methodology of good practice for educational needs. Problems relating to this lack of a full and encompassing concept has to be seen from different perspectives and within different contexts of education. The implementation therefore depends from pedagogical, sociological, legal, technological and organisational as well as other disciplines.

Taking these obstacles into account co-operation among institutions was needed in integrating different domains of expertise in research and demonstrating a collaborative approach for the implementation of a model for Virtual studies in Higher Education.

One advantage of online courses is the potential for communication, collaboration, and the constant exchange of knowledge between students and educators, which brings them closer to (and perhaps supersedes) "real life" teaching. The Online Seminars has opened up new possibilities for students and teachers, and permit interdisciplinary and international collaboration. Our experience also points in the direction of that online teaching with international cooperation and participation are far more time and personnel intensive than regular courses.

The design of collaborative learning

Collaboration and co-operation needs to be designed on an institutional level too. Co-operation involves determining the settings and the implementation. Collaboration is applied practice in the field.

The online seminar is a co-operative international venture. Hence, the results of the analysis faze helps guide the roles of each of the co-operating institutions dependent on the focus, resources, personnel, and disciplines of those institutions. Currently (Summer 2000) this co-operative venture involves collaboration between Higher Education institutions in Germany, Austria, Sweden and Kazakhstan. Each of these institutions may have additional collaboration from local institutions. Co-operative decisions are based on common educational and research interests, competence, persons in charge, technical resources and the cultural background. Educational interests can therefore be implemented in ways not known before IT and the Internet were available.

Collaboration

Collaboration takes place among students, between students and teams, and among team-members. Student collaboration needs to be organised and co-ordinated too. No learning environments are known in Higher Education, where students meet voluntarily in order to collaborate for performing certain certified tasks.

Taking a closer look at the role of collaboration will show considerations to be globally viewed on four levels. These are:
- on the students level within the course
- on the team level within the course
- on a local level and finally
- on an institutional level: collaboration between international universities.
The Online Seminar-environment teams consist of 30 individuals from many different countries. These team members are lecturers, agents, volunteers, former seminar participants and students doing research work. Most of today's volunteers in the moderation of group discussions are former students of the seminar. Several tightly bonded groups have been formed as a result of the seminar on varying levels. For example, "Cyber Grannies" was formed by some of the student cohort during the 1999 seminar. Learning processes are also encouraged for the team — currently we are developing training for moderators.

Learning within the environment is structured to be multi-levelled and complex. Learners are learning from the team, but also from other learners. The team is learning from learners and other team members and participating institutions are learning from learners, teams and other institutions. This complex web of different learning levels are intimately related to the collaboration taking place across all these levels. Meta-learning is built into the design. Feedback has shown that learners rate this collaboration structure highly.

The design

The issue of designing an environment for collaborative learning are complex and varied. Some of the requirements needed to attend to are motivation and affording interactivity. A vast investment of time and energy during the design, development and the realisation of such online courses are mandated to ensure organisational and support activities to ward off potential problems. One central role in the Online Seminar is moderators for group work, the moderator to a very high degree are in fact mentors. Mentors not only in the task at hand but also in handling the media itself. Online VLEs present technical, transitional and pedagogical concerns. As Harasim [4] notes, "an online mentor is a professional in a particular subject area who provides on-going feedback until the apprentice (student) masters the learning task. At that point the mentor fades away, and the apprentice engages in the exploration of expert practice." The VLE presents a new atmosphere that the student and teacher must learn how to navigate. This melding of mentorship and purpose begins to reshape the face of learning and education. Without the active help of professors and lecturers (occupied with content support, management and didactics) as well as a number of student moderators who volunteered to assist during the online course the high goals set for the course could not have been reached.

In an online environment, you can expect mentoring to take on a new dimension. Here we are challenged to mentor in ways that Feuerstein [3] and others define as mediation. Dialogue and inquiry become a powerful medium for collaborative learning. Discussion begins to carry a flow a meaning. Threads of conversation can be woven together. Opinions and points of view become circulated as observations, assumptions and interpretations become visible. Effective guidance and mentoring can be achieved through selective intervention. A skilled moderator is a mentor who can keep the fragile balance between advocacy and inquiry. The moderator must facilitate rather than dominate the discussion. When we focus on Vygotskys [8] [9] idea of the learner's zone of proximal development, scaffolding, and dialogue, we have to turn our attention to fostering learning via virtual discussions, using strategies that include "voice", address learning and writing styles, and utilise Socratic dialogue. These ideas require us to tend to both the individual and group learning process. If we want to further online discourse, it is important not to forget that this learning process is complex, social and interactive. Research in social collaboration and negotiation in the vein of Slavin [7] and others, calls attention to the design and support of what these learning environments require. Responsibilities for discussion become shared, feedback becomes integral, and all participants, including the moderator, are equal. Both instructor and learner are challenged to grow and develop in this environment. Instructors grow to become moderators and guides and students grow as learners.

Online collaboration as well as effective moderating must be designed if it is to have comparable impact to face-to-face instruction. Through conscious effort and application, "virtual" moderators can bring voice and tone into an otherwise sterile and distant environment, accompanying the learner as a reflective guide or maybe even much like a personal muse. Moderators are mediators and facilitators; generative guides and conceptual facilitators. The same issues that can be a weakness in a virtual learning environment can be exploited creatively to make learning come alive.

Active learning is at the heart of the design of the Online Seminar. Designing activities that ensure active participation is part of the moderation and discussion process. Facilitating the discussion is one aspect. Another aspect is making the discussants responsible for their own learning by sharing the responsibility and leading group discussion and work. All participants in the course are provided the opportunity to experience being facilitators in
discussion, team leaders, presenters of information, observers, and all are responsible to provide feedback and input into the learning process. However, for any of this to occur, a certain amount of control needs to be relinquished and turned over to the group. Moderators must stay in the shadows allowing the learner to shine.

However, perhaps at the heart of design is the feedback, feedback that the moderator needs to provide in order to support the learning process. Feedback that promotes and encourages continued growth as a learner and encourages collaboration. Substantive feedback not only needs to be built into the course design, but also needs to be modelled by the facilitators if we are to expect quality feedback from students. Feedback needs to be constructive. Connections need to form between participants; commonalties as well as differences need to be discussed. A shared interdependence creates a collaborative environment.

Our goal was that course design and development would reflect a commitment to high quality related to state of the art research for teaching and learning. Hence, "active learning" and a focus on the "communicative process" between and among students and teachers were considered to be essential as we investigated designing "rich online learning communities". Since it is a virtual environment to be implemented based on the Internet, it was clear that quality could be enhanced if the potentials of the Internet could be exploited. Those potentials include information and communication potential; the flexibility of time and space of learning; and access for everyone without the need of additional financial investments in equipment or tele-communication.

As McGreal [6] notes that commercially available integrated distributed learning environments such as CourseInfo (http://www.blackboard.com/) are popular given: the lack of sustained yields for individual course development within curriculum, the high time investment for instructors, and the lack of a supportive technology infrastructure. Despite the administrative and implementation advantages these course management systems offer, these packages lessen the authoring power of the instructor, assume specific pedagogical approaches, confine in some ways the delivery of instruction, and limit the control of the instructor over the learning environment. Given our requirements and needs, we wanted control over the tools and delivery method to be able to be responsive and adaptive to learner and instructor needs relative to the content being presented.

We wanted the learning environment to be able to evolve and grow. We also wanted the environment to be learner centred and learner driven – hence our focus on creating community and a collaborative learning environment. Subsequently design looked to the aforementioned needs for input rather than limiting the design and development to adhere to a singular learning theory. Rather, we focused on developing a set of tools for the learners and designed how we asked that learner to engage the information to create the kind of interactivity and the level of ownership needed within the learning process. We intended to create a "rich" learning environment, which Wilson describes as a setting in which the student is "engaged in multiple activities in pursuit of multiple learning goals, with a teacher serving the role of coach or facilitator" [10].

Since the idea is the building of "learning communities" to achieve better and more active learning processes by the students a definition of constructivist learning environments given by Wilson [10] would fit best to the Online Seminar environment: "a place where learners may work together and support each other as they use a variety of tools and information resources in their guided pursuit of learning goals and problem-solving activities". However, not all tasks performed within the courses are constructivist. It is apparent within the design the influences of other learning theories and pedagogical assumptions e.g. such as cognitivism and social constructivism. Cunningham et al. [2] listed several principles for the design of a learning environment: a) provide experience with the knowledge construction process b) provide experience in and appreciation for multiple perspectives c) embed learning in realistic and relevant contexts d) encourage ownership and voice in the learning process e) embed learning in social experience f) encourage the use of multiple modes of representation g) encourage self-awareness of the knowledge construction process.

Results

Learner profile of participants in the 1999 summer term Online Seminar in short are; 224 students from 46 different universities, 19 academic specialties were represented from humanities to technology, 88 participants held some form of employment, 37 countries were represented an the ages ranged from 20 to 64. Preliminary statistics for the summer 2000 seminar is 521 participants registering, more then 30 countries from all continents are represented.
As the seminar has evolved so has our awareness of the importance of this intellectual role of the moderator. In our situation, given the nature of distance learning, the characteristics of our learners, and the number and nature of the seminar participants, it was necessary to augment the instructional support for the course to provide the feedback and guidance that is critical to participant success. That augmented instructional support is present in the seminar in the presence of volunteers who moderate, co-ordinate and mentor the discussion groups. As we have mentioned these individuals come from a variety of perspective and backgrounds. One of our current challenges is providing the support and training necessary to ensure quality moderation and mentoring of the upcoming cohort of participants. We are in the process of establishing some concrete guidelines to facilitate this process. A few aspects of these guidelines follow.

Facilitation of student learning needs to be a scaffolded process – especially given the obstacles of a virtual learning environment. In brief some of the obstacles that need to be considered and overcome by the moderation and mentoring process include: individuals may not be familiar or experienced with technology; learning in a virtual environment is very different from face to learning – there is the potential isolation of the student, the unfamiliarity of the electronic classroom, and the challenge of communication in an international environment in a text based medium. Our concerns for guidelines can be centred around the need to bring relative novices up to speed rather quickly – but our concerns focus on skills that will provide a quality experience for the participants.

Specific considerations for the moderators include how to scaffold this learning process in order to guide and enhance the quality of the discussion. Issues that we are currently dealing with include:
- How much moderation is called for
- Course organisation needs to define the roles and goals of moderation
- How to specifically scaffold the learning process
- How do we distribute the responsibility between moderators and learners

For example: if part of the learning objectives for the students to learn how to collaborate and engage in group collaboration part of the objectives for the course, then it is the moderators duty to explain and scaffold those activities through the course. Necessarily then the moderators participation and influence as the course progresses changes as the students become more self-sufficient.

Concluding remarks

We have investigated several aspects related to creating a socially constructed course design model. We have also reflected on, and asked if teachers and learners are flexible enough to adapt to these innovative forms of education. Active learning needs to be encouraged and facilitated through supportive design. This design needs to have structure and clearly demarcated support, the learner, especially within the current education system, cannot solely construct it. But there need to be guidance for teachers as well in order to get acquainted with and used to new methods and attitudes of learning.
The future of learning is still to be found by exploring the connection between organisation and collaboration. Organisation will be facilitated through carefully constructed collaboration. There are still questions to be answered. How are media selections for communications viewed and preferred by participants – and why? The research related to administrative functions is sparse. Collaboration needs to be organised on three levels: institutional, conceptual, and on an individual level. Investments of time, money, and effort need to be considered.

As we consider the Online Seminar, several things have become apparent to the team in the design, development and delivery of this course. Current work and research has been based on face-to-face instruction, we are only just beginning to compile information and experience for virtual learning environments. Adapting pedagogy from face to face instruction to virtual environments is first step in the emergence of a pedagogy that is rooted in VLE’s. For example, research in computer-mediated discussion in quasi-synchronous environments has found that the learner assumptions and interpretations are very different in a VLE because their assumptions and interpretations are based on face-to-face interactions. Continued efforts and investigations will help refine the research process.

The courses within this collaborative learning environment demonstrate that there is no need to discuss whether there will be a future for teacher’s profession competing with online courses. The concept of this environment foresees a very active role of the teacher as an organiser, mentor and/or moderator. But there are still strides to be made in the research on applying effective methods for teaching in collaborative learning environments.

What has the Online Seminar accomplished so far? It is believed that progress to date has produced a very good test bed for investigation of the following aspects: the organisational methods for this kind of activity, methods of training teachers in online teaching, and how to use available resources more effectively.

Implementing a Digital Campus: Nuisance or Nirvana

Steve Schlough
University of Wisconsin-Stout
102 Communication Technologies Building
Menomonie, WI 54751 USA
schloughs@uwstout.edu

Abstract: Many universities are moving to a notebook computer environment for their students. The University of Wisconsin-Stout is one of these universities. This paper presents an overview of a pilot implementation and steps required to move to a full implementation, from a department chair’s perspective.

Introduction

There has been a movement to requiring students to obtain their own computers, when enrolling in university programs. There are numerous universities that have been requiring students to purchase or lease notebook computers. The Chancellor at the University of Wisconsin-Stout (UW-Stout) has charged the University to become a Digital Campus. One of the major goals of this initiative is to require all incoming students to have notebook computers by the fall of 2002 [http://www.uwstout.edu/laptop].

Background

Many universities are moving to either require or support the use of notebooks computing [http://www.vcsu.nodak.edu/offices/ite/notebooks/other_notebook_us/] and that number is growing. UW-Stout studied the following three schools in the most depth: the University of Minnesota-Crookston, which became the first notebook university in 1993 [http://www.crk.umn.edu/technology/thinkpadu/thinkpadu.htm], Winona State University [http://course1.winona.msus.edu/luniac/], and Northern Michigan University [http://www.nmu.edu/laptop.htm].

UW-Stout is located in Menomonie, Wisconsin and one of 13 University of Wisconsin System four-year campuses. During the fall of 2000, UW-Stout had an enrollment of 7,162 undergraduate students and 540 graduate students [http://www.uwstout.edu/geninfo/facts.html]. The University has 27 undergraduate programs and 18 graduate programs [http://www.uwstout.edu/programs]. The author is chair of the Communications, Education, and Training Department (CET) [http://www.uwstout.edu/ctem/cet]. The CET department offers the core courses for five of these undergraduate programs and four of the graduate programs, plus several service courses. In the fall of 2000, one of these programs, Graphics Communication Management required incoming freshman to have (Apple) notebook computers. In the fall of 2001, another of the programs, Telecommunications Systems will require incoming freshman to have (PC) notebooks. One other program, outside of the CET Department, Technical Communications required Apple notebooks in the fall of 2000. For an estimate of numbers of student in program see Figure 1.

Figure 1. Estimate of Student Numbers in Implementation.
Purpose

There are many reasons that a university would decide to require students to invest in notebook computers. One of the basic reasons is that mobile computing is a technology that students will be required to use when they enter the workforce. The number of businesses moving mobile computing solutions is increasing dramatically and the students who have skills in a mobile computing environment will have an advantage working in them [http://www.mobilecomputing.com/][http://www.survey.com/]. Beyond using the computer as a tool there are curricular, and pedagogical reasons for moving to a digital campus.

Technology

To prepare for the transition to a mobile digital campus several steps were taken. Over the past several years the university has updated the campus network and installed an integrated relational database system [http://www.uwstout.edu/infotech.shtml]. Prior to the fall of 2000, the CET Department prepared for the transition by making sure all classrooms were wired for instructor access to Ethernet and that two classrooms had wired access for students. In addition to wired access wireless access was installed. Seven classrooms were equipped with permanent computer projection equipment mounted in them and there are two additional projectors available for checkout. All thirty-seven department members that have appointments relating to instruction have been assigned notebook computers. Included in these notebook computers are Apple PowerBooks, Apple iBooks, IBM ThinkPads, Gateways, Dells, Microns and Toshibas.

Findings of the Fall 2000 Implementation

The first implementation had several positive outcomes. It was decided to use block scheduling for several required courses including: English 101, Communications and Information Technology, Electronic Prepress and Chemistry. This scheduling brought several faculty together who knew that they would have the same students. This interaction led to discussions on ways to more effectively have the students use the computers in the classroom. As an outcome of these meetings a grant proposal to study innovative ways to redesign the classroom experience was written. The availability of the new tool let students set up better management systems for themselves. It also allowed the instructors to provide improved testing, communications, and web enhancements to create a learning environment not available with typical computer labs.

There were some early problems with the network infrastructure and some students had problems maintaining their computers which caused some difficulty for instructors and students. There was at least one student that was unhappy with the experience, but overall student satisfaction was high. Originally, there was to be an orientation session for notebook students that was not conducted because of scheduling conflicts.

Moving to a Full Implementation

Using the information from the first pilot several things have transpired to add to the success of the fall of 2002 roll out. Several committees have been formed, including a steering committee, a request for proposal committee, a committee looking at pedagogical issues, and implementation teams for both PC and Mac implementations for the fall of 2001. The University hired a notebook computer implementation project manager, who is a consultant with Compuware Corporation.

Summary

The move to a mobile digital campus is neither a nuisance nor nirvana, but an exciting journey that has the much potential for faculty, staff, and students. It is journey that is in constant fluctuation and one must remember that the goal is to provide an enhanced experience for students and not implement a particular device.

Preparing Oral Examinations of Mathematical Domains with the Help of a Knowledge-Based Dialogue System

Peter Schmidt
Department of Computer Science, University of Bonn, Germany
email: peter@uran.informatik.uni-bonn.de

Abstract: A conception of discussing mathematical material in the domain of calculus is outlined. Applications include that university students work at their knowledge and prepare for their oral examinations by utilizing the dialogue system. The conception is based upon three pillars. One central pillar is a knowledge base containing collections of mathematical objects: theorems and their proofs, concepts, and task types. Manifold attributes complement the object specifications including attributes related to categorization, to didactics, to applications, to transition to other objects, and to error handling. The second pillar consists of question types, of dialogue strategies, and of a user model. To formulate the answers a restricted natural language is used. The selection and the order of the questions may be controlled by an explicit specification or implicitly by the choice of a dialogue strategy including an exploration dialogue, a spot check dialogue, or a problem solving dialogue. The third pillar consists of procedural knowledge to monitor and verify the answers. For that, techniques of the fields of theorem proving and of formula manipulation are employed.

Introduction

Mathematics is a part of many branches of study in the universities. Oral and written examinations are regular events which challenge the students, but also burden the students. The students employ a bunch of strategies to cope with the examinations. Success or failure of the students depend upon a large set of variables including the nature of the individuals, their learning history, the quality and conscientiousness of the instruction, and many more characteristics.

We here suggest conceptions of discussing mathematical material to serve several applications: University students may work at their knowledge and prepare for their oral examinations by utilizing the knowledge-based system. Or universities may use the system to replace oral or other written examinations. For that purpose, we describe the representation of the mathematical knowledge, a list of possible questions and the monitoring of the answers, some dialogue strategies to discuss the knowledge, and a scaffold of a student model. We chose the domain of calculus (see e.g. Smith 1983) to study dialogues because of the importance of calculus for the edifice of mathematics and for many practical applications and because calculus belongs to the first mathematical fields which are studied at the universities.

There are some typical characteristics of oral examinations which our conception takes into account: The subjects of an examination in the field of mathematics are the theorems, proofs, concepts, applications, and problem solutions of one or more domains. An examination should cover the whole material. Therefore the examiners employ typical dialogue strategies. Some of the topics are discussed in a detailed way and the rest of the material is covered by a series of spot check questions. The transition from one question to another is generally controlled by mathematical connections or by the answers of the student. The time which is spent on the detailed exploration of a topic essentially depends on the performance of the examinee. When the student shows knowledge gaps or insecurities with a topic the examiner will further inquire to clarify the background knowledge and abilities of the student, e.g. by sticking to the the central points, by asking additional questions related to the foreknowledge, or by giving another problem to solve. In that case, the reaction of the examiner is strongly triggered by the answers. Usually, the rating of the examinee's performance does not only depend on the ratio of correctly answered questions and wrongly answered questions, but also on the flexibility and easiness with which the student deals with the questions and hints during the dialogue.

Mathematical Knowledge Base

The mathematical knowledge groups around the following objects: concepts, theorems, and task types. The specification of the objects includes a series of attributes referring to the object itself and its use of holding a
dialogue. We will describe the representation of theorems in a more detailed way and mention only a few details related to concepts and task types because of space limitations.

To word the premises, the conclusions, and the proof(s) of a theorem we employ a restricted natural language (see Schmidt 2000) or the website (see Schmidt 2001).

Representation of Theorems

The specification of a theorem consists of a series of attributes related to various information: Object describing information, classifying information, didactical information, application related information, transitional information, and error information. In the following we describe the attributes in the context of the specification of the mean-value theorem (Fig. 1). To represent the mathematical knowledge we use XML (see e.g. Goldfarb & Prescod 1998). The informal representation of figure 1 is chosen because of readability.

THEOREM

DOMAIN: calculus
SUBDOMAINS: differentiable functions
CATEGORY: existence of a point
PRIORITY: high
FOREKNOWLEDGE: continuous, differentiable
NAME: mean-value theorem
PREMISES: f [a,b] -> R
   f IS continuous IN [a,b]
   f IS differentiable IN (a,b)
ERROR: (CONDITION "f IS differentiable IN [a,b]",
   REACTION "IN [a,b] is not necessary.")
CONCLUSIONS: SOME x0 IN (a,b):
   f(b) - f(a) = (b-a)* f(x0)
USES: (THEOREM, CONCLUSIONS, "f IS monotonously increasing IN[a,b]")
TRANSITION: (THEOREM, generalized mean-value theorem,
   FORMULATE(THEOREM, generalized mean-value theorem),
   "There is a generalization of the mean-value theorem.")
TRANSITION: (THEOREM, mean-value theorem IN R^n, ...)

Figure 1: Partial specification of a theorem

Object describing information. The object describing information consists of a series of attributes including the external name (if one exists) of the object, its internal name, the premises, the conclusions, and the proof(s). See the example of the figure 1.

Classifying information. Each object belongs to a domain and possibly to one or more subdomains and subsubdomains. The theorem above e.g. belongs to the subdomain of the differentiable functions. The theorems are moreover classified with regard to their conclusions; the category of the mean-value theorem is e.g. existence of a point. The underlying idea of that classification is that the proofs of the theorems belonging to the same category often employ a similar proof strategy and utilize related heuristics. That information becomes relevant in the context of proof related questions. Further categories of theorems among about a dozen others are e.g. property of a function and uniqueness of a value, a point or a function.

Didactical information. Didactical information among others refers to the foreknowledge and to the priority of the object. The information regarding the priority which is high in the case of the mean-value theorem is utilized to control the selection of questions.

Application related information. Application related information employs two attributes. The attribute uses states the use of the theorem with respect to proofs of other theorem. The example of the figure 1 shows that the mean-value theorem is used to prove a theorem which concludes about a function being monotonously increasing. The other attribute applications refers to practical applications.

Transitional information. Transitional information refers to the order of questions and successors of questions in a dialogue. Transitions from one object or attribute to another are explicitly or implicitly defined by the knowledge base. Implicit transitions are e.g. triggered by the premises or the conclusions of a theorem. The specification of the figure 1 contains two explicit transitions to two other theorems, a generalization of the mean-value theorem and a version of the theorem in the case of n dimensions. The attribute transition takes four parameters: The object classification, the name of the object, the question (see below), and possibly a text which is used to word the transition in a dialogue.
Error information. Error information may be attached to some attributes of a specification. That information serves the purpose of specifically treating expected errors. Simple error information takes two parameters: The first one specifies the error and the second one words the reaction of the system. The error attribute of the figure 1 refers to the preceding statement "f IS differentiable IN (a,b)". See the discussion of errors below. Error information may be nested to cope with succeeding errors.

Representation of Concepts and Task Types

The specification of a concept consists of a series of attributes including among others its name, the premises, the defining statements, examples, and counter-examples.

A mathematical task type covers tasks which may be solved by the same or by similar methods. With the specification, we make a distinction between formula manipulation task types (e.g. the calculation of a limit or the solution of a differential equation and word problem types (e.g. extremal value problems which describe a geometrical situation). The tasks of both kinds of task types are on the top level classified into subtypes which may be characterized by certain patterns, by the solution methods, or by the values of certain relevant parameters of the task type.

The Questions and the Monitoring of the Answers

The various types of questions employ a certain format. There are several attributes attached to the question types including the question template, the answer directions, and possibly an answer template. In general, the questions of the system are presented in a natural language and the students word their answers by using the above-mentioned restricted natural language.

Questions Related to Theorems and Proofs

There is a list of standard question types which refer to the premises, conclusions, proofs, uses, and applications of a theorem. The following list of question types shows their formal statements. The formal statement of a question type is among others used in the context of specifying a dialogue (see below). The program system employs an XML representation as with the knowledge base.

(a) FORMULATE (THEOREM, theorem name)
(b) FORMULATE (PREMISES, statement)
(c) FORMULATE (CONCLUSIONS, statement)
(d) FORMULATE (USES, theorem name)
(e) FORMULATE (APPLICATIONS, theorem name)
(f) FORMULATE (PROOF, theorem name)

The question type (a) refers to the formulation of a theorem when its name is given. An example of a concrete question is "Formulate the mean-value theorem". The answer template consists of the words "mean-value theorem", "PREMISES", and "CONCLUSIONS". The user has to particularize the premises and the conclusions by using the above-mentioned restricted natural language. The answer directions consist of the format of the statements which may be used to word a theorem.

The question type (b) refers to the formulation of premises from which a given conclusion may be derived. An example of a concrete question is "Which premises are sufficient so that the function f[a,b] -> R is monotonously increasing in [a,b]?".

The question type (c) refers to the formulation of conclusions which may be inferred, if given premises are valid. An example of a concrete question is "The function f[a,b] -> R is continuous in [a,b]. Which properties of the function f may be inferred?"

The question types (d) and (e) refer to the listing of uses and of applications of a theorem. An example of a concrete question is "Give applications of the theorem of Taylor."

The question type (f) refers to the formulation of a proof. An example of a concrete question is "Prove: If f is differentiable at a, then f is continuous at a."

The above-mentioned standard question types may be modified so that the answers are shorter, more specific, or easier. Some examples are: With (a) some parts of the theorem may be provided so that the wording of the theorem must only be completed. With (f) the question may refer to the proof ideas or to completing a given proof by adding e.g. lacking foundations or lacking statements. We here omit further details.
Monitoring and Verifying the Answers Related to Theorems and Proofs

To monitor and to verify the answers of a user the system employs on the one hand the knowledge base of concepts, theorems, proofs, and task types and on the other hand methods of theorem proving and of formula manipulation. In the following we assume that the reader is familiar with the basic concepts of theorem proving, especially with the transformation of a logical formula into a quantifier free form and with the process of unification (see e.g. Bibel 1987 or Chang & Lee 1973). Regarding the theorem proving techniques we utilize methods which are similar to the methods of Bledsoe, Boyer, and Henneman to automatically prove limit theorems (Bledsoe et al. 1972).

An important goal is that correct answers are recognized as correct by the system. It is known that theoretical limitations restrict the possibility of deciding whether an answer is correct (see e.g. Richardson 1968 and Bibel 1987), but such cases here are of a minor importance. The aim here is to also accept alternative, correct answers which are not identical to the correct answers which are calculated, derived, or stored by the system. One cannot expect that a computer program could compete with a human in the field of intelligently treating the answers of a user. Nevertheless a detailed knowledge base and the methods of theorem proving and of formula manipulation allow for a useful and reliable treatment of the answers.

Earlier research in the domain of Intelligent Tutoring Systems suggests that competent error handling is a difficult and tedious task even in the case of apparently simple procedural problem solving (see e.g. Wenger 1987). The framework provided by Collins and Stevens who list 24 rules in the context of the Socratic method of tutoring is helpful with respect to classifying general errors like e.g. overgeneralization bugs or overdifferentiation bugs (Collins 1977; Stevens & Collins 1977). When an answer is recognized as not being correct, several mechanisms may be applied to diagnose the error and to react in an appropriate way. The mechanisms which are used depend on the question types, on the contents of the knowledge base including the specification of errors within the concrete objects, and on the methods which are provided by the logic subsystem and by the formula manipulation subsystem. The specificity of the possible feedback of course depends on the detailedness of the knowledge base and on the error classifying possibilities of the subsystems.

In the following we will give some examples of how the answers are diagnosed and treated.

Monitoring the questions of the question type (a). To check a user's formulation of a theorem the system employs the theorem of the knowledge base. The answer is correct when the user's premises and conclusions correspond to those of the theorem in the knowledge base. The statements are compared using a quantifier free form and the process of unification.

Some general errors which may occur are: A premise or a conclusion is lacking, a premise is not sufficient or not necessary, and the conclusion is too weak or too strong. Assume that the question refers to the mean-value theorem and the user enters "f IS differentiable IN [a,b]" as a premise instead choosing the open interval (a,b). That error can be corrected by utilizing the specification of the error in the object mean-value theorem (Fig. 1). The reaction of the system succeeds the error condition (Fig. 1). In the case that the error is not specified with the mean-value theorem, the error could have been detected by comparing the user's answer with the correct answer and by establishing that the statement "f IS differentiable IN [a,b]" subsumes the statement "f IS differentiable IN (a,b)" and so is not necessary.

Monitoring the questions of the question type (b). The basis of checking the premises from which a given conclusion may be derived are the theorems of the knowledge base which infer that conclusion. When a user e.g. enters the premises P1, P2, and P3 the system checks whether there is a theorem in the knowledge base with the premises P1, P2, and P3 and the stated conclusion. Similar considerations as in the case of (a) apply.

Monitoring the questions of the question type (c). Assume that the premise P is given and the knowledge base contains several theorems inferring the conclusions C1, C2, ..., Cn from P. When the user enters one of the C's the answer is correct. Assume the user enters D which does not correspond to one of the C's. Then the theorem "P implies D" might be wrong or correct. In the correct case, the theorem is likely a marginal one, because it is not a part of the knowledge base. In the wrong case, certain errors can be detected by checking whether a theorem "D implies P" is a part of the knowledge base. If "D implies P" is a valid theorem and D and P are not equivalent, there will probably be a counter-example in the knowledge base. An concrete example of that case is the wrong conclusion "f is continuous at x0 implies f is differentiable at x0".

Monitoring the questions of the question type (d) and (e). The questions referring to the uses and applications of a theorem mainly involve keywords as answers. Providing a list of synonyms is sufficient in most cases. More difficult questions may be handled by multiple choice questions.

Monitoring the questions of the question type (f). The monitoring of a user's proof is discussed in (Schmidt 2000).
Absurd answers. A human examiner cannot only check the correctness of an answer, but also the degree with which an answer is sensible in contrast to being foolish or inadequate. The worth and the assessment of a system increases when the system can eliminate absurd answers by a corresponding reaction. One such method is based on decomposing an answer into its syntactical parts and checking whether they correspond to the correct answer. In the case of the mean-value theorem the conclusion consists of an existential quantification which is followed by a formula containing the quantified variable. An answer which does not fulfil that restriction is regarded as being not appropriate and is treated by a corresponding comment. Since the XML representation of the objects covers the decomposing, such syntactical means may be applied without adding further knowledge elements to the mathematical objects.

Questions Related to Concepts and Task Types

We here just mention some question types related to concepts and task types. We omit further information because of the lack of paper space.

The question types related to concepts are: (i) The formulation of the definition of a concept, (ii) stating examples of the concept, (iii) stating counter-examples of the concept, (iv) deciding whether a given object is an example of the concept, (v) stating equivalent definitions, and (vi) stating sufficient conditions which imply the concept.

The questions related to task types are: (i) Calculation or solution of a formula manipulation task (e.g. calculation of a limit, an integral, the solution of a differential equation). (ii) classification of a task and stating the solution method, (iii) listing classes of tasks holding a certain property, and (iv) setting up initial equations to solve a problem which is stated in a natural language (e.g. an extremal value problem).

Dialogues

The Selection and the Order of the Questions in a Dialogue Session

A dialogue consists of a series of questions and answers. The selection and the order of the questions on the top level may be controlled by three different mechanisms: (i) By an external explicit specification of the subjects of the dialogue, (ii) by several dialogue strategies which are offered by the system, and (iii) by an explicit choice of single questions by the user. In the following we briefly describe the three mechanisms.

(i) Explicit specification of the subjects of the dialogue. The selection of the questions and their order may be explicitly specified in a DIALOGUE statement. Specifications of typical dialogues are provided by the system. They may be easily joined to form a complete session. This mechanism is useful when there is information about which knowledge is relevant in the current situation. The example of figure 2 shows a part of a dialogue specification (the program system employs a corresponding XML representation). There is a sequence of questions at first asking the definition of differentiable, secondly inquiring after a counter-example of a not differentiable function, and thirdly asking the formulation of the theorem of Taylor.

DIALOGUE
  FORMULATE (DEFINITION, "f IS differentiable AT x0")
  FORMULATE (COUNTER-EXAMPLE, "f IS differentiable AT x0")
  FORMULATE (THEOREM, theorem of Taylor)

Figure 2: Explicit specification of a dialogue

(ii) Dialogue strategies which are offered by the system. The objects which the knowledge base contains automatically trigger questions (e.g. the above-mentioned questions of the question types) and transitions to questions related to other objects (e.g. by the specified transitions or by the specified or implicitly given foreknowledge). For an implicit selection of questions we currently distinguish between the following three dialogue strategies which take into account the characteristics of oral examinations:

(a) A spot check dialogue relates to a domain, subdomain or subsubdomain and chooses questions so that all the parts of the subdomain are essentially covered by the questions. A corresponding statement is e.g. SPOT CHECK DIALOGUE (SUBDOMAIN, continuous functions) which triggers questions related to the subdomain of continuous functions. By the choice of additional parameters one may definitely include certain topics (e.g. all the theorems with a high priority) or exclude certain topics (e.g. task types or transitions to objects to other subdomains).
(b) An exploration dialogue tries to explore one or more objects or a small subdomain in a systematic way to a certain degree. E.g. the statement EXPLORATION DIALOGUE (THEOREM, mean-value theorem) triggers the questions which are explicitly or implicitly related to the mean-value theorem. By the selection of parameters one can include or exclude certain questions.

(c) A problem solving dialogue refers to a task type. It consists of solving problems and of answering questions related to the methods which are used to solve such problems. An example is PROBLEM SOLVING DIALOGUE (TASK TYPE, ordinary differential equations).

(iii) Explicit choice of the user. The user can traverse the objects of the knowledge base and get a list of the questions and problems from which he or she can choose anyone.

The Student Model

The scaffold of a student model is based upon the subdomains and their objects. The model stores information regarding three general aspects. One aspect is the material which is relevant to the student. The student may explicitly or implicitly (by selecting related questions) choose the subdomains or the objects. The second aspect is the self-assessment of the own knowledge. A student may state his or her own understanding or performance (good, medium, poor) with the subdomains, with single objects, and with the general categories of theorems, proofs, concepts, and solving tasks. Whereas the utility and the use of diagnostic processes are main subjects with tutoring systems, the topic of self-assessment is widely neglected as a basis of tutorial actions. That is surprising since the students may in most cases realistically assess their mathematical abilities and they usually know when they do not understand a subject and they know their deficiencies. The third aspect refers to the concrete dialogues and the student's performance. A trace of the details of the dialogue (e.g. questions, hints of the system, errors) is stored and abstracted to form a view of a student's knowledge and ignorance of the material of the subdomains and of the theorems, the concepts, and the task types. Another factor is the user's ability of correcting errors or utilizing hints. The contents of the user model may influence the progress of the dialogue. Wrong answers may change the order of questions (e.g. it is not sensible to discuss a concrete application of a theorem when the user does not know the theorem) or trigger additional questions (e.g. an answer may show that a user is not familiar with some foreknowledge; the system would then put some questions related to the foreknowledge).

Summary and Outlook

We outlined a conception of a knowledge-based dialogue system dealing with mathematical material in the domain of calculus. Such a dialogue system may be employed in the context of a virtual university or of a face-to-face university and the applications may include the preparation of oral examinations.

Our current prototype includes an interface to print the questions and enter the answers, some procedures of theorem proving and an own formula manipulation system. The programming language is Java including the servlet API. The program system is developed as a web application. The knowledge is represented using XML. The prototype will be further developed with respect to the methods and to the knowledge base.

References

Since the arrival of the affordable personal computer, some educators have heralded it as the vehicle for a new paradigm of education, whereas others have argued that "the use of computers as a medium of instruction and as a tool for learning is largely incompatible with the requirements of teaching."

Those who would argue against the use of technology in the classroom seem to be individuals who are not personally comfortable with utilizing it themselves and are unlikely to have experienced it applied to their own educational process. Whereas those teachers who are more at ease with information technology, and use or have experienced it themselves, are three times more likely to utilize it as a resource for their students.

Interestingly enough there also seems to be a division of educational philosophy that correlates to these two groups of educators. The former category tend to be individuals who see education as carefully planned direct instruction on narrowly defined content or skill. They believe in "standards based" assessment that seeks to provide a fair degree of accuracy regarding

The latter group generally seems to be more interested in a student's capacity to understand and the development of a sense of meaningfulness of the information and are more likely to use measures of "performance of understanding" as a means of evaluating a student's mastery of the material.

Consequently, if we are moving into a future where the use of technology in the classroom it would be integrated into the entire educational experience, the teacher would be familiar with information technology and would model its use to resolve a variety of academic problems. He or she would have had the genesis of this experience during his or her training to become a teacher.

Such training in many ways is not different than the training needs that face most major global corporations. What is needed is a central repository of critical information that can be transmitted to the end user in a "just-in-time" fashion, that does accurate user profiling as well as accurate assessment of the student's mastery of the specific subject area or skill. In addition there would be exposure to a variety of more creative thinking tasks where the student had a chance to experience simulations or develop applications of information to problems in such a way as to demonstrate a true and deep understanding of concepts. Ideally this process is tailored to a student's individual learning strengths. And the student could study any time around the clock and from any distance away.

The "technology savvy" teacher might have a 'master educator' who would start from a 'baseline' that was acquired by some form of interview or "test" that would determine the student's current understanding. This is best done in a manner that doesn't leave the student with a sense of failure or incompetence thereby diminishing self-confidence.

There might also be a strategy wherein this 'master teacher' would determine individual learning style by identifying if a student's preference would be auditory, visual, tactile, or multi-sensory. Furthermore, methods may be developed to determine an individual student's frustration tolerance in order to know how to pace the instruction as well as identifying positive reinforcers.
that would serve as rewards for consistent effort. Assessment techniques could evaluate broad content coverage as well as in depth on specific skills.

Other variables that could be identified to maximize the student’s learning could be:

- Instructional History - To remember exactly where the student left off, what was discussed, what was learned, and what needs to be covered.
- Error Analysis - To determine a student’s area of weakness.
- Study Scheduling - To generate reminders about the duration and frequency of sessions required for mastering the material.

To really place demands on this ‘master teacher’, he or she would be available 24 hours a day, 7 days a week, 365 days a year. This teacher would never be impatient or tired and would even attempt to make learning more pleasurable by appearing as a character more to the student’s liking or interest.

And finally, and perhaps most remarkably, this teacher would be able to meet all these demands for every student in the class!

Information technology and artificial intelligence research has yielded software with natural language understanding. Software robots (or ‘agents’) have already been developed that "tutors" to teachers in training and can follow them into their educational careers as their “virtual assistants”. They would bring an availability that could also extend to parent’s as well. There could always be an answer to “What was the homework” or “How are my child’s grades?” or “Was the assignment passed in?” Depending on how ‘wired’ the parent is, this “virtual teacher assistant” could be accessed by computer or any wireless web device.

These smart bots have other applications as well. Anywhere that a human guide would be helpful by answering repetitive questions for information are ideal applications.

They could serve as online human resource representatives who could give information on policy and procedures or the status of retirement plans or accrued sick days. They could automate attendance or tardiness records and have them immediately available for parents to check.

Guide students through online admissions procedures or course listings. Have them take courses at their own pace, any time day or night; without having to commute. Use them to set up intellectual neighborhoods or search for information for papers and research.

And all of this is done without having to browse a website or determine the appropriate keyword for a query. You just ask the smart bot and it takes you exactly where you want to go.

This is not the future...this is now. This is the marriage of technology and education that will make not only make the computer compatible with the requirements of teaching it will make it a necessary component.
Teaching Scientific Thinking Skills: Students and Computers Coaching Each Other

Lisa Ann Scott and Frederick Reif
Center for Innovation in Learning
Carnegie Mellon University
5000 Forbes Avenue
Pittsburgh, Pennsylvania 15213, USA
lscott@andrew.cmu.edu, freif@andrew.cmu.edu

Abstract: Our attempts to improve science education have led us to analyze the thought processes needed to apply scientific principles. Using a reciprocal-teaching strategy to teach the necessary thought processes explicitly, we have developed computer programs called Guided-Practice (GP) PALs (Personal Assistants for Learning) in which computers and students alternately coach each other. These computer-implemented tutorials make it practically feasible to provide students with individual guidance and feedback ordinarily unavailable in most courses. This guided practice however is not sufficient to ensure that students develop the ability to perform independently. Accordingly, we developed Independent-Performance (IP) PALs in which students work independently, receiving only the minimal feedback necessary to complete the task. GP PALs are then frequently followed by IP PALs to create effective instruction which facilitates a gradual transition to independent performance.

In a comparative study, GP PALs were found to be nearly as effective as individual tutoring and considerably more effective than instruction provided in a well-taught course. Another study is currently being conducted to assess the added efficacy of the IP PALs.

Introduction

Many students emerge from science courses unable to apply the scientific principles that they ostensibly learned. This paper describes work specifically aiming to teach the application of Newton's law (a fundamentally important principle in introductory physics). To address students' difficulties in applying this principle, we analyzed the required procedural knowledge and thinking skills, including the basic skills of decision-making and assessment. By using instructional strategies for teaching these thinking skills explicitly and using computers as practical means of providing individual guidance and feedback, we devised highly interactive instruction where the computer and student take turns coaching each other. A gradual transition toward students' independent performance is also facilitated. And finally, we carried out a series of studies to assess the efficacy of this instruction.

Computer Implementation of Instructional Strategies

To help students learn to carry out the thought processes needed to apply Newton's law, we have developed a set of highly interactive computer tutorials called PALs (Personal Assistants for Learning). These PALs employ cognitively-based instructional strategies and are a practical means of providing the individual guidance and feedback lacking from most traditional instruction.

Explicit Training of component skills: "Reciprocal Teaching

We have employed a modified form of "reciprocal teaching" (Palinscar & Brown, 1984) which involves two alternating modes of interaction between a student and a tutor. (1) Tutor coaching student: The tutor decides what to do and gives corresponding directions, the student implements these, and the tutor assesses and corrects. (The tutor acts as a coach.) (2) Student coaching tutor: The student and tutor reverse roles. The student decides what to do and gives directions, the tutor implements these (but may deliberately make mistakes similar to those common among students), and the student assesses and corrects. (The student now acts as a coach.)
This strategy should be effective for the following reasons: The instruction is highly interactive and keeps the student actively engaged. The basic processes of deciding, implementing, and assessing are made highly explicit. As the tutor and student alternate in their coaching roles, the tutor repeatedly models good performance that the student can then emulate. The tutor constantly monitors student performance, providing feedback and instruction designed to remedy the student’s mistakes.

Computers were used to implement this instructional strategy resulting in two types of Guided-Practice PAL tutorials (corresponding to the two modes of interaction in the reciprocal teaching strategy).

1. Implementation Guided-Practice PALs: PAL (the computer acting as a Personal Assistant for Learning) plays the role of coach, deciding which actions the student should implement and then assessing the student’s implementations.

2. Coaching Guided-Practice PALs: Roles are reversed and the student now acts as a coach deciding on actions and assessing the implementations done by PAL (who may make mistakes).

Progressive Development of Independent Performance

The reciprocal-teaching strategy provides students with good individual guidance and feedback. But repeated guided practice alone is not sufficient to guarantee that students will ultimately perform well independently without external assistance. There is a need for a strategy helping students to attain such independence.

We use a strategy where guided-practice sessions, using reciprocal teaching, are frequently followed by independent-performance sessions. In these the student is asked to work independently on a somewhat similar task, while getting only the minimal feedback necessary to complete the task successfully.

This strategy has a number of advantages. The transition to independent performance is integrated throughout the instruction. Also, students are more motivated to engage in careful learning during a guided-practice session since they know they will be required to perform similar tasks independently.

Computers were used to implement this instructional strategy. In the resulting Independent-Performance PALs, students are presented with an entire problem to solve independently on paper. The student then enters his answers on the computer. If the student’s answers are correct, PAL congratulates the student and considers the tutorial satisfactorily completed. Otherwise, PAL gives the student some feedback and asks him to try again. This cycle is repeated, with progressively more detailed suggestions, until the student manages to successfully complete the problem.

The goal of the Independent-Performance PALs is to encourage the student to complete the problem with minimal assistance. Interspersing these Independent-Performance PALs with the Guided-Practice PALs is our attempt to help the students develop the ability to perform independently.

Assessment

In the Fall of 1996, we carried out a comparative study to assess the efficacy of the Guided-Practice PALs which showed the following (Reif & Scott, 1999): (1) The Guided-Practice PALs were found to be nearly as effective as individual tutoring by experienced tutors, but required much less instructor time. (2) The Guided-Practice PALs prevented nearly all the students from failing the subsequent test (i.e., getting scores less than 65%). By contrast, about half of the equally able and motivated students failed this test when they received only the instruction provided in the course. (3) Students liked the PALs, found them helpful to their learning, and perceived they were learning useful ways to think about physics.

Another study is currently being conducted to assess the added efficacy of the Independent-Performance PALs. Results from this study will be reported in the presentation.

Using Electronic Art to Define Navigation Paradigms for Hypermedia Communication

Patricia Search
Department of Language, Literature, and Communication
Rensselaer Polytechnic Institute
Troy, New York 12180
searcp@rpi.edu

Abstract: Hypermedia computer programs are an important part of today's educational curricula, and the computer interface plays a critical role in the interpretation of information in these programs. Students are fascinated with the amount of information that is available, but they often feel overwhelmed because they don't know how to organize the information into a coherent whole. The ability to synthesize information is hampered by interface designs that separate information into fixed categories and hierarchical structures rather than emphasizing relationships. Electronic artists are developing new forms of audiovisual discourse that reflect the networks of associations in interactive electronic communication. This paper discusses the parallels between the semantic structures in various forms of electronic art and the complex information matrices in electronic communication. This paper shows how electronic art can provide new perspectives for hypermedia interface design.

Introduction

With the explosion of the World Wide Web, interactive multimedia computing is fast becoming the standard for communication in the information age. In these multimedia environments, it is easy to become absorbed in the detailed process of selecting and following links, and lose sight of original goals and the relationships between individual pieces of information.

Navigation in these environments creates new semantic structures that are changing the way we organize and interpret information by enabling us to modify perspectives and restructure reality. In these discursive environments, the lines between image and language become blurred. Text takes on characteristics of visual imagery because words derive meaning from their positions in space and time. In turn, the semiotic structure of the digital image defines a new visual aesthetic in which symbols become interpretations of symbols, and multiple levels of graphic encoding take on discursive characteristics similar to linguistic syntax (Search 1993). In these environments, where conceptual links between images and text replace tactile and kinesthetic interaction, new forms of creative expression codify form, space, action, and time into diverse levels of abstraction.

However, we are just beginning to understand the power of this medium to reshape the way we communicate and interpret audiovisual information. Unfortunately, the designs of most interactive programs are still influenced by Western perspectives of space and time that emphasize logical analysis and sequential hierarchies. These perspectives are often at odds with the spatial and temporal experiences in an interactive multimedia environment where simultaneity, random access, and non-narrative communication are emphasized. Moreover, in interactive programs, the navigation process defines cycles of action and events that establish a dichotomy between the possible and the actual. In other words, there is always the actual information at hand as well as the potential for new information or associations. This tension is not accurately represented by the language and structure of electronic interface designs (Search, 1999). The interactive process represents a fluid, temporal transformation of ideas. A new audiovisual grammar that uses the holistic synthesis of audiovisual patterns is needed to represent the metastructural dynamics of this transformative process. In "The Sadeian Interface: Computers and Catharsis," Mike Phillips points out that we have no "interactive" heritage to deal with the "fifth dimension" of computer interaction. Although we can look to individual disciplines for ideas and inspiration, it is the "convergence of these design practices that should be forcing a paradigm shift to a holistic media experience rather than a fragmented mish-mash of muddled aesthetics" (Phillips, 2000, p. 28).
For many years artists working with electronic media have been experimenting with techniques that could be used to enhance multimedia interface design. This paper examines the work of some of these artists and shows how these techniques could be used in hypermedia interfaces to reduce the fractionization of information and encourage the creative synthesis of ideas.

**New Navigation Aesthetics**

In interactive electronic environments, text and images appear and disappear on the screen as links are selected. The changes in the spatial location of the text and graphics impact the semantic structure of the text and audiovisual information. A navigation structure emerges that defines text and images in terms of events in space and time. Text takes on graphical as well as linguistic characteristics. Conventional perceptions of space and time are easily altered depending on the "location" of the audiovisual information in a spatiotemporal matrix.

Image maps that link to other information take on additional layers of meaning. There is the semantic meaning of the image based on the context of the image, and there is the syntax of the image based on the design (layout, color, etc.). There is also the navigation structure defined by the links to other information. As a result, the visual symbols do not necessarily represent sequential logic or causation. Instead, they represent the process of transformation. These visual matrices are even more complicated when the images are abstract images because abstract images, which do not depict specific objects, represent fluid relationships that are open to interpretation.

The aesthetics of navigation in hypermedia communication has not been fully explored. Navigation paradigms should create dynamic structures that encourage the exploration of new interpretations and relationships. At the same time, the navigation structure should help the user identify the continuity between ideas and synthesize information. Links or associations between ideas create cognitive patterns based on relationships not objects. How do we identify and visualize these patterns?

Before we can learn to identify and use these patterns we need to recognize some obstacles that limit our perception of spatiotemporal events. Language and graphics are the primary methods of defining spatial and temporal relationships in computer interfaces. With the development of language in the West came linguistic categories, deductive reasoning, and diachronic logic, all of which define sequential hierarchies in space and time (Search, 1996). Current interface designs in hypermedia programs use language and graphics that reflect these cognitive hierarchies. Most navigation paradigms are defined by the Western perspective of time that represents a linear, one-directional perspective in which space is an empty area that separates objects. Windows, files, and folders separate information and isolate moments in time instead of emphasizing interrelationships. In these electronic environments, events occur in space as well as time. The space between events, which represents the links or interrelationships between ideas, is no longer empty and void of meaning. Navigation through these spaces represents the process of transformation. We need navigation structures that emphasize the fluid dynamics of these information spaces. We need structures that represent the possible as well as the actual.

Phillips defines this new area of study "Activity Theory." This theory "explores the complex feedback loops between the impact the use of a tool has on the environment and the impact the modified environment then has on the human" (Phillips, 2000, p. 80). We need audiovisual interfaces that represent this dynamic, transformative process.

The rest of this paper investigates the aesthetics of design and action in various forms of electronic art. The paper makes recommendations for incorporating some of the design elements in these works into interface designs for interactive multimedia or hypermedia programs. Many of the artworks cited in this paper can be viewed on the web sites cited in the footnotes.

**The Multiplicity of Text**

Artists working with electronic text have created projects that present some new opportunities to experiment with the syntax of language when there are multiple layers of meaning in text. These projects demonstrate interesting ways to use text to represent the multiple levels of interpretation that we find in interactive information spaces.
Thorne Shipley conducts theoretical research in "pattern and matrix vision" (Shipley, 1974). His work investigates the different levels of perception and cognition that are defined by visual patterns or textures in linguistic messages (Search, 1993). Shipley is exploring what he terms "heterological message duality" or "message multiplicity" (Shipley, 1993, p. 27). He illustrates this concept using words that are typographically constructed from other words. For example, in one of his illustrations, the text for the word yes is repeated in a pattern that forms the shapes of the letters in the word no. Similarly, the text for the word you forms the shape of an I, and the word will creates each of the letters in the word won't. When these typographical constructions appear in phrases like No. I won't, the visual patterns within each word communicate a secondary message--Yes, you will (Shipley, 1993). Symbols become interpretations of symbols.

The work of artist Jim Rosenberg adds another level of inquiry to these visual-linguistic maps. He uses "word clusters" to experiment with the syntax of words that occupy the same point in logical and physical space (Search, 1993). In his interactive program Intergrams (1990) [1], groups of phrases, made up of words that overlap each other in the same space, appear on the screen as masses of black lines. In this form, the phrases are indecipherable. However, by moving the computer mouse over the word cluster, individual phrases in the group appear one by one (Rosenberg, 1991).

Both Shipley and Rosenberg create layers of words within words in order to define new relationships and meanings. The revealing of these layers takes place in a single location, emphasizing the fact that the layers of words and meanings are related. A similar technique can be used in an interactive environment where related information, that forms a single visual entity, changes into new words or graphics and by so doing, reveals the integrated structure of the relational web. As Rosenberg points out, this syntax "... allows for elements that are juxtaposed without structure to be combined into a larger structural whole... Syntax becomes an option but not an obstacle" (Rosenberg, 1993, p. 12).

Other examples of electronic art that use text to represent different layers of interpretation can be found in hypertext fiction. In his work entitled Hegirascope [2], Stuart Moulthrop uses a similar visual layout on each page. This layout consists of individual textual links that surround a body of text. However, the text in the links changes on each page. The standard layout provides a coherent structure for the information while the changing text in the links results in a dynamic, open syntax that is always evolving.

In all of these examples, text maintains an inherent structure with an underlying, "original" meaning, but the text also takes on many different visual and linguistic interpretations based on events in space and time. In a hypermedia environment, we can embed text and graphics with layers of meaning and use this "message multiplicity" to represent the pluralistic meaning of complex information structures and the possible as well as the actual relationships. Plumb Design, a web site design firm, created the Visual Thesaurus which is an experiment in using linguistic syntax and text to map relationships in an information space [3]. The company's Thinkmap™ software creates Java Maplets™ that connect related words by fine lines to form a dynamic visual diagram. The diagram changes when the user conducts a new word search and/or specifies a different grammatical use of the word (noun, verb, adjective, adverb). Unfortunately, in the Visual Thesaurus and in the commercial applications created by Plumb Design, the relationships between the words are not always intuitive. Sometimes there are too many visual links in the diagrams, and the relationships are obscured. Nevertheless, these efforts by Plumb Design are a first step toward visualizing the networks of associations that exist in interactive databases.

Metastructural Dynamics of Digital Images

Computer graphics provides techniques for visualizing the fluid relationships in complex information networks. Computer-generated images can symbolize spatial structures with multiple links and layers of association. For example, highly reflective and transparent images that show the surrounding environment on their surfaces become image maps that represent the multiple dimensions of complex, integrated media spaces. The reflective and transparent surfaces show specific detail within the context of an integrated whole. In Yoichiro Kawaguchi's computer animations, these types of surfaces appear on organic, flowing forms [4].

Visuals like these can represent the fluid structure of hypermedia computing where relationships continually change. Images with reflective surfaces, which show surrounding space and objects, embrace space and time from all directions rather than limiting the vantage point to a singular perspective. The space becomes all-inclusive and nth-dimensional (Search, 1993). In hypermedia environments, this type of image can symbolize the simultaneous existence of different layers of information. Because the images show detail within the whole, the images represent microcosmic as well as macrocosmic relationships.

Computer-generated images also provide new ways of visualizing navigation and the dynamic transformation of ideas. Images that integrate geometric objects with variations in texture, color, transparency, or reflection symbolize the underlying structure of the database, and at the same time, represent the fluid nature of the relationships in the database. Such works include the computer paintings of David Em (Transjovian Pipeline, 1979; Zotz, 1985) [5], William Montgomery (Peaceful Sky, 1996; Rotated Sphere, 1997) [6], and my own artwork (Coloratura 100, 1988; Kaleidoscope, 1992). In these works the geometric objects represent the continuity of ideas while changes in color, texture, transparency, and reflection create perceptual transformations that challenge the viewer to abandon the limitations of fixed hierarchies and search for new associations (Fig. 1). Because of their Gestalt-like, holistic properties, visuals similar to these types of images can be incorporated into electronic interfaces to symbolize the dynamic relationships in information networks and at the same time, help the user synthesize information into an integrated whole [7]. The potential for using computer-generated images as navigational aids in hypermedia computing is not limited to three-dimensional images with intricate surfaces. Many artists transform the lines and planes of two-dimensional art into volumetric extensions of space (Search, 1993). These types of graphical transformations have been an integral

Figure 1: Geometric objects with reflective surfaces represent the continuous whole as well as the relationships between the individual components that make up the whole. Coloratura 100 Copyright 1988 by Patricia Search. All rights reserved. http://www.rpi.edu/~searcp/coloratura.html

[7] Geometric shapes such as circles and squares are continuous entities that represent a unified whole. Research in Gestalt Psychology has demonstrated that we visually link similar shapes, lines, colors, etc. Interface designers can use these laws of visual perception to help viewers combine individual components of the interface into an integrated whole.
part of computer graphics for many years. Examples include the works of artists such as Eudice Feder (Homage to Mohology-Nagy, 1979) [8], Vera Molnar (Hypertransformations, 1973-76), and Daniela Bertol's collage Bending and Twisting: Hypothesis #3 (1988) [9]. By making subtle changes in the width, color, texture, and position of lines and planes, the artists transform the flat line or plane into an all-inclusive space with "ubiquitous perspectives and orientations" (Search, 1993, p. 8). Such images can represent the integration of multiple perspectives in hypermedia environments.

Finally, the medium of light in electronic media creates a metaphysical extension of space that gently encloses the surrounding areas and objects without creating hard boundaries between objects. Diffuse areas of light enable artists to visualize the spatial relationships in and between objects. Daniel Brown, a creative technologist at an Internet design agency called Amaze, is experimenting with visual interfaces that use these qualities in light. Some examples are found in a collective work called Mr. Noodlebox [10]. In his animated graphic titled Colourspace, diffuse areas of colored light slowly change shape and color. In Sanded Curves and Electron Fields, free flowing curves carve out continuous forms in various light intensities as they sweep across the screen. The potential for using these types of graphics to symbolize the temporal transformation of ideas in interactive computing is compelling. Different intensities of light can represent flexible webs of relationships. Links embedded in areas of diffuse light can represent the possible as well as the actual.

Repetition and Rhythm

The dominance of European art in contemporary culture has led to the dismissal of symmetry and repetition as significant design elements. Western cultures fail to recognize and appreciate the rhythms of repetition and the layers of multiple rhythms that occur when there are subtle variations in forms, space, or time. These subtle changes, which result in the interweaving of different levels of symmetry and rhythm, create a tapestry of space-time relationships (Search, 1999).

Interactive electronic programs provide many opportunities to explore the use of repetition and rhythm to visualize the patterns that emerge from navigating through complex information spaces. Combinations of different layers of rhythmic patterns can create a "counterpoint" of rhythms that mirrors the webs of information in the database. For example, visual patterns can help the user organize and synthesize relationships. Transitions in electronic interfaces provide opportunities to use repetitive movements, design, and sounds to create continuity in complex information spaces. By controlling the speed, rhythm, and audiovisual design of transitions, it is possible to define relationships between groups of information.

Sound also provides new ways to use rhythm in interactive computing. Musical rhythms can underscore visual rhythms and add emphasis to patterns and relationships. Finally, there is the rhythm of silence. Pauses or breaks in repetitive elements add moments for reflection that give the user an opportunity to fill in the patterns with his/her thoughts. Silence provides the space for new levels of interaction that free the user from the constraints or limitations of the database.

I am creating multimedia installations that challenge established perspectives in hypermedia interface design [11]. Repetition and rhythm are central design elements in the installation entitled Ancient Voices in Cyberspace. This installation explores the aesthetics of repetition and rhythm, prominent design elements in the audiovisual symbols of oral cultures, as a foundation for new perspectives in human-computer interaction. The installation contains a hypermedia program that weaves the rhythmic patterns of images and sounds derived from oral cultures, into integrated audiovisual designs that symbolize the webs of associations in hypermedia networks. Pauses in the rhythm of the audiovisual display, created by the absence of sound or visual information on the screen, give the user time to reflect on the interactive process. The installation demonstrates how repetition and rhythm in an audiovisual interface can help the user synthesize multiple perspectives into a coherent whole.

Conclusion

In hypermedia programs, students, educators, and researchers not only need interfaces that provide access to large amounts of information, they need interfaces that encourage them to investigate new relationships and help them integrate individual pieces of information into a coherent whole. Interactive multimedia environments consist of complex information matrices that evolve in space and time. In the nineteenth century, the linear determinism of Euclidean geometry was replaced by dynamic mathematical models that used terms like betweenness, translation, reflection, projective, inversive, and hyperplanes to describe flexible, multidimensional relationships (Search, 1993). These same terms describe today's hypermedia environments where webs of information are subject to continual change.

The artwork of artists using electronic media can provide insights into new ways to use the patterns and rhythms of the audiovisual interface to communicate dynamic information structures. We need to explore new ways to use text and images to represent flexible relationships within the context of an integrated whole. We need navigation paradigms that reflect the multiple layers of information in a hypermedia program. We need a new design syntax that represents the dynamic transformation of ideas. The audiovisual syntax of the human-computer interface should help the user visualize the actual as well as the possible. In other words, the interface should encourage the user to explore relationships that haven't been defined. The process of interaction transforms these information structures, and the interface should symbolize this transformative process.

Heidelberg, Germany

Abstract: This panel focuses on underlying design principles for creating case-based hypermedia learning environments for building problem solving skills in two professional practice fields—teacher preparation and medical education. The panelists provide an opportunity to actively view and compare a sample of interactive cases that integrate application scenarios, domain knowledge bases, authentic case information, expert modeling, and problem-solving activities. Similarities, differences, and design decisions will be discussed based on a set of design principles for creating practice fields in hypermedia learning formats. The audience will engage in applying these principles, concerns, and opinions to their respective areas of expertise.

Introduction
Louis Semrau

The nature of training all workers as well as professionals is changing dramatically. The increase in the sheer amount of information in our knowledge bases as well as the shifting of how these knowledge bases are employed make it critical for training to be both effective and efficient. Hypermedia case-based training, especially when electronic performance support systems (Laffey, 1995) and collaborative work activities (Barab & Duffy, 2000) are incorporated, provide such training environments for professional fields.

Hypermedia case-based learning has the potential to provide complete information, expert modeling, and challenges to be solved by the learner in his or her own situation (Fitzgerald, Semrau, & Wilson, 1997). Case-based training systems help educators develop, implement, organize and re-use multimedia cases for problem-based learning (Riedel, Singer, Leven, Geiss, & Toenshoff, 2000). Hypermedia case-based learning environments are active learning environments in which users explore case scenarios through video and audio, gather contextual information, access domain knowledge, draw on expert modeling of solutions, define contextual problems, and revise solutions based on prompts and scaffolds. Hypermedia-based training goes beyond traditional simulation models by allowing learners to take control and responsibility for their own learning through nonlinear access to information, problem identification, access to information on demand, instructional scaffolds, and feedback on problem solutions.
Design of Practice Fields

While a great deal of literature is available concerning the design of effective hypermedia case-based learning environments, until recently this information has been confusing due to subtle distinctions between instructional design models and applications to differing learning contexts. Design concepts continue to evolve to guide developers in conceptualizing and designing learning environments. The following design principles have recently been recommended for creating practice fields based on situated learning that emphasize engaging the learner in authentic tasks that require problem-oriented learning (Barab & Duffy, 2000).

- Doing Domain-Related Practices
- Ownership of the Inquiry
- Coaching and Modeling of Thinking Skills
- Opportunity for Reflection
- Dilemmas are Ill-Structured
- Support the Learner Rather than Simplify the Dilemma
- Work is Collaborative and Social
- The Learning Context is Motivating

While these principles provide a solid basis for the development of hypermedia case-based learning environments, they may not apply universally across programs with widely differing goals, activities, appearance, audience and disciplines. The principles will be discussed relative to the following demonstrations.

Demonstration #1

Instruction and Management in Emotional and Behavioral Disorders: The Case of Martelle
Gail Fitzgerald

Instruction and Management in Behavioral Disorders is the third title in an interactive training series for use in teacher education programs (Fitzgerald, Semrau, & Standifer, 1998). The program is based on case study scenarios in which the user takes the role of a teacher in planning for different youngsters with significant behavioral and emotional problems in classrooms.

The computer program contains computerized background information on a child named Martelle. Content in the program includes policies in his school, a resource information base related to behavioral interventions, a series of problem solving activities based on authentic job responsibilities, scaffolds for the user related to the activities, and 35 template tools for creating intervention plans. Multimedia material on the CD includes videos to observe Martelle in a variety of classroom settings, audio interviews with adults with information about him, mini-presentations on specialized curriculum, and commentary by experts in the field. The resources and template tools are designed as stand-alone applications for users to have following successful completion of the case study activities. Through these tools and information resources, a direct bridge is provided to support the application of knowledge and skills to real-world use through electronic performance support systems.

Figure 1 displays the main menu screen for the case study Martelle.
Figure 2 displays the resource site for gathering case, school, curriculum, and tool resources.
Figure 3 displays a prompted activity of assessing Martelle’s classroom environment.
Demonstration #2

The CAMPUS Training System in Medicine

Jens Riedel

CAMPUS is a case-based, Web-based training shell system to develop, organise and (re-)use flexible, simulative medical multimedia cases to be used by educators, students and physicians at different levels (Riedel, Singer, Leven, Geiss & Toenshoff, 2000).

To minimize acceptance problems and maximize effectiveness and efficiency of case data input, CAMPUS is designed as a flexible, adaptable system that can be used by different users (medical students and physicians at different levels) in different learning scenarios (e.g. self-study, presentation, learning groups, tutorials, assessment). For medical students and physicians the improvement of the own problem- or case-solving competence is the main goal to achieve. With CAMPUS this competence can be trained by using the most realistic form of possible presentation forms. This form is simulative, meaning that the user can do about everything he wants to do (like in reality, e.g. anamnesis, physical and technical exam, lab tests) until he reaches a decision/feedback point, where he has to make diagnoses. Having made diagnoses the user gets feedback about the things he has done so far by giving a comparison between the things done by him with the things the author of the case thinks to be the right ones. At these decision/feedback points the user has to reflect his steps done so far. With the possibility to get knowledge on demand (expert comments, extern knowledge via extern digital libraries) the learner can be trained to become a knowledge manager, a competence becoming important in the medical field more and more.

CAMPUS is a system developed completely in Java using a detailed case-database. It can be used over the Web and locally (see http://www.medicase.de).

An Intelligent Tutoring System on the WWW Supporting Interactive Learning

Hassina Seridi-Bouchelaghem, Univ. of Badji Mokhtar Annaba Algeria, Algeria; Mokhtar Sellami, Univ. of Badji Mokhtar Annaba, Algeria

Web-based education is currently a hot research and development area. Thousands of Web-based courses and other educational applications have been made available on the Web, but the problem is that most of them are nothing more than a network of static hypertext pages. This paper describes the new features of an adaptive intelligent tutoring system (ITS) on the Web.

The architecture presented in this paper provides a protected learning environment to facilitate efficient learning to the students with adaptation of the learning environment to the learner's goal and capability. To produce this educational system, we distinguish three spaces:

- Adaptive navigation space to support the student's orientation and help them to find an "optimal path", with use of the case-based reasoning technique (CBR). We introduce the use of experiments which constitutes the keystone of this system of aid for learners.
- Adaptive collaboration space to use the system's knowledge about different users (stored in user models) to form a matching collaborating group. In our system, the learner is an actor of the course construction and not a consumer. The learner can do annotations on the course pages following the link included on all the pages where annotations are allowed. This, will be guide the adaptation of the collaboration between the tutor system and the learner or learner/learner or group with tutor.
- Adaptive information space to adapt the content of pages to the user's goals stored in the user model.

The architecture of our system will be presented and the implementation outlined.
Build It . . . But They May Not Come: Designing, Maintaining and Assessing a Successful University-Level, Instructional Technology Multimedia Center

Abstract: Internationally, Multimedia Centers (MMCs) are becoming critical for enhancing instructional technology in institutions of higher learning. This paper discusses concept development, policy, and assessment of a successful MMC at Radford University. The first question concerns specific objectives of a MMC - realistic goals should be sensitive to client-specific constraints. For example, faculty may face a lack of time or motivation, students may be generally unaware of benefits, and staff may lack support for continuing education. The second question concerns policy. At Radford University, for instance, types of services and accessibility were deemed critical factors for formulating policies. The third issue concerns assessment. We used measurables such as recurring, year-end monitoring of the number of workshops and participants, most-used hardware and software, downloads of class/workshop materials and so on. Previously mentioned data are presented within the context of size, staffing, cost and facilities of the MMC at Radford University.

Introduction

On campuses across the United States and in other countries, Multimedia Centers (MMCs) for instructional technology are increasingly taking center stage. Such MMCs are viewed as a critical component of a college or university’s infrastructure for meeting the instructional technology needs of faculty, students, and staff. In this paper we highlight some of the key issues that we have found to play a critical role in the eventual success or failure of such resource-intensive facilities. In addition to presenting a list of questions or planning areas, we shall also suggest possible solutions from our experience at Radford University that can be adapted by institutions for meeting their own needs.

We hope that such a sharing of ideas stemming from first-hand experiences with a successful multimedia center, such as the one at Radford University, will prove useful for other individuals involved with the design, maintenance, and assessment of similar education-oriented multimedia centers.

The Three Key Questions

This paper will focus on three primary and sequential areas pertaining to design, creation, and evaluation of MMCs in a college or a university setting: a) Articulating goals/objectives, b) Development and implementation of policies for use of the MMC, and c) Planning and implementing realistic assessment strategies.
I. Articulation of Goals/Objectives

The first step in building a successful MMC is developing a well thought out, realistic understanding and statement of goals of the center. What specific objectives does the institution hope to meet? Are those objectives compatible with the institution’s strategic planning statement or mission? Do the objectives cater to each of the different stakeholders in the institution, such as faculty, staff, students, and public?

Goals for a MMC can only be achieved with a clear understanding of potential impediments faced by the different types of clients (Albright and Graf, 1992, Lamb, 1992, Rivard, 2000). For example, it may be important to recognize that faculty may find it difficult to use such a facility due to either a lack of time, or lack of incentive, or even a lack of awareness of potential benefits of such facilities in their teaching and research. Similarly, students may be unaware of resources available at a MMC or be ignorant of the benefits of mastering multimedia instructional technology both as a student and after graduation. Lastly, staff may face an unenthusiastic technology climate at their workplace coupled with a general lack of support for continuing education opportunities that a MMC may present.

II. Design and implementation of policy

The success of any MMC hinges on its set of policies that should be based on these key questions:

a) What is the size range of our intended audience?
b) What types of services will the MMC provide for faculty, staff and students?
c) How accessible will the MMC be for members of the home institution, and where should the center be located?
d) Who will provide training, consulting or development?
e) Will the MMC be a training facility where faculty are taught how to use specific software and/or hardware or can faculty reasonable expect the MMC staff to do their project work for them?
f) Will there be any charge for select or all services?

III. Planning and implementation of realistic assessment strategies

Assessment is key to long-term viability and efficiency of any MMC (see Millar, 2001). Assessment, however, must be conducted on a day-to-day basis as well as over an extended time frame (for example each semester or academic year). With rapidly changing and evolving technology products and shifting foci of user needs, the importance of comprehensive assessment for overall efficiency of a MMC cannot be overstated. Assessment feedback can allow for a rapid response to enhance and fine-tune types of services provided by a MMC. Such data can also help in making more accurate assumptions about user profiles. Lastly, assessment data are indispensable in most, if not all, successful efforts for procuring additional funding for a MMC.

Profile of a Successful MMC: Case Study from Radford University, Virginia, U.S.A.

The following section describes some of the key features of the Radford University-Multimedia Center (RU-MMC) that we found to be particularly important in the overall success of the Center. Prior to listing such points, we feel that any such profile must be presented within the context of resources available. Obviously the determination of success for a MMC will likely be based on differing criteria for a public four-year college with 4,000 students and a annual budget of ten million dollars versus a public four-year college with 25,000 students and a annual budget of seventy million dollars.

The RU-MMC serves a university with approximately 8,500 students and is located in a separate section of the Library. It consists of one main lab/classroom and two sets of offices for staff. It was launched in 1999 and the total cost for the initial set-up of the MMC (excluding space and utilities) was approximately...
as follows (in U.S. dollars): $30,000 for equipment, $10,000 for software, $100,000 for a staff of one director and four expert instructors. The RU-MMC consists of a total of six high-speed graphics stations (each equipped with a flat-bed scanner, CD press/burner and speakers), two video-editing stations for state-of-the-art, non-linear, all-digital editing, one high-end slide scanner station and one 96-channel, digital-audio recording station.

RU-MMC: Articulation of Goals/Objective

The key to designing any multimedia center is using the resources available to find a balance between supplying individual and curriculum enhancement and fulfilling the overall institutional strategic plan for technology. In order to accommodate both audiences at Radford University, the RU-MMC goal is to “Raise the level of technology usage on the RU campus. For students so that they might have a better understanding of the state of technology in their fields of study. For Staff that they might be more effective in their work environment. For Faculty to allow for professional development as their fields progress through the information/computer age.”

In the case of the RU-MMC, impediments in the way of reaching specific goals were determined to be

a) Experience of clients
b) Time required for learning advanced technology
c) Time available away from work/classes
d) Attracting each of the different audiences (faculty, students, and staff).

An action plan was implemented that effectively addressed each of the aforementioned impediments. The plan mostly revolved around the clients' needs and was set in a positive attitude so that any newcomer to technology would feel at ease with the instruction. Clients with different experiences are likely to create different levels of knowledge of technology on any campus. To accommodate these varying levels, the MMC staff conducts (on an ongoing basis) a careful assessment of clients who enter the Multimedia Center and then makes appropriate recommendations depending on the client's understanding of the material. Time concern for each audience is also addressed. The result of the assessment provided the impetus for the following actions:

- A total of thirty-five, compact, 2-4 hour, workshops are offered at varying times throughout each month by seasoned professionals in the fields of multimedia.
- An information-based website has been implemented that provides calendars, downloadable class notes, presentations, illustrations, examples and "How to" movies.
- Monthly publications of new and interesting events surrounding the Multimedia Center are printed.
- Monthly printed calendars are distributed throughout the Radford University community.

Each type of audience (faculty, staff and students) needed specific marketing plans to attract them to the new center. Collaborative efforts between multimedia center staff and faculty allow faculty to incorporate technology into the curriculum without spending excessive time learning the material. The faculty member learns the technology as the MMC staff teaches each course. In order to attract staff more readily, the benefits for technology training are presented to supervisors who then incorporated training allocation into each job description. Students are introduced to the Multimedia Center through a series of tours arranged through faculty who teach multimedia-related subjects such as graphics, administrative systems, media studies, music and sciences.

RU-MMC: Design and implementation of policy

Specifically, the creation of policies for the RU-MMC was guided by three key points: Types of services, Accessibility, Flexibility to constantly monitor and respond to shifting needs of the client base. Types of services included

1) One-on-one expert project development/training help solely by appointment
2) Classes/workshops conducted at varying times and of varying lengths and that were in high demand (5-20 registrants)
3) Collaboration with faculty to design custom classes that would incorporate instructional technology into
their current curriculum thereby immediately empowering and impacting their students.

Policy pertaining to accessibility issue was primarily guided by the MMC's need to maximize usage as defined by at least 100 hours/week; the RU-MMC was housed within the library so that it would represent a neutral, non-departmental facility and would be secure and staffed 100% of the time.

Policies concerning use of the RU-MMC consisted of the following guidelines:

a) That the RU-MMC be a facility for educational and research/professional (non-commercial), instructional technology-based multimedia projects,
b) That the RU-MMC be accessible by any member of the RU campus community,
c) That all classes, workshops, consultations be free of charge for all users, and
d) That the RU-MMC staff help be used exclusively for training and consultation purposes, and not for creation and completion of individual user projects.

**RU-MMC: Planning and implementation of realistic assessment strategies**

A variety of assessment measures were utilized. The first step involved was to create a resource-rich web site highlighting the activities and resources available at the RU-MMC as shown in Figure 1. In addition, use of specific software and hardware was monitored via an online database as shown in Figure 2. Lastly, semester-end and year-end summation of data thus collected provided meaningful statistics that represented activity in all key areas of the RU-MMC operation including workshops, individual consulting and online utilization of the MMC resources and products.

![Figure 1: A screen-capture image of the main web-site screen for the Radford University Multimedia Center.](image)

Examples of measured parameters measured for the first year of operation of the RU-MMC included:

- total number of training workshops
- average number of participants in a workshop
c) total number of users over a semester or academic year
d) most and least-used software and hardware
e) number of downloads of class/course/workshop materials
f) total number of 'hits' for the different web-accessible sections of the RU-MMC web-site
g) percentage breakdown of users in terms of faculty, staff and students, and so on.

Figure 2: A screen-capture image of the online data screen used for monitoring use of specific software and hardware facilities at the Radford University Multimedia Center.

In the case of the RU-MMC, the following data were collected between May 3, 1999 and May 2, 2000 representing one year of service. The first year, Radford University's Multimedia Center saw a total of 1015 patrons with nearly 3000 visits making nearly 2000 repeat visits. The center operated for 318 days or 3589 hours and provided over 5000 hours of personnel service. The average number of visits per day was 9 with an average stay of 2 hours. The number of workshops offered was 128 in the first year while the number of hours of instruction was 226. Workshop attendance for the year was 1161 or 11% of the university population.

Analysis of data (as shown in Table 1) shows that hardware associated with the Analog Video Editing station was clearly the most utilized, closely followed by the HP ScanJet scanners, and the Philips CD-RW drives. In terms of usage of software (usage instances), Adobe Photoshop was the most used software (530 usage instances) at the RU-MMC followed by Adobe Premiere (411) and Microsoft PowerPoint (367).

</tbody>
</table>
Table 1: Data for usage of the different hardware facilities at the Radford University Multimedia Center for the first year of operation (1999-2000).

It is notable that preliminary analysis of data collected for the Spring, 2000 semester (the MMC’s second year) revealed an overall 2% increase in the number of workshops and tours given (in comparison to the period between Summer 1999 and Fall 1999). The Multimedia Center also saw an 11% increase in instructional time, and a 47% increase in the number of patrons served. The number of repeat visits per patron rose from 1.5 to 2, with the average patron making a total of three visits over the course of the academic year.

Conclusion

In summary, this Multimedia Center has accomplished its goal of raising the level of technology expertise on the campus. It is likely, however, that many other multimedia centers around the world may not have seen such attendance and support from its patrons and administration. Empty chairs are a clear indication of failure on some level. The advice we offer is to follow the guidelines of this paper in the design, policy creation and assessment for your particular multimedia infrastructure. We also suggest you do something else.

➢ Design your multimedia center to be part of the entire university community. At Radford University, the Multimedia Center has supported every single department, college and office in some way. The administration admires this distribution of resources.
➢ Hire a dynamic staff that has professional standing. This will give your center the credibility it deserves.
➢ Finally, insist on an attitude of true ‘service provider’ by the staff. A good helpful attitude by the staff will increase learning by the technologically faint of heart and ensure repeat visitors.

Abstract: In recent years, several CD-ROM-based, instructional technology applications have been developed for use in both high school and college-level classrooms. As multimedia authoring techniques evolve as important tools for teaching, it is imperative that teachers and multimedia authors understand the importance of focusing on specifically how the CD-ROM product will be used. The concept, functionality and type of user-interface of such applications must be driven by a clear understanding of the specific manner(s) in which they are intended for use. In this paper we present a comparative study of two different types of CD-ROMs in terms of their design and use. Both CD-ROMs were recently produced for use at the college level. The “EarthShow” CD-ROM is intended for use as a ‘presentation manager’ whereby a teacher can seamlessly integrate images, audio, video and animation for communicating information in a sensory-saturated manner. On the other hand, the “Groundwater Pollution” CD-ROM is a self-study tool, characterized by ‘situation-based learning’ with practice and feedback features and designed for use by a learner on an individual, unsupervised basis.

Introduction

In recent years a significant number of educational multimedia applications have been created for use both at the high-school and college levels (Wheeless-Gore, 1997, Williams et al. 1997, Sethi, 1998). In particular, educators have become increasingly sensitive to the diversity of learner styles among students and therefore have sought ways to communicate content more effectively (Gardner, 1983, 1993, Lazear, 1991, Armstrong, 1994, Herrington and Oliver, 1997, Butler and Lamberson, 1998). A number of both web-based and stand-alone CD-ROM-based multimedia applications have been produced for use in the teaching/learning of geoscience subjects (Prothero, 1996, Steele et al., 1997, Powell, 2000). Several teaching/learning modules have been created specifically for use in General Education courses (such as for first-year, non-science major students); examples include the work by Levine, 1998, and Saini-Eidukat et al. 1998. Examples of multimedia applications for teaching specifically the upper-level geology courses include the work of Rigsby, 1998, and Sharma and Hardcastle, 1999. In addition, attention is being directed towards making such multimedia material accessible for students with disabilities (Grogger, 1999).

Often however, there seem to be disconcerting gaps between design and actual manner/mode of use of such applications across a variety of teaching and learning environments. Such discordance in the design and creation process invariably leads to failure and/or low success rates of otherwise robust educational applications. It becomes imperative, therefore, that the entire design and development process of a multimedia teaching/learning tool be tempered by sensitivity to the manner(s) in which it is intended for use.

In this paper, we present a comparative analysis of two rather different multimedia CD-ROMs, both
of which were designed for use by students in the introductory-level geoscience courses in college. One of the CD-ROMs, titled *EarthShow* was designed wholly as a "presentation manager" intended for use by an instructor in a group setting and all aspects of the design and functionality of this CD-ROM are in coherence with its intended use. The second CD-ROM, titled *Groundwater Quality Issues for the Future Decision-Maker*, is a one-on-one, situation-based, learning application that is firmly rooted in recent models of multiple intelligence types (sensu Gardner, 1983) in learners. In addition, a strong emphasis is placed on determination of learner outcomes via practice sessions and feedback opportunities to help assess success or failure of a specific interactive learning session.

This paper will focus on two issues: 1) the importance of rooting interactive, multimedia applications on established models of learner styles and learning psychology, and 2) a presentation and analysis of some of the key interactive, multimedia screens from both of the aforementioned CD-ROMs.

**Models of Learning Styles as a Basis for Designing Multimedia Applications**

Howard Gardner’s revolutionary work on recognizing multiple intelligence types in learners (Gardner, 1983, 1993) can provide for a logical and a firm footing for design and use of interactive, multimedia applications. Insofar as Gardner’s multiple intelligence (MI) theory highlights a total of eight basic intelligence types in learners, it forces teachers to ask a fundamental question: “Is my teaching style reaching out to the diversity of intelligences in the classroom?” Another relevant question that needs to be answered is, “Is my teaching strategy/technique/tool most effective in catering to different learner styles in my students or is there a better way?” An interactive, multimedia application such as on a CD-ROM or on the internet represents a very powerful medium for delivery of information. Content can be communicated as a variety of sensory stimuli, including images, sounds, video clips, animations and interactive feedback. Advances in processor speeds and storage capacities of digital media including CD-ROMs have enabled teachers to store and access information of different types such as graphics, sounds, and text, from a single platform such as the internet, CD-ROMs, or DVD-ROMs. In other words, once a teacher has digitized and stored any combination of images, audio files, video clips and animation files on a web site, CD-ROM, or a DVD-ROM, he/she no longer has to worry about having access to outdated audio-visual devices such as slide projectors, laser-disc players, tape players, and/or video cassette players. A single CD-ROM, for instance, can be accessed in real-time, for sharing information in a truly multimedia and a seamless, interactive format thereby engaging most, if not all students in a learning environment.

Ongoing results of our assessment concerning the effectiveness of such media-intensive, interactive teaching/learning CD-ROMs show that on average, students respond better to use of such delivery methods. It is likely, therefore, that increasing numbers of educators will adopt and adapt such multimedia tools for communication of content both in and out of classrooms in the near future and in a variety of disciplines.

The other significant issue centers on the need for all multimedia authors to clarify the exact manner in which a particular multimedia application will be used be it in a classroom setting or on an individual, self-study basis. In this paper we discuss a variety of pedagogical features that have been built into the design and functionality of the two CD-ROMs for teaching and learning physical geology and environmental geology. It is hoped that sharing of the design strategies and of examples of types of use will provide a model for other teachers seeking to find examples for adaptation for creation of multimedia applications for teaching their own specific disciplines.

**The Earth-Show CD-ROM**

The EarthShow CD-ROM was designed for use as a presentation manager for introductory-level courses in physical geology and earth science. This CD-ROM was designed via story-boards at the Department of Geology at Radford University. Creation, testing and publishing were done by a reputed publishing company (Prentice Hall) in 2000. This CD-ROM was developed to accompany a specific physical geology text (*Foundations of Earth Science* by Lutgens and Tarbuck, 2000). Illustrations and images contained in the textbook and the CD-ROM were closely tied together. The CD-ROM chapters followed the same sequence of information as was presented in the textbook. Such a relationship was deemed critical in
helping students feel that the CD-ROM was a natural extension or a supplement of their specific textbook.

In terms of use, the EarthShow CD-ROM is designed for a lucid, seamless, fast access and presentation of a variety of media for teaching and learning physical geology. In addition to quick and non-internet dependent access to images, videos, sounds and text, a number of pedagogical strategies were utilized in the CD-ROM. The following section explains some of the key design features of this CD-ROM.

The Main Screen consists of a total of seventeen hyper-linked buttons in addition to buttons for actions/events such as Quit, Help, Sound level, Back by One Screen, and Forward by One Screen. A user can choose and explore any of the seventeen chapters by simply clicking on the appropriate button. Each chapter’s opener screen consists of a variety of multimedia features that are kept consistent in all chapters. For example, The Slide Show feature appears on the opening screen of each of the seventeen chapters. A user can click on the slide show icon to view the slide show. A slide show consists of a series of aesthetic and content-oriented images that are set to a contemporary, unobtrusive sound track. The user can set the volume of sound via an easily accessible icon on each screen. Images in a slide show are derived from both the accompanying text and other sources so that students have the choice of studying images that are from outside the text but relevant to the text.

Each of the seventeen chapters also have an Image Viewer integrated into each one of them. Most text entries have small, quick-loading thumbnail images that can be accessed easily for reinforcement of content. Some text entries have several images linked to them, and users have the option of viewing some or all of the images at their own pace via buttons on the screen. Each image is accompanied by a detailed caption that ties the visual content with textual content of the chapter. A key assessment feature of this CD-ROM is the Self-Quiz that accompanies each chapter. A user can study an image, diagram, or any type of an illustration and try to identify labels or other text-based information that are shown as blank spaces (as exemplified in Figure 1).

![Figure 1: Illustration of a self-quiz screen from the chapter on rocks. A user has to think about the terms contained in the blank rectangular fields. The user can find out the correct answer by simply moving the cursor over a blank label as shown for the first blank field towards the middle of this screen (Olivine being the correct answer for that field).](image)

To find the correct answer, a user simply moves the mouse over a blank field and the answer pops up in the field. The programmed answer disappears as soon as the mouse is moved away from the label. Figure 1 shows an example of such a Self-Quiz feature. From an authoring/programming perspective, such a blanks-based quiz can be constructed to cover almost any kind of subject matter. For example, applications of such self-assessment can easily be imagined for disciplines as diverse as architecture, biology, anatomy, chemistry and geography among others. In addition, such assessment techniques can lend themselves elegantly to a
variety of situation-based learning and training settings, ranging from a primer on identifying parts of an aircraft's cockpit to the components of a PCB (printed circuit board) in a computer manufacturing plant and so on.

The Groundwater Pollution CD-ROM

The groundwater pollution CD-ROM, Groundwater Quality Issues for the Future Decision-Maker, is intended for individual use by college freshmen enrolled in environmental geology or environmental science classes. Although a number of educators have integrated aspects of pollution in the introductory-level geology courses for non-science majors, there are distinct voids that need filling. For example, there is a clear lack of educational materials for college students that specifically address groundwater pollution. The goal of this CD-ROM is to educate and help non-science majors make choices as decision-making adults that will protect groundwater. Relevance to all students is a key to this application. The work of this project is based on two respected educational theories, multiple intelligences theory (Gardner, 1983), and the ARCS theory of motivation (Keller, 1987).

The CD-ROM is a simulation of a conversation with a groundwater hydrologist who answers the student's questions about groundwater pollution issues. Students are placed in their own hypothetical futures as homeowners who use groundwater for drinking water. The information on the CD-ROM is divided into seven sections. Two introductory sections, Groundwater Basics and Lab Reports, help students understand background information for all groundwater pollution issues. Five separate issues, Landfills, Septic Systems, Underground Storage Tanks, Fertilizers and Pesticides, and Karst Aquifers, are covered in the CD-ROM. In each of the seven sections, students are prompted to ask specific, relevant questions about the lesson and about the subject matter. For example, the student may choose among the following questions from the landfills screen:

- What are the objectives of this section?
- What are landfills?
- What safeguards prevent groundwater pollution from landfills?
- What pollutants come from landfills and what are their health effects?
- What can I do to prevent groundwater pollution from landfills?
- What is my responsibility for groundwater pollution from landfills?

Educational theorists (Dick and Carey, 1996, for example) tell us that students need opportunities to practice new knowledge. They also tell us that students should review new skills and knowledge and transfer the knowledge to a new situation before leaving the learning experience. Therefore, students using the CD-ROM have two additional choices on each subject matter home screen:

- I want to practice.
- I want a coffee break to review and transfer.

Practice questions are clearly based on the learning objectives for the section. Multiple choice or short answer questions cover each objective. On multiple choice questions (Figure 2), students click the button beside the answer they choose. A bell or buzzer indicates whether their answer is correct. Then students can move their mouse over a button labeled "WHY" for an explanation of the correct answer. On short answer questions, students type their answers on a blank. When they have finished typing their answer, they move their mouse over a button labeled "CHECK" to compare their answer with the correct answer. Students can go through the practice as many times as they wish.

In the coffee break, students are encouraged to take a break from the CD-ROM to review their new skills and knowledge. Students are given a bulleted list of things to think about as they review. Then, students are encouraged to consider the groundwater pollution issue they just studied in a new perspective. For example, in the landfill section, students are asked to imagine that they are on the town council of a town whose landfill is filling up. "What will you have to consider about the people who drink groundwater and live near sites you propose?" the groundwater hydrologist asks. As shown in Figure 3, multimedia components are incorporated into the information presentation sections of the CD-ROM. Text, photographs, diagrams, videos, animations, and sounds are used to illustrate concepts in each section.
Figure 2: This screen is an example of a practice question from the Lab Reports section of the CD-ROM.

Figure 3: This screen from the septic systems section of the CD-ROM uses text, a diagram and photograph combined, and an illustration. The video button links to an animation showing how the septic system works.

Conclusion

It is our hope that sharing of such educational CD-ROM products will provide focus for other instructional technology users in their own multimedia projects. We also strongly feel the need to share work that has already been done so that the collective body of multimedia authors may continue moving forwards and charting new ground instead of expending efforts in re-inventing the wheel. Lastly we hope that insights into our multimedia design strategies and finished CD-ROMs empower other Earth Science educators in schools and colleges both within the United States and other nations to explore the feasibility of creating similar technologically advanced and pedagogically sound, customized teaching tools for use in their own classrooms.

Abstract: This paper presents an innovative, multimedia CD-ROM recently created for supplementing microscope work associated with teaching/learning Optical Mineralogy at the college/university level. State-of-the-art multimedia authoring and curriculum design techniques were used to create a CD-ROM based on recent learning models involving multiple intelligences and learner styles. This brief paper highlights specific objectives that we wanted our CD-ROM to help accomplish. In addition, we present the key steps employed in the successful design and creation of this educational CD-ROM. It is hypothesized that use of such a CD-ROM by students in a laboratory setting will allow students to – 1) engage more closely with the subject matter due to its 'sensory-saturated', audio-visual format, 2) spend 'more time on task' outside of the classroom via use of the CD-ROM, 3) become comfortable with using such CD-ROM data bases, and 4) demonstrate enhanced understanding of the subject matter via improved scores on controlled tests.

Introduction and objectives
Optical Mineralogy involves the study of optical properties of rock-forming minerals in very thin slices that allow light to be transmitted through them. Courses pertaining to Optical Mineralogy are a key component of most undergraduate geology degree programs in the U.S. and abroad. In such courses, students routinely spend a significant amount of time learning to recognize optical properties and diagnostic features of a variety of common, rock-forming minerals with a petrologic microscope. Often students consult textbooks containing images of minerals in thin sections for reference. However, full-color textbooks containing high-resolution images of such minerals tend to be prohibitively expensive and therefore of limited use.

Modern imaging techniques and advances in multimedia authoring software, however, can provide for an easy and affordable solution to the aforementioned problem of lack of adequate and appropriate reference images for students investigating optical properties of minerals. This brief paper highlights some of the key design and user-interface features of a recently-created interactive, multimedia CD-ROM for use specifically in Optical Mineralogy laboratories across the world. The following two sections explain the specific objectives of this CD-ROM project and key steps involved in creation of this educational CD-ROM.

Specifically the CD-ROM was designed to allow college-level students in a Optical Mineralogy laboratory setting to
- Readily access mineralogical information in the form of over 300 high-resolution, microphotographs in a non-linear fashion for a total of thirty commonly-occurring minerals
- Study several different examples of specific minerals so that students can get accustomed to the ‘natural variety’ in which such minerals occur,
- Easily access a total of sixty digitized video-clips of rotating mineral thin sections to understand natural variation in optical properties of a crystal in different optic orientations,
- Use hyper-linked buttons to aid pronunciation of phonetically-difficult mineralogical names and terms, and
- Easily navigate to screens containing information pertaining to mineral chemistry, classification, occurrence and diagnostic optical properties.

Key steps employed for creation of the CD-ROM

In the following section we highlight the methods we used so that other workers may use such information as a model to facilitate their own projects. Briefly, the steps included -
- Selection of a total of thirty thin sections of minerals for microphotography, microvideography, digitization and editing,
- Microscope, camera, hardware and software calibrations (color, contrast, saturation and intensity of light). Microphotography, microvideography, scanning and digitization, digital editing and integration of .jpg, .avi, and .wav files into ‘Power Point’ screens,
- Design and creation of the interactive, multimedia CD-ROM user-interface including elements of - title screen, table of contents, table of technical specifications (for microphotography and microvideography), navigation buttons, screens for photographs and video clips of minerals in thin section, and interactive testing or Q&A screens,
- Microphotography minerals in thin section with a high-resolution camera attached to a petrographic microscope. Each mineral was photographed in two types of light (‘plane polarized’ and ‘cross polarized’),
- Scanning, digitization, and digital editing of the microphotographs and integration of the image (jpeg) files thus created into PowerPoint screens,
- Paint Shop Pro – TM software was used to screen capture all of the PowerPoint screens. Captured screens were then integrated into PODIUM-TM files and hyper-linked buttons and icons were then created to infuse interactivity into the over 300 + screens,
- The completed CD-ROM was then tested and de-bugged. In addition, the finished CD-ROM was configured so that it would run smoothly on a variety of CPU speeds and with a variety of Windows-based Operating Systems.
The Relationship Between Performance in a Virtual Course and Thinking Styles, Gender, and ICT Experience

Abstract: This study examines the relationship between students' performance in a virtual course and three factors: thinking style, gender, and prior experience in ICT. The dependent variables were: use of communication channels (e-mail, bulletin boards, forums, and surveys); scholastic performance (grades, successful Web searches, and completion of assignments), and the students' attitudes and level of satisfaction. Independent variables included six of the student's thinking styles (according to Sternberg's classification): Global, Local, External, Liberal and Conservative, gender, and prior experience in ICT. Participants were 110 eighth and ninth graders who were enrolled in a virtual course. The findings show considerable individual differences in student performance and attitude. Learners with the "liberal" thinking style clearly outperformed the other students in the course. Prior experience with ICT affected the virtual learning, while gender, did not. The results suggest that though virtual courses provide opportunities for all learners, such opportunities may be greater for some learners than for others.

Keywords: Thinking styles, virtual course

Introduction

The Internet's penetration of our lives and of both formal and informal education has created a need to examine the various aspects of this new way of learning and to explore how it fits in with different learners' needs. Which students can be expected to function better in this new learning environment? To what extent is this environment accessible to students with particular styles of thinking, and compatible with their needs? Can one predict success in a virtual course on the basis of students' thinking styles or other characteristics? Our study attempts to shed light on these questions, which take on even greater significance given the increasing computerization of schools throughout the world and their connection to the Internet.

In many schools, the World Wide Web serves as an instrument for teaching and learning, be it in classroom activities, research projects, or virtual courses (Mioduser & Nachmias, 2001). A virtual course is a Web-based learning environment in which communication occurs by means of computers. Such courses make use of the Web and its many resources to create a meaningful educational environment that facilitates and supports learning. Typically, a virtual course consists of on-line classes in which elements such as hypertext, graphics, audio, video, and animation are supported by a graphic interface that is easy to use and helps arouse interest. This Web-based environment offers access to a wide variety of resources, including libraries, museums, archives, and databases. In most cases, a virtual course employs two types of media: asynchronous, such as class bulletin boards, forums that promote cooperative learning, and electronic mail for correspondence among teachers, students, content experts, and fellow Internet users; and synchronous, such as text-based chat rooms and video conference calls, which enable students who are separated geographically to engage in discussions and brainstorming. The various media support active, independent learning at an individual pace, as well as cooperation among students, between the student and teacher, among teachers, and between the class and other communities (Khan, 1997; Saltzberg & Polison, 1996; Sherry, 2000). Thus, models of Internet-related instruction and learning emphasize challenging activities that provide students with relevant learning experiences, promote cultural awareness, and foster information-gathering skills. Students take responsibility for the processes of learning and teaching, largely as a result of opportunities provided by computers and telecommunications. With the Internet, students have access to up-to-date information; join virtual communities; and navigate through sites as they follow links. These features offered by the Web facilitate the
acquisition of higher-level—analytical and critical—thinking skills and take the students from the curricular objectives to active learning environments (Mintz & Nachmias, 1998; Salant 1999).

Virtual courses have the potential to provide new solutions to the constant search for teaching tools that will address the needs of different kinds of students. These needs derive from the differences in the way people acquire knowledge, formulate ideas, feel, and behave—in other words, differences in their "style" (Gild & Garger, 1985). A "style" is a way of thinking. It is not an ability; it is the preferred way of using the abilities that one has. Thinking styles do not fall in the domain of either abilities or personality traits but, rather, in the area of interface between them (Sternberg, 1997; Riding, 1997). Each of us has not one thinking style but a profile of styles. Although we "prefer" certain styles, we are not locked into any single one, as the thinking style is likely to change according to the task and the situation. An awareness of thinking styles can help people better understand why certain activities are appropriate for them and others are not and, consequently, why one person is suited to a particular activity whereas another person is not.

Researchers have proposed a variety of theories about thinking and learning styles, all of which attempt to describe how people think and learn. In the classroom, these theories are important in terms of the teacher, the student, and the institution. Almost without exception, the way in which a person teaches tends to be most effective for students whose thinking style is similar to that person's. Moreover, teachers are more likely to value students whose learning and thinking styles resemble their own (Sternberg & Grigorenko, 1995). Maoz and Barley (1992) observed that the use of teaching methods that were compatible with the individual learning styles of the students raised their levels of achievement and improved their self-confidence. Through various approaches to learning and thinking, educators are now actively engaged in attempting to understand and identify individual differences, and the knowledge that is accumulating will constitute a significant new tool for teachers and schools.

A virtual course is appropriate for different kinds of students because of its flexibility, its ability to handle various kinds of information, its collaborative value, and the high degree of control that it gives students over their own learning process. Quintana (1996), offers examples of features of the Internet that are suitable to different styles of learning. So, for example, images, three-dimensional models such as those created through Virtual Reality Modeling Language (VRML), are compatible with visual and spatial styles. The transmission of audio and video sequences is appropriate for students with musical and auditory styles, and use of electronic mail and forums is suitable to students with interpersonal communication style.

Various models exist for virtual courses. One example is a course in which students study completely independently, in their own free time, and all interactions with peers and the on-line instructor take place by means of telecommunications. In contrast, our study concerns a virtual course that is conducted in a classroom setting with a live teacher; in addition, students communicate with another teacher via the computer.

**The goal of the study**

This study seeks to determine whether a relationship might exist between students' performance in a virtual course and the students' thinking styles, gender, and prior experience with information and communications technology (ICT).
Method

This section describes the variables that were examined in the study, the subjects who participated, and the procedure that was followed.

Variables

The students' performance is represented by the dependent variables, which fall into three categories:

- **Use of asynchronous communication channels**—the extent to which students communicated with the on-line teacher via electronic mail and participated in bulletin boards, forums, and surveys. Each instance of such use was documented, and then all the instances were tallied.

- **Scholastic performance**—grades, successful Web searches, and completion of assignments as instructed. By "successful Web searches" we refer to the number of sites that a student found that satisfied the needs of the assignment.

- **Attitudes and satisfaction**—the students' attitudes toward studying in a virtual course and their level of satisfaction from this course. We ascertained the students' attitudes from the answers that they provided in questionnaires. The students were asked whether they prefer virtual courses or traditional instructional media; whether they would be willing to study with an on-line instructor only, in the absence of a classroom teacher; whether they felt the virtual course enabled them to study at their own pace; and whether they were satisfied with and enjoyed the course.

The independent variables consist of thinking style, gender, and prior experience with ICT.

The term *thinking style* is described by Sternberg (1997) in reference to his theory of mental self-government. The types of thinking styles that our study examines are as follows:

- **Global**: Prefers to deal with relatively large, abstract issues
- **Local**: Likes concrete problems that involve working with details
- **Internal**: Is concerned with inner worlds, task oriented, and prefers to work alone
- **External**: Tends to be extroverted, people-oriented, and outgoing
- **Liberal**: Likes to go beyond existing rules and procedures, to maximize change, and to seek out situations that are somewhat ambiguous
- **Conservative**: Prefers to keep to existing rules and procedures, to refrain from change, and to avoid ambiguous situations where possible

Subjects and procedure

The subjects consisted of eighth- and ninth-grade students (N=110) in two Israeli schools that are part of the ORT network, a group of schools that specialize in technology and science. One school is in the Tel Aviv metropolitan area, and the other, in a city in the southern part of the country. The students took a virtual course on the retrieval and use of on-line information, a course given by Aviv, a virtual school based in Israel (see Aviv's Web site, in Hebrew, at http://aviv.org.il/info/home.htm). Conducted in the students' own school computer laboratory, the course consisted of 12 weekly sessions of two hours each. Two teachers were involved—one in the classroom and one who communicated with the students by means of the computer. In this paper, we refer to the latter as the "virtual" teacher.

During the course, we monitored and recorded student participation in interactive, asynchronous communication (electronic mail, bulletin boards, and forums) and observed three randomly chosen class sessions. Toward the end of the course, the students filled in three questionnaires, whose objectives were, respectively, to obtain relevant personal information, to ascertain the students' thinking styles (Sternberg, 1997), and to gauge how the students performed in the course, their attitudes, and the degree of their satisfaction. In addition, we interviewed the teacher and held a discussion with the classes to find out more about the students' attitudes toward studying in a virtual course, their level of interest, and the aspects of the course that they considered positive and negative. When the students finished the course, we recorded their grades. Quantitative methods were used to analyze the data.

Results
Table 1 presents the degrees of correlation between the students' performance in the virtual course and their thinking styles, gender, and prior experience with ICT.

As seen in the table, performance in the virtual course is positively correlated with a number of thinking styles, some of which show a stronger correlation than others. The liberal style is correlated with seven of the eleven variables, whereas the conservative style is correlated with none. A greater correlation with performance is demonstrated by the internal style (four variables) than the external style (two), and, similarly, the local style shows a stronger correlation with performance than the global style (three variables as opposed to one). Prior ICT experience is found to be correlated with seven of the variables. The table indicates that the r values of the correlations are low, and no correlation exists at all between the students' gender and any of the variables.

Discussion

Students with the liberal thinking style clearly outperformed the other students in the study. We can also see that students with the external style performed better than those with the internal style, and, similarly, students whose learning style is local functioned better in the course than those whose style is global. These results suggest that virtual education can provide opportunities for different kinds of learners, though such opportunities may be greater for some kinds of learners than for others. Students with a liberal thinking style might well become active users of asynchronous communication channels, while students whose thinking styles are global, local, internal, or external are likely to perform well in tasks related to searching for information and integrating various pieces of information in their work.

The students who completed the course most successfully (as measured by their grades) were those who had prior experience in ICT. The amount of experience is correlated with almost all the aspects of performance that the study examined. Similarly, these students were the most active users of asynchronous communication
channels (bulletin boards, forums, and electronic mail), which constitute a major component of virtual courses. In general, the degree to which the subjects of the study used asynchronous communication was smaller than expected. Gender in this study was not found to explain student performance. This finding is encouraging but is in a contradiction with other studies that find significant differences between boys and girls (Nachmias, Mioduser, & Shemla, 2001).

Conclusions and Implications

Our research suggests that virtual education can provide a learning environment that is compatible with a wide range of personalities and needs, and hence such courses would be appropriate for the general school population. By assessing students' thinking styles, educators may be able to predict which students can be expected to perform better in virtual courses. McIsaac and Gunwardena (1996), have found that some combination of thinking style, personality characteristics, and self-expectations can be predictors of success in distance education programs. Those students who are most successful in distance-learning situations tend to be independent and prefer to control their own learning situations. Furthermore, the results of our study indicate that schools should provide training in computer literacy and computer-based communications to improve the students' chances for success in an on-line learning environment.

The planning and development of virtual courses will necessarily benefit from investigations of students' behavior, their learning patterns, and the degree to which they are suited to virtual education. Similarly, the various technological options for constructing such learning environments should be examined. Such research will enable educators to exercise an informed use of technology; to apply this knowledge to the development of tools that will enhance the teaching and learning processes; and to offer virtual courses that conform to the needs of the broadest range of students.

Inspiration and Drawing: a Computer-based Learning Package in Drawing

Robin Shaw, TLTP3 Project: Seeing Drawing, The London Institute, United Kingdom.

r.shaw@linst.ac.uk

Abstract: In the manipulation of images and in the creation of art, lecturers and students in Art Schools have possibly formed the most expert group of computer users, but have made little use of computers for teaching and learning. In art few facts need to be absorbed. What is important is creativity and the development of ideas. There are few right answers. So many artists and lecturers feel that while the computer is a great tool, it has no place in the complex interaction between tutor and student. That's the challenge which has faced a consortium of British art schools led by the London Institute. The consortium has completed an interactive multimedia learning package on drawing. The product, on DVD, approaches drawing from many different angles covering the range from measured drawing to fine art and departs from traditional modes of navigation and the usual attributes of learning technology.

With a grant from the United Kingdom Higher Education Funding Council of $500,000 and matching funds to give a budget of around $1,200,000 a consortium of art schools and universities led by the London Institute has completed a three year project to create an interactive multimedia learning package on drawing. The package seeks to enrich the student's experience in the area of drawing and make a significant contribution to art education.

There has always been a healthy scepticism as to whether computers have anything to contribute to teaching and learning in art schools. This contrasts with the situation in other areas of HE where computer assisted learning has been seen as ideal in many courses. The computer encourages independent self-paced work and can be used to pose questions and provide often quite sophisticated feedback to the student. In art the emphasis is less on facts, the needs of the student are individual, and the assessment of the students is through a piece of work demonstrating creativity and the development of ideas.

In 1995-96 almost 5% of students in UKHE were in art and design. If related subjects with a clear interest in drawing such as architecture, and engineering and technology, are included the total rose to almost 16%. The growth in HE student numbers and in the diversity of their nature has placed continuing strain on teaching resources, not least in the teaching of drawing.

The approach adopted by the London Institute and its partners in the Falmouth College of Arts, Ravensbourne College of Design and Communication and the Universities of Ulster and Brighton has been to emphasise the richness of the subject. In the program the importance of how to see, how to interpret and how to innovate is paramount and due weight is given to the theoretical, philosophical and contextual elements. The package explores the different approaches to drawing of artists working in areas such as graphic design, fashion, product design, architecture, ceramics, advertising and fine art.

There is a considerable body of evidence that in order for learning to take place effectively on the computer, the user has to be involved in tasks where decisions have to be made. The finished package is now ready for distribution on a platform-independent DVD available to UKHE at cost.

Since the project was probably the largest investment ever in learning technology in art it posed a considerable challenge. The product does not supplant the traditional relationship between staff and student but makes a

2 Students in Higher Education Institutions 1995-96 Higher Education Statistics Agency July 1997

significant contribution to the richness of the learning environment in the area of drawing. The focus remains on traditional drawing tools while promoting the new approaches to drawing possible with technology. It aims to improve the ability to utilise software applications for three-dimensional modeling and to enhance the teaching of formal drawing systems such as projection and perspective. Much of the development work in the DVD is very innovative and challenging to the user. The product moves away from traditional modes of navigation and the usual attributes of learning technology.

The proposed presentation will discuss the issues underlying the use of computers for teaching and learning in art and design and demonstrate the finished product.
Time Versus Utility: What IT Staff Say About the Educational Use of the Web

judy.sheard@csse.monash.edu.au

Abstract: This paper reports on a quantitative and qualitative study that investigated the impact of the provision of Web-based teaching resources within the Faculty of Information Technology of Monash University. It presents staff perceptions of the time and effort required in development and maintenance of Web-based teaching resources and any perceived advantages. The study found that the production and maintenance of Web resources, with the necessary acquisition of the required skills, has significantly impacted on staff workloads. Many staff were spending considerable time on the development and maintenance of Web resources for their students, often providing these in addition to the traditional paper resources. Some staff were enthusiastic about the use of the Web in their teaching, however most described benefits in terms of subject management rather than from a pedagogical perspective.

Keywords
World Wide Web, teaching resources, teaching and learning environments, tertiary teaching

Introduction

In the last decade the tertiary teaching scene has changed dramatically. Economic pressures have forced universities to look beyond their traditional markets. This has led to the expansion of the universities globally and the emergence of multiple campuses, necessitating different methods of course delivery. University lecturers have had to adapt their courses to teach in a variety of modes such as distance education and video conferencing, in addition to the traditional face-to-face method. The adoption of World Wide Web (Web) technology by the tertiary institutions has facilitated many of these changes, providing effective ways for widespread delivery and access of course information (Barnard 1997; Hansen, Deshpande & Murugasen 1999; McDonald & Postle 1999).

The use of the Web in tertiary institutions has seen many advantages to students. The Web enables the development of new and exciting integrated learning environments. Subjects may now be enhanced by the addition of Web-based resources that provide support for self-managed learning, and contain interactive elements that encourage student engagement in learning (Cornell 1999, Oliver). In many subjects, students are now typically provided with Web-based resources that they have the flexibility of accessing on or off campus, and at any time (Owston 1997; Ward & Newlands 1998). These electronic resources either replace, or are in addition to, the traditional paper resources. However, the time and effort required to provide Web resources are a cost to the staff involved in subject development and management (Bruce & Desloge 1999). The Web is a new and unfamiliar teaching environment for many tertiary lecturers. Web-based teaching resources are time consuming to design and develop, often requiring ongoing maintenance. Many resources need a knowledge of programming for their construction. Staff have had to acquire new skills to produce effective teaching resources on the Web, and make appropriate use of this new technology (Alexander 1995; Hansen et al. 1999).

Therefore, a question of interest is “What are the costs and benefits of the provision of Web-based teaching resources?”, and related to this, “What motivates staff to use the Web in their teaching programs?”. This paper reports on a quantitative and qualitative study that investigated the use of the Web in teaching within the Faculty of Information Technology (FIT) of Monash University. It presents staff perceptions of the time and
effort required in development and maintenance of Web-based teaching resources and any perceived advantages, either pedagogical or for subject management. FIT, with over 200 academic staff, is the largest faculty of its kind in Australia. We have made the assumption that an IT faculty incorporating Web technology in its course curricula would show significant use of the Web in its teaching programs. This has provided an opportunity to study issues in the development of Web-based teaching resources with a group of teaching staff who have made a commitment to the use of Web technology in their teaching.

Survey of Teaching Staff

All subject lecturers in FIT were invited to participate in a survey that aimed to establish the extent to which the Web was being used in teaching within FIT, and their perceptions of its impact. Each lecturer was asked to complete one questionnaire for each subject they had responsibility for. This contained questions to determine what resources were provided for a subject and what percentage of each resource was provided in Web-based format. The survey also contained questions to establish the time taken to develop Web resources, the average time spent each week maintaining Web resources, and who (e.g. self, subject staff, external person or group) were responsible for these tasks. Provision was made on the questionnaires for staff to provide open-ended comments.

Over 180 surveys were distributed to subject lecturers and a total of 93 completed questionnaires were returned. A corresponding survey was given to students in selected subjects in FIT in order to gauge how they valued the Web resources provided and how important they felt they were for their learning. The results of these surveys are reported in detail elsewhere (Sheard, Postema & Markham 1999).

Provision of the Web Teaching Environment

The survey showed that teaching staff in FIT are making extensive use of the Web in their teaching programs. Of the questionnaires returned, 86% of the subjects had a dedicated Web page. This finding is supported by an audit of subject Web pages during the same semester, which located Web pages for 80% of the subjects in the Faculty. Staff of the remaining 14% of subjects in the survey, which did not provide Web resources, indicated in their responses that this was a deliberate decision. The reasons they gave were that they did not wish to make resources freely available, the students did not have ready access to the Web, or it was not worth the effort as the subject was terminating.

In forty percent of the subjects, all resources were provided in Web format and in most subjects (82.5%) at least half of the resources were provide in Web format. Many of these resources were also provided on paper. For more than one third of the subjects in the survey, all the Web resources were new. The most common resources provided on the Web were the functional resources of lecture notes, subject updates, and subject information and these resources formed the basis of most of the Web sites.

Seventy percent of the subject Web pages were designed, developed, and maintained by the subject lecturer and for a further 20%, these responsibilities were shared by a small group of subject staff. They are consequently individual, reflecting the variety of teaching styles and content of subjects in the FIT. This is in line with the Monash University Education Policy which recognises that for effective teaching and learning “it is important for universities to maintain a sense of diversity (in education) ... allowing room for individual perspectives and randa & Pinto 1996).

Seventy seven percent of the Web pages were updated at least weekly with the most common practice being to update once a week. However, in the extreme cases, one lecturer updated subject Web resources daily and eight Web sites were not updated at all during semester.

There were large variations in the times spent on developing and maintaining subject Web resources. Cornell found similar variations in his study of university teaching staff in 1998 (Cornell 1999). A couple of lecturers indicated that they spent up to 200 hours before semester on initial development and another lecturer spent an average of 28 hours per week during semester maintaining subject Web resources. These were however
extraordinary cases and the average times were much lower. Over all the subjects in the survey, an average of 15 hours were spent at the beginning of semester setting up the Web page and resources. A further 2.0 hours per week were spent on maintaining existing resources or adding new resources during the semester. However for subjects which provided most resources on the Web an average of 20.6 hours were spent setting up the Web page and resources and an average of 3.7 hours per week were spent on maintenance and additions.

There are a number of factors that help explain the large variations in the initial development and ongoing maintenance times for Web resources.

- **Different management strategies for Web resources.** Some lecturers set up all or most of their Web resources before the beginning of semester, while others developed their Web sites as the semester progressed and therefore spent more time on ongoing development throughout the semester. This dynamic style of subject delivery has the advantage of flexibility and adaptability as discussed by Arnold (Arnold 1997). Ten percent of the subjects in the survey had Web pages that were never updated during the semester, but most (78.7%) were updated at least weekly.

- **The proportion of new Web resources.** The development and maintenance times increased as the proportion of new resources increased. Over 90% of the subjects in the survey had new Web resources and in 36.3% of subjects all the Web resources were new. Added to this the Web is a changing environment with new features and improvements to Web technology constantly being developed (Owston 1997).

- **The types of resources.** Web resources range from direct conversions of paper resources that take very little time to produce, to those that require many hours of work in design and development, e.g., animations. Web resources may be provided as static items that are never updated, e.g., a subject handbook, or a series of static items that are developed as the semester progresses, e.g., a set of lecture notes or tutorial exercises which are provided for classes each week. Alternately, Web resources may be dynamic items that are intended to be modified or developed over the semester e.g. subject updates. Some require regular updating such as feedback or newsgroups.

**The Staff Voice**

In the written responses on the open-ended section of the survey questionnaires, staff generally discussed their own use and management of the Web for their teaching. Their comments focused on the types of Web resources they provided for their students and the time and effort that was involved, rather than presenting pedagogical perspectives of the use of the Web for their teaching. The issues involved in the technology implementation rather than the impact on students is a common theme in current literature, as noted by Windschitl (Windschitl 1998).

Many lecturers were very positive about the practical advantages of using the Web for their subjects. They saw the Web as an effective and efficient system for distributing course material and information to students.

"(The Web) saves an enormous amount of paper, saves time queuing at photocopying machines, improves "reach" to students, enables quick publication of "hot news" items or error corrections, stimulates email contact from students to tutors and myself..."

By placing teaching resources on the Web, some lecturers are shifting the responsibility for obtaining these resources over to their students. This was highlighted as a saving in time because of the reduced amount of printing and photocopying needed. The amount of paper distributed to students is also reduced, although there is evidence from student surveys that resources provided electronically are often downloaded and printed by students anyway, producing no net saving in paper as found by Jones (Jones 1999).

The use of the Web as a distribution centre for course materials is not always popular with students. This agrees with the findings of an experiment by Ward & Newlands (Ward & Newlands 1998). There was evidence from the staff surveys that many lecturers, often in reaction to student requests, were providing students with paper copies of resources available on the Web.
"My lecture notes are all up on the Web I give the students paper copies as well, they demand this!"

Resources placed on the Web are instantly accessible by every student on or off campus. Many lecturers saw this as one of the main advantages of providing resources on the Web. However intellectual property protection was an issue with a couple of lecturers who expressed concern about the security of the Web, and the fact that their Web resources were freely available to students in other courses and the outside world.

"I think it is a wonderful idea to have Web-based resources available to students. But I would prefer to make the resources available only to students enrolled in the course"

The Web has made possible the provision of new types of learning environments for students. Some lecturers appear to be using the Web to facilitate a move towards a distance education style of teaching as discussed by Miranda (Miranda & Pinto 1996). One lecturer had actually moved all class-based tutorials for his subject into a forum on the Web.

"This semester I moved all formal tutorials onto the Web allowing occasional lecture times as needed. The response was great. Part timers and those with language problems fully participated in active debate. No more discussion-based format tutes for me!"

Other lecturers took a negative view of this style of teaching, expressing their opinions that the Web should not be used as a substitute for face-to-face teaching.

"Having one integrated teaching environment is convenient for students however there is a danger that they may become reliant on this totally for their learning, not experiencing lectures and tutorial classes, contact with other students or exploring other sources of information such as libraries."

The trend towards putting most subject resources on the Web was seen by some lecturers to be giving students unintended messages. A couple had experienced problems with students not attending lectures because they decided that all they needed was available to them on the Web.

"Drop in attendance at lectures since introduction of Web page...difficult to teach students who you do not see"

The Web provides facilities for instant contact and communication with students however this often results in less personal contact. Some lecturers expressed concern about the Web encouraging a remoteness from students and they were not able to easily monitor how their students were progressing through their subject. There are mechanisms to measure how often and how many accesses are made to Web pages however this does not provide the same quality of information as personal contact with students.

A typical subject Web page in this survey contained at least basic functional subject information, subject updates and lecture notes. The Web pages ranged from basic repositories of passive information, to totally integrated Web environments including interactive learning elements. Many lecturers commented about the amount of work required to produce and maintain Web resources, and especially the effort required to produce well designed and effective Web-based teaching resources, as also discussed in other studies (Gillani 1998; Ward & Newlands 1998). Typical comments were:

"Putting all the resources on the Web required a significant effort, which I think is usually underestimated..."

"They take a huge amount of time to do properly"

"No effort toward standardisation of subject Web pages is being made, 'n' subjects -> 'n' styles of Web pages"

The lack of skill in working in a Web environment and not being able to produce good quality resources was a concern to some lecturers, as also found by Ward (Ward & Newlands 1998). There were a variety of tools used to produce Web resources, ranging from writing HTML using basic text editors through to WYSIWYG editors.

"...time constraints on exploiting the potential of the Web; lack of support for more ambitious use of the Web"

"Difficult getting some resources into computer format..."
One lecturer expressed disappointment about the variation in standard of subject Web resources in FIT:

"There is a very wide range of quality in respect of subject resources. Some of the Faculty's are innovative which reflects in a high standard of teaching materials being delivered over the Web. In other cases it is almost embarrassing to think that it appears under the Monash logo."

The surveys revealed that some lecturers were providing Web resources for reasons other than subject management or pedagogical considerations. Some lecturers indicated that they felt obliged to provide resources on the Web because of pressure from students or other colleagues. With 86% of the subjects in FIT providing a Web page, there are indications that students now have an expectation that Web resources will be provided for them in each subject they study.

"Students are expecting to find information in all of the following ways with a high expectation of instant satisfaction of need, with constant pressure to provided up-to-date resources at all times for immediate student gratification; lectures, printed lecture notes, tutorial, printed tutorial notes, Web page, anonymous discussion, email, help desk. Time spent by staff on subject is extensive."

There were few comments from lecturers about the benefits to students of providing Web resources, and these were expressed only in terms of convenience, availability, and accessibility of resources.

"From the informal feedback from students, it appears that students find it very useful to have a specific Web page for each subject which stores all relevant information and resources"

"...very convenient for those students who do not come to the lectures, for announcements outside the lecture hours, and for correcting mistakes found in the course material and providing solutions to homework"

"Extensive use made (by students) of on-line materials at numerous sites"

The lecturers' responses to the open ended section of the survey showed their perspectives of the costs and benefits of the use of the Web in teaching. These comments focussed around issues of developing and managing the teaching environment. None of the lecturers who responded to the surveys mentioned the value of the Web for student learning. They remarked on the students' demand for Web resources and how much they were using them, but none indicated the possibility that this enthusiasm may then translate into a greater engagement in their learning.

Conclusion

The Web has transformed the tertiary teaching environment. This study of the use of the Web by lecturers within the Faculty of Information Technology indicated that there is a trend for most lecturers in the Faculty to provide a dedicated subject Web page for their students. The Web pages range from static pages with basic functional resources to totally integrated interactive learning environments. The production and maintenance of Web resources, with the necessary acquisition of the required skills, has significantly impacted on staff workloads. The survey revealed that many lecturers are spending considerable time each semester on the development and maintenance of Web resources for their students, often providing these resources in addition to the traditional paper resources. However, the survey also showed that most of the time was spent on the initial development of resources, and the ongoing maintenance times were considerably lower. It was a considerable saving in time to reuse Web resources.

The responses from the questionnaires indicated that many staff were enthusiastic about the advantages of using the Web in teaching. However most viewed the Web as an efficient and effective means of distributing resources to students rather than providing pedagogical benefits. A number of lecturers had developed or were in the process of developing engaging integrated Web-based teaching environments that were valued by their students, but to many others the Web was seen as a convenient facility to provide students with instant and
ready access to subject information. Some lecturers indicated that they were producing Web resources because of students' expectations rather than any perceived teaching or learning benefits. Several lecturers expressed concerns about observed changes in student learning behaviour since the introduction of Web-based teaching resources in their subjects. An impressionistic view is that the provision of resources on the Web has encouraged students to disengage from face-to-face learning in subjects that were not designed or intended to be taught in that way.

The Web has changed the practices of tertiary educators. The Web enables the provision of new learning environments with a greater variety of teaching resources. The development and management of these resources is an added cost to the staff in time, effort, and acquisition of the variety of new skills necessary. With the widespread use of the Web in tertiary education, students now have an expectation that Web resources will be provided for them in every subject. This raises the issue of what the learning outcomes of the provision of these resources are. The question of the benefit for students considering the extra cost for staff remains unanswered. This is a critical issue for educators involved in the long-term design and management of Web based learning environments.

Issues in the Management of Information Technology in Changing Educational Organizations

Sheppard Wade, Centre for Distance Learning and Innovation, Canada; Stevens Ken and Dibbon David, Centre for TeleLearning and Rural Education, Memorial Univ. of Newfoundland, Canada.

The development of Internet-based technologies and the choice these provide of synchronous and asynchronous teaching and learning is changing educational organizations.

The first part of the presentation considers issues in the management of information and communication technologies for teaching and learning in the context of a shift from distance education to telelearning. A significant feature of this change in the management of Canadian education is the emergence of new teaching and learning structures - digital intranets, and, within these, virtual classes.

The presentation will explore issues in the management of effective teaching and learning in these new educational environments. Successful integration of information and communication technologies for tele-teaching students is in part dependent on the transition from closed to open teaching and learning environments.

The challenge of Internet-based teaching and learning environments for schools includes a need for collaborative professional development and new approaches to the nature and location of leadership.
EVA: Collaborative Distributed Learning Environment Based in Agents

Abstract: In this paper, a Web-based learning environment developed within the project called Virtual Learning Spaces (EVA, in Spanish) is presented. The environment is composed of knowledge, collaboration, consulting, experimentation and personal spaces as a collection of agents and conventional software components working over the knowledge domains. All user interfaces are Web pages, generated dynamically by servlets and agents. Each EVA host has an agent associated with it, which can establish links with the other EVA hosts forming shared knowledge and collaboration space of a distributed EVA learning environment. The article focuses on the description of the system architecture, implementation of software modules, and the application results.

Introduction

The technological innovations on the one hand, and the growing popularity and availability of Internet on the other, are the main reasons of development in the last years of numerous applications and investigation projects in the field of technology-mediated education (Youngblut, 1994; O'Malley, 1995; Hamouda & Tan, 2000). The virtual teaching, integrating computer and communication technologies in different educational scenarios, is advocated as a solution to the problem of exponential growth of knowledge in the contemporary society (Collis, 1999). As a matter of fact, information technologies offer exciting opportunities to thoroughly redesign the education process and to achieve, among others, the following benefits: integration of means (text, audio, animation and videotape), interactivity, access to big quantities of information, plans and individualized work rhythms and immediate answer to the apprentice's progress.

However, the introduction of the technologies in the real education environment is a difficult problem. Therefore, the intense search of new pedagogic solutions and teaching/learning technologies is a time challenge, where the advanced information technologies play the main role. The EVA (Espacios Virtuales de Aprendizaje in Spanish - Virtual Learning Spaces) project is dedicated to the development and implementation of a Distributed Learning Environment (DLE), personalized and collaborative, by means of which different academic and administrative activities can be offered in a distance manner to the students of different institutions and public and private companies (Nuñez et al., 1998; EVA, 2000).

EVA is a learning paradigm that considers different forms of acquiring, transmitting and exchanging knowledge among people and work groups that don't usually have physical access to the conventional sources of knowledge: books, magazines, schools, universities, laboratories, libraries, good professors, etc. EVA constitutes a conception of the education that uses advanced information technologies like, for instance: JAVA servlets and applets, Multiagent Systems (MAS), Groupware, Multimedia and Virtual Reality (VR). The EVA system is also composed of a number of authoring tools for virtual teaching and learning according to the EVA methodology. The main two authoring systems are: visual environment for the development of Multibooks, ELVA - an auxiliary tool facilitating the development of learning materials; and a CASE tool for the development of VR...
worlds with complex behaviour of their components: EASYVRML facilitating the development of virtual laboratories and simulations in VR. (Quintero, Armenta, Balladares & Nuñez, 1998).

The EVA philosophy is congruent with the existing classroom practice: mainly aims at learning goals and outcomes that are already embedded in traditional curricula, do not neglect the use of conventional learning materials, and can usually be plugged into existing curricula with minimal change to course plans. It benefits from explicit representation of the topics that students investigate, but it doesn't need to be omniscient. Further, since EVA does not attempt to tutor, it is free of obligations to model students' cognition and to make complex pedagogical decisions. In the rest of the article, the architecture of EVA environment, implementation of software using Java servlets and agents, and the application results are considered.

EVA architecture

The conceptual architecture of EVA is structured into the four essential learning elements, called Virtual Learning Spaces. These spaces are: knowledge - all the necessary information to learn, collaboration - real and virtual companions that get together to learn, consulting - the teachers or tutors (also real and virtual), who give the right direction for learning and consult doubts, and experimentation - the practical work of the students in virtual environment to obtain practical knowledge and abilities. These four spaces are complemented with the personal space where user-related information is accumulated. These spaces are supported by a number of tools developed using different information technologies (fig. 1).

The knowledge space is composed of a set of "Multi-books" (or POLiLibro, in Spanish), personalized electronic books, generated by concatenating selected Units of Learning Material (ULM) along the learning trajectory for each knowledge domain. Planning of learning trajectory for students who navigate in EVA (they are called EVAnauts) in discretized knowledge space allows a student to establish her own route and learning rhythm, according to her scientific and professional interests, to the time and resources at her disposal, making possible to combine her more immediate requirements with the long term objectives.

The systems of virtual education traditionally use the client-server architecture since it is the basic principle of operation of the Web: a user (client) by means of a browser requests a service (pages HTML, etc.) from a computer that serves as a server. Usually, in the DLE each user has a personal account at the corresponding DLE server, which makes it impossible to share similar learning activities with students and tutors subscribed to another DLE servers, even in the case they use the same environment. EVA, also using the client/server architecture, tries to solve this problem making use of agent technology (see the next section for details).

The EVA environment is installed on the servers which we call EVA nodes. It is formed by the HTML pages, Java programs (Applets and Servlets), a number of MAS and a database (Sheremetov & Nuñez, 1999a; Peredo, Armenta & Sheremetov, 1999). To customize the learning spaces for each user, we have adopted the technology of dynamic page and link generation and interactive pages using servlets, applets and agents (fig. 2). For the client's request, a servlet communicates with the database by means of the SQL (Structured Query Language) and generates the answer as an HTML page in the client's navigator. The servlets, being programmed in Java operate with controller JDBC (Java Dates Base Connectivity) to access databases. Since the controller ODBC (Open Dates Base Connectivity) is used by Windows, a controller bridge between Java and ODBC is required, that allows the servlets to operate with the database. Java Web Server (JWS) or Apache Web Server are used to mount servlets, which so far constitute the concept of virtual classroom and virtual laboratory providing flexible mechanism to communicate with the database manager that manipulates the entire page related information. EVA user interface generated by EVA servlets is shown in fig. 3.

At the current stage of our experiments, the EVA environment as it is configured in the CIC-IPN, makes use of a number of servers each playing different functional role. Server EVA uses Apache Web Server, installed in a ULTRA SUN 10 work station to host the static information of the system related with the educational material included in the Multibooks, the personal Web accounts of the professors and students and the security system. It serves as a gateway to the rest of the system. Server HERA is the main server of the EVA environment. It also makes use of Apache Web server and is dedicated to the generation of dynamic pages and transmitting them via http to the client machine. The server is a PC computer with microprocessor Pentium III Dual at 500 MHz. The database for the operation of the system is installed in this server. Finally, server AGENTES uses a JWS server installed in a PC computer with microprocessor Pentium III Dual at 500 MHz. It serves to store the information related with the videoconferences and video-on-demand, as well as to host platforms for the MAS of different purposes.
Actually, the architecture described above is not that fixed. Each node of EVA controls the corresponding knowledge domain. It means that all the information about the ULMs pertaining to it is stored in the database. So each ULM, which forms the content of Multi-books may have its own location specified by the URL in the database, and there is no need to have all the materials on the main server (EVA, for example). Sure, knowledge domains are interrelated between them, so usually to study in EVA means to study Multibooks pertaining to different domains. In other words, the distributed model of the knowledge space is needed, which integrates these parts into the common knowledge space. It is done by means of the use of domain agents carrying out trajectory planning functions. In the same way, the MAS of the personal assistance permits to generate groups of students with common interests physically connected to different EVA nodes.

At the current stage of our experiments, the architecture illustrated in fig. 4 is used. This figure shows an excerpt from the model actually implemented in the IPN creating groups of users from different colleges having similar study plans. Each client uses a Web navigator to communicate with his EVA server (where he is registered). However, his personal assistant agent establish communication with the personal assistants of his working group (possibly registered to other servers) and, if needed, with the domain planning agents to create virtual distributed learning space for each particular user. The next section explains it in more details.
Multi-agent Systems in EVA

As it was already mentioned, while implementing EVA, we have detected several problems of the traditional client-server architecture that impel the search of new solutions in the organization of environments of distributed software and the software for the Internet. One of these technologies of recent creation is the technology of agents, which seems to be a promising way to approach the problem of DLE development. The notion of agents is the central part of contemporary learning environments, where they act as virtual tutors, virtual students or learning companions, virtual personal assistants that help students to learn, mine information, manage and schedule their learning activities (Müller, Wooldridge & Jennings, 1997; Chan, 1996; Gordon, & Hall, 1998). One of the main purposes of our project is to develop models, architectures and multi-agent environment for collaborative learning and experimentation.

The core of the EVA environment consists of a number of components, composed of a set of deliberative and auxiliary agents, forming three multiagent systems: a virtual learning community, a multiagent planning system and a multiagent virtual space of cooperative experimentation. For details of these MAS implementation see (Sheremetov & Núñez, 1999a, Sheremetov & Núñez, 1999b). In the learning spaces, students and tutors receive help from their Personal Assistants. Personal assistants (PA) is a class of intelligent agents that act semi-autonomously on behalf of a user, modeling his interests and providing services to the user or other PA's that require it. PA has the following functions, implemented as plug-ins of the PA's kernel (fig. 5):

- Implements environment for collaborative problem solving. Helps tutors, coordinating collaborative activities. It can give privileges in the acceptance of the contributions, define the problem to discuss, among others. Helps students, regulating their participation in the discussion, showing coordination messages, etc.
- Implements a News system for the communication between students and professors.
- Implements a system of Electronic Agenda where all the information on the student's activities is stored.
- Implements the structured Chat tool with the possibility of the users' connection registered in different EVA environments.

In the Collaboration Space, our prototype of learning community incorporates also a Group Monitor agent. Agents have mental states represented in terms of beliefs, knowledge, commitments, with their behaviour specified by rules. A Group Monitor Agent maintains the shared knowledge model of a group and compares it with a group problem model from the knowledge base that contains the objectives, concepts, activities, etc. that characterize a group. His behavior is guided by a set of domain independent conversation rules, which refers to the interactions between the group members. During the group session, the monitor agent maintains the current problem state (shared group knowledge space) and the history record of all contributions for each participant. The problem state in terms of shared beliefs and knowledge is used to change the interaction mode, choosing one of monitoring techniques from his rule base. This result in changing behavior of learning companion from group leader (strong companion) through a week companion to a passive observer. User interface of this collaborative environment is shown in Fig. 6.

Personal assistant is implemented as Java Application and can be loaded in any computer with Java support and Internet connection. With this, we can say that each user will have a PA agent according to the social role that plays in the cooperative environment, as a tutor or a student. The personal data for each user are stored in EVA's database, so, when being invoked, his PA will already have a previous knowledge about the person to whom it assists and of the social role that he plays in the environment. Two types of utility Agents are also used in this MAS, a Broker Agent (or Directory Facilitator) and a Wrapper Agent. The first of them is considered a service facilitator, since for any Assistant (Professor or Student) it will look for the services provided by other agents and other assistants. Wrapper Agent can be defined as DB service provider, because it administers the EVA database with the purpose of consulting and it's modification in an explicit way (fig. 5). All the agents use Knowledge Query and Manipulation Language (KQML) for communication.

Prototypes of agents have been developed using Microsoft VC++, LALO, JAVA, and JATLite with rule-based inference capabilities, programmed in Jess (Friedman-Hill, 1998; JATLite, 1998). Personal Assistant and Planning agents are Java applications implemented with Swing package of the JDK 1.2 development environment and with the integration of a Java component for the creation of JATLiteBean agents.
Current experiments and conclusions

At the moment of writing, the first version of EVA is in the implementation and testing phase. The following results have been obtained since it was launched:
1. In the fall semester of 1998, the EVA environment was first used to impart the seminar of Software Agents in the CIC. The server was accessed by near 20 students from the PC's of the LAN of the CIC and from remote computers from the periphery of Mexico City, from an approximate distance of 50 miles. Since then, the EVA environment and the Multibooks have been used by the professors of the CIC as an additional didactic support in the Postgraduate courses in Computer Sciences.
2. Started in October, 1999, the first international course in EVA called "The digital documentation in means of social communication" was imparted twice, jointly by the Center of Training of Educational Television (CETE) of the General Direction of Educational Television of Mexico and the Complutense University of Madrid, with the participation of students from Mexico, Colombia, Argentina and the Dominican Republic.
3. Also in October, 1999, under the supervision of the Coordination of Academic Computation of the IPN, the development of the institutional project "Installation of the model and system EVA (virtual spaces of learning) in the IPN" has begun. This project has as objective to support the educational modernization of the IPN, taking advantage of the methodology and the EVA software environment, within the framework of the Program on Educational Technology for Academic Innovation. The EVA environment is installed at the servers of diverse schools and colleges of the IPN, as, for example, UPIICSA, CECyT Wilfrido Massieu, CECyT 6, which serve as nodes in the training network and in developing of the corresponding Multibooks.
4. Starting in October 2000, the Virtual Master's Degree Program in Computer Science using EVA as a platform of distance education for the students from the system that integrates about one hundred of Technological Institutes in Mexico has also begun. Only 50 students have been admitted for the first stage of this experiment after presenting their admittance exams in EVA. Four Technology Institutes were selected through Mexico as regional sites, where EVA nodes have been installed enabling 4-nodes distributed Virtual Postgraduate Department.

We have also begun to work on the digital library of the CIC and the National Library of Science and Technology (BNCT) of the IPN that will allow to have an interactive portal of the BCNT that takes advantage of all the benefits of the ATM network using an EVA-like middleware written in Java. The digital library will be integrated into the current version of EVA environment which is under development to enable the creation of a virtual campus EVA-IPN.

Our experiments to-date have demonstrated the high flexibility for the EVA MAS system as well as the interoperability with non-agent software modules. We have also detected some difficulties while working with the proposed architecture. For example, all the agents and protocols must exist (be active or able to be initialized automatically) for a service to be provided. Also, working with different databases, we have detected some
problems when accessing them with JDBC drivers on WindowsNT platform. Nevertheless, our expectation is that as the set of agents grows, the development will be easier.

The work on virtual learning community, composed of learning companions and personal learning assistants is in process. We have developed a number of prototypes but a lot of work is still to be done to convert them into a real DLE.

Acknowledgements

The EVA project is the effort of many people. The author would particularly like to thank his colleagues and students of the Agents Laboratory for their determination and contribution of ideas and talent to EVA programming. This work was supported in part by REDII CONACyT and CEPI IPN.

Distance-Collaborative Design: An Approach to the Design of Children's Electronic Textbooks

Norshuhada Shiratuddin, Univ. of Strathclyde, UK; Monica Landoni, Univ. of Strathclyde, UK

This paper describes a design approach, called Distance-Collaborative Design (DCD) which is used in the process of designing Malaysian children's electronic textbook (e-book) interface. Distance users are employed as design partners in order to elicit user requirements with users who live far apart from where the e-book is being developed. DCD has three major phases: initiation, construction and implementation. Initiation involves seven steps: identifying existing problems with teaching-learning materials, develop ideas to solve the problems, report on the rationale of choosing the idea, identify possible solutions, plan new system, develop conceptual model of new system and plan general requirements of the new system. Construction is iterative and consists of at least three mini-projects. Each iteration contains all the usual system development life cycle of analysis, design, development and evaluation and it tackles a small objective beginning with first objective to assess users' perceived usefulness of system concept. Firstly, however, this paper explains the concept of the e-book, whose design is based on a model which allows content to be presented by mixing graphic page mode, talking page mode, hypermedia page mode and web page mode. Each mode includes various activities which support and nurture as many children's intelligences and learning styles as possible.
Designing Children’s Electronic Textbooks With Distance Partners

Abstract: This paper describes a design approach, called Distance-Collaborative Design (DCD) which is used in the process of designing Malaysian children’s electronic textbook (e-book) interface. Distance users are employed as design partners in order to elicit user requirements with users who live far apart from where the e-book is being developed. DCD has three major phases: initiation, construction and implementation. Initiation involves seven steps: identifying existing problems with teaching-learning materials, develop ideas to solve the problems, report on the rationale of choosing the idea, identify possible solutions, plan new system, develop conceptual model of new system and plan general requirements of the new system. Construction is iterative and consists of at least three mini-projects. Each iteration contains all the usual system development life cycle of analysis, design, development and evaluation and it tackles a small objective beginning with first objective to assess users’ perceived usefulness of system concept. Firstly, however, this paper explains the concept of the e-book, whose design is based on a model which allows content to be presented by mixing graphic page mode, talking page mode, hypermedia page mode and web page mode. Each mode includes various activities which support and nurture as many children’s intelligences and learning styles as possible.

Distance-Collaborative Design Approach
A prototype of a children’s electronic book (e-book) is under development. This e-book is designed based on Howard Gardner’s Multiple Intelligence theory. According to him, children learn in at least seven different ways: verbal/linguistic, logical-mathematical, visual/spatial, bodily-kinesthetic, musical, interpersonal and intrapersonal. Each child could learn in any one of these ways or through a combination of several ways. Taking this into account, our e-book is defined in terms of structure and content presentation. The e-book structure is made up of at least three main sections: front section, main section, and back section. Main section can have as many chapters as required and in each chapter there are no limit to the number of required pages. However, in each page, the number of paragraphs for children textbooks is frequently less than five, with an average of three. Children textbooks also normally do not have foreword, preface, acknowledgement, dedication, list of tables, list of figures, footnote, reference, index, glossary or appendix. The content presentation components should be carefully designed. The types of activity in which the users will be involved play significant roles in the success of pedagogic design (Barker and Manji, 1991). With regard to this, the seemly activities, which should be included in the design of children e-book contents so as to meet the seven intelligences, include writing essays, play with word processors, reading, drawing and painting programs, sing along programs, listening to rhythms, puzzles, using email and chatting programs, creating notes on daily activities/on-line diary and etc. (for a more detail description on many other activities and their suitability for the seven intelligences refer to Norshuhada and Landoni, 2000). We group the above activities into four modes: graphic page, talking page, hypermedia page and web page. Each mode will have activities that support at least one learning style.

In the process of designing the above-described e-book, few design approaches were considered: traditional system development, user-centered design and participatory design (PD). PD or collaborative design is popularized for such reason that it involves users in all the design phases as testers, informants and design partners (Druin et al., 1999; Scaife and Rogers, 1999). In this project, we recognize the importance of involving users in the design phases, however since the prototype is developed for Malaysian schools (which is located far from Scotland where the project is run), where medium of instruction is Malay and whose culture is different from the western countries, we introduce an approach called Distance-Collaborative Design (DCD) whereby distance users are involved in the design process. In this approach, users (1 head teacher, 1 teacher, 2 children and 2 parents) who live in Malaysia are selected, as in any participatory design activity, major stakeholders should be represented. Communication is performed through the use of email, Internet (web site, chatting program) and telephone instead of face to face meetings. The head teacher and teacher are employed as informants and design partners to provide the content and verify the teaching strategies, as well as give feedback on interface design issues. Since the children in this project are young (aged 7-9) and we are aware of the extent they can be involved due to limitations on their knowledge and experience, we employed them as testers and informants rather than design partners. Their parents help them in the communication processes. The parents of the selected children are knowledgeable in computer system design as they themselves are working in system development environment. Thus they represent not only parents but also design experts and become informants and design partners. DCD has three major phases as shown in Figure 1.
The **first phase** (Initiation) involves seven steps in which the head teacher is involved in the first two. The seven steps are: identifying existing problems with teaching-learning materials, develop ideas to solve the problems, report on the rationale of choosing the idea, identify possible solutions, plan new system, develop conceptual model of new system and plan general requirements of the new system. The **second phase** (Construction) is iterative and consists of at least three mini-projects. We adopt this method from Uden and Dix (1999) and make modifications to fit our purposes. Each iteration contains all the usual system development life cycle of analysis, design, development and evaluation. Each iteration tackles a small objective beginning with first objective to assess users’ perceived usefulness of system concept. Then if the perceived usefulness of the system is reported to be high, construction process move to second level of mini project with the objective of refining the first mini project and testing other usability aspect of the system. Each iteration is completed with an evaluation to confirm that each mini project has met its objective. The iteration continues until the usability is reported to be high and system is ready to be implemented.

Since we are using Gardner’s theory as a guide to the development of our proposed children’s e-book, we first need to have evidence that our design idea is indeed useful in catering and nurturing children’s learning styles and well accepted by potential users (there is no point of proceeding to the next mini project construction if design idea is poorly accepted by users). It is widely suggested that as the functions and interface features of a new system are made, it is an ideal time to measure user assessments of a proposed system in order to get an early reading on its acceptability (Davis, 1989). Hence for this reason, our project concerns only with the first construction iteration (i.e. mini project 1). The construction phase of mini project 1 consists of six stages: create storyboard, design navigation structure, design system interface, develop content, produce media element (graphic, audio, animation and etc.), and evaluate users’ perceived usefulness of the e-book system. All these stages involve users in various ways. To start with, three interface design ideas are electronically posted to all partners and they are asked to make comments on the lay out of the e-book, placement of icons, choice of icon designs, metaphors used to described icons and size of icons. Second stage involves asking them to produce their own design ideas and each design is then posted to all partners to be commented. Finally, they are asked to choose, in their opinion, the best design. Most voted design is then selected as the system design. While children are involved as informants and testers mainly about icon metaphors and design, the head teacher and teacher propose content and instructional strategies.

**Conclusion**

Our investigation started from the observation that flexible electronic textbooks could play a crucial role in education. In particular they could allow to nurture and stimulate multiple intelligences in children. We have since then developed a Distance-Collaborative Design approach to allow us to produce prototypes suitable for our user needs.

Fractal geometry has changed our view of natural processes and geometric forms. The Guide is a software kit supporting a university course on this science. It contains an introductory electronic textbook, annotated list of publications, favorite Internet links and provides facilities to run programs. One program visualizes the mechanism of birth of classical and IFS fractals. A student can grow fractals by himself and explore their features by trying different generators and mappings. Another program demonstrates connection between the Mandelbrot and Julia sets. It has certain advantages over analogous programs and throws a bridge to nonlinear dynamics and chaos theory by showing different variants of behaviour inherent in underlying quadratic process. Particular attention has been given to the programmes that model natural processes and structures: aggregation, percolation, plants, landscapes, etc. To create the most complete educational software we would be pleased to collaborate with other specialists and enthusiasts.
Using Concept Mapping as an Interactive Learning Tool in Web-based Distance Education

Ann Marie Shortridge
Dale Bumpers College of Agriculture
University of Arkansas, Fayetteville
United States
ashorttr@uark.edu

Abstract: Issues and trends discussed in literature across a number of disciplines including distance education, instructional design science, sociology, human factors engineering, visual communications, and computer and information science indicate that there is a critical need for web-based courseware to be theoretically grounded and interactive. A thorough search for web-friendly, interactive, instructional techniques highlighted concept mapping as a possible solution. Therefore, the purpose of this study, was to explore the integration of concept mapping into web-based distance education courseware as a tool to increase interactivity and learning outcomes.

Introduction

The goal of this paper is to provide a possible model for achieving effective web-based instruction using concept mapping as an interactive learning tool. The model is the result of the author's work on a grant at The University of Arkansas, Fayetteville (UAF), that included the design, development and evaluation of two undergraduate web-based distance education courses. The model outlines a possible definition for interactivity called adequate dialogue and a description of how concept mapping successfully increased interactivity and learning outcomes based upon this definition. Course authors may decide to adopt the model as it is presented or choose other components that meet the criteria of adequate dialogue in order to achieve interactivity in their own web-based courses.

Defining Interactivity: A Synthesis of Perspectives

Since the design and development of technology-based learning environments is cross-disciplinary many different definitions exist for the term interactive. Therefore to begin this project, it was necessary to establish a possible definition for interactivity. Within this study, the definition of interactivity is taken from two sources: Moore’s (1990, 1996) theory of transactional distance and Laurillard’s (1993) discursive, adaptive, interactive and reflective conversational framework. Moore’s concept of transactional distance describes the nature of distance in all educational settings. Laurillard’s conversational framework elaborates on the character and complexity of academic learning, the roles of students and teachers in the learning process, and the strengths and weaknesses of various technological mediums as support mechanisms for those roles.

Briefly, Moore (1990, 1996) detailed three different types of interactions which he argued are essential to distance education: learner-instructor interactions, learner-content interactions, and learner-learner interactions. McIsaac and Gunawardena (1996), who discussed Moore’s theory at length, said that highly structured course content decreases the dialogue between students and instructors, whereas less structured course content increases that dialogue. Laurillard (1993) added depth to Moore’s theory by stating that all teachers must recognize the special character of academic knowledge while encouraging dialogue between the teacher and student that is discursive, adaptive, interactive and reflective. In addition to her conversational framework, Laurillard (1993) also provided a media comparison that detailed the strengths and weaknesses of various types of media as support mechanisms for the twelve steps of discourse responsibility she described.

Combined, Moore’s theory of transactional distance and Laurillard’s analysis of technological mediums provide a working framework for the concept of interactivity for this project and study which may be described as...
adequate dialogue. Adequate dialogue may be established by using instructional techniques or technologies that enhance the exchange of ideas/knowledge between instructors, students and media while fitting within Moore's theory of transactional distance, and fulfilling at least 8 of Laurillard's 12 conversational framework guidelines.

Concept Mapping: Increasing Interactivity & Learning Outcomes

A review of the WWW for available web-based distance education courses reveals that many of the university level courses currently offered on-line are limited because they are designed to mimic a traditional textbook and contain only one element of interactivity in the form of, a listserv, a thread discussion group, or email. Such courseware can provide only weak instruction and is best used to support the traditional classroom, as opposed to providing good distance education. The integration of concept mapping exercises into a web based learning environment (made up of the components listed above) can dramatically re-create that environment by providing an mechanism within the course interface which extends and supports adequate dialogue.

Concept maps graphically illustrate relationships between ideas and greatly aid students in the process of restructuring their own knowledge and/or expanding their own conceptual understanding. Within a concept map, two or more concepts are linked by words that describe their relationship. A concept is "a perceived regularity in events or objects or records, designated by a label" (Novak & Wandersee, 1990, p. 29). For example, "free fall is due to gravity" could be described with a concept map containing two ideas, free fall and gravity (which both appear in symbols), and three linking words, "is due to".

The Results of the Research Stage UAF Study

The results of the research stage of the UAF grant project revealed that the integration of concept mapping into web-based distance education provided effective web-based instruction. Twenty-one students volunteered to contribute to the UAF study by completing pre- and post-content knowledge concept mapping exercises; 6 students were chosen to participate in the nominal group interview process based upon their pre-content knowledge concept mapping exercise performance. Triangulation of all of the data gathered indicated that the integration of concept mapping into web-based distance education courseware created more opportunities for students to learn by establishing adequate dialogue. The pre- and post-content concept mapping score data revealed that participating student knowledge of poultry physiology increased during interaction with the physiology test module. The nominal group interview data clarified how concept mapping impacted interactivity and the learning process.

Abstract: This paper presents a discussion on mentoring strategies in an online learning environment. Material has been culled from numerous research studies in distance learning and practical experience mentoring over 150 graduate students in a learning and technology program. Topics include what mentors should know about adult online learners, beginning with the end in mind, developing goals, frequent communication of expected goals and outcomes, fostering relationships of trust, and providing adequate follow-up and support.

Introduction

The purest form of distance education occurs independent of time and place (Simonson et al., 2000). In other words, learners, not institutions, choose when and where to learn. This is also called asynchronous distance learning, and the Internet has made this a reality to the world. One of the greatest challenges in distance learning is fostering continuous progress and achievement since attrition rates in distance education programs are usually much higher than in traditional programs, in some cases as high as 50 percent (Picciano, 2001). Western Governors University (WGU) is an online, competency-based university which provides every student with a mentor to help foster this environment for successful learning. The role of the WGU mentor encompasses the roles of advisor and instructor at traditional institutions. Mentors at WGU have educational backgrounds in the disciplines in which they mentor and advise students. In addition, they work closely with their students across several domains of knowledge from matriculation to graduation.

What Mentors Should Know About Adult Online Learners

As student-centered learning continues to take hold in education, the role of the teacher is shifting in both traditional and distance education from the “sage on the stage” to that of facilitator and mentor (McVay, 2000). This is especially true in an online environment where the adult learner is expected to learn by integrating life experiences with new information to construct meaning. This transition includes a movement from (a) lecturing to coaching, (b) taking attendance to logging on, (c) credit hours to performance standards, (d) competing to collaborating, (e) passive learning to active learning, and (f) textbooks to customized materials (Oblinger, 1994).

Part of being a successful online mentor involves improving the mentoring relationship by helping to make these transitions and identifying the characteristics of successful online students. Research studies have provided a number of characteristics of those most likely to complete distance learning coursework and programs. Completers are more likely to (a) have an internal locus of control, (b) possess advanced degrees and higher grade point averages, (c) study at least 10 hours per week, and (d) have already successfully completed a distance learning course (Bernt & Bugbee, 1993; Dille & Mezak, 1991; Laube, 1992). Research has also confirmed that completers possess more positive attitudes about their tutors than those who drop out early (Laube, 1992). At-risk students, or those that have the greatest potential to be non-completers, are students who (a) have not completed college and are therefore more likely to lack the metacognitive skills for approaching coursework and assessments and (b) have an external locus of control and do not take responsibility in managing the learning process (Dille & Mezak, 1991). At risk students are particularly benefited by having mentors to share and discuss issues and concerns related to their academic performance (Picciano, 2001).
Strategies for Success

We have developed four basic strategies from our own mentoring experience that have proven to be effective in producing successful online learners. These strategies are important in any learning environment but are particularly meaningful for online student learning. First, students in most online programs begin their studies with only a vague understanding of the various projects and activities required to complete their degree. Most do not appreciate how the individual program components are related to each other. This understanding often comes only at the end of the program when students have completed several classes and projects. The online mentor should help students begin with the end in mind by describing how each project is related and how projects should be aligned to culminate into a final project if required. This not only saves students a great deal of time and resources but also builds a more cohesive understanding of how the program works and what students need to know to successfully complete the program.

Second, for any mentoring relationship to work, goals need to be well defined. Smith (1995) provides five criteria for creating “SMART” goals. Goals must be specific (S), measurable (M), action-oriented (A), realistic (R), and timely (T). Since goal setting is an evolutionary process, the mentor and mentee “revisit their learning goals throughout the mentoring relationship” (Zachary, 2000, p.94). A key to online mentoring at WGU is working individually with each student to develop an academic action plan which serves as a road map for the student’s academic journey through the program. The academic action plan articulates specific components of the learning agreement, outlines learning opportunities such as coursework, independent learning resources, textbooks, and Internet resources. It also helps define both short term and long range goals and tracks student progress.

Third, frequent communication of expected goals and outcomes is essential to the mentoring relationship. Zachary (2000) calls this process “accountability.” A simple, “How is it going?” is a good strategy to ask frequently instead of only when things go wrong. This is most often conducted through email and phone conversations but is done more formally by holding regularly scheduled interview sessions with the student wherein the academic action plan is reviewed, expectations are defined and redefined, goals are set, adjustments are made, and the mentoring relationship is strengthened. A helpful strategy is to have the mentee summarize the session and send it to the mentor in an email to support accountability and ensure understanding of what was discussed.

Finally, an essential component to online mentoring is providing adequate follow-up and support. Students should know that the mentor is aware of their individual needs, abilities, and learning styles. Email and telephone requests should be responded to promptly, within the day if possible, and no longer than 48 hours. It is important to remember that the mentor should facilitate the learning process, not provide all the answers. Students will inherently make mistakes but mistakes are an opportunity for learning. This comports to the analysis of a mentor by Cross who relates the pursuit of a degree to a journey that is full of unexpected outcomes in which the mentor is “not so much interested in fixing the road as in helping the [mentee] to become a competent traveler” (Cross, 1987, p. ix). As students gain skills and explore new concepts and theories, they discover both learning goals and obstacles previously not considered. By applying their newly found knowledge and skills, students realize fulfillment in opportunities previously unknown.

Abstract: This paper springs mostly from experience gathered in relation with conducting a Socrates funded ODL project: named 'Computer Network Based Learning in Project Group Environment'. The project objective was set to test working methods in practice and evaluate how academic institutions can gain from using computer networks in learning processes and everyday communications. The project started in Autumn 1998 with a one-week seminar. The beneficiary of the project is EVTEK Mercuria Business School, Finland. Partner institutes are from the United Kingdom, Ireland, the Netherlands, Germany, Italy and Spain. Presently the project is in the stage of evaluation and dissemination of its various activities. The project will end in August 2001. This paper is focusing on reporting on our experiences and our presentation will be focusing on the learning points based on these experiences. Updated information on the project can be found at http://virtual.mbs.fi/virtual

Project Activities
After having learned technicalities on how to prepare network based learning material we focused on understanding network learning pedagogy, including

- different aspects of ODL and the attitude to ODL in different cultures
- the evaluation of the effectiveness of web-based learning in the educational environment, i.e. how effective web based learning is for the individual student, teacher and institute
- what organisational requirements should be met to promote ODL
- evaluation of the techniques of ODL as tools for academics
- the role of effective communication and how that can be achieved using net-based learning
- dissemination of learning experiences and outcomes

During the second year of the project we have been able to focus on the above-mentioned factors as well as network pedagogy. Transnational project groups defined their project work plans in a seminar held in October 1999 in Holland.

Subproject 1: Handbook on how to combine IT with traditional working methods
This handbook, "Tips for Online Learning", is intended to form a pool of lecturers' and students' experiences with online learning. We take special interest in how the technology is supporting learning. Each section takes the form of a series of "tipsheets", a list of observations or ideas, distilled from implementing online courses. We are more interested in how the technology has been used to support teaching, rather than the specifics of how to use certain learning environments.
The working draft of the handbook is at the website http://virtual.mbs.fi/virtual/oltips indicating what sort of content we are interested in. The integration of this material into a pilot of the handbook is presently in construction and will be ready by end of May.

**Subproject 2: Web based study modules combining IT with traditional learning**

Project partners have started pilot web courses in order to develop, share and further evaluate the web-based learning environment. We provide practical information on development of online courses, including experiences and evaluation of both lecturers and students.

During the first project year investments/choice of platforms took place and training was mainly provided to achieve technical skills and positive attitude for staff. The objective for the second year was to have all partner institutes involved in starting pilot courses, with different objectives to be developed and evaluated. Out of seven partners, only one has not achieved this result.

Other objectives have been to offer a base for quantitative analysis. The project members created a feedback form. At Mercuria Business School some 6-7 different courses were started during the spring season 1999 on the purchased server. In July 1999 the courseware tools were purchased and by the end of August there were already some courses working with the new environment. At this stage there are some 50 courses up and running on the server. Assessment software has been installed and will be used with courses in the near future. The pedagogical course on NBL has been attended by 33 of our teaching staff from November 1999 until April 2000. Joint courses have been conducted with Glasgow Caledonian University and Sheffield-Hallam University. Here are some examples of online courses (http://student:visitor@webct.mbs.fi/webct/homearea/homearea) at Mercuria Business School: Online Courses in Open University, Polytechnic and International Co-operation. Supportive Intranet platforms have been constructed for both staff (MBS info) and students (Opiskelijainfo and Studentinfo) in autumn 1999. External web site information has been improved; the layout leaves a lot to be desired, and has not been worked on due to strategic organisational changes at the institute. Having now experienced visible results, the organisation is very devoted to invest in NBL and its supportive web based activities. Several teachers of online courses are working on pilot courses in order to evaluate and disseminate the experiences of them.

At Wolverhampton University the Online courses have first been provided for postgraduates, (http://www.wlv.ac.uk/wbs/olbaba) arranged by a specific department supporting this activity. The project was promoted through distribution of a CD-ROM presenting the advantages of online learning. In addition there is a huge development programme going on (http://wolf.nt.wlv.ac.uk) The Wolverhampton Online Learning Framework (WOLF) is a purpose built computer based learning environment developed by the University of Wolverhampton. In this respect Wolverhampton goes its own way but in the long run it will have a lot to disseminate on the topic.

Starting July 1999 Hogeschool Holland/Hogeschool International Business School, invested in a learning platform and courseware tools, testing them during the autumn semester. Due to different solutions in allocation of time and resources the organisation was not able to support fast development of working out new online courses.

Starting spring 1999 Hochschule Anhalt purchased the needed equipment and know-how of their own. First they worked out tutorial activities for student teams. The training started in the autumn semester 1999 with a workshop for tutors (6) on FP Express and html-language. During the winter they trained 25 of their teachers on the same subjects. Several web-based courses have been started.

The Institute of Technology, Tralee has been using the courseware tool TOP Class for some courses in the Department of computer science and IT. As part of a major move to an integrated MIS at institute level, WebCT is the new platform.

University of Alicante has been developing its own courseware tool, VirtualCampus for course communication for two years. Further development has been done with MicroCampus web course toolware for online courses, which has been designed by the Multimedia Lab of the University.

**Subproject 3: Web based support for transnational studies**

The IOI (International Office Information) stemmed from a need to make better use of new and innovative Internet based technology to manage the growing numbers of international partners, student and staff mobility flows and project participation. The set goals were the effective dissemination of information, increasing student and staff mobility and paralleling and replacing existing paper based systems. The process was designed to maximise throughput, effectively use the resources and technology becoming available, simplify student access and increase individual autonomy.

Web sites (Internet and Intranet) with provision of information were produced. The development work was produced separately in each institute, co-operation on methods of analyses are presently worked on.

The aim of this project was to use web based technology to facilitate mobility and non-mobility international activities. The IOI project was co-ordinated by MBS International and the partners were Universita' di Genova, Italy
and the Institute of Technology, Tralee, Ireland. Although partners for mainly logistic and practical reasons did much of the work independently, the initial input and sharing of ideas at workshops and seminars was essential. Partners were able to view each others progress through the Internet and also via both informal contacts and regular reporting to the subproject manager.

**Subproject 4: Work placement & Supervised Work Experience**

We are working on setting up an international and multilanguage recruitment support system before the end of July as a 'beta' version between some of the partners. Based on experiences it may be elaborated to work globally, focusing on providing opportunities for recruitment of graduates from abroad.

NettiRekry is an asp-based software program, which is running on Microsoft NT-server with IIS4. This new version of NettiRekry is the second model in our NR-family. The pilot version Nettirekry was used by for Mercuria Business School to serve at national level: connecting companies looking for employees and students who are looking for work opportunities. Already this version was a success story. It has been running over a year now and has more than 1300 users.

We are also working on a 'Supervised Work Experience Module'. With SWE-module students and companies can easily access the school’s SWE database and look for material updates and leave reports etc. Supervised Work Experience-sites are dealing with supervision of the work training of students in connection with EBA studies; a double-degree programme that is taking place at Hogeschool Holland, Wolverhampton and Mercuria Business School. This operates in situations when students are performing their work-training phase of their studies. In order to make the training function in accordance with the objectives of the working practice period it requires constant interaction between the student, the supervisor of the working experience from the institute and the student himself.

**Workplan plan for 3rd project year (September 2000-August 2001)**

**Subproject 1: Further evaluation of transnational projects**

The outcomes of this subproject are related to what can be disseminated and contributed to the handbook. Therefore, this subproject should be active as soon as possible. All partners should contribute to the extent that they help in collecting information. Analysis will all be done at MBS.

The major assessment work should focus on the effectiveness of network methodologies used to improve network-based learning.

By the end of the 2nd year, some evaluation efforts were made, basically to the extent of testing the methodology of assessment. Both internal and external assessment including the users and providers of the NBL will be executed. The results will be implemented in the Handbook on Network based learning and its help desk in order to be disseminated to a wider public. This will lead to a broader understanding of the specific features, benefits, challenges as well as resources needed with the NBL.

Presently (April 2001) the evaluation work has been gathered and the conclusions of evaluation will soon be published to evaluate the utilisation of network facilities in implementation of courses, both from the perspective of the teacher and the students. Also evaluation of activities within Web-based support of transnational studies can be further evaluated as well as the activities of work placement and supervised work experience.

**Subproject 2: Dissemination of the project outcome**

All partners are expected to contribute to making dissemination work during the springtime (especially February - May) of year 2001.

Communication in the Virtual Teaching and Learning Space

Antonio Simão Neto
Pontificia Universidade Catolica do Parana
Brazil
4simao@terra.com.br

Abstract
This research project addresses broadly the issue of whether the new media, being potentially interactive (and thus bridging teachers, students and other educational agents) may open new ways of teaching and learning, which are more adequate to contemporary life and the global society.

"Technology is the campfire around which nowadays we tell our stories."

Laurie Anderson, American artist and multimedia pioneer, chose the image of the campfire to drive our attention to the central role of technology in our society, shaping out collective views of the world and mediating human relations.

The university, as a social and cultural institution, could not be untouched by this phenomenon. In fact, there are many similarities between the mass media and the traditional teaching model. Both are marked by the separation between the main agents (producers/audience, teacher/student) of the communicative process.

New media, being potentially interactive, may help educators in their efforts to close the gap related above, creating new learning environments which are more “in sync” with post-modern society and culture.

More directly, it aims at identifying the degrees of teacher awareness and understanding of the communicative changes brought by the new interactive media such as the Internet and its impact on the learning process as it happens at the Pontificia Universidade Catolica do Parana.

This project is part of the research being carried on by the research group Virtual Learning Communities, itself part of the broader Theory and Practice of Higher Education project, linked to the Masters and Doctoral programmes at our institution.

Our university began to implement last year a new educational model, for all its 51 undergraduate majors, based upon “learning programs” developed jointly by teachers and students. This model leans heavily on problem-solving, investigative skills as well as on collaboration and tutoring.

Eureka is a collaborative learning environment, developed at our university, in cooperation with Siemens Corporation. As many other such environments, Eureka offers discussion forums, e-mail, chat room, scheduling, message board, repository, and other online and offline resources aimed at facilitating collaboration and learning.

At the end of academic year 2000, there were more than 10,000 Eureka registered users, of a 23,000 (staff and students) academic population.

Eureka’s 350 virtual rooms will be our research universe. They are the environment in which the central issue of the use of new technologies as support for educational changes can be addressed. We will follow the tutors from the moment they open their virtual rooms until the end of the academic year, looking into the ways they communicate with their students in this environment, the tools they use and how they use them, the ways the students react to stimuli and how they start and keep their own forms of collaboration and communicative exchange.

So far we have been able to identify a close resemblance between the way mass media mediates communication and the way traditional teaching happens.

We want now to find out whether new media can be associated with a new learning paradigm: a student-centered, problem-based, research-oriented, knowledge-building model, where collaboration and interaction are essential.

Mass-Media and Traditional Teaching Common Characteristics.

Centralized control: messages (content and form) are constructed by the few who control the medium
One-way communication: messages travel in one direction only, from those who control the medium to those who receive them.
Prevalence of “cold” media prevail: as defined by MacLuhan, the more finished the message is, the less space the medium leaves to the spectator, the colder the medium.
The spectator: from the Latin expectare (to be there, just watching); spectators/students are expected to sit quite and listen/watch, without interfering with the production of messages.
Linearity: messages built along a pre-defined, pre-built sequence, in a linear flow with its own temporality, independent from the spectator, who cannot alter this direction or speed, nor choose alternative ways.

New interactive media characteristics

Decentralization: one the main characteristics of the internet, the first big media without owners and central controllers, opened to all.
Two-way communication: information flows in multiple directions, allowing new communicative exchanges.
Interactivity: hot media prevails (if we take the potential for interaction in its fullest sense).
The “users”: so new that there isn’t a good word for it, these new spectators refuse to “just watch”; they want to participate, to interact, to wet their hands in the ocean of information, to manipulate messages and create new meanings.
Multimedia: more than just a new audiovisual medium, multimedia is opening a universe of multiple stimuli.
Non-linearity: the wide use of “water metaphors” (to navigate, to surf, to dive...) to describe user movements in the information “ocean” reveal the non-linear structure of the new media; one can move in the surface, or dive into depths never made possible by linear media.

New media and contemporary education

As we develop and spread new tools around campus, new forms of communication between teachers and students can take place. New tools, however, are not enough to make a difference. It is the attitude of the learning agents that counts more.
If we want to depart from traditional, informative teaching, and move towards new directions for learning, we must try to establish new communication spaces and to develop new communication skills, alongside with the ones we are familiar with (at least as consumers of media products).
That is the challenge for nowadays educators. New forms of teaching and learning surely will employ new technologies and resources, more interactive and flexible. On the other hand, educators must change their views and attitudes accordingly. It is imperative that we find a common ground upon which true, rich communication exchanges with our students can occur.
Learning can and must be a joyful, stimulating activity.
The university (and the school as well), as a communicative space, must go beyond the model based on the mass media, reaching for the new digital, interactive media - if education is to keep on being significative and important to students and to society.
Insuring Quality for Online Instructors:  
The Walden Certified Online Instructor (COI) Program:  
Marilyn K. Simon, Ph.D.  
Walden University  
155 Fifth Ave South  
Minneapolis, MN 55401  
msimon@waldenu.edu

Abstract: Since the summer of 1999, Walden Institute (the parent organization of Walden University) has been offering a 3-month certified online instructor (COI) program providing educators, managers, and other professionals, with the basic skills and knowledge necessary to be an effective online facilitator. This presentation will explore the rationale of the COI and its effectiveness in training online instructors.

Rationale for the COI

Online courses have become a major component of almost every major post-secondary institution, and corporate training department. Teachers and trainers are expected not only to facilitate these courses, but very often to create them as well, despite the reality that they may have little or no actual experience with online learning/teaching. Teaching online requires new skills and knowledge beyond those of traditional classroom instruction. However, there has been relatively little public or scholarly discussion about what these requirements are and how best to meet them. This session will provide an opportunity for such a discussion, using the Walden Institute COI course (www.waldeninstitute.com) as a case study and basis for the discussion.

Questions/Issues addressed in the formation of Walden's COI

- What are the skills/knowledge needed to effectively teach online?  
- What is the best format for online instructor training?  
- How long should an instructor-training course be?  
- How much web/internet/computer background does an instructor need to teach online?  
- What are the typical problems that online teachers encounter?  
- Are all teachers/trainers capable of being online instructors?

Development of the COI

Most tertiary school systems have offered some degree of in-service training to their faculty, usually in the form of short workshops/seminars that provide introductions to online teaching. In addition, many schools of education now have one or two courses about online education as part of their teacher-training curriculum. But these efforts tend to be too brief and limited to provide the extensive, hands-on experience needed. What is needed is instructional approaches aimed at developing understanding, supporting peer interaction, and facilitating learners participation and use of technology by taking theory to practice.
In 1999, Walden Institute began to offer a Certified Online Instructor (COI) course (see http://www.waldeninstitute.com/coi_ov.htm) intended to provide the kind of training needed by teachers and trainers. The COI is a 12-week, instructor-facilitated course offered entirely online. Separate course sections are offered for academic and business training participants with slightly different course materials. To complete the COI and earn certification, participants must demonstrate their mastery of the following major competencies:

1. Basic elements of on-line courses: email, threaded discussions, real-time conferencing
2. Characteristics of distant, diverse, and adult learners
3. Qualities of effective on-line educators
4. Instructional and interface design considerations for on-line education
5. Different tools available for creating and managing on-line education
6. Strategies for integrating on-line and classroom instruction
7. Techniques for evaluating the quality of on-line learning courses and programs
8. Critical aspects of implementing a successful on-line course or program
9. Ethical and legal issues associated with on-line education
10. Emerging developments that will affect on-line learning

Requirements to obtain a Certificate

Participants must complete a course design project that spans the topic areas in the syllabus, which results in a working lesson prototype. Some of the successful projects from the COI include: An online course in Stress management; ESL instruction; a course on the basics of Yoga; a workshop on Creative and Critical thinking; and a course for undergraduate Interns to link the knowledge obtained on the job to theoretical principles learned in the classroom.

During the course, participants are also given opportunities to serve as the facilitator of discussion forums and web conferences. Since the course was first offered in 1999, more than 500 teachers and trainers from institutions and organizations across the U.S. have completed the COI and received certification.

The COI provides a community of learning for teachers and trainers where they can share and acquire ideas from each other – making it possible to cultivate diverse perspectives. The theoretical framework for developing the COI coincides with Fleischauer's (2000) report from the National Education Associations summit on quality online instruction. The COI offers a solid foundation to proceed with the development and management of on-line education. In particular, the project the participant completes provides a specific plan that can be (and often is) implemented. However, there are many additional factors, specific to your institution/organization, computer systems used, and the participant's position/role, that will determine what additional knowledge is needed to pursue on-line teaching or mentoring activities. Upon the successful completion of the COI the participants is aware of what is needed to further their work as an online instructor.
Usability and Learning in OnLine Environments: A Case of Interactive Encounters

Rod Sims
Learning Services, Deakin University, Australia
rsims@deakin.edu.au

Abstract: This paper proposes a set of strategies to maximise learner-content and learner-learner interactions in on-line learning environments. Extrapolating the outcomes of a research study that investigated the ways in which users responded to the interactive constructs embedded within interactive multimedia applications, the concept of encounter theory is introduced. Using observation and interview techniques, participants in the study identified a range of options by which learner-computer interactions might be enhanced. The implications of these findings for on-line and desktop environments are considered, specifically in terms of the independent learner's encounter with content material and other learners. Developing a comprehensive understanding of the interactive phenomenon will not only lead to more effective usability and learning in on-line environments, but also to their working better for the learner.

Introduction

With the current demand for on-line content and communications, people are making extensive use of the internet for both human-human communication and information retrieval, and within this context there is a substantial and sustained demand for learners to have rapid access to and quick but meaningful responses from content material. The momentum towards on-line learning as a de facto educational delivery system is also emphasising the value of communication and interaction between learners, teachers and content.

This paper derives the concept of encounter theory, which predicts that conceptualising the on-line learning experience as a series of encounters will enhance the overall learning experience, based on the outcomes of a research study that examined the interactive constructs within a series of CD-ROM applications. Given the research data generated, it was evident that people work with the same interactive products in quite different ways, having different expectations, deriving various meanings and achieving various levels of engagement and communication. Consequently, the ways in which producers of on-line applications perceive the learner as undergoing a series of encounters between a fellow learner, a teacher or some digitally presented content will be crucial to learning outcomes being achieved. Conceptualising the on-line learning experience through encounters will potentially make on-line content more intuitive, and therefore more accessible and interactive to the learner.

The following discussion briefly reviews the way in which interactivity in computer-based environments is currently understood and describes the methodology and results obtained from the research study. The implications from the study for on-line learning environments are then addressed in terms of the potential encounters between learner and content or learner and learner, and the how the production team has the responsibility for creating the environments in which these encounters will operate effectively.

What is Interactivity?

Interactivity, in the context of computer-enhanced learning (CEL), can range from simple navigation through web pages to human-human collaborative experiences to immersion in interactive virtual worlds. While the many dimensions of interactivity are well documented (Sims, 1999), considerable uncertainty remains about how best to design and implement interactions to achieve the desired learning goals. In the field of educational
technology there has been a distinct shift from interactivity as overt physical reactions to those involving internal cognitive processing. From a broader perspective, Laurel (1991) and Shedroff (1994) have emphasized the potential of theatre, specifically in relation to the way interactive multimedia technology has been implemented within the commercial sector. The use of concepts such as narrative, play and performance were considered a potential source for addressing the complex nature of interactivity, and from the design perspective would involve rethinking the way the learner's position within the learning environment is presented.

To address the ways that people work with interactivity, specifically in relation to learner-content interactions and their effects on usability and learning, a research study was designed to observe people working with the interactions provided in contemporary computer-based multimedia applications. The importance of this research lies not only in developing a better understanding of the learner-content relationship in human-computer interactions, but also in identifying the means for achieving maximum teaching and learning advantage from the rapid growth of on-line content and communications.

In examining these interactions, it became apparent that the success of learner-content interaction is not so much dependent on the learner's ability to use the technology, but on the strategies implemented by the production team in maximizing the communication potential of content, whether it be through a web-site, discussion group or desktop application. Better understanding the ways in which learners interpret the content is the key to the ongoing success of computer-based learning environments, especially when that interpretation is expressed as a series of encounters between learner, content and the underpinning design.

**Methodology**

To examine the phenomenon of interactivity and provide a baseline for its understanding, seven different CD-ROM titles were selected based on their range of design, interface and interactive elements. Forty-six participants from an undergraduate multimedia program volunteered to contribute to the study and were randomly allocated to one of the titles. Each participant was requested to work through the content for a period of approximately 30 minutes, speaking out loud their interpretations of, and responses to, the interactivity being presented. All participants were videotaped and each video sequence was analysed to generate data identifying the major sections and/or content areas accessed, the duration of that access and the types of interaction undertaken by the participant during that access. The data relating to content and interaction types were processed using a custom-built software application that not only generated graphical and numerical information for reporting purposes, but also allowed a dynamic view of the participants' interactive experienced working with that title. For each participant, an audit trail (Misanchuk & Schwier, 1992; Fritze & McNaught, 1996) of the major content areas visited and a profile of their interactivity was generated by this application. To record the diversity of interactions undertaken by participants, seven different forms of interactivity were derived from the taxonomies of interactivity (Schwier & Misanchuk, 1993; Aldrich, et al, 1998) as illustrated in Table 1.

Table 1: Interaction Types
Results

The audit trail depicted in Figure 1 shows an example of one participant in terms of both the content accessed and types of interaction being undertaken while working with one of the titles. This audit trail highlights that while participants worked through a range of the content available, the form of interactivity varied over the contact time. A second means to represent this data was through a profile of the interactivity, expressed as a percentage of the total session time, as illustrated in Figure 2.

Figure 1: Content/Interactivity Audit Trail

Figure 2: Interactivity Profile - Percentage Over Time
In this example, after the initial presentation, the participant began to explore the various options presented within the application, becoming involved with some of the material at approximately the 10th interaction. This data can be compared with the Content Audit Trail (Figure 1), where the first interaction associated with the user being involved with the content occurs at approximately the 4th minute of the overall encounter. The profile depicted through plotting the percentage of interaction type over time provides a visual representation of an individual's path through an application.

Discussion

Working with Interactivity

The process of collecting and analysing the data provided the opportunity to reflect on the relationship between the design of a title (in terms of interface and interaction) and the ways in which users gained benefit from their encounters with the embedded content. What became evident, and is supported by the data recorded, was an apparent discrepancy between the time a user might work with a product and the time it would take to gain benefit from that product. For example, participants often indicated they had not determined the purpose of the application and I believe this was because it would have taken an extensive amount of time to develop a satisfactory understanding of the application's underlying structure.

The significant outcome from the audit trails generated from the research data is that they both confirm and contradict the theoretical positions of learning and interactivity. In terms of confirmation, the variation in audit trails (see Figure 1) substantiates the claim that computer-based learning products provide for individualised experiences, as participants chose a variety of routes by which to explore and engage with the content. However, when considered in terms of the interactive profile (see Figure 2), this individualisation did not appear to convert into meaning, thereby contradicting the assertion that such individual experiences will also enable engagement and meaning.

Consequently, if a product underwent useability testing such that an interactive profile was generated, the trends presented by that profile would reflect the extent to which those interactions were balanced. From this analysis, achieving a convergence and resultant balance of interactivity, over the shortest period of time and after the fewest number of interactions, would be desirable, and indicative of the user working effectively with the product. Applications that did not achieve a balance, consistent with Norman's (1986) guls of execution and evaluation, would need to undergo some form of interactive adjustment.

Interactive Encounters

The word encounter is defined as "a meeting with a person or thing, especially casually or unexpectedly" (Macquarie Dictionary, 1998:365). This seems most applicable to what happens when users first activate a CEL application, where they may be familiar with the content and aims of the overriding curriculum, but their first encounter with the computer options will potentially be confronting. As the research participants worked through the titles it became apparent from their interactions and spoken comments that the casual and unexpected aspects attributed to encounters were equally applicable to the interactive experience. This complex integration of audit trail and profile demonstrates that it is not adequate to simply build interactions and trust in the user to interpret and benefit from them. There is also a responsibility for the application (whether web-site, discussion group or CD-ROM) to be created in such a way that it too has a responsibility for maintaining communication with the user – thereby supporting the creation of truly interactive environments. In this context, the relationship between human and computer might better be envisaged as a series of encounters, with both parties responsible for playing the appropriate role within those encounters. Ultimately, this is the challenge for the producers and designers of computer-based learning environments.

Introductory Encounters

When a learner first commences working within an on-line application (whether a web-site, discussion group or management system), an attempt to make introductions between the major players is recommended. Depending on the structure of the application, this may involve actual members of the development team presenting the
background to the design and its intended operation. Alternatively, the use of characters within a microworld and the roles they are to play in the subsequent presentations can be introduced. Learners also have the responsibility to introduce themselves and to inform the designer of their experience and expectations, as suggested in the context of negotiation. In this way the application can use the information to configure the way in which it will be presented and the means by which the learner can progress through the associated interactions. The notion of an introductory encounter can also be applied to that of the parting encounter, where the learner is recognised for the role they played and information exchanged. It is a relatively simple technique to record user responses and integrate them into future presentations – placing value on the individual learner is a means to enhance the purposeful nature of the application.

Controlling Encounters

In human-human encounters, the participants may operate equitably or one may dominate the process, and in the case of interactive applications, the research participants demonstrated that the two-way exchange of information is essential. However, based on their observations, there was little opportunity to control the content other than the selection of high-level menu items, the navigation between locations, choosing to activate clickable objects or scrolling through large amounts of textual information. While participants were quite able to operate the various controlling items, the responses made by the application were often unpredictable as well as unvarying. There may be a relatively simple means to address this observation. If interactions were structured so that the user could control or act as a spectator then it becomes more their choice as to how the presentation is revealed. By generalising this to a wide range of content domains and metaphors, independent of the technological environment, there will be a likelihood of achieving even more effective learning outcomes.

Strategic Encounters

It is also important that the encounters between learner and designer be strategically positioned throughout the application in such a way that they can be initiated by either of the two parties. The activation of these encounters will be dependent on the extent to which the user has achieved interactive balance and control over the application. While the use of agents has been applied to personalise the environment and provide contextual advice, the responses provided by those agents are typically defined by the program to operate under prescribed conditions, rather than those conditions being negotiated by the user and designer. Of importance is the extent to which the user has the illusion that they are being communicated with on an individual and personal level. Thus a teacher working with a discussion group has the responsibility to keep learners informed of the strategy in play at any one time.

Empathetic Encounters

Finally, the encounters between learner and designer need to manifest a level of empathy and tolerance. There is no reason why an application cannot indicate an inability to undertake a task, or to be apologetic for being limited in its range of responses. The underlying arguments for negotiations and encounters is one of personalising the application, of integrating the designer into the process, and continually ensuring that the learner is comfortable with their progress. A typical response to this form of encounter was when one participant attempted to locate information within a database. Although the search was successful from a technical perspective, the information returned could not be interpreted because he had difficulty linking his request with the material returned. Had the application (as a manifestation of the designer) informed the user of the way in which the search would be performed, the range of data being searched and the potential retrievals, either the search request would have been terminated or the information returned interpreted more easily.

Encounter Theory

In the same way that Kearsley & Shniederman (1998) proposed that an engagement theory provide a set of prescriptions for successful computer-mediated communication, the encounters presented in this analysis provide a framework for what I have termed encounter theory. If the development of on-line learning applications is considered as a sequence of inter-related encounters, then the interactions provided to the user will be of consequence, as they will have been presented in a conversational framework as integral to the operation of the application. In addition, navigation through the application will be more directed and destinations reached...
predicted by the user rather than unexpected, and the content subsequently presented generating more value for
the learner. Reeves (1999) declared that we know how to build these applications, we just need to do it better.
Envisaging applications as a series of encounters, rather than a means to structure content, is one way this might
be achieved.

Conclusion

In recent years, the word interactivity has tended to be applied more frequently to the facilities afforded through
calendar-mediated communication and the increased promotion of on-line learning and web-based training.
Regardless of the computer-based medium, effective interaction between learner-learner or learner-content
cannot be assumed to be an implicit facility of computer-based environments. Rather, considerable design effort
must continue to be placed on the ways in which learners will both adopt and adapt to the exchange of ideas and
engagement with content through computer-mediated resources. Moving to an on-line environment, with the
perceived benefits of synchronous and asynchronous human-human communications, can mask the importance
of human-computer interactions. However, I maintain that interactivity can enhance engagement and learning,
which is the critical component of any computer-facilitated learning artefact and that this interactivity needs
constant maintenance regardless of the medium of delivery. Using the concept of encounters is one means to
generate this enhancement and facilitate its maintenance.

Developing a comprehensive understanding of the interactive phenomenon will not only lead to more effective
useability and learning in on-line environments, but also to those applications working better for the learner.

AIOLOS: A TUTORING SYSTEM FOR WASTE MANAGEMENT

Spiros Sirmakessis, Computer Technology Inst., Greece; Maria Rigou, Computer Technology Inst., Greece; Athanasios Tsakalidis, Computer Technology Inst., Greece

AIOLOS is a multimedia based training system on the subject of hazardous industrial solid wastes, using the recent advances in the field of IT. The learning process is based on autonomous, self-paced principles and a variety of on-line sources available via a CD-ROM. It aims to inform and sensitize the high level personnel in industries that have to manage hazardous solid industrial wastes, so that emissions into air, water or soil will be reduced. In short, the user engaged in a training session can -at any given time- navigate to one of the available thematic subjects, use the custom controls (previous, next, up, main), view any scheme/diagram/animation enlarged, view the definition of unknown terms, print selected sections of the current educational unit, take notes, activate/deactivate the sound, view the EC waste-related Legislation, learn from the Theory-in-Action scenarios, use an English translator and evaluate the progress made using the self-evaluation exercises.
Developing a Model for Technology Based Learning: A Practitioner Response to a Constructivist Learning Model.

Jane Sisk, South Birmingham College, UK. Email:janes@sbirc.ac.uk

Abstract
This paper outlines a proposed model for technology based learning. The learning processes identified within the model are considered in the context of recent research and feedback from practitioners working with adult learners. This is followed by an attempt to identify the characteristics of each process and analyze these in the context of programme delivery.

1. Introduction

The aim of this paper is to present an exploration of a model of Information and Communication Technology (ICT) based learning and suggest how the model may be adapted for use as a tool to support the development of shared understanding for practitioners working with adult learners in technology based learning projects.

2. Background to the Employment and ICT Learning Project

The work on learning models was commissioned as part of the Employment and ICT Learning Project. The Project was co-ordinated by the City's Economic Development and was conceived as practitioner-led and complementary to broader policies and planning within the Department. The Department funds Projects which deliver employment and training skills to local adult learners. The Project brief was to disseminate information and develop tools to support the sharing of knowledge and understanding around the use of ICT in training and education programmes for disadvantaged adult groups. The Project had a core team and a steering group and met with a wider group of practitioners on a number of occasions throughout the life of the Project.

Previous research indicated that within the EDD funded ICT Learning and Employment Projects there were many examples of process focussed, constructivist online learning models. There was also a willingness to share and collaborate on developing best practice methodologies. It was felt that constructivist approaches should be made explicit and explored in the context of a model which could promote shared understanding of how learning is supported through the use of ICT.

Another factor in the focus for the research and development was the complementary nature of this approach in relation to the Government sponsored national initiative, Learn Direct, which has taken an instructional approach to the delivery of online learning. There are currently moves to incorporate additional communication functionality in the Learn Direct environment to provide a less rigid instructional model. These developments have emerged through what Learn Direct call 'good practice models' including various funded sources. As locally based projects within the EDD funded programme have developed their methodologies for clients with a constructivist rather than an instructional focus, it was considered that exploration of a model offering a constructivist approach could promote discussion with Learn Direct colleagues.

3. The learning model

It was agreed in initial discussions that proposed learning models promoted within the project should try to meet the following criteria:
- a focus on the processes of learning
- reflect the particular way of working that was emerging across Projects, that is, constructivism,
- indicate the significance of what learners bring with them into the learning process
- include a variety of methodologies, for example, mixed delivery, that is face to face and on-line delivery.
It was then agreed within the learning models planning group that Reeves' model for effective dimensions for learning on the web could support the Project brief. In presenting this model Reeves is careful to qualify the scope of the model "people value even simple models because these models guide thinking about extremely complex phenomena such as learning" (Reeves, 1998).

Within Reeves' model the identified processes can be viewed as generic processes which can also be applied in an ICT context. In this way, the model offers the potential flexibility to develop face to face and mixed methodologies. It was also felt that, while Reeves focuses on the use of the world wide web, it would be more helpful for the Project to reference ICT in general whilst acknowledging the particular strengths of the web in the context of Reeves' findings. However, Reeves' model was also seen to present some rigidity in its style which could inhibit flexibility. It was felt that a looser model structure may facilitate practitioners' access to the model. In this way, Reeves' processes have been become the main focus for the Project model and these have been represented as a system metaphor which shows the interactions and boundaries of the model. In separating out the range of processes it has been possible to integrate concepts from other models which enhance Reeves' model.

Figure 1. Processes facilitated by use of ICT

---

The general principles of constructivist approaches to teaching and learning have been variously described. These principles are summarised in the points below where constructivist learning:

- takes place in the real world
- involves social negotiation and mediation
- content and skills should be relevant to the learner
- student’s prior knowledge and skills are acknowledged
- assessment is formative
- students encouraged to be self mediated and self aware
- teachers are facilitators and should encourage multiple perspectives

The processes of Reeves’ model have been researched for the Project model and are described below within the context of constructivist approaches to the use of ICT in teaching and learning.

3.1 Opportunities to construct learning
The process of opportunities to construct learning is key to the constructivist approach. The approach which stresses the importance of the active involvement of the learner where the learner has the opportunity to engage in activities which facilitate the active restructuring of existing knowledge and skills. As Reeves writes:

"...because the constructivists emphasise the primacy of the learner's intentions, experience and cognitive strategies, the web may prove to be an even more powerful tool for constructivist pedagogy" (Reeves 1998)

Recent research has led to the development of further theoretical models of learning with ICT where active involvement in the learning process is a key characteristic. Papert (1989) and others have highlighted the action based element of constructivism, as Papert describes "people don't get ideas, they make them", and have extended the concept to include the construction of personally meaningful products/artefacts, that is, constructionism; a combination of constructivism and the teaching strategy of construction.

This vision puts construction (not information) at the center of the analysis. It views computer networks not as channel for information distribution, but primarily as a new medium for construction....within a community' (Resnick p.2)

The extended activity of learners working collaboratively across networks has been described by Papert et al as 'distributed constructionism'.

3.2 Learner ownership of tasks

One of the key elements of effective learning has been identified as the importance of authentic context for student activity. This is referred to in a wide range of learning models including Reeves(1998), Resnick (1997) and Schneiderman( 1997) who see ownership of learning as a key process to be facilitated in technology based learning .

Kearsley & Schneidnerman (1998) have recently published a number of papers on engagement theory; a proposed approach to technology based learning which has commonalities with Reeves model and stresses an approach to technology based teaching and learning which is constructivist, collaborative and experiential. They describe a methodology which

'Promotes human interaction in the context of group activities, not individual interaction with an instructional programme.' (Kearsley and Schneidnerman (1997)

The key activities in the engagement framework comprise relate, create and donate activities in learning with technology, that is, collaboration, construction and authentic tasks in a genuine setting. The donation cycle of the theory relates to completing tasks that have an authentic task for an authentic audience.

Team working is also a key feature of constructivist learning which relates back to theories of social interaction

3.3 Sharing knowledge

Practitioners working with learners linked to EDD projects reported that learning with technology provides opportunities for learners to engage in sharing and representing knowledge for a wider audience. This sense of audience has had a positive impact on learners through providing opportunities for learners to present their work to varied audiences through websites and CD Romans, for example. Findings on projects where learners used the web to publicise their work show that "...students demonstrated great concern for accuracy in their displays, students quickly assumed the major responsibility for content and editing decisions despite the fact that the original task of designing the displays had been structured for them by the teacher, students accessed wide ranges of science materials to find the content they desired, and their commitment to and enthusiasm for the project remained very high." (Reeves 1999)

This indicates that the web has a role in facilitating the development of metacognitive skills.

3.4 Access
Accessibility of resources is widely seen as one of the major benefits of the new technologies. The web has been harnessed for use in learning in many ways, for example, through the development of web quests (Dodge, 1998) where students are provided with scenarios and guided to resources.

There is considerable discussion around the use of the Web as resource in learning where the balance of the power of the web to customise resources to learner’s needs is checked by the requirements of cultures which demand the authentication of information available.

Issues of authenticity of information are compounded by other access issues which may mitigate the access to learning with technology including cost, connectivity and usability issues. The issues of usability of technology for learners was very important for the Project practitioners and these concerns are well described by Resnick, Rusk and Ceolhe (1999) in the context of the Computer Clubhouse.

The model of distributed constructionism described earlier has been successfully applied to community based capacity building projects in the US. Projects, for example, the computer Clubhouse, have targeted disadvantaged and excluded communities and provide access to technology and, critically, access to support to enable participants to develop the ‘technological fluency’ required to maximise technology opportunities. The Computer Clubhouse reports that access is not enough and strategies to support technological fluency in order to engage meaningfully with technology is essential. Strategies include use of local volunteers as mentors and authentic project work. This aspect of fluency is significant within EDD Projects as many organisations worked with disadvantaged communities and have recognised the need to balance access with an underpinning principles which promote the development of learners’ technological fluency.

3.5 Tutor support

The model suggests the development of facilitative tutors in the learning process where the tutor takes on the roles of coach, collaborator and mentor. This style of tutor support suggests a shift in control and an increasingly active role for other ‘stakeholders’ in the learning process, for example, through the use of other learners as mentors and through peer working.

In terms of working with learners through technology there are implications for tutor skills which are widely documented and were of concern to the Project group. Berge (1996) has proposed a range of skills that the on line tutor needs which relate to strategies to support effective communication and facilitate interactivity, strategies to coordinate learning and strategies to maximise use of the medium.

For the Project group issues regarding on-line and off-line models of support and the support structures required to facilitate tutors working in this way.

3.6 Collaborative support

Collaborative activity reflects the more open aspect of the web and other technologies which provide a framework and control mechanism for opportunities for many to be involved in the sharing and construction of knowledge. Collaboration may enhance learning by bringing together a wealth of information and experience for the sharing and restructuring of knowledge through interaction as described by Vygotsky and others. Collaborative activities have been a key characteristic of most Project delivery where practitioners appreciated the flexibility to provide learning opportunities to work collaboratively with otherwise isolated learners. The ability to archive discussions was seen as a great advantage for the learner group in terms of providing opportunities for reflection and learning from others. It was also recognised that the process of working collaboratively may present a steep learning curve for some learners who require support to work effectively in this way.

Kearsley and Shneiderman identify the development of communication, planning, management and social skills as the potential learning in collaboration in electronic environments.

3.7 Learning to Learn

Learning to learn, or metacognitive skills, are described by Flavell as:

“.... learner’s awareness of objectives, ability to plan and evaluate learning strategies, .. capacity to monitor progress and adjust learning behaviours to accommodate needs”

(Flavell, 1979).

The development of these skills may be facilitated by a number of other processes within the model, for example, through collaboration and may, as Reeves suggests, be facilitated through technology itself through intelligent agents and by storing feedback to other learners.

Practitioners felt that it is also important to acknowledge that the scope of learning skills required in the future because the changing nature of these impacts greatly on learners perceptions and behaviour. These skills have been
described by Reeves and comprise a range of technological skills including the sending and retrieving of digital information.
The changing nature of learning and working skills is also noted by Resnick
"A technologically fluent person should be able to go ' from the germ of an intuitive idea to the implementation of a technological project. Increasingly, technological fluency is becoming a prerequisite for getting jobs and participating in society." (Resnick 1998)

4. Extending the model

Another example of work around constructivist approaches to use of ICT includes Ewing's work where researchers have identified the characteristics of constructivism in relation to ICT. (Ewing, Coutts and Rusk 1999). This model has been used to identify the elements of constructivist use of ICT within the primary curriculum. The framework of this model, where characteristics of the constructivist approach are compared with observed teaching practice, provides an opportunity to extend the model above (see fig.1) to make more explicit the characteristics of the model which may then be used in the as a tool for the planning and development of programmes.

4.1 Characteristics of technology based learning processes

As a means of creating a checklist for practitioners to use in planning, delivering or evaluating technology based programmes, the processes of the model are listed below with appropriate characteristics underneath.

**Opportunities to construct learning**
Students are actively involved in their learning through structuring and restructuring existing knowledge
Activities require interaction and reflection

**Learner ownership**
Learners take responsibility for their learning through planning
Learning is related to learners' everyday experiences
Learning relates previous knowledge and skills

**Sharing knowledge**
Learners use technology to represent ideas, demonstrate skills
These representations are available to a wider audience
There are opportunities for learners to engage with this wider audience
Learners may operate in a number of roles within the learning process; author, editor etc.

**Accessing resources**
Learners have access to the appropriate software hardware and resources
Guidance on accessing resources through technology is available
Opportunities to personalise and tailor resources are available
Learner opportunities to access resources are not restricted

**Tutor support**
Tutors have appropriate skills in terms of key characteristics of tutor skills described
Tutor support is available within technology based programmes
Tutor roles are characterised by facilitation, mediation and negotiation

**Collaborative support**
There are planned opportunities to work with other learners
Collaborative support may involve peers, experts, etc.
Individual and group knowledge constructions are available to others

**Learning to learn**
Resources to support the development of metacognitive skills is available
Guidance on working on line is available
Reflection on learning available
Learning development opportunities are available
Experience and learning from previous learners is available

5. Application of model

The characteristics of the model can applied to a programme to indicate the extent to which the programmes are operating within the constructivist paradigm. In this case the process characteristics are set against an online learning programme, Learning in Electronic Environments, which aims to develop tutors' skills in on line delivery. The comparisons are made against evidence from programme evaluation.

</table>
6. Conclusion

The development of the learning model has been seen as a positive outcome for the Project. The application of a tool based on the model has shown that it has uses in supporting programme evaluation and development. In working on an additional tool to support shared understanding between practitioners it is hoped that opportunities will be available to further test the effectiveness of the model and tools.

The Unwired Classroom – Innovative Technologies in Computing Education

Stephen Skelton
UNITEC
Carrington Road, Mt Albert
Auckland, New Zealand
skeltand@xtra.co.nz

Abstract: Access to technology, where you want and when you want. This is the promise of Wireless Mobile Technology, combining the management and control of a computer lab, the freedom of portable computers, and the power of the Internet into a single solution. So just how practical is this technology and where is it being implemented? This paper reports preliminary results from research conducted within business and education facilities in New Zealand into new and innovative technologies such as wireless laptops in schools. In particular, the use of wireless laptops and LAN networks in St Kentigern’s College in Auckland, New Zealand, as implemented by Walker Wireless Ltd of Auckland, is the focus of this paper.

The Unwired Classroom

The purpose of this paper is to assist educators in becoming aware of the increasing role that technology plays in the classroom. Facilitating classroom activity without wires and cables brings a whole new flexibility to the classroom itself and where the class is conducted. The following paradigms were evident in the use of this new technology:

- Ease of movement
- Personalization
- Flexibility
- Convenience and time saving
- Cost effectiveness

The Technology

Computers bring many challenges with them in terms of attachments, cords and other peripheral devices. Add networks to that and we have cable and wiring all over our office or classroom which takes up a lot of space. Every time we want to move our position in the office or go to another class we have to log in again and use a computer set up differently to the one we are used to. With the arrival of high performance wireless laptops such as the Toshiba laptop with built in wireless LAN, we have the possibility of a different learning dynamic, one which involves a great deal of personalization and flexibility.

Walker Wireless is a relatively new company, 1 year old with around 20 technicians on board. Alan Leigh, the Marketing Manager, provided the information and support for this study. Walker Wireless operates off a spectrum of 5.7 to 5.8 and has purchased licensed spectrum in the 1098 spectrum, opening up different customers and ways to transmit. Wireless has significant advantages over PDSN, which involves laying cable or fibre with only 15% of its costs proportioned towards establishing the network.

St Kentigern’s College is a well-established secondary school in Auckland with a commitment to the knowledge and technology economy. Waiter Chieng provided the information and support for this study. The whole campus is wireless LAN. When a student starts at the school part of their package is to purchase a laptop. They are then able to access services around the whole school. Currently just under 1000 of the 1100 students have laptops.

The Market and Case Study – Walker Wireless and St. Kentigern’s College, Auckland, New Zealand
The market in New Zealand for wireless is new, focused on the business sector with an educational component. Virtual private networks with multi-sites and IP connections are the main market as there is a big demand for Internet connectivity with lower cost solutions. Customer dissatisfaction with current systems, such as slow modem speeds is also a good reason for a move into wireless as even ADSL has a raft of disclaimers, ranging from your distance from the central server point, to electromagnetic exchange and even PC performance. Wireless is clean and crisp, with in excess of 11MB in terms of delivery and a potential offering of up to 26MB.

Walker Wireless has just recently installed Wireless LAN at St Kentigern's as part of the school's ongoing commitment to a mobile knowledge and technology educational base. With the whole campus being wireless LAN and the students having laptops, access to services is easy, convenient, very personal and extremely cost effective.

The school is aware of the following paradigms:

- Ease of movement and effective space dynamics – Rather than cluttering their classrooms with computers, St Kentigern's are encouraging students' freedom of movement with laptops. Wireless laptops are quite small so can be used in places without any special need for tables or desktops. This same concept is encouraged in small offices with teledesking.
- Personalization – As I am sure we all find, there is nothing more annoying than logging on to a computer that doesn't have the software or utilities we require for our task. The students can personalize their laptops with all they need for their daily study. The school provides the major software suite that the students use for their curriculum.
- Flexibility – Laptops are used in many different ways, from access to services on the campus, to classroom activities, to simple communication with teachers or other students via email concerning the day's classes. Going from class to class, a student still has access to all the syllabus right there on their laptop. Their primary use is for syllabus work from the teachers and for collaborative activities with other students. In the future the network will be used for online testing and for the parents to connect to. It is driven by the curriculum and used in a way that enhances delivery.
- Convenience and time saving – The laptop is configured by the school and the student so it is easy to use, and the teacher can concentrate on teaching. A lot of time wasting is saved and trouble-shooting avoided. Having a laptop available all the time means the student becomes very familiar with its operations. The need to set up is minimized and there is a greater focus on learning. Like the telephone, wireless laptops and portable devices will soon be second nature.
- Cost effectiveness – The school is unable to achieve their objectives economically with desktops. They, like many schools, wish to have computers available across all curriculums and can't afford to have desktops. With laptops, which are subsidized through the Toshiba SNAP programme, the laptops are provided at very reasonable rates along with the software, making the purchase accessible for all parents and an investment for the student. The laptops are available at any time and students learn to use it when they need it. It is a partnership between the school and the parents. This makes it a true Win/Win for all concerned, community, school, parents, teachers and students in terms of a commitment to our growing relationship with technology.

Conclusion

The Wireless LAN network developed for laptops by Walker Wireless and St Kentigern's College in Auckland is an example of pioneering mobile technology "where you want it, when you want it". It facilitates classroom activity without wires and promotes education that is truly a partnership between parents, teachers and students. With its cost effective strategies and ease of use, flexibility and convenience, Wireless laptops in education represent cutting edge technology and state of the art collaboration on a very inspirational level. The author would like to thank both Walker Wireless and St Kentigern's for providing the knowledge and information for this paper.

Supporting Social Interactions in Distance Education with a 3D Virtual Learning Space

Daniel Skog, Ulf Hedestig, Victor Kaptelinin
Department of Informatics
Umeå University
Sweden
{dskog, uhstig, vkaplin}@informatik.umu.se

Abstract: The paper introduces main ideas underlying an ongoing project directed at supporting social interactions in distance education with 3D virtual learning spaces. It is assumed that Active Worlds can constitute environments, which will make it possible to capitalize on tacit aspects of social context, critical for effective learning. In addition, challenges for the technical and educational design of such environments are discussed.

Introduction

Learning environments for traditional education have a long history. Their features have developed to fit the practice of teaching and learning in its entirety, that is, to support both formal and informal, explicit and implicit processes. Any attempt to translate educational practices to a new type of environment is associated with a danger of overlooking “invisible” phenomena, which are nevertheless critical for effective learning. The area of distance education based on new information and communication technologies (ICT) seems to justify these concerns. Even though much research has been done in this area, it is evident that we do not yet have a clear picture of how students’ learning in distance education should be supported (IHEP, 1999).

One of the most obvious problems with distance education is the lack of everyday social support for students taking distance courses. Considering learning as not only a cognitive process but also as a social practice (Lave & Wenger, 1991; Vygotsky, 1978), there are reasons to believe that the lack of social support may have negative consequences for knowledge and skill acquisition, social competence, self-confidence, and motivation. In our view, the potential of modern ICT makes it possible to revisit this problem and suggest new solutions that can be implemented in practice. An especially promising opportunity appears to be providing students and teachers with a virtual environment that can be used for social interactions by people who are physically located in different places.

The aim of this paper is to present an outline of future work focusing on the use of a 3D virtual learning space to support social interaction in distance education. The learning space is being implemented in the Active Worlds (AW) (www.activeworlds.com) system, which consists of multi-user 3D virtual worlds that can be accessed online. The learning environment created in AW will be analyzed and evaluated with attention to existing and emerging types of social interactions while being used at distance courses given in Northern Sweden. The design of the 3D space emphasis on earlier work on multi-user 3D environments performed within the Department of Informatics, Umeå University (Croon Fors & Jakobsson, 2000; Holmström & Jakobsson, 2001).

Why Active Worlds?

AW is one of the most sophisticated and popular 3D virtual worlds available online today. The AW system consists of more than seven hundred worlds in the main universe and more than a hundred in a separate universe dedicated to educational use. A user can enter a world within the universe and navigate through a 3D environment viewed from a first-person perspective. In that environment one can meet other people and interact with them, build one’s own home and explore the surroundings. Besides real-time chat capabilities, it is also possible to communicate with other users by sending them messages through contact lists and by using one’s avatar (which is the graphical representation of the user within the 3D environment) to make gestures and to position oneself in the environment.

When trying to establish a social context in distance education, we find many potential benefits connected to using an interactive 3D virtual world. In addition to giving students online access to course materials that can be
distributed and announced in the world, this environment also constitutes a place for interaction between students. Spontaneous or arranged meetings with fellow students give opportunities for sharing problems or findings with each other. Furthermore, it helps maintaining informal social bonds between students, which is crucial when trying to create a rich and supportive social context. Perhaps, this is a way to prevent feelings of loneliness and alienation that are not uncommon in distance education and often hinder students from active participation in a distance learning setting. In the long run this could lower the dropout rate that is one of the problems connected to distance education.

Challenges for the Technical and the Educational Design

The challenges associated with creating a 3D virtual learning environment relate to both technical and educational issues. At the technical level the main challenge is to find a design strategy that will generate a 3D environment with the desired functionality. Some of the key features of being in virtual worlds seem to be interaction, movement, and construction (Heim, 1998). When using virtual worlds in educational activities it is crucial to make use of these characteristics. Otherwise the participants will lose their feeling of being there (notion of presence), and they will probably not be motivated to spend time there (Holmström & Jakobsson, 2001). This means that the design of virtual worlds should capitalize upon these key features so that the virtual world becomes a tool to create a sustainable social context for learning activities.

The main educational design challenge is to accomplish a tight coupling between the course content and the educational strategy employed by the teacher, on the one hand, and the structure of the 3D virtual "social space", on the other hand. Besides, it is important to make the virtual space attractive and easy to use. Teachers will most likely not engage in these kind of learning settings if it means a lot of extra work or if the setting is hard to manage, and hence the design must be made so that overhead is minimized. Furthermore, the virtual environment must be designed so that the students are allowed to express themselves and have fun. It should be a place that facilitates interaction and invites the students to construct their personal space within the learning environment (Dickey, 2000). Currently the work in progress reported in this paper mostly focuses on the above challenges. Hopefully, the end result will be a virtual learning space facilitating formal and informal social interactions and thus effectively supporting the social context within a distance education setting.

Movie-based Media in Teaching Business English

Tatiana Slobodina
Department of Foreign Languages, Northern International University, Russia
tatiana_slobodina@hotmail.com

Abstract

The presentation is supposed to demonstrate the first outcome of the project entitled Learning Business in Hollywood. It includes the multimedia language-learning module based on seven episodes from the 1987 20th Century Fox movie, The Working Girl, and developed with the Wiser Educator multimedia authoring system. The project aims in developing the whole series of Business English learning modules based on movie episodes that present professionally oriented communication in business settings.

Introduction

The steady growth of the international business and the globalization of economy in the age of information determine the increasing value of English as a lingua franca used in the professional settings all over the world. As a vehicular language of the global business community, English, in the format of English for Specific Purposes (ESP), has been taught on the university level outside the English-speaking world. Quality ESP courses need quality teaching and learning materials and efficient technologies to help optimize the language-learning process.

Technologies in ESP

Traditionally involved with technologies for language teaching, ESP practitioners have been widely using such routine aids as audio and video, however, tend to employ little of multimedia - partly because of technofear (Delcloque 1997), which has been typical for the Humanities faculty, and partly because of the lack of professionally oriented, technology-enhanced, linguistically valid, and culturally authentic learning materials to be integrated into the ESP curricula. Most of these have been developed in the format of video courses and as such suffer the typical drawback of any language-learning video, the weakened feedback that can hardly be compensated by the workbook, with its limited interactivity.

Movie-based Multimedia Modules in ESP Courses

The combination of the video presentation efficiency and the computer interactive capacity has been known as multimedia capable of developing desired skills in students. But even those few available multimedia language can be just partly used only on the beginning level because they are not as specific about professional issues as should be. Besides, ideally, they should be as close to the particular ESP course as possible.

Multimedia Authoring for ESP Faculty

The issues of insufficiency, fragmentality, and obscurity can, and should be, addressed by individual ESP practitioners; today, due to the development of multimedia authoring systems, it is slowly but steadily becoming the routine part of language teaching.

While elaborating the criteria of the choice, an ESP practitioner should consider his/her personal characteristics as well as the needs of his/her course. General characteristics of an average ESP practitioner include the comparatively low level of technology proficiency, even technophobia (Glendinning 1997) which means that one of the choice criteria should be the maximum author-friendliness of the software.

Another criterion comes directly from the peculiarities of ESP as a subject: an ESP course aims in developing communication skills based on a certain language material to be practised. This means that the authoring software should include the language-exercise template.
Finally, the software should also be user-friendly, which means that students should have no problems using the outcome learning modules.

These considerations determined the final choice of The Wiser Educator™ as the environment for producing the series of Business English learning modules based on movie fragments, Learning Business in Hollywood.

Movies as Language-learning Materials

The idea of using the movie fragments as the learning material is based on several considerations. First, situations and language in the movies are truly authentic and, as such, present the real-life communication. Second, videos also display the communication background, which increases their impact on the student. Third, their soundtracks, to some extent polluted with genuine background noises, are those of the real life. Finally, the plot of the movie is much more attractive than that of the language course, which adds up to students' motivation in their work with the movie-based multimedia.

Movie-based Multimedia Module Production

The work on a single learning module comprises the following stages: selecting the movies and its episodes to be used, copying the episodes on the computer hard disc (e.g. using the Avid Cinema™ software), editing the episode (total length not to exceed one minute, according to the US copyright laws), inserting the episode, in the format of *.mov file, in The Wiser Educator™, submitting and smartlinking the text of the episode with the video, developing tasks (matching, gap filling, sequencing, true/false, and multiple choice formats), and posting the module on the Web, if necessary or desirable.

Conclusion

The outcome of this work is the original multimedia language-learning material that can be used in Business English courses as an absolutely authentic source. The format of multimedia facilitates not only multiple revisions of the discourse patterns presented but also provides feedback enforced by formal tasks that guarantee the internalization of the language material. In the future, the author plans on developing more modules presenting various situations and problems in business practice.

Abstract: Different levels of interaction in a computer game-like situation were compared as means of learning efficiency on an internet-based spatial visualization task, involving polyomino puzzles. 109 undergraduates were divided among three treatment groups: pilots, who interactively attempted to solve the puzzles; consultants, who watched and talked with pilots without interacting; and co-pilots, who alternated between pilot and consultant roles every 40 seconds, and collaborated. Participants were pre-tested before and post-tested after engaging in the experiment. Repeated measures analyses showed pilots and copilots learned more than consultants. Differences were significant at 0.05. Copilots learned most. These results suggest that alternating between interaction and observation is the best way to learn spatial visualization.

Introduction

With the proliferation of interactive computer environments, such as simulations, tutorials and "edutainment", in a variety of highly spatial content areas such as math (especially geometry), chemistry, and physics, it is important to investigate the relationship between hands-on interaction with computer programs and the acquisition of spatial visualization skills. Typically educational situations involve both hands-on and observational activities. For example in a math class, students might first watch the teacher solve problems on the board, then attempt to solve problems themselves. Similarly in a class on Excel, students might first watch the teacher create spreadsheets and then create spreadsheets themselves. Cooperative learning groups in school computer labs often place one student at the mouse and keyboard with one or more other students watching and advising; an alternate model of cooperative learning in computer labs has students taking turns at the controls. The comparative effectiveness of different variations of hands-on interactivity (hands-on, observation, taking turns, etc.) for learning spatial visualization is an important issue for the pedagogy of computer-based learning.

Although measurable by a number of standardized tests and accepted as a valid psychological construct, because of its non-verbal nature, spatial visualization remains elusive to unambiguous definition. I offer the following eclectic definition: Spatial visualization is the ability to solve multi-step problems involving configurations of shapes, primarily using mental imagery or other mental representations and transformations of same which explicitly preserve the topological and geometric relations of the problem, while optionally involving additional logical, verbal and symbolic reasoning.

Spatial visualization is an important factor in student success in a variety of spatial domains such as geometry (Battista, 1990), other higher forms of mathematics (Battista, 1990; Smith, 1964), chemistry (Pribyl & Bodner, 1987) and physics (Pallrand & Seeber, 1984).

Interestingly there is a relationship between time and spatial visualization. Without time pressure, people often resort to entirely non-spatial strategies for solving spatial problems (Smith, 1964). Moreover the measurement of elapsed time as well as success of solving the task provides a more accurate measure of spatial skill. If someone takes an exceedingly long time to solve a spatial problem, their success may be more indicative of patience or persistence than spatial visualization skill. For the purposes of measurement, it is more productive to record elapsed time, as well as success rate and determine spatial visualization efficiency as the success rate divided by elapsed time.

Additionally there is a relationship, long posited by scientists, between acquisition of spatial visualization skill and hands-on interaction. Piaget & Inhelder (1948) suggested that a combination of hands-on touching and integration of different viewpoints, is instrumental in children's development of spatial ability and mental models of spatial objects. There are similar connections between spatial visualization and interaction.
with virtual shapes in computer programs. Interactive computer graphics can facilitate improvements in adolescents and adults’ spatial visualization (Okagaki and Frensch, 1994; Gagnon, 1985).

The principle of spatial weaning (Smith, 1998) suggests that hands-on, interactive situations may initially be more beneficial to novices to a spatial domain who may not be familiar enough with the geometry of that new spatial domain to construct mental imagery necessary for visualizing solutions. Once students become more familiar with the geometry of the new domain, they may benefit more from less interactive situations. They are now familiar enough with the geometry of that domain that they can construct mental imagery necessary to visualize hypothetical solutions without the scaffolding of hands-on stimuli.

However, the very opposite of hands-on interaction, i.e., relatively more passive observation, sometimes has the advantages in educational settings (Sweller, 1994). Hands-on manipulation may divert short term memory resources needed for students to comprehend a new schema requiring the simultaneous mental manipulation of a larger number of elements. When algebra or geometry students are learning specific principles or techniques, it is often more beneficial for them to observe the teacher working a problem than to immediately try to solve it themselves. Immediately solving problems applying principles only recently introduced imposes an extraneous “cognitive load” on the students short term memory (Sweller, 1994). As students mentally manipulate the elements of the problem, they must also hold in mind the new principle that the problem illustrates, straining the capacity of their short term memory.

Considering that there are theoretical advantages for both interaction and observation, an important question is ‘How do interaction versus observation compare as learning situations?’ Smith (1998) provided some evidence that fifth-grade students, less skilled in spatial visualization, benefit more from computer interaction, while fifth-graders already skilled in spatial visualization benefit more from observation. However, it is unclear how these results extend to other age groups and other learning situations. Moreover, it is unclear how alternating between interaction and observation, another possible variation of spatial weaning, might effect acquisition of spatial visualization skills. These questions have important implications for the pedagogy of interactive computer programs in a variety of subjects involving spatial visualization skills, such as geometry, chemistry, physics, etc..

The current study seeks to statistically test the principle of spatial weaning discovered with think-aloud methods on fifth graders (Smith, 1998) and extend it to another age group, i.e., college undergraduates. Spatial weaning predicts that students unfamiliar with a spatial domain will benefit most from either high interaction, while benefiting least from observation alone.

Furthermore, we are interested in looking at these concepts from the point of efficiency in spatial visualization. Timed spatial tests emphasize mental imagery and provide a more accurate measure of spatial visualization skill than tests with no time limits. Therefore we are interested in efficiency in spatial visualization, i.e., how many problems can be solved divided by average time to solve them.

Our main research question is: How do a) hands-on interaction and b) observation compare as collaborative computer-based situations for learning efficiency in spatial visualization?

Since the pedagogy of computer interaction and spatial visualization is relatively new, a broader search of learning conditions is warranted. Perhaps some variation of hands-on interaction might be most beneficial. Thus we examined another variation on spatial weaning, i.e., alternating between interaction and observation/consulting. A secondary research question focuses on variations in hands-on interaction with a computer: How do a) exclusively hands-on interaction compare, b) intermittent hands-on interaction (alternating between hands-on and observation) and c) observation compare as learning situations for efficiency in spatial visualization?

The Study

The study used polyomino puzzles because they require a variety of spatial visualization skills, such as mental rotation, that are often used in solving geometry problems. 109 college undergraduates (48 male, 61 female, mean age 18.3 years) solved two types of computer-based polyomino puzzles: 'I-puzzles': Interactive puzzles, where participants drag and rotate pieces via mouse to assemble them into a target shape (see figure 1), and 'M-puzzles': multiple choice static 'visualization puzzles' where pieces cannot be moved, but participants must use spatial visualization to determine which of four static puzzles could be hypothetically solved (see figure 2). Validity of the M-puzzles as a measure of spatial visualization was previously obtained through correlation (.518) with a standardized test of spatial visualization, the Differential Aptitude Test, Space Relations Subset (DAT, authored by Bennett, Seashore, & Wesman, 1947).
In both types of puzzles, mirroring (or reflection) was not an allowed transformation. This created situations where the students had to accurately mentally rotate shapes to determine if a shape and a space it might hypothetically be placed in were congruent. If a hypothetical solution required a reflection, obviously it was not valid.

The M-puzzles and I-puzzles are complementary, using the same types of shapes. The M-puzzles are designed as a test of spatial visualization. The I-puzzles are intended as an interactive activity to exercise and improve spatial visualization and thus performance on the M-puzzles.

![Figure 1: Beginning position of an I-puzzle: the shapes on the left can be dragged and rotated by mouse to assemble the shapes into the shape on the right. Ending position of an I-puzzle: the smaller shapes have been assembled onto the larger shape classified as a solved I-puzzle.](image)

Which of the following puzzles can be solved?

A) ![Puzzle A](image)  
B) ![Puzzle B](image)  
C) ![Puzzle C](image)  
D) ![Puzzle D](image)

![Figure 2: An M-puzzle: the participant must pick which puzzle could be solved without removing the shapes already on the larger target shape.](image)

The experiment employed a pre-test, treatment, post-test design. Both pre-test and post-test each consisted of 9 randomly ordered M-puzzles presented to the participants by a web-browser over the internet via a Java-script program, with the results being written back to the server machine. Elapsed times were recorded locally on the computers used. Only when a participant finished the entire set of puzzles, was the data sent over the internet. Thus there was no issue of inaccuracies as a result of internet lag.

The pre-test and the post-test are approximately equal in difficulty, the M-puzzles having been calibrated at an earlier period. The M-puzzles were partitioned into two groups (pretest and post test) of approximately equal difficulty.

Participants were specifically instructed, in writing and orally, that time was a factor and they should solve the pretest and post test m-puzzles as quickly but as accurately as possible.

On the M-puzzles, used in the pre-test and post-test, participants received feedback, after each puzzle, as to whether they answered it correctly. After the full set of puzzles were completed, they were told how many total they answered correctly and given a whimsical ranking, such as "Space Cadet", "Sargent" or "Master-at-Arms" based on the number correct. Thus participants were able to monitor their progress from pretest to post-test. The pretest and posttest were completely individual activities. Participants were not allowed to talk or otherwise collaborate with each other in any way during pretest and posttest. Because the M-puzzles were presented in a different random order to each participant, opportunities for copying from each other were minimal.

In order to isolate and analyze the effects of high and low active control during the treatment, two thirds of the participants were "yoked" together in "pilot-consultant" pairs. The pilot interactively solved as many, progressively harder, I-puzzles as possible within a 40 minute period. The consultant sat next to the pilot, in front of the same computer and watched the pilot solve the I-puzzles, but was unable to interact in a hands-on manner (via mouse or any other input device) with the computer display. However the consultant was instructed...
to pay close attention to the pilot’s progress on the I-puzzles. The pilot and consultants were instructed to talk with each other as a collaborative team working towards the common goal of solving as many puzzles as possible within the 40 minute period. The pilot and consultant scenario just described represented two of the three treatment conditions.

For the third treatment condition, referred to as the co-pilot condition, pairs of participants alternated every 40 seconds between being pilot and consultant. In the co-pilot pairs, two people, via two mice, were connected to one computer. A switching device, known as the Siamese Twin Computer Mouse (patent pending) allowed only one of the mice at a time to be active and automatically switched which mouse was active every 40 seconds. See figure 3.

Figure 3: Siamese twin Computer Mouse

Thus for 40 seconds, one participant had interactive control over the I-puzzles, while another participant paired with him/her watched the same visual display without being able to interact with the mouse. The next 40 seconds, the roles were reversed so that the participant last observing now had interactive control, and vice-versa. LED’s positioned on top of the monitors alerted participants of their current role. A lit LED indicated interactive control, an unlit LED indicated observation. Co-pilot pairs were instructed to talk with each other and work towards the common goal of solving as many of the progressively harder I-puzzles as possible during the 40 minute period.

All participants, pilots, consultants and the co-pilots, were explicitly instructed to talk, collaboratively, with their partner during the treatment and to learn as much as possible from the treatment as this knowledge would be useful for the post-test. The pretest and posttest data from the three groups, pilots (39), copilots (36), and consultants (34), provided data focusing on the secondary research question: "How do a) exclusively hands-on interaction compare, b) intermittent hands-on interaction (alternating between hands-on and observation) and c) observation compare as learning situations for efficiency in spatial visualization?"

With the experimental design used, approximately two thirds (or 75) of the participants (pilots and co-pilots) were "hands-on", experiencing a significant amount of interaction with the computer during the treatment. Approximately one third (or 34) of the participants were "consultants", experiencing no direct interaction with the computer. The pretest and posttest data, grouped by hands-on versus consultants, provided data for answering the main research question, "How do a) hands-on interaction and b) observation compare as collaborative computer-based situations for learning efficiency in spatial visualization?"

Findings

As a baseline to determine if learning took place on average for all the participants, pretest to posttest progress in efficiency was analyzed with an F-Test of Multiple µ's. The test was significant at alpha = 0.05, F-Ratio = 4.68, with an obtained significance level of 0.032. Mean of pretest efficiency was 0.0798, while for posttest the mean was 0.0972. Standard deviations for pretest and posttest were 0.0556 and 0.0628 respectively.

To investigate the main research question, how hands-on versus observation compare for learning of efficiency of spatial visualization, repeated measures analyses were used. One analysis of variance, with repeated measures of efficiency on pretest and posttest as the dependent variable, and with independent grouping variable hands-on versus consultant, and gender as covariant, was significant at the 0.05 level (F =
3.98, obtained significance level was .049). Table 1 shows the means for the efficiency for the two groups (hands-on versus consultants) in pretest and posttest.

</table>

Table 2: Means of efficiency by group, pilots, co-pilots and consultants.

Note that the copilot group had the highest posttest mean efficiency, as well as the most improvement in efficiency from pretest to posttest, while the consultant group had the lowest in both. The results for the pilots group were similar to that of the copilots. A second repeated measures, focusing on copilots and consultants only, with efficiency as the dependent variable, and role as the independent variable, was also significant at the 0.05 level (F=5.861, level of significance obtained was 0.018. A third repeated measures analysis of pretest and posttest efficiency, looking at the pilots and the consultants only, and also with gender as a covariate, was not significant at the 0.05 level (F=1.886, obtained significance was 0.174).

To investigate the secondary research question, how exclusively hands-on (pilots) versus intermittent hands-on (copilots) compare for learning efficiency in spatial visualization, we compared how the two interactive groups (pilots and copilots) progressed, pretest and posttest, in terms of efficiency. Selecting only the groups, pilots and copilots, a repeated measure of pretest and posttest efficiency, with grouping variable role during the treatment (pilot versus copilot) and gender as covariant, was not significant at the 0.05 level. F was .357.

**Conclusions**

Since across all the participants, the posttest mean of efficiency was significantly greater than the pretest, learning of spatial visualization apparently occurred. The experiment provided an appropriate scenario for comparing different situations for learning spatial visualization.

We can also conclude that some amount of interaction with the computer is superior to no interaction, since the repeated measures analysis, comparing hands-on (pilots and copilots) versus consultants, indicated a significant difference in improvement on efficiency in spatial visualization. Similarly intermittent interaction with a computer is clearly preferable to consulting/observing, since the repeated measure analysis comparing the copilot and consultant groups indicated a significant difference. On the other hand, there was no significant difference in learning between exclusive interaction with a computer and intermittent interaction.

The first theoretical constructs motivating this study was spatial weaning, the idea that hands-on/interactive situations may be initially more beneficial to novices to a spatial domain (system of shapes) than hands-off/reflective situations. The additional sense information, the integrated visual, tactile, proprioceptive and motor processes associated with the hand-eye coordination of interactively solving spatial problems provide a scaffolding for learning mental image-based transformations, such as mental rotation, particular to that spatial domain (system of shapes). The results indicate that the principle of spatial weaning, discovered in the context of young children, apply as well to adults. That the copilot/alternating group performed best indicates that length of time period needed for spatial weaning is relatively short for college students. Hands-on/interactive situations provide additional advantages such as involvement, greater attention and motivation.
The second theoretical construct motivating this study was cognitive load, or the idea that hands-on interaction may impose an extraneous cognitive load that interferes with learning of the new skills. Cognitive load theory predicts that the consultant group should outperform the two hands-on groups, definitely not the case in this experiment. This is especially surprising considering that the consultant treatment condition was much more similar to the posttest than was either of the hands-on conditions. Since both the consultant and posttest activities were hands-off and reflective, one might have expected optimal transfer. However, since the copilot (or alternating) group learned most, perhaps periodic role-switching promotes meta-cognition, or productive reflection on the problem-solving process, i.e., interaction evokes reflection. Hands-on and consulting are complementary. Both spatial weaning and cognitive load theory are supported by the results.

The recommendation for teachers is to have their students alternate interactive activities with more reflective activities. In terms of classroom logistics, when pairing-up students on computers, intermittent interaction via the Siamese Twin mouse, provides twice as many students with hands-on interactive experience, than is possible with an exclusive hands-on situation.

Abstract: This qualitative study investigated differences, from the point of view of instructors, between teaching college courses over the WEB vs. more traditional face-to-face formats. We interviewed 21 college instructors who had taught in both formats. Four of the interviews were by telephone and 17 by email. Interview fragments were categorized and counted for frequency to highlight emerging trends. Results indicate that web-based classes have profoundly different communication style than face-to-face classes. This has far-reaching consequences for online classes, in terms of greater equality between students and instructors, greater explicitness of written instructions required, greater workloads for instructors, deeper thinking manifested in discussions, initial feelings of anonymity giving way later to emerging online identities. Authors propose a model with two competing systems, isolation effects and community effects.

Introduction

Experiencing a huge demand for college courses taught over the WEB and not wanting to be swept aside by competitors from the commercial sector, universities are often pressuring faculty to teach courses online. Many such faculty have never taught online, and therefore wonder what they are getting into. What are the differences between teaching online versus face to face? What can faculty expect from the experience of teaching college courses over the WEB? Other faculty have some experience teaching online, but haven't shared their experiences, nor read the literature on distance education. Their knowledge remains fragmentary. Are faculty experiences with teaching online specific to the their content area or representative of the larger experience of teaching over the WEB? The current study seeks to integrate the experiences of professors currently teaching online into a qualitative description.

Before embarking on the research, we were aware of a number of research-based notions of distance education. Firstly that it requires a considerable amount of time to design and develop an online class (Williams & Peters, 1997). The instructor must shift from the role of content provider to content facilitator, gain comfort and proficiency in using the web as the primary teacher-student link, learn to teach effectively without the visual control provided by direct eye contact (Williams & Peters, 1997). Moore 1993) suggested that there are three types of interaction necessary for successful distance education: 1) learner-content interaction, 2) learner-instructor interaction and 3) learner-learner interaction. Distance learning courses need to ensure that all three forms of interaction are maximized. Peters (1993) criticizes distance education saying that it reduces education to a kind of industrial production process, lacking the human dimension of group interaction, and even alienating learners from teachers. He compares distance education to a mass-production assembly line process where a division of labor (educators and communications specialists) replaces the more craft oriented approach of traditional face-to-face education. However Peter's (1993) pre-dates the current web-based boom in distance education. His notions, like the computer themes in Stanley Kubrick's 2001: a Space Odyssey, sound slightly like industrial age paranoia towards computers. The personal computer and the internet have probably been a greater force towards individualization than mass production. An updated overall qualitative description of the current instructor experience of college web-based teaching is needed. What are the differences between teaching web-based distance education courses versus teaching face-to-face? The current investigates the online experiences of a number of college instructors.
The Study

We interviewed 21 instructors who had taught both in the distance and the face to face format. The instructors ranged from assistant professors to adjunct professors. 15 of the 21 instructors taught in the context of the SUNY Learning Network, a non-profit grant funded organization that provides the 15 State Universities of New York (SUNY) with an infrastructure, software, web space, templates for instructors to create their online course, workshops on developing and teaching online courses, a help desk and other technical support for web-based distance education. The remaining 6 informants taught web-based distance education courses in similarly supported situations at state universities in California and Indiana. Four of the interviews were conducted over the telephone and 18 via email. The four telephone interviews occurred first and were used to develop a set of open ended questions for email interviews. Since email interviewing did not require the laborious process of transcription, the email interview process allowed the gathering of data from a much larger number of participants than possible with telephone or face to face interviews alone. By reading over the transcriptions of the telephone interviews, the investigators found emerging themes that were converted into 27 open-ended essay questions comprising the “email interview”. The email interview, as it is used in this study, is differentiated from a questionnaire on several counts. It uses open-ended essay-style questions, as opposed to Likert style, fill in the blanks or multiple choice items common to questionnaires. The initial questions included some “chit-chat” and informal questions designed to put the interviewee at their ease. It also involved some degree of interaction between the interviewer and the interviewee. The interviewers often emailed participants follow-up questions to particularly interesting responses. The informants averaged approximately 45 minutes to complete the email interview. The investigators read over all the interviews at least two times, looking for trends and consistencies and generating 39 categories of responses and mnemonic codes to symbolize these categories. Some typical coding categories include ">WK" meaning that the online classes require more work and "N FUNNY" meaning that humor was problematic in the online environment. Three investigators coded the interviews and then counted up the frequencies of the categories of responses, as the number of times a particular response occurred (not the number of informants who said or wrote a particular response). So if one informant wrote at three different times in the interview that online classes required more work, that interview contributed three occurrences of the >WK category, not one occurrence. The coding system was done, not to be objective, but rather to uncover trends in the data. This type of qualitative research is by its nature non-objective. Never-the-less, to get some estimate of the level of consistency between the three investigators who coded, six of the email interviews were coded by all three coders and a comparison made between their codings. We calculated the correlation matrix a between the three coders, with the correlations being 0.681 between coders 1 and 2, 0.685 between 1 and 3, and 0.744 between 2 and 3. The determinant of the correlation matrix, which would be zero if the coders agreed 100 percent and 1 if they were totally independent, is 0.208, certainly much closer to agreement.

Table 1: Most common types of responses in the interviews.
Findings

Table 1 shows the twenty-one most common types of responses, including in the columns from left to right, the frequency of the response, the mnemonic name of the category and a short description.

Some of the most important, most emphasized and most frequent responses made points we had not directly asked about. A lot these issues related to bandwidth limitations and the dominance of text in the WEB-based classes. Some instructors feel like a life time of teaching skills go by the wayside. They can not use their presence and their classroom skills to get their point across. Nor can they use their oral skills to improvise on the spot to deal with behavior problems or educational opportunities. Because of the reliance on text-based communication and a lack of visual cues, every aspect of the course must be laid out explicitly, in meticulous detail to avoid misunderstandings. Every lecture must be converted to a typed up document. Directions for every assignment must be spelled out in a logical, self-contained way. Therefore web-based distance classes require considerably more work, often including hundreds of hours of up-front work to set up the course.

On the other hand, the development of an online class, especially if it is the conversion of a face-to-face to the online environment, makes the instructor confront and analyze the material in new and different ways.

"The web course was interesting to develop because it required that I break down pieces of information into small parts and sequence each part in such a way as to make sense to someone who is reading the information online. Wrestling with how and what to link to what presented many challenges that were good for me. I really had to think about the course and the nature of how it was presented to students."

Once the course begins, the long hours continue. Online instructors must log on to the course web site at least three or four times a week for a number of hours each session. They respond to threaded discussion questions, evaluate assignments, and above all answer questions clearing up ambiguities, often spending an inordinate time communicating by email. The many instructor hours spent online create an "online presence", a psychological perception for students that the instructor is out there and responding to them, without which, students quickly become insecure and tend to drop the class.

This great amount of work sounds intimidating, however, most online instructors looked forward to their time spent online as time away from their hectic face-to-face job, a time spent in an alternate abstracted more intellectual world: "This is why I like the online environment. It's kind of a purified atmosphere. I only know the students to the extent of their work. Obviously their work is revealing about them."

The web environment presents a number of educational opportunities and advantages over traditional classes, such as many informational resources that can be seamlessly integrated into the class. Instructors can assign web pages as required reading, have students do research projects online using online databases. However it is important that the instructor encourage the students to learn the skills to differentiate valid and useful information from the dregs, as the Internet is largely unregulated.

Some instructors also had online guests in their classes, authors of articles, experts in their field, residing at a distance, yet participating in online threaded discussions with the students in the class. All these things could theoretically be accomplished in a tradition class by adding an online component, however because online classes are already on the web, these opportunities are integrated far more naturally.

Other advantages of online classes result from psychological aspects of the medium itself. The emphasis on the written word, resulting from bandwidth limitations, encourages a manifest deeper level of thinking in online classes. A common feature in online classes is the threaded discussion. The fact that students must write their thoughts down and the realization that those thoughts will be exposed semi-permanently to others in the class seem to result in a deeper level of discourse.

"The learning appears more profound as: the discussions seemed both broader and deeper, the students are more willing to engage both their peers and the professor more actively. Each student is more completely "exposed", and can not simply sit quietly throughout the semester: the non-participating students are equally as noticeable by their absence from the course as the verbal are noticeable by their presence. The quality of students' contributions can be more refined as they have time to mull concepts around in their thinking as they write, prior to posting."

The asynchronicity of the environment means that the student (or professor) can read a posting and consider their response for a day before posting theirs.
Every student can and, for the most part, does participate in the threaded discussions. In online classes, the instructor usually makes class participation a higher percentage of the class grade, since such participation can be more objectively graded (by both quantity and quality) through instructor access to the permanent archive of threaded discussions, unlike in face-to-face classes, where, because of time constraints, a relatively small percentage of the students can participate in the discussions during one class session. Because of the absence of physical presence and absence of many of the usual in-person cues to personality, there is an initial feeling of anonymity, which allows students who are usually shy in the face to face classroom, to participate in the online classroom. Therefore it is possible and quite typical for all the students to participate in the threaded discussions common to web-based classes.

"... I enjoy these courses and the 'forced' voicing of all the students. One cannot simply sit there and not participate!"

This same feeling of anonymity creates, some political differences, such as more equality between the students and professor in an online class. The lack of a face-to-face persona seems divests the professor of some authority. Students feel free to debate intellectual ideas and even challenge the instructor.

"In a face-to-face class the instructor initiates the action; meeting the class, handing out the syllabus, etc. In online instruction the student initiates the action by going to the web site, posting a message, or doing something. Also I think that students and instructors communicate on a more equal footing where all of the power dynamics of the traditional face-to-face classroom are absent."

"On line you establish yourself again and again with each response."

Students are sometimes aggressive and questioning of authority in ways not seen face-to-face. With the apparent anonymity of the internet, students feel much freer to talk.

"Students tended to get strident with me on line when they felt frustrated, something that never happened in f2f classes because I could work with them, empathize and problem solve before they reached that level of frustration."

In the opening weeks of distance courses there is an anonymity and lack of identity which comes with the loss of various channels of communication. Ironically, as the class progresses, a different type of identity emerges. Consistencies in written communication, ideas and attitudes create a personality that the instructor feels they know.

"Interesting story: recently I had printed out a number of student papers to grade on a plane. And (damn them!) most forgot to type their names into their electronically submitted papers. I went ahead and graded and then guessed who wrote each one. When I was later able to match the papers with the names, I was right each time. Why? Because I knew their writing styles and interests. When all of your communication is written, you figure out these things quickly. I would know if someone else wrote a paper."

This emergence of online identity may make the whole worry of online cheating a moot point. Often stronger one-to-one relationships (instructor-student and student-student) are formed than in face to face classes.

Conclusions

The authors' interpretation of the data is that the different factors discussed above in the results section interrelate with each other in ways that seem complicated at first but turn out to be quite simple if looked at diagrammatically with vectors of causation. We therefore propose a theoretical model. The most common response from online instructors was <CHN, meaning fewer channels of communication online. Fewer channels of communication, <CHN, is the major factor driving two competing systems of causation, 1) isolation effects and 2) community effects, which together form an online paradox.
Figure 1 shows the isolation effects. Fewer channels of communication (<CHN) results in a need for more explicit communication (X). The need for explicit communication causes the instructor to spend more time developing the material before the course begins, in turn creating more work for the instructor (>WK). The need for explicit communication continues as the course progresses, resulting in still more work for the instructor (>WK). All this online work may minimize time for face-to-face relationships further isolating the instructor. Fewer channels of communication (<CHN) has a number of other isolation effects. <CHN creates ambiguity and student insecurity sometimes forcing the instructor to communicate excessively by email, with a number of negative effects. Since other students can not see the email, the instructor often has to answer the same questions more than once, resulting in more work, >WK, for the instructor. If questions are asked in a public forum, such as threaded discussion, other students can also answer questions, helping to build an online community. On the other hand, email can build individual relationships between the instructor and student. Thus email between instructor and students encourages the instructor-learner interaction and lessens the transactional distance talked about by Moore, but instructor-learner email also lessens learner-learner interaction. If questions are posted in a public place, then often students will help each other, promoting community. The authors advocate minimizing email and suggest that it should be used only for questions requiring confidentiality, such as discussion of grades. <CHN also forces students to be more self-reliant (O) and to exercise greater time-management skills (>TM). These are valuable skills, however some students may need more personal or community support to develop these skills. Thus undergraduate courses may be less appropriate for teaching in online, asynchronous, text dominated environments. Because of <CHN, and the resulting requirement for greater self-reliance and time-management skills, there is a greater attrition rate in online courses (category --). Distribution of grades in online classes often has a "U"-shaped curve, instead of the bell-shape normal distribution. Finally, <CHN creates ambiguity making humor risky in the online environment (N FUNNY). Since humor is a tension releaser, and often a norm binding groups together, N FUNNY is an isolation effect.

Figure 2. Community Effects
CHN is the major factor and the advantages of asynchronous environment (ASYN!) the minor factor in creating an array of community effects (See figure 2). CHN results in an initial loss of identity online (N ID). N ID promotes more equality between instructor and students (=) and greater student freedom of speech online because of the anonymity (:0). The minor factor, advantages of asynchronous environment (ASYN!), allows all of the students to participate in class discussions (ALL). Equality, freedom of speech and all students participating (=, :0 and ALL), result in three other effects, emergence of identity based on consistencies (style) of written communication and ideas (UR), greater individual relationships (>1-1) and building of relationships between instructor and students (>><<). The six effects, greater equality between instructor/students, freedom of speech, all students participating, emergence of online identity, greater individual relationships and building of relationship between instructor/students, are the community effects of online, web-based, asynchronous distance education. The six community effects, in combination with the advantages of asynchronous environment, the availability of greater information resources over the net (>INFO) and the effects of the written medium itself; result in a deeper level of thinking in this text-based environment (WR>>).

The paradox of online education is that less channels of communication result in a tension between isolation effects and community effects. When isolation effects predominate, students drop out, when community effects predominate students succeeding the course; creating a "U"-shaped grade distribution. For those students who do stay with the course, there the potentiality for community is at least as great as for face-to-face classes.

Current web-based online college courses are not an alienating, mass-produced product. They are a labor-intensive, highly text-based, intellectually challenging forum which elicits deeper thinking on the part of the students, and which presents, for better or worse, more equality between instructor and student. Initial feelings of anonymity, not withstanding, over the course of the semester, one-to-one relationships may be emphasized more in online classes than in more traditional face-to-face settings. With the proliferation of online college classes, it is important for professor to understand the flavor of online education, to be re-assured as to its intellectual and academic integrity of this teaching environment.

References

The Campus Neo project will develop an integrated environment for distance education and life-long learning. This environment enables Nordic universities and other organizations to establish a new virtual campus, the interregional university Campus Neo, which focuses on the advanced use of networking for research and educational purposes. The main objective with the Campus Neo project is to integrate existing interactive services, collaborative learning environments and communication methods in a way that should enhance tele-presence among students and university professionals. Combining asynchronous learning services with synchronous communication tools fulfils the need of a complete environment. The project seeks synergy benefits and forms user friendly, functioning and permanent possibilities for collaboration on the basis of already existing solutions for on-line education. This is achieved through three dimensions: the innovative utilisation of infrastructure and networking, the use of technological applications and tools, and the implementation of appropriate pedagogy and learning mechanisms.
Technology Opportunity Centers: Closing Digital Divide

Tatiana Solovieva
West Virginia University
918 Chestnut Ridge Professional Building, Suite 12
Morgantown, WV 26506-9127, USA
tsolovie@wvu.edu

Abstract. In 1996, the West Virginia High Technology Consortium (WVHTC) Foundation, with 20 partners, received a U.S. Department of Education Challenge Grant titled “Your Future in West Virginia... Growing Together.” Beginning from an “idea” in 1996, WVHTC Foundation’s Education Division forged dynamic partnerships with the WV State Department of Education, the WV Board of Education, County Boards of Education, and other education advocates. They have equipped and managed the Technology Opportunity Centers, trained teachers in computer-technology skills statewide, and have been instrumental in other education initiatives and accomplishments throughout West Virginia. In the variety of training courses offered by the WVHTC Foundation, at no cost to the participants, thousands of teachers and community members have gained practical experience in use of various computer applications. The present brief paper examines the input, process, and outcomes of the Technology Opportunity Centers (TOCs) in the state of West Virginia.

TOC Background

The Technology Opportunity Centers (TOCs) operate in a state that has earned top ratings on its climate for education in the past few years. West Virginia ranks near the bottom of the 50 states on health status of its citizens and its economic picture. In contrast, West Virginia is a rising star on the education horizon.

In 1996, the West Virginia High Technology Consortium (WVHTC) Foundation, with 20 partners, received a U.S. Department of Education Challenge Grant titled “Your Future in West Virginia... Growing Together.” The partners included Barbour County, Harrison County, Marion County, Monongalia County, Preston County, Taylor County, Clay County, Mingo County, and Nicholas County. The initial grant was for $4.1 million over a five-year period. The competitive grant was one of 24 funded from 538 applicants.

Goals of the challenge grant were:
To expand and enhance the capacity of teachers to teach, using technology.
To expand and improve curriculum and technology applications in schools.
To plan and implement education and training programs in the area of career information and decision-making for students and community members.
To enhance the marketability of displaced workers in the community.

Thus, the grant-funded program was to benefit students, teachers, and community members in the Technology Opportunity Centers (TOCs). The WVHTC Foundation’s program for Education is active in advertising these TOC course offerings. For the most part, word-of-mouth of these valuable, free-of-charge courses keeps the enrollments high. When the waiting list gets low, the WVHTC Foundation sends out advertisements and public-service announcements. Scheduling for a particular course and registering students begins about two months prior to the start date. If enrollment for a course is not full, the WVHTC Foundation attempts to fill the remaining slots with teachers. Full enrollment is defined in terms of the number of workstations in the particular TOC.

These centers are computer laboratories located in the schools, equipped with at least 15 multi-media computers, a server, a scanner, a computer projector, and two printers. The TOCs are used day and night. During the school day, students and teachers use the lab to learn basic computer skills, integrate computers with a variety of subject matters, and develop career decision-making skills. In the evenings, students, parents, teachers, and any community members are able to enroll for the computer-skill and career-oriented courses. If a student 15 years of age or younger enrolls for an evening course, he or she must be accompanied by a parent (guardian) and share a workstation with that adult. Students of all ages can benefit from the evening courses. Computer training offered in evening courses, at no charge, has included the topics of Windows, Microsoft Office, the Internet, and Career Explorer. Courses have been designed and are offered at the basic level and the intermediate level. The intermediate-level courses cover these topics in greater depth, in addition to Microsoft Access. Many teachers have enrolled in these courses along with displaced workers and other community members. These computer labs, equipped by funds from the challenge grant, have grown in number to 21 schools in Year 4.
Each TOC has two Directors who are teachers in that school. They receive an additional salary stipend for their services as TOC Directors ($1,250 for each ten-session course taught). All of the TOC Directors are experienced teachers, most with more than 15 years in public school teaching. They teach in elementary, middle, and high school. They teach reading, sciences, English, social studies, math, computer education, business, library, music, vo-tech, and physical education. As Directors, they maintain the TOC laboratory and teach the evening courses. Each Director usually teaches four evening TOC courses per year. The evening courses usually have been enrolled at full capacity and are offered across a 10-week period at three hours per evening (6 p.m. to 9 p.m.) once per week. The 30-hour evening courses usually begin in September, November, February, and April. Depending on the needs and preferences of the Director, a different schedule can be offered. For example, a course might be scheduled (1) beginning in January rather than February or (2) operating two evenings per week for five weeks totaling 30 class hours rather than one evening per week for 10 weeks totaling 30 class hours. Two course offerings per year for a Director must be on the one-everying-per-week for 10 weeks schedule. The other two offerings can be scheduled to accommodate the Director’s availability. Thus, each TOC attempts to offer eight evening courses per year (four by each director).

Findings

At the start of each evening course for community members, these adult students filled out a “Pre-test.” They filled out the same form as a “Post-test” at the conclusion of the course, 10 class sessions later (after 30 hours of instruction in a TOC laboratory. There are ten application areas for the community students to rate their “knowledge/skill level” in the Basic course (computers generally, word processing software, spreadsheet software, basics of the Internet, career software, MS Windows, MS Word, MS Excel, MS PowerPoint, and Internet Explorer). Two applications (database software and MS Access) are added to these ten for participants in the Intermediate course. For each application, the community member enters a number from 0 (know nothing or no skills) to 9 (can teach others or maximum knowledge/skills).

A summary of the analyses of variance is reported in Figure 1. Recall that the alpha level selected for these tests was a conservative p < .01 level. As the reader will note in Figure 1, all applications showed a significant gain from pre-course to post-course. Means (but not standard deviations) also are listed in Figure 1. The analysis of variance takes the standard deviations into account in computing the F value. Taken together, the means, F values, and significance levels fully describe the findings. Thus, the Basic courses and the Intermediate courses demonstrated powerful effects in support of the hypotheses. That is, beyond any reasonable doubt, both Basic and Intermediate courses produced significant gains in perceived knowledge and skill in computer applications through 30 hours of targeted instruction and experience.

Conclusions

The climate of education in West Virginia has been positively influenced by TOC process and product. The full set of 21 proposed TOCs has been brought to productive operation with day and evening services to the broad constituency of learners. Evening courses at the TOCs (Basic and Intermediate) continue to be fully enrolled, and healthy waiting lists for all counties are maintained. Community members extol the virtues of their educational experiences at the TOCs. These adult learners consistently indicate statistically significant gains in confidence and competence. Participants in TOC courses give superior ratings of the TOC Directors, including being well prepared, being competent, answering questions, and giving individual attention to students as needed. Formative and summative, formal and informal, quantitative and qualitative data point to (1) extensive use of TOCs by community members, students in the TOC schools, and teachers in TOC and other schools and (2) extensive benefit to those who use the TOCs.

In the variety of training courses offered by the WVHTC Foundation, at no cost to the teacher, thousands of teachers have gained practical experience in use of various computer applications. They not only learn how to use the technologies but also gain experience, guidance, and networking with other teachers on integrating computer technology into student learning.

Integrating XML-based Courses into a LTSA-Environment

Ralph Sontag, TU Chemnitz, Germany; Uwe Hübner, TU Chemnitz, Germany

The Chemnitz University of Technology was the first one in Germany, which was able to offer an internet-based study about information and communication technology.

The first lessons was developed in HTML, but this causes some disadvantages. To overcome the problems we changed to a XML-based approach. We identified a relevant set of XML-elements, e.g. to mark important hints, examples or personal opinions. The XML-code will be translated by different tools into a controlable HTML layout.

This concept makes it simple to generate different views. Assistents can see the answers to some exercises, while the participants get links to the "virtual seminars". The learners evaluate her progress by on-line-tools.

This design implements the main components of Learning Technology System Environment. It uses small tools written in Tcl and standard protocols. All data are saved in XML-documents and can be used by different tools. The components communicate about open protocols.
Collaborative Knowledge Building in Web-based Learning:
Assessing the Quality of Dialogue

Abstract: This paper addresses the question of how to qualify a knowledge building dialogue in web-based collaborative learning. It investigates the idea of qualifying the dialogue through grading requirements and through providing students with meta-awareness around their dialogue. We investigate and analyze the changes in quality of student interaction in three different deliveries of the course that emerge in response to three different types of instruction on expected behavior. From this we draw preliminary conclusions on the extent to which descriptions of expected behavior influence the interactive process and the quality of the interaction.

Introduction

Web-based learning is assuming an increasing role in education at college and pre-college levels (Bates 1999; Collis 1996; Fjuk et al. 1999). It is not only situations of continuing education and lifelong learning which call for flexible organization of the learning process, e.g. with the purpose of bridging distances. The obvious advantages in terms of a more flexible, time and space independent organization of the learning process, also within higher education, are clear (Harasim 1999). The flexible organizational design of web-based learning, by itself, does not make this method superior to other methods. Of more importance is the quality and design of the learning process. Many flexible designs offer no possibilities for interaction and collaboration among students, but are rather sterile and lack a framework to stimulate collaborative knowledge building. Others do so, but have problems - even when interaction occurs - in qualifying a knowledge building dialogue.

This paper deals with the question of how to qualify a knowledge building dialogue through grading requirements and as an effect from providing the students with meta-awareness around the functions of the requested comments in the dialogue. The paper suggests that grading requirements as well as providing awareness around the requirements related to the function of comments in the dialogue contribute to qualifying a knowledge building process in collaborative learning.

In section 2 we provide some brief information of the web-based course producing the data of our analysis. Section 3 provides an account of our knowledge building perspective and the criteria of quality used in our analysis of web-based dialogues. Section 4 addresses the communicative conditions of web-based environments, forming part of the rational behind our hypothesis. In section 5 we give a more detailed account of our research design and of the method used in our analysis, while section 6 provides the basic analysis. We reflect on the results of the analysis in section 7 and discuss future research perspectives.

Development of Dialogue Requirements in “Global Change”

Global Change (GC) is a conventional science course for senior undergraduates or beginning graduate students at a US university. It gradually has been migrated to a web base over the last 6 years, with new features being added as ancillary software has become available. Learner-centered activities in place of or supplemental to conventional lectures have been introduced.

The course consists of a sequence of learning modules on different global-change topics, each having evolved from a conventional university class time period. Each unit has a set of objectives, summary information on the topic, student-submitted collaborative (2-3 students) summary of class time discussion, “problems to
ponder" as discussion starters for the electronic dialogue, and extensive lists of web and other information on the learning module topic. Each unit has its own electronic dialogue for student discussion among themselves and with outside experts or representatives of selected groups. Electronic dialogue on individual learning unit topics is graded. The course is viewed by the designers as a laboratory for experimenting with a variety of pedagogical techniques and initiatives (Taber et al. 1997).

The course went on the web in Spring 1995. Affiliated with the course was an opportunity to engage in electronic dialogue. The use of dialogue and associated instructor evaluation of student engagement in dialogue changed over the years as follows:

1995:
Electronic dialogue was available separately for each lecture topic, and 5% of the evaluation of student performance was based on whether or not a student participated. There were no minimum requirements on amount of discussion and no attempt was made to judge quality as part of the evaluation of students.

1996:
Same as 1995 except 15% of the grade depended on the electronic dialogue. Some weak attempt was made to judge quality but primary criterion was participation and not quantity or content.

1997:
Requirements for participation in electronic dialogue were substantially enhanced. For full credit, the student was required to post at least 15 entries, which had to include responses to at least 6 other students' comments. Furthermore, these entries had to elicit comments from 3 other students. They also were required to respond to 3 questions issued by the instructor and to give their views on 3 additional ethical questions relating to global change. Thirty percent of evaluation of students was based on these numbers but no evaluation of quality was attempted. A virtual portfolio was introduced for each student to manage discussion.

1998 and 1999:
Same as 1997.

2000:
Same requirements as 1998 with addition of the knowledge-building process (Stahl 1999) that required students to meet specific quality criteria in their discussion. Also, students were required to assess their own writing and demonstrate how they had met the criteria. Forty-two percent of the evaluation of student performance was based on discussion.

Criteria of Collaborative Knowledge Building in Web-Based Learning

To put our analysis of electronic dialogues in perspective, we briefly outline the set of criteria which we assert are signs of quality in a web-based collaborative knowledge building process.

In the principles of collaborative learning, the process of learning is viewed to be a fundamentally social phenomenon, regardless of the varying theoretical emphasis in each single approach (Dillenbourg et al. 1995). Several other learning theories confirm this view, e.g. Etienne Wenger in his latest book, "Communities of Practice" (Wenger 2000).

The process of knowledge building (KB) in collaborative learning, first explored by Harasim (1989), involves mutual exploration of issues, mutual examination of arguments, agreements and disagreements, mutual questioning of positions, dynamic interaction and weaving of ideas (Harasim 1989; Kaye 1992; Sorensen 1997). Mason (1993) finds this view to be in agreement with the communicative potential of the online environment, although she also points out the weaknesses of the online dialogue being that it quite often never reaches synthesis or closure (Mason 1993).

In view of the generally recognized difficulties in fostering online student dialogue that converges (e.g., synthesizing) rather than diverges (noted by Mason), Stahl (1999) suggests a set of factors that characterize quality in the KB process:

- **Brainstorming** is the introducing of new ideas that relate to the topic or task and offer a perspective not previously considered; **Articulating** includes explaining complex or difficult concepts;
Reacting provides an alternative or amplified perspective on a concept previously introduced by a student;

Organizing refers to assembling existing thoughts or perspectives in such a way that a new perspective emerges;

Analysis includes comparing or contrasting previously articulated views or puts new understanding on existing data;

Generalization takes comments or data already presented and extracts new information or knowledge that applies to a broader set of conditions.

Implementing these learning quality criteria of collaborative KB requires a corresponding meta-functional pedagogy or instruction that facilitates and motivates such collaborative dialogue (see section 4).

Reflective Dialogue Primary to Involved Dialogue

Promoting knowledge-building dialogue within the context of collaborative learning appears to be a complex challenge. In searching for reasons for this, some research has focused on the design and nature of the collaborative activities implemented in the learning process (Collis 1997), and others on the quality and nature of the virtual environment and the evolvement of electronic inter-human dialogue (Scardamalia & Bereiter 1996; Sorensen 1993). Alternative studies have concluded the social aspect of a group process to be an essential motivator for collaboration in online learning (Harasim 1993; Cornell & Martin 1997). It seems to carry a rather high proportion of a group member's inclination to engage in any interaction with the group at all (Moore & Kearsley 1996). This seems in total agreement with the widely acknowledged insight, that inclination to interact online is sensitive to the perception of interaction (Gunawardena 1995).

Considerable research has been directed towards the role and meta-communicative behavior of the instructor (Feenberg 1989). Recent studies along this line of thinking have described the online universe as a meta-communicative world. Contrary to the physical world in which involvement is viewed to be primary to reflection (Heidegger 1986) - the virtual universe provides a context and an "ontology" in which reflection may be said to be primary to involvement (Sorensen 1999). Assuming this new dialogical paradigm, and this primary position of reflection and meta-communication, it is very conceivable, from the perspective of collaborative interaction and dialogue in Web-based learning, that also the task of scaffolding learning processes that aim at supporting both interaction and (self)reflection, must move at a meta-level in terms of creating awareness of the function in a dialogue of a contributed comment.

Research Design

In our analysis we wanted to investigate the role and nature of the instructions in the requirements given to the students, stimulating them to interact. We wanted to assess whether meta-communication in terms of providing meta-awareness of "the function of a comment" in the KB process, will improve the quality of the KB dialogue, according to the definition of quality as suggested by Stahl (1999). In our research design and analysis we make the following assumptions:

1. Characteristics of discussion and comments that contribute to a KB process are (Stahl 1999): brainstorming, articulation, reaction, organization (including synthesis), analysis, and generalization.

2. Use by students of characteristics of the KB process in written dialogue contributes to student learning (as characterized in section 3).

Our hypothesis for the analysis is then, that by explaining the characteristics of a KB-process, and by grading (Sorensen & Takle 1999) student discussion on the basis of their reflected use of these characteristics, students will measurably increase their use of these characteristics. The rational behind the hypothesis is an acknowledgement of the need in primarily reflective virtual environments (as described in section 4) for communicatively providing meta-awareness in relation to expected communicative actions (as described in section 3).

We have evaluated characteristics of student dialogue and its relationship to course requirements by assembling 10 comments from 1995, 10 from 1997, and 10 from 2000. These were drawn at random (although
not strictly with statistical rigor) and represent comments made under quite different criteria for evaluation of student performance. In drawing the comments from the respective databases, care was taken to draw comments from the same (or very closely related) topics in each of the three years.

The data sets represent (a) comments with no obligations attached as far as evaluation of student performance was concerned (1995), (b) comments when numbers of responses and numbers of interactions among students were used for evaluation (1997), and (c) comments when the KB requirements were imposed. For 2000, we also have, for some database entries, the student self-assessment of their own writing. We also have assigned a numerical value from 1 to 10 representing the quality of the comment.

Analysis of Dialogues

For the purpose of our analysis we have categorized the analyzed comments in the online dialogues according to the knowledge building quality requirements presented by Stahl (1999) in section 3:

- comment with no KB characteristics
- question (a request for clarifying information)
- analysis (comparing or contrasting previously articulated views)
- articulation (the explanation of complex or difficult concepts)
- reaction (presenting an alternative or amplified perspective on a concept previously introduced)
- brainstorming (the introduction of new ideas that relate to the topic or task and offer a new perspective)
- organization (the organization of existing thoughts or perspectives)
- generalization (extracting new information or knowledge from comments already presented, that applies to a broader set of conditions)

A level of quality (1-10) was subjectively assigned to each comment. The mean quality went from 4.4 to 3.2 to 5.3 from 1995 to 1997 to 2000, respectively. In 1995 a preponderance entries were questions, whereas in 1997 there were more reactions to other students. In 2000, more student comments were characterized as articulation.

From these results, we draw the following tentative conclusions. In 1995, with no requirements on volume or quality of writing, students used the electronic dialogue for asking questions. The questions did not seem “forced” since their postings had essentially no bearing on how they were evaluated in the course. For 1997, the overall quality of the postings went down. There seemed to be more “forced” responses. More questions were of a rhetorical nature, rather than seeming to originate out of curiosity about the subject matter. We attribute this to a sense of urgency on the part of students to meet the volume obligations of the evaluation scheme. The increase in quality from 1997 to 2000 suggests that students responded to the demands for higher quality of writing by meeting the requirements of the KB process. A notable difference in the 2000 discussion as compared to previous years was the reduction in the “social” or “social” content. But at the same time, the number of comments increased. Comments were much more like individual essays and less spontaneous.

Perhaps the largest difference over the change in dialogue requirements was in the length of each entry. In 1995 the average length of the 10 entries was 88 words and in 1997 the average was 93 words. In 2000, however, the average soared to over 2,500 words. And the quality of the grammar of each posting increased markedly as well. This likely is attributable to the fact that students wrote their postings as essays in word processors on their own computers, subjected them to spell checking, and reviewed the grammar before cutting and pasting them into the course web-site. This increased quality and quantity came at the expense of spontaneity and “social” content.

Discussion and Future Perspectives

How do we evaluate the results of our analysis? Assuming that meta-awareness (Gutwin et al. 1995) of KB characteristics among students as well as grading of comments increase the process of collaborative learning, and accepting the value of the KB characteristics used in our analysis, we think it is fair to say that our experiment has proved itself to be relevant. Over the three trials the quality of student comments has increased, both as a

1825
result of grading requirements and as an effect from the meta-awareness around the functions of the requested comments.

Our sample size was quite small and therefore the results are subject to large uncertainty. Therefore, the extent to which the results can be generalized may be questioned. The selected comments, however, were drawn at random and taken out of the social context of the specific dialogue in which it appeared. Perhaps this could be considered a problem of the data set, since the KB requirements are concerned with the sequential development of online interaction.

As pointed out, the largest difference over the change in dialogue requirements was in the length of each comment, and the increased quality of the grammar used. It seems that the more carefully composed essay-like style of comments as well as the increased quality and quantity came at the expense of spontaneity and "social" elements in the interaction. It is conceivable that dealing with electronic dialogues and an electronic comment in terms of a request for reflection on its function, is inhibiting the evolvement and practice of a spontaneous and dynamic dialogue.

As such, the question could be posed, whether the strong meta-reflective requirements enforced on a dynamic phenomenon as human interaction (even though it is not in terms of formalization) appears problematic. Or perhaps whether the lack of recognition of social elements in the interaction works against an incitement to engage in collaborative interaction or knowledge building with others. Moreover, it may be pertinent as a basis for a potential conclusion around this aspect to specify, whether one is using data from an off-campus course (where the students have no complementary social interaction) or an on-campus course (where social interaction among students is part of daily life) as in the present study.

In the data from our experiment there is some indication, that the "forced requirements" on the collaborative dialogue actually functioned like a "kick-off" to engage in dialogue, and that it actually caused more interactivity than required to appear. But we find the data set from this study too small to conclude more precisely around this aspect. It is beyond any doubt, though, that - as default - to be forced to reflect on the function of one's action before carrying it out is likely to decrease spontaneity, phatic behavior and high interactivity. Above all, we believe that the optimistic results of our analysis have demonstrated that, once again, the problem is a complex one. And perhaps the usual controversial points to discuss in this respect will be "how" to do it and "to what extent". All these are questions to be further studied and pursued in the future.

We acknowledge the contribution of Kathryn St. Croix, Iowa State University, for collaborating with us in the analysis of dialogues. Contributors to the design and implementation of the Global Change course include Doug Fils, Michael Taber, Jennifer Hodson, and David Flory. The course is implemented under the auspices of the International Institute of Theoretical and Applied Physics.
VIDEOGAMES AND GAMEPLAY

Matt Southern, International Centre for Digital Content, UK
m.southern@livjm.ac.uk

Abstract

Aside from the scientific and mathematical knowledge required to work in the videogames industry, there is also the relevant artistic and cultural discourse. Of particular importance here is the concept of gameplay, regarded as the most important aspect of a successful game. This paper addresses the key components of gameplay, and then suggests what the effects this gameplay can have upon the player. The implications these effects have, particularly in relation to education and the future uses of gameplay, is then discussed. The intention is to shed light on the often oblique interactive nature of videogames.

Videogames and Gameplay

The purpose of this paper is to describe some of the key aspects of a central pillar of contemporary digital content – videogames and the videogames industry. At the ICDC we recognise that videogames are one of the most vital elements of modern culture and industry. For those interested in working within this industry, the potential rewards are huge. Videogame design is, essentially, an art. However, it is still regarded as axiomatic in the games field that programmers (i.e. mathematicians), are not ‘creative types’, and vice-versa. As far back as 1982 the legendary games designer Chris Crawford suggested that:

"Games must be designed, but computers must be programmed. Both skills are rare and difficult to acquire, and their combination in one person is even more rare”

Chris Crawford (1982), p.47

And the chairman of Nintendo has said that it is “artists, not technicians, who made great games” (Sheff, 1993, p.37). So we need to understand the fundamental concepts underlying this art, if we are to progress it. To begin however, I shall briefly describe the scale of the industry.

The Industry – Size and Constitution

The global leisure software industry is now worth nearly $17 billion. The European leisure software market is now on a par with the US market – worth $5.96 billion in 1999, expected to rise to $6.27 billion this year, that's $2 billion more than the Japanese market (ELSPA/Screen Digest). Britain is a crucial player in this trend. The videogames industry in Britain has now rather famously surpassed the combined revenues of the British film and video industries:

"The leisure software sector recorded a positive balance of trade in 1998 of £218 m compared to a total net trade deficit of £195m recorded by the film and TV industries combined" (Interactive Leisure Software Market Assessment and Forecasts 1999 – 2003)

Britain is one of the European leaders in terms of creative output. Before this ‘transition period’ we are currently in, there were approximately 6000 people working in 250 British development studios. Titles such as Rare’s ‘Goldeneye’, The ‘Tomb Raider’ series and ‘Driver’ by GT Interactive were award-winning global hits.

But then, Britain is a gaming nation: Last year, total spending on hardware and software in Britain rose by 10% to almost £1.4 billion. 31% of UK households own a modern console. This is especially remarkable when one considers that in Britain the console is a comparatively new development. We were all playing on our ZX Spectrums and Commodore 64’s when the biggest seller ever (Super Mario Bros. 3 - $500 million dollars in the US alone) was released (on the NES, which hardly anyone in Britain bought). This home computing legacy is a key reason why we have a tradition
of programming. Many top development houses and publishers, such as Codemasters, formed Richard and David Darling, and Rare, initially called Ultimate Play the Game and formed by Chris and Tim Stamper, started life in the bedrooms of home computing fans.

With the release of Playstation 2 (October 26th), Microsoft's 'Xbox' and the Nintendo GameCube and GameBoy Advance, the lull in the vibrancy of industry will dissipate, and growth rates are expected to become the fastest ever. So with this in mind we can see that the potential for work in the games industry is massive. The problem here is that this home programming generation is getting old – we need to train new generations of game designers, and fast. This is why the International Centre for Digital Content, formed the MA Digital Games in 2000, and many other courses are emerging globally.

So, what should we know about games, aside from the technology, to help us find work, and contribute? Most of us will have played games, but can I suggest we have played them without thinking too much about the processes that make the experience so compelling and attractive. I will now suggest what these processes might be. In order to do that, a little history might be useful.

'Cras hes'

Two crucial events occurred during the Seventies and Eighties that, for both the industry and gameplayers, provided vital lessons as to what might make a game successful. These were the two 'crashes', both of which almost crippled the games industry.

The first of these 'crashes', which has been called the 'Hardware Plague', occurred in 1977, the era of handheld machines which played one embedded game.

The rise of cheaper microprocessors led to a flooding of this handheld market, forcing prices down and bankrupting many new companies. Fortunately, the industry soon recovered, simply because machines such as the Atari VCS 2600 became available, which could play more than one title.

In fact, the second 'crash', a 'Software Plague' in 1983, occurred when these home machines had become what we now call 'consoles', capable of playing many separate game cartridges rather than one. Before long, far too many low-quality cartridges became available, the market flooded again, and consumers, unable to discern the quality without first paying a substantial fee, once more abandoned the industry.

Prices tumbled, and, famously, Atari made a loss of $539 million, and buried 'thousands of over-stocked cartridges in a New Mexico landfill' (Herz, 1997, p.39). At this point the videogames industry in the US had almost completely collapsed. If it were to recover again, then some standards would be required in order to avoid another glut of poor software. Exactly what it was that made some of these titles so awful became clear – the interaction, now a common expression, had to be of primary importance. Without doubt, the developers who recognised this, and rejuvenated the industry, were Nintendo. Formed in 1889 to produce playing cards, or hanafuda, by Fusajiro Yamauchi, Nintendo was taken over by Grandson Hiroshi, and in 1969 (Sheff, 1993, p.26), he created a games division. The hiring of a young designer, Shigeru Miyamoto, was crucial – his understanding of these new priorities led him to develop some of videogames' most legendary titles – "Donkey Kong", "Super Mario Bros.", "The Legend of Zelda" and many more.

A kind of 'Golden Rule of Games' emerged: that of the two, it was Software, not hardware, which determined the success of a game. One only needs to look back to the demise of the Panasonic 3DO, one of the most advanced home consoles available in the mid-Nineties, to see that, with a roster of low-quality software, the hardware is redundant.

Developers now accept that technological advances in graphics, sound and processing power, whilst essential in terms of increased verisimilitude, and indeed still highly attractive to games players, were essentially cosmetic, and that conventions borrowed from other visual cultures, usually cinema, whilst predominant, were also not intrinsic to a 'game'. The conclusion was simple: It is these 'rules of the game' - the processes of interaction, that largely engage the player. The term we of course now use is Gameplay.
Ian Livingstone, designer of both board and video games, and chief executive of major publishers Eidos, typifies this approach:

“When people ask what are the three most important things in a computer game...I say, “Gameplay, gameplay, gameplay” (Edge, Iss. 65, p.118)

So it is this notion of gameplay then, that is at the heart of what constitutes interactive digital entertainment. Yet clearly it is somewhat oblique: rarely defined and regarded in almost mythical, metaphysical terms by reviewers. It is an interesting paradox - gameplay is regarded as the single most important element of games (perhaps even the only important one), by an industry which continues to devote thousands of pounds and column inches to graphics, sound and processing power, which are easier to identify and write about. But I must make it crystal clear that whilst gameplay is the most important element, one must always temper this with the fact that more sophisticated graphics and processing power are extremely attractive to videogame fans.

One of the most useful attempts to define gameplay can be found in ‘Edge’ magazine, issue 12 (September 1994), in an article entitled ‘The Rules of the Game’. Whilst the article lists several elements that combine to create ‘gameplay’, I would argue that several are actually only conventions - not intrinsic to gaming. For example, ‘Save Points’ or ‘End of Level Bosses’, whilst common, are not always necessary. Indeed, I would like to suggest that these elements are subordinate to three in particular: the concepts of Incentive, Risk, Reward, and, as a counterbalance, Frustration (Edge 12, p.48).

By definition, the playing of a game must involve some justification for continued play. Whether it is the retrieval of some prize, the rescue of a loved one, a high score, or the completion of a narrative, all games provide constant incentive, often with a dense structure of mini incentives. These incentives encourage the player to take risks in the game, and will, if the risk was successful, turn into rewards. If the incentive is too little in relation to the risk involved, then the game will fail. Similarly, if the challenge is too simple for such a vital reward, then any sense of achievement will be lost:

“Whether applied to the game as a whole, or to any activity within it, you must always feel that it is worth your while carrying on....A game should make you confident that higher risks will result in higher rewards” (Edge 12, p.48).

This is why most games will involve an equal amount of frustration - compelling the player to refuse failure and to try again. Frustration, the article notes, is an extremely difficult thing for the designers to ‘get right’. Herz notes that videogame companies carry out “market research about stress levels and frustration thresholds of adolescent videogamers” (Herz, 1997, p.119), in order to ensure that the frustration is extremely finely balanced. This process – balancing – takes up a great deal of the designer’s time. One can argue that Shigeru Miyamoto’s success is largely down to his remarkable ability to pace and balance a game to perfection.

Frustration also occurs when, due to bad programming, the game or the computer appears in some way to ‘cheat’, or permit ‘cheating’. As we all know, computers cannot make mistakes, so “If something goes wrong, you should feel that it is entirely due to your own mistakes” (Edge, Iss.12,p.49). Imagine spending hours perfecting fluid ‘combos’ on “Soul Calibur”, only to be beaten by a novice pressing as many buttons as possible. Any games where the rules seem to ‘shift’ or appear inconsistent will seem unrewarding, and invariably be switched off.

These incentives are at the heart of that concept often associated with games, addiction. The idea of ‘just one more go’, is essentially bound up with the replacement of one reward with another, greater incentive, i.e. the promise of a greater reward, and so on. If you design a game which harnesses the power of ‘just one more go’, you are on to a winner. ‘Tetris’, ‘Championship Manager’ and ‘Tony Hawks Skateboarding’ are all examples.

There is another gameplay element to add to these three, which exists in some form or another in practically every videogame: Levels. Whilst the insertion of levels, or ‘waves’ or ‘stages’ might seem (and often are) merely a convention, the use of the term is necessarily broad - and at times levels are less delineated and difficult to recognise in a game. A game, which provides no increase in
challenge - the ladder of challenges, will be quickly abandoned, and indeed, the length of time a game will last is dependent entirely upon the exhaustion of 'levels'. Stages usually increase in difficulty, as one might expect, although easier 'breather' levels have also proved popular (perhaps one can argue that the use of hierarchical levels are a reflection of cultures reliant upon capitalism). This 'Ramping of Difficulty' is again a difficult procedure, and one, which differs depending on age and culture. Japanese games are regularly 'balanced' (i.e. made easier) before they become available in the West, to suit American 'frustration thresholds'- "They [the Japanese] judge products on how long it takes to complete it and not the quality of the experience". (Herz, 1998 p.120)

These aesthetics, which are as equally applicable to 'Pong' as they are to the very latest games, can be regarded as somewhat constant, and so are useful in that they are less susceptible to the massive technological advances that can often make arguments quickly seem outdated. It is crucial to remember that there are always far more low-quality third-party games in the shops than there are good games (much like the video and music industries), so these 'rules' are still ignored by more exploitative developers. But these devastating crashes taught not just developers but also the consumer lessons about how to avoid bad titles. Unlike other cultural industries, it has become generally accepted that the biggest-selling games are amongst the best. However, aggressive marketing occasionally disproves this, as anyone who has compared EA's 'Fifa Soccer' to Konami's 'ISS Evolution' will testify.

The Effects of Gameplay Upon the Player

Having defined gameplay, we need to address exactly what effects these processes have upon the player. I shall concentrate upon the effects of more immediate, reflex-based games. The racing game is an example, as is the 'First-Person Shooter', such as 'Quake'; and we would expect it to deliver an immediate, visceral experience than, say, a Real-Time Strategy. These have become known as 'Twitch' games, some have even described them as 'Thumb Candy'.

Let us take a specific example of a reflex-based game I'm sure many of us know - 'Tetris', developed at the University of Moscow by Alexey Pajitnov. In this puzzle game, seven shapes, each constructed from four squares (hence the title - a form of the Greek 'four') fall in random order from the top of the screen one at a time and land in a pile. By rotating the shapes and moving them left and right, the player can 'fit' the blocks into solid lines, and upon doing so, the line disappears, hence the ability to keep the pile low - increasing one's score.

Vital to the interactivity in 'Tetris' is the box, on the right of the screen, which indicates what shape will fall next. It is close enough to the action to allow it to be seen from the 'corner' of the player's eye, so that one needn't glance at it. This constant process, of manipulating one shape to fit 'best' whilst another is 'in mind', radically affects the gameplay - a trance-like gaming experience occurs. It's designer has described puzzles as:

"metaphors and mirrors that reflect nature, emotion and patterns of thought....games were sublime examples of the intersection of logic and humanity. They worked because of logic and mathematics, but also because of psychology and emotion" (Sheff, 1993, p.298, my emphasis)

So, what we have is the emotion of identifying and engaging with the gameplay structure, and the underlying science of the puzzle. This emotion, or identification, is key. For psychologist Sherry Turkle, the interactivity of games is crucial, in that there is a combination of identification and action, which provides a 'special kind of hold' (Turkle, 1984, p.83), one which, for example, cinema cannot provide because it relies upon identification alone. As anyone who has played 'twitch' games will know, one of the crucial factors is pace. These games require immediate, extremely fast reflexes.

One might not expect such a visceral, demanding experience to always be that pleasant, but as Turkle has suggested,

"For people under pressure, total concentration is a form of relaxation" (Turkle, 1984, p.84).

Turkle likens this process to playing the piano, requiring knowledge of improvisation, memory and repetition, all in a split second:
"It’s more than just thinking - in a way it is beyond thinking. The hand learns what to do and does it automatically" (Turkle, 1984, p.68)

So these types of action-based games create a very particular response in humans. This high paced identification / action contains the ability to provide a release of tension - a rush can be achieved, much like when watching or participating in sport, when the body naturally releases endorphins - "proteins that mask pain and cause a sense of euphoria" (Sheff, 1993, p.205). Like when a jogger hits ‘the wall’, the release of endorphins is a natural ‘high’. In fact, because they are natural painkillers, it has been noted that interactive software therefore has the potential to be used in a therapeutic context. ‘Distraction therapy’, where interaction is used to distract the patient from painful ailments such as arthritis and wounds, is now possible, and we can expect to see it become a common practice over the coming decade. With the rise of physical software such as ‘Dance Dance Revolution’ (Dancing Stage) will surely increase the potential for this ‘rush’, as well as being a healthy activity. Perhaps the next Jane Fonda will be virtual!

We can see then, that in many ways games have the potential to provide very positive benefits. Yet these benefits are often obscured, because of the very masculine, violent games that dominate the headlines. Let us now look more closely at this.

Benefits: education and skills

Currently, forces of moral outrage are again attacking the videogames industry. The High School shootings in the USA, and in particular the one Columbine, have been associated by both parents and the media with violent games, and in particular Quake. Research into the effects of violent media is almost always inconclusive, for every report making a link between the two, one can find another suggesting that there is no connection. Regardless of one’s own personal experiences or opinions, what we can immediately make is an obvious but vital observation that in countries with tougher weapon laws, there is less gun-related violence. The National Rifle Association is a powerful lobbying group in America, with the resources to maintain a strong pro-firearms agenda, based upon defending the Second Amendment of the Constitution. As a result, from afar it can seem nonsensical that the US seems willing to ban lightguns, but not handguns.

This moral panic – for that it what it is – is dangerous, because it does indeed obscure a more sober, objective analysis of games, which might actually reveal this potential for games to improve and educate. We have already described ‘distraction therapy’, so are there other elements of interaction which can be seen as positive? Patricia Marks Greenfield has looked at potential benefits. She suggests that “they incorporate types of complexity that are impossible with conventional games” (Greenfield, 1984, p.96), and illustrates several examples:

"Parallel processing"

Whereby one can process information from a multitude of sources simultaneously, is recognised as a skill which can be developed by games playing and is extremely useful when applied to contemporary IT jobs.

The ability to observe ‘interacting dynamic variables’.

The behaviour of several ‘elements’ can reveal information as a result of their interacting - information which would be impossible to discover if the elements were in isolation. One is reminded here of the suggestion that “certain things that are incredibly abstract and confusing in two dimensions can seem intuitive in three” (Herz, 1997, p.220), essentially, games can teach the player to observe processes that can be difficult to otherwise comprehend.

‘Spatial integrative skills’

Involving the ability to better comprehend perspective and dimensional depth, can be developed by interacting with games that exploit conventions of point-of-view. The advent of 3D game engines - such as the ones used to such dramatic effect in ‘Mario 64’ and ‘Tomb Raider’, make this skill ever more possible. There is the use of memory, repetition and improvisation, for example, in “deciphering the
logic of the game" (p.68), and “a socialisation into the computer culture” (p.67), again crucial in terms of contemporary information-based employment.

Also, David Sheff, author of Nintendo history ‘Game Over’ suggests that:

“Video games...help develop problem-solving abilities, pattern recognition, resource management, logistics mapping, memory, quick thinking and reasoned judgements” (Sheff, 1993, p.207)

Finally, compiling research, Griffiths also highlights the suggestion of directly therapeutic uses: building a rapport with therapists, releasing aggression, learning to co-operate, and building self-esteem (Griffiths, 1999, np). Whilst the American Conservative Eugene Provenzo claims that “games are pointless to most educational, social and cultural needs”, it is claimed that “There are many authors who ardently support the use of video games for educational reasons” (Griffiths, 1999, np). Several benefits can be gained from games playing in an educational context - including their use as a ‘catalyst’ in motivating education, boosting confidence in children who lack it, and promoting social interaction (Griffiths, 1999, np).

To conclude then, those who are interested in becoming games developers should bear these potential benefits in mind. Firstly, because moral panic presents a very real threat to the games industry – linked as it is to censorship. Secondly, because it is in these areas – of the development of social, spatial and cognitive skills, and of harnessing the artistic power of emotion and psychology, that games can and perhaps should progress. At the ICDC we are investigating educational software - we have a group of kids helping us to design a game – and we believe that educational software is often ‘found out’ by kids, to be over-worthy, slow and dull. They much prefer Lara Croft and Pokémon, and as we have seen they can learn from these titles. The educational software industry is in almost constant crisis. If we can harness the attractions of commercial software – the fact that it is ‘cool’, then we can use digital content to improve the quality of education, perhaps for all ages. Imagine a ‘Quake’ where instead of shooting each other, kids hunt down plans and information, then co-operate to build a bridge to one another. The educational potential is huge. We should exploit it.

Abstract: This paper explores issues concerning the skills and competences of online teachers. We report on an international two-day workshop with practitioners and researchers. We cover a range of ways of understanding online teaching, including competence, humanistic and cognitive perspectives. The main emphasis here is on a competency-based approach. We suggest a starting point based in current practice and research that is aimed at how online teachers might be recruited, trained, assessed and certified. We elaborate our view of the roles of the online teachers and report work leading to a framework and set of associated competences.

The Centre for Studies in Advanced Learning Technology (CSALT) at Lancaster University and the International Board of Standards of Training, Performance and Instruction (ibstpi) organized a two-day, international conference in Windermere, England, in June 2000 to address issues pertaining to competences and standards for teachers involved in designing and delivering online courses and course materials. This presentation provides a summary of the outcomes of the conference.

Participants included 9 ibstpi Board members (including university and corporate representatives from Norway, the Netherlands, the UK, and the USA), and about as many professional online educators from the UK (representing Lancaster University, Glasgow University, Motorola University-UK, Sheffield College, the Open University, Portsmouth University and several governmental organizations and projects). There was a mixture of university and professional practitioners and strong international representation. The aims of the conference were to create an improved understanding of the competences (abilities, attitudes, knowledge, and skills) involved in planning and implementing effective online education. The focus was primarily on distance education for adult learners, including university students and workplace learners.

The impetus for the meeting came partly from requests for standards and certification for online teachers and partly from growing concern with wide variations in the quality of online teaching. The Board recently updated its instructional design competences to reflect the impact of technology on the design of instruction. Additional motivation came from current projects underway in the UK that raise issues about competences for online teaching. The outcomes of the meeting were a preliminary set of competences and a commitment from the Board to continue the effort. This presentation is the first formal presentation of the draft set of competences for online teaching developed at that conference.

1 ibstpi has internationally recognized established standards and competences for technical trainers, instructors, instructional designers, and training managers; the Board is considering how to define standards and competences for online teachers in response to growing concerns with quality and divergent practices.

2 This workshop was co-sponsored by the Centre for Studies in Advanced Learning Technology at Lancaster University, the Joint Information Systems Committee of the UK universities funding councils, and ibstpi. Participants included academic and industry representatives in the UK and sponsors.
1. The growth of online learning and teaching

There is very little sound research on the extent and effects of online learning and teaching. Many commentators and analysts are making dramatic claims about growth in the market(s) for online learning, though it is hard to find such claims being made by people who do not have a vested economic interest. Drucker (2000) suggests that the market will grow to hundreds of billions of dollars in the near future.

While it is possible that a shift towards greater use of online learning may reduce the relative cost of teaching staff, online teaching continues to be labor-intensive. The UK Open University, for example, aims at an average of 25 students per online teaching discussion group. The for-profit University of Phoenix operates in learning groups of 8-15 students, each with an online teacher. This implies a substantial growth in demand for online teachers in the next few years. The Open University Business School has recruited and trained 400 online teachers in the last 4 years and seeks to recruit and train another 100 in the coming year (Salmon 2000). The newly established US Open University is currently recruiting Associate Faculty across all disciplines and programmes. They will be trained to work entirely online with their students. How should such online teachers be recruited and trained? How is competent online teaching performance defined? What competences should be used in recruitment? What should be the objectives of a training course for online teachers and how can they be assessed or certified? These are pressing issues for many companies and universities. Researchers on defining competences for online teaching often builds on earlier accounts of competences for distance teaching and sometimes starting anew (see Cyrs 1997). The following section briefly reviews a first draft of such competences.

2. Competences for online teaching

Major roles for online teachers included the following: advisor, assessor of progress and outcomes, designer, manager and administrator, researcher, process and content facilitator, and technologist. These roles represent clusters of related competences. A partial elaboration of the content facilitator cluster is:

- Informing participants: pointing to and finding resources, suggesting and negotiating time frames for activities, suggesting and negotiating criteria and terms for completion.
- Managing learning activities: designing learning tasks, identifying and integrating suitable challenges for learners, maintaining focus, organizing activities and learners.

3. Conclusions

The Board has developed an initial set of competences based on the Windermere meeting and subsequent ibstpi meetings and focus groups. In February 2001, ibstpi met in Amsterdam to refine the initial set and produce a more comprehensive set of competences for the large survey. The project team has created a model of online teaching and refined the initial set of competences and performance statements. Further refinement will include an international survey of professional practitioners to determine the frequency and criticality of various online teaching skills and activities.

4. References

Instructional Technology has become an important teaching tool in the classrooms of Colleges and Universities all over the country. Instructional Technology is still a new tool and as such, the benefits, cost of creation, and cost of implementation are still being realized. The need to reward faculty for their involvement with Instructional Technology, however, is both immediate and real. In 1999, the Southeast Missouri State University Information Technology Faculty Roles and Rewards Action Team developed guidelines for evaluating the effort put forth by faculty involved in creating and implementing Instructional Technology. The final document describes the importance that the use of Instructional Technology by faculty should have in the promotion, tenure, and merit process. The document was written to include the faculty and administrators involved in promotion tenure decisions who may not be familiar with the uses of Instructional Technology. The document was first implemented in the fall 2000 semester.
Novel Client Representations for the Collaborative Virtual Learning Environment sTeam

Projekgruppe sTeam

Abstract:
The Paderborn Open Source Project sTeam (Information Structuring in a Team) currently develops a net based environment to assist cooperative learning in virtual communities. The following paper describes the activities of a group of students involved in the project at the University of Paderborn, who researches various approaches for presenting information, interaction and communication structures in a virtual learning environment. A prototypic implementation of a two- and three-dimensional client for the sTeam system does create new ways of interaction between learners and the learning materials in a virtual space.

Introduction
Learning is a socially embedded design process. But most of today’s hypermedia systems fail to properly support both the design-related and the social aspects of learning. Authoring and web-publishing systems aim to support the authors’ design process. Consequently, learners’ activities are confined to selecting and reading. Based on some fundamental reflections on the role of technology in learning processes, we conclude that top priority must be given to the construction of infrastructures that support cooperative learning processes if we are to properly harness technology’s potential.

In Paderborn we focus on a learner-centered wholly java-based approach for structuring information in teams (sTeam). (cf. http://steam.uni-paderborn.de) The key concept in sTeam is the virtual space. It draws together cooperation and communication, at the same time embodying the common external memory of a (virtual) learning group. Therefore the focus is not on interactive systems for individual accessing of knowledge bases, but rather on the cooperative management and structuring of distributed knowledge bases.

Since the emerging of the World Wide Web, knowledge management consisted of creating and providing information on CD-ROM’s and WWW-Servers. Because of the difficulties in actively providing structured and organized information, most users were forced into the consuming role. Even today, providing information in the World Wide Web, needs a lot of patience and the knowledge of at least one programming language of the WWW.

In its basic sense, distributed knowledge organization means the cooperative generation, management and maintenance of artifacts embodying knowledge. Artifacts represented by documents, graphics, notes and comments, and their linking by learners, thus form the basis of any method for supporting learning processes using suitable environments and tools. Asynchronous mechanisms for handling multimedia learning components or hypertexts, such as are frequently familiar from document management, are combined with strongly synchronous approaches from the area of session based systems. Such a synthesis allows new, less familiar, hybrid forms of asynchronous and synchronous cooperation between learners.

Thus the sTeam system combines the idea of a room-based virtual world with the basic functionality of document management. Rooms function not only as a social meeting-point and center of a virtual learning community but also as a collaborative external memory, providing the primary media functions (cf. Hampel & Keil-Slawik 2001) as a basis for cooperative learning.

This paper presents the work of a students group of the University of Paderborn, who develops new forms of Java frontends for the sTeam system.
Both a two-dimensional and a three-dimensional client visualization were developed (Java/Java 3D). These clients evaluate novel ideas to support the user in navigation and interaction in these structures:

One goal of our work was to evaluate novel forms of interaction within such a virtual world. This includes both the structuring of communication within the room and the semantic structure of the room’s objects.
A good example for the structuring of the avatars communication within the room may be the concept of chat circles. Avatars may easily form a so called chat circle by approaching a virtual conference table. The range of the chat is limited to the members of one particular chat circle. This mechanism can for example represent the usual structure of a tutorial or a course, in which students in small groups work on different topics and compile their results afterward as a group. One advantage of presenting information in three-dimensions is that a large amount of objects (documents, graphics) are easier to position and to display than in a two dimensional space. Additionally, semantic relationships between the objects can easily be represented through grouping them in space or simply by proximity. The realization of the various approaches in a two- or three-dimensional client explore these relationships in particular.

![Figure 1: Two different client representations for the sTeam system](image)

In the virtual space different avatars have different ways to interact. Documents can be given to others by simply dragging them with the mouse. Each sTeam user owns his personal virtual backpack in which he/she can store and transport documents between rooms.

In a virtual sTeam room various objects and materials (media) can be created, which support the cooperate learning process. These objects include for example graphics, hypertext-documents, links to external web-sites, but also tools such as a cooperative shared whiteboard.

The content of the documents can be viewed and altered in conventional browsers or in a sTeam-module especially created for a certain type of document. Objects representing graphics are displayed in the virtual space and can be viewed there.

Those two approaches correspond to different views on the same information structure of the presented data. They are not competing ways of presentation but rather combine different but basics ones.

The strength of the three-dimensional client is certainly in the field of communicating the information structure. It surely will be attractive to users who explore virtual communities for the first time and are not expert users. The communication in groups is viewed as a main feature and can easily be done for all users.

The two-dimensional client offers main advantages for daily use and structuring of learning- and educational material, because its functionality and look and feel are like conventional applications.

Future sTeam developments will explore in particular further ways of interaction in virtual learning environments and extend the interconnection with the daily learning- and working environment.

Novel Client Representations for the Collaborative Virtual Learning Environment sTeam

Henrik Beige, Univ. of Paderborn, Germany; Ralf Bilger, Univ. of Paderborn, Germany; Bernd Essmann, Univ. of Paderborn, Germany; Christian Enklaar, Univ. of Paderborn, Germany; Christoph Grote, Univ. of Paderborn, Germany; Karsten Nebe, Univ. of Paderborn, Germany; Alexander Schlicht, Univ. of Paderborn, Germany; Christoph Schmidt, Univ. of Paderborn, Germany; Ludger Merkens, Univ. of Paderborn, Germany; Thomas Bopp, Univ. of Paderborn, Germany; Thorsten Hampel, Univ. of Paderborn, Germany;

The Paderborn Open Source Project sTeam (Structuring Information in a Team) currently develops a network-based environment to assist cooperative learning in virtual communities.

This poster presentation describes the activities of a group of students involved in the sTeam project at the University of Paderborn, who researches various approaches for presenting information, interaction and communication structures in a virtual learning environment. A prototypic implementation of a two- and a three-dimensional client for the sTeam system creates new ways of interaction between learners and the learning materials in a virtual space.

In the virtual space different avatars have different ways to interact: e.g. objects/documents can be exchanged simply by dragging them with the mouse. Each sTeam user owns his personal virtual backpack in which he/she can store and transport documents between rooms.

In sTeam various objects and materials can be created, which support the cooperative learning process. These include for example graphics, hypertext-documents, links to external web-sites, but also tools such as a cooperative shared whiteboard.

In the field of supporting the learners' communication the three-dimensional client offers new approaches. Discussion groups may be formed just through spatial closeness of the corresponding avatars. (Learners sit together at a "virtual conference table").

Avatars may easily form a chat circle by approaching the table. The range of the chat is limited to the members of one particular chat circle.

1. Introduction

This paper gives an overview of MediBook, a joint project of the Medical Department of University Gießen (Germany) and the Department of Electrical Engineering and Information Technology at Darmstadt University of Technology (Germany) funded by the Hessian Ministry for Science and Arts (HMWK). The goal of the project is the enhancement of education in Medical Schools by means of a flexible system. The flexibility of the system aims at self-studying, independently from space and time. MediBook is a system which provides tools for storing, managing and especially locating and combining learning resources. It offers means for both describing single sources (thereby putting them into a context) and combining single resources to courses. Thus MediBook represents a knowledge base with efficient access and tools to generate arbitrary coherent courses from single information units.

2. Knowledge Base

The basis of MediBook is a formal representation of the medical domain. The formal representation consists of the important medical concepts -- e.g. colon, kidney, bacterium -- which are associated with each other by semantic relations -- e.g. colon 'is_part_of' digestive system. For this formal representation we introduced the notion ConceptSpace. Information units -- in MediBook the notion MediaBrick is used -- are associated with concepts, whereby each MediaBrick is described by metadata. Furthermore MediaBricks are associated with each other by rhetorical-didactic relations in such a way as to put them into a context -- e.g. MediaBrick A 'deepens' MediaBrick B -- thus building the MediaBrickSpace. Since in MediBook we are dealing with educational content we use the Learning Objects Metadata (LOM) [1] for the description of the information units. Using this widespread IEEE proposal for a standardized description of "learning objects" other systems are able to access MediBook resources. MediBook is designed to deal with resources of different formats such as plain text, images, graphics, video, audio or animations which may contain information, theses, motivations, exercises, etc. Existing resources shall be integrated in order to support reuse of multimedia-elements which creation often is very expensive. The basic approach to describe Media-Bricks on different levels -- LOM, rhetoric-didactic relations, associations with concepts -- is not limited to the medical domain. It can easily be applied to other knowledge domains by defining the concepts in the ConceptSpace and if necessary adaption of the set of semantic relations.

3. Scenario

In MediBook we define three roles which are supported:
- **Author**: The author is a physician and an expert in the medical domain to be modeled. The problem of building the knowledge base is divided into three sub tasks which are: generating the ConceptSpace, integrating the contents (MediaBricks in the MediaBrickSpace), and associating the MediaBricks with the corresponding concepts.
- **Teacher**: The teacher (physician) selects the MediaBricks which are relevant for his course and puts them into the appropriate order and structure. To achieve better coherence the teacher can create transitions between the single information units. In the process of navigating through the knowledge base the teacher is assisted by the system in such a way that the system is showing the relevant details adaptively according to the teacher's user profile.
- **Learner**: The learner can either follow the way proposed in a stored course or he can navigate through the knowledge base quite like a teacher can, though in a read-only modus. The view on the knowledge base is adapted by means of individual user profiles.
4. Outlook

Currently learners in the context of MediBook are students of Medical Schools but the system can easily be used for advanced education of physicians or as an information system e.g. for patients. Therefore only the knowledge base has to be extended with respect to content -- an extension of the system is not necessary.

In a further step of this project it would make sense to give the learner the possibility to annotate learning material, to define bookmarks or to work through interactive tests. Furthermore the automatic generation of lessons and courses by the system is desirable, particularly regarding a heterogeneous group of users. This necessitates extended user profiles and a rule-based system module which compares the profile entries with the MediaBricks metadata in order to select the relevant MediaBricks and present them as a course including a table of contents.

While the LOM-Editor [10] and the ConceptSpace-Editor described later in this paper are already implemented and the authors are working with the tools, the presentation generator is still work in progress.

5. Architecture

MediBook integrates the access to different information systems, managed at different locations. This scenario requires a broker oriented middleware, to combine the metadata descriptions of the physical resources with the formal representation of the specific domain. With this architecture users have a single point of access not only to different types of informations, but also to information which is managed and stored at different places. Figure 1 gives an overview of the MediBook architecture. Retrieval, tagging and composing requests from all clients are passed to the broker middleware which is responsible to select and query the appropriate database.

Access to the databases is realized by a query based architecture. In opposite to index based techniques, where full indices of the data managed by the different databases are exchanged, a query based system implies a more transparent global data management. The Open Archives Group [2] has specified a simple harvesting protocol to access arbitrary databases. The problem is, that this protocol is limited to a restricted set of metadata. In MediBook we are using the Learning Objects Metadata (LOM) from the IEEE to describe the learning resources and the courses. According to this set of metadata, we have defined a query protocol based on the LOM approach. To integrate a database which manages LOM descriptions the database is registered by sending a message to a central content location service. This announcement includes the kind of metadata the database is responsible for. The content location service is contacted from all retrieval services inside MediBook. Examining the request from the clients, the content location service is choosing the appropriate databases for executing the query. The service collects all the results from the different databases and sends them to the requesting client. Currently we are using the relational database Oracle 8i and the XML database Tamino to store the metadata. Therefore the protocol must be capable of mapping the requests from the clients to an SQL- and also to a XQL query. Regarding the fact, that there are already solutions available to map
between XML data structures and relational schemes [3], our query protocol is XML-based. The mapping is realized with the freely available JAVA-based framework Castor [11]. Based on a LOM-XML-DTD published by the IMS Consortium we have developed a LOM Working Draft 4.0 compliant DTD to describe a search request. The clients, described in the next chapters, are using an object model representing the LOM approach.

In addition to the integration of different databases, the MediBook middleware also has to implement the connection between the metadata and the semantic network. The Ontology Inference Layer (OIL) [12] is an approach to standardize the description and exchange of ontologies. However we are using a proprietary approach, the Smalltalk Frame Kit, to combine the different information, as there is an integrated development environment at hand. An integration of the ISO-Standard Topic Maps is not planned.

The amount of information which currently is available through the Web has lead to the development of different metadata standards like Dublin Core [13] for general resources, LOM or MPEG7 [14] which is used to describe multimedia resources. A crucial point for a widespread use of metadata standards is the question how the user has to deal with this amount of information. The problem with metadata information like LOM is mainly the accurateness and the amount of time a user has to invest to describe a resource. Although many of the LOM elements can be generated automatically, there is still a significant number of elements, where the user has to decide about the entries. In the area of semantic networks the situation is even worse. Building an ontology does not only require knowledge about the domain. Regarding the available tools a user also has to be an expert in computer science and data structures to build an ontology.

In the following chapters we want to describe two client tools we have developed for MediBook and we want to show how we deal with these problems in every tool. The next section will give an introduction and introduce the ConceptSpace-Editor which is used to build the ontology. The last tool will be the presentation generator. In this section we will describe how an on-line available course can be presented out of reusable modules described with LOM.

6. The ConceptSpace-Editor

Throughout the following section we focus on how the medical knowledge to be represented in MediBook can be modeled with our editing tool, the ConceptSpace-Editor. We give a brief survey on how the ConceptSpace-Editor works and which requirements it meets in the MediBook project. We are concerned with the logical layer of the ConceptSpace-Editor, which was implemented using the Smalltalk Frame Kit (SFK) [7]. Knowledge Representation in our system MediBook is based on an ontology. An ontology is (formal) conceptualisation of a (knowledge) domain [4]. From our point of view modeling special domains of knowledge always has to fulfill certain tasks. In consequence ontological design as a first step of ontology engineering already has to investigate the later use of the ontology [5]. In our case the ontology is a networked structure which allows browsing and navigating through medical termini. Moreover MediaBricks are attached to the medical knowledge which originally is independent from the media. A logical and consistent ontological design requires types of concepts to reflect the entities within the knowledge domain (i.e. medicine), relation types to model the relations between concepts, and axioms [Staab/Maedche].

Axioms supervise the process of knowledge modeling logically, they come into play while building conceptual and relational instances. For example we use inverse relations, which are automatically triggered, when a relation is drawn between two concepts. Another example is the maintenance of hierarchical relations. We have to formalize rules, which guarantee the establishment of a relation like 'diarrhea is caused by bacterium x' whenever we draw a relation 'bacterium x causes diarrhea'. If we order concepts hierarchically, we want to avoid relations like 'the skeleton is a part of the bones', if we already have the relation 'the bones are a functional part of the skeleton' [5].

The Smalltalk Frame Kit (SFK) is a high-level programming language, which enables us to create an ontological scheme, i.e. a data model for an ontology. Such a scheme contains types of concepts and relations and additionally axioms. It is filled with the actual domain specific concepts by a medical expert. Our approach tries to make this kind of work easier for the expert: he or she should focus on the actual concepts, their classification and relations, the 'weaving of a web' [7]. Formal logic, axiomatic definitions or implementation techniques are due to a software engineering process, which we keep apart from the knowledge engineering process. What we get is a division of labour: the ontology is designed by a software engineer, ontological contents are modeled graphically and intuitively by a medical expert, who relies on the SFK-procedures, which are invisible to him or her, but work as a solid background.

Without any idea about implementation, the medical expert is able to use necessary axiomatic support. Of course the software engineer using the SFK and the expert have to keep in touch closely and to discuss, how the knowledge should be organized basically. In the MediBook project we elaborated four concept types: DiseaseOrSymptom, Cell, Substance, Aspects (other concepts). We minimized the number of concept types for the first version, because SFK,
embedded in the object-oriented Smalltalk environment, allows extensions of an ontological scheme rather than changes: we could re-import the instances already modeled by the expert into a more fine grained second version. This means that starting with a more abstract scheme may be followed by instantiating and evaluating it by the expert. This does not have to be followed by a loss of data when implementing a new model. The SFK works with and is based on frame classes. We describe them as semantic entities, which carry attributes called slots. The slots may be restricted concerning their range (defining which frame types are permitted for a slot) or cardinality (how many values might be attached to a slot), whereas other facets of the slots describe its relational properties: in our previous examples this means defining an inverse slot or adding acyclicity and the extinction of short cuts (direct relations to a superconcept if there are other superconcepts from the hierarchy in between). The SFK yields a rich archive of meth-

ods, which compute additional frame instances and their slot values (or extinct or overwrite frame instances and their corresponding slot values). For example a transitive hull is computed in the background whenever a facet 'transitive' induces triggering new relations automatically. The features reflected by the relational property facets cover the systematic collection of axioms for ontologies described by [8]. An ontological scheme implemented with the SFK-support is a hierarchy of frame classes, which become interconnected by defining slots. This can be done either using SFK as a programming language (in our example: stating that is 'functional part of' is a 'hierarchy-relation-up-slot' in a model method before the classes from hierarchy is generated) or entering the classes from the hierarchy just created to assign 'acyclic' and 'no Short Cuts' to the slot corresponding to 'functional part of'. Inconsistencies like naming conflicts are identified by the system right after the installation of the class hierarchy as an ontological scheme. The SFK continuously exports the state of the instanciation of a scheme. For this purpose it uses XML, which is the input for a Java client, which is able to visualize the export. On the other hand, all actions (creating a concept by selecting a node of one of the special concept types and naming it, deleting and renaming nodes, drawing or deleting a relation between two concepts) at the client side are sent via XML to the SFK. The SFK tests, if the actions are correct according to the scheme, if so the new state of the ontology is sent to the client, if not a warning is sent and a rollback takes place. This would be the case, if the skeleton would be indicated as a functional part of the bones after the relation 'the bones are a functional part of the skeleton' already had been created. The Java client is the medical

Figure 2: GUI of the ConceptSpace-Editor
expert's tool, the SFK is the software developer's tool. Together with their XML-communication they form the ConceptSpace-Editor, which combines a visualization of arbitrary graphs with the logical checks necessary in ontology engineering.

7. Presentation Generator

The module named presentation generator generates presentations of the courses, which were produced with the course-editor (see Figure 1 for a detailed overview of the modules). The courses to be presented are composed of lessons, that are an enumeration with a fixed sequence of MediaBricks. Lessons are realized by a LOM object, that references all containing MediaBricks by their metadata objects with a HasPart relation. Vice-versa the referenced MediaBricks of a lesson references the lesson by IsPartOf relation. Both types of relations used to build lessons are part of the LOM specification. The tree-like structure of the courses, where leaves always contain MediaBricks, results in the possibility to refer to lessons as parts of lessons. This rule defines sublessons in lessons. Without this sublessons there would not be any possibility to compose MediaBricks to a complex structured learning resource like books or lectures. Figure 3a shows a part of a slightly abstracted structure of a course. It should explain the logical context of lessons and courses. The file-formats HTML and PDF are primarily suitable for the automatic generation of presentations of these courses. We assume a learning scenario with a learner working with the computer, but also another scenario, where the learner uses a portable printed version of courses without any computer. From this, two in principle different requirements emerge for the presentations. That leads to two different solutions for the generation of presentations.

One of the advantages of HTML presentation is, that a learner can directly work through the course at the computer without any further software installation except a web browser. However the most important advantage with the generation of HTML pages is the probability to use continuous media, like sounds and videos, in the presentation. This shapes a multimedia presentation in the sense of [9]. In the presentation generation process the MediaBricks are composed to small units that correspond to HTML files. Working through the course and locating the relevant learning resources should be simplified by it. Figure 3b shows an example for the presentation of the course in HTML files.

The presentation of the MediaBricks assigned to a course as a PDF file is predestinated for print outs, but can also be viewed easily and comfortably at the computer. However the course representations as PDF files is mainly suitable for printing them on paper. For this reason, the presentation of the courses is restricted to MediaBricks with static content, like texts and pictures. Unlike HTML presentations in the presentation of the course as a PDF file the MediaBricks are not composed to small units. Rather the MediaBricks have to take a linear order, in which they are printed sequentially in the PDF file. The proper order of the MediaBricks results in a pre-order traversal of the course tree. However before a presentation is generated by the presentation generator a description of the course is generated.
This description can be stored as an XML file to speed up later generations of presentations. Together with the path within the course, that points to the lesson from which a presentation should be generated, and the XSL stylesheet that should be used for the generation of the presentation, the presentation can be generated automatically from this description. There is no difference in generating PDF presentations of courses when distributing them over the web or storing them on CD-ROM, but there is a slight difference in generating presentations of courses in HTML files because of the storage and access to the file. While all resources of HTML presentations, that are distributed over the web, may be accessed via web servers, all resources of a local presentation on a CD-ROM have to be stored on this CD-ROM. Therefore there have to be different HTML files with different links in the presentations depending of the way the courses are distribution or stored. Additionally to an HTML presentation of a course the structure of the course is displayed as a table of contents. This table of contents is presented by a JAVA Applet and should support the learners in the navigation through the course and give them the opportunity to get an overview of the course. The lesson actually shown is always highlighted in the table of contents to ensure that the learners do not lose track of the course by the well-known lost in hyperspace syndrome.

Collaboration and concept mapping

Collaboration is seen as an important element of a distributed learning environments. Many designers of software design for the isolated and individual learner, and many programs reflect the belief that the interactions will be made by a single user. Group use of computers does not guarantee collaboration (Hooper, 1992). Katz and Lesgold (1993) point out that collaboration is more than cooperation: 'Cooperation ... involves a division of labour in achieving a task. Collaboration happens synchronously; cooperation is either synchronous or asynchronous' (p. 289). It is through discussion with others that students are able to negotiate the meaning of a concept by questioning existing understandings as well as explaining, evaluating and clarifying new and developing understandings. This process can be likened to a scaffold where the teacher and more capable peers support students as they work within their zone of proximal development (Vygotsky, 1978). Forman and Cazden suggest that true collaboration is not simply working together but also 'solving a problem or creating a product which could not have been completed independently' (cited in Repman, Weller, & Lan, 1993, p. 286). A number of researchers have explored how concept maps can be used as collaborative tools (e.g., Van Boxtel, Van Der Linden, & Kanselaar, 1997). Concept maps can be used in a variety of educational contexts and for many purposes such as: addressing students' misconceptions, assessing learning, determining prior knowledge, reducing anxiety in low ability students, and designing instructional materials (Jonassen, Reeves, Hong, Harvey, & Peters, 1997; Kennedy, & McNaught, 1997). In many of these settings, concept maps are used by individuals, or by a single student with a teacher, to delve more deeply into the student’s understanding. However, when used as collaborative tools, they appear to promise far greater learning returns.

The study

Broadly, this study explored the implementation of computers as cognitive tools in an environment that acknowledged the distributed and shared nature of learning. In keeping with the view that learning is enhanced if it is distributed across a variety of sources found within the learning environment, students were encouraged to exploit their own intellectual resources (e.g., prior knowledge, metacognitive knowledge), physical resources (e.g., computers, journals) symbolic resources (e.g., diagrams, tables) and social resources (e.g., the teacher, peers). This paper focuses on the distribution of learning that occurred when the social resources were maximised in conjunction with the computer. In particular, it describes the preliminary findings that emerged when small groups of preservice teachers collaborated around the visual concept mapping tool Inspiration (Helfgott & Westhaver, 1997) in a graduate unit which examined cognitive theories of learning.

Students undertook weekly tutorials in groups of three, collaborating around the computer, with the computer and through the computer (Crook, 1996). For example, as part of the module exploring a categorisation of learning strategies, the groups were invited to critique their own lesson plans or videotaped lessons to identify the different types of learning strategies they typically encourage in their classes. Each group negotiated the existence of strategies in their lessons, which were subsequently built into an ongoing map for this topic. The evident imbalance in the maps enabled the students to realise that teachers often place greater emphasis on cognitive learning strategies to the detriment of metacognitive and resource management strategies. These
maps became the starting point for subsequent topics which encouraged students to make links between concepts and build a solid profile of an effective learner. While working on these sorts of tasks, four groups of students were audio-taped on three occasions. These students were also individually interviewed and kept self-reflective journals in which they recorded thoughts about their learning as it unfolded over the semester. This data was transcribed and imported into NUDIST (Qualitative Solutions & Research, 1997) for analysis.

Preliminary observations

From day one, the computers served as motivational tools that engaged the students in activity and discourse. A preliminary examination of the data generated in this situation has seen the emergence of several themes:

**Negotiation of meaning:** This was clearly evident in the students' discourse where discussions often revolved around the formation of consensus in relation to the addition of a new concept or the linking of one concept to another. This negotiation process was unique to each group.

**Metacognition:** The visual representation of material encouraged the students to not only articulate their thoughts, but to reflect upon them in a metacognitive way. As a group, they often monitored their progress, evaluating and proceeding accordingly.

**Cooperation vs: collaboration:** There was no 'division of labour' in an attempt to work cooperatively rather than collaboratively, and concept maps were created synchronously rather than asynchronously. Students enjoyed collaborating and welcomed the opportunity to pool interpretations in an effort to understand concepts.

**Group dynamics:** The groups observed remained focused on the tasks and consistently engaged in the process. While group dynamics were certainly more productive in some groups than others, it was rare to find a non-contributor to the process. Students provided scaffolding for each other's developing understanding of concepts.

**Visual learning:** One of the strongest findings was the students' high regard for the visual representation of the subject matter. Throughout the tasks, in the interviews and journals, students noted that being able to picture the formation of their understandings provided them with a solid, meaningful record for later study and as a springboard for the development of subsequent topics. Most students said they would probably continue to create concepts maps in their future studies even if Inspiration was not available.

**Limitations of software:** As the maps grew in size, however, students were frustrated that they could only view one or two sections at a time. The outline view, which is a text version of the nodes, did not reflect the links between concepts as the students interpreted them. The outline view, therefore, was not an accurate summary of the interrelationships between concepts and could not be used as a point of reference for later study.

Conclusions and further study

In keeping with Vygotsky's (1978) contention that all mental functions have social origins and occur between individuals before they become internalised within the individual, this study capitalised on the potential offered by collaborative group learning. The mental functions that occurred within these groups were mediated by the use of Inspiration software, which is also aligned with Vygotsky's belief that individuals act through tools in their environment to gain greater control over their world. In this regard, the classroom resembled a learning community where the construction of knowledge was shared and distributed across a variety of resources. Further analysis of data will focus on the exploration of more data-driven themes and patterns, and will investigate other issues, such as the quality of the concept maps produced by the students, the influence of the electronic setting, and the students' discourse associated with actions such as revision and the creation of nodes and links.

The Development of Pedagogy for TeleLearning Within Knowledge-Building Communities

Ken Stevens
Centre for TeleLearning and Rural Education
Memorial University of Newfoundland
St Johns, NF, Canada, A1C 5S7
stevensk@mun.ca

Abstract: In the development of a knowledge society in the Canadian province of Newfoundland and Labrador, selected rural high schools are collaborating in new ways. An on-line Digital Intranet facilitates collaborative approaches to teaching, learning and the building of new knowledge. This paper examines the role of synchronous and asynchronous instruction and symmetrical and asymmetrical knowledge advancement in the development of pedagogy appropriate to this new educational environment.

Five years ago Betty Collis (1996) noted that telelearning is the future of distance learning. This paper supports her claim based on current research in rural Canadian school districts in which schools have been brought into new relationships with one another. The academic and administrative interfacing of dispersed classes as sites within electronic teaching and learning networks challenges the institutional autonomy of traditional schools. As teleteaching and telelearning are integrated into the life of classrooms and as more schools link with one another to enable virtual classes to construct and deconstruct, new ways of teaching, organizing learning opportunities and managing increasingly complex multi-media classrooms have to be considered. The development of virtual classes to include areas of the curriculum not previously available in rural communities has provided new pathways for learners and created a need to develop new pedagogy for teachers to facilitate the interaction of on-line and face to face teaching.

Pedagogy for TeleLearning

Teaching in classrooms that are electronically linked to other sites requires different lesson preparation and delivery skills from teaching face to face. For teacher – student interaction in a new electronic educational structure to be effective, the strengths and weaknesses of the new environment have to be understood by those who participate within them. Students often have more independence in managing their learning in open electronic classes but must have to be assisted by teachers in the setting of goals, the meeting of deadlines and in evaluating their progress (Stevens, 1999). Teachers are effective in open electronic classes if they can be flexible in ways that they allow students to participate in on-line lessons. Strategies and protocols for on-line teaching have to be developed between participating schools if all students are to be able to fully participate (Stevens, 2000). The introduction of a rural school to an open electronic network considerably improves its resource base for both teachers and learners although it is often difficult to coordinate timetables between sites to enable synchronous instruction to take place. A considerable measure of inter-institutional and intra-institutional cooperation is required for effective collaboration.

This research focuses on synchronous and asynchronous teaching and learning and the development of symmetric and asymmetric knowledge advancement in virtual classes. From this matrix, preliminary evidence of "student types" in knowledge-building communities are being explored.

Knowledge-Building Communities

The relationship between synchronous and asynchronous instruction in a digital Intranet and symmetrical and asymmetrical knowledge advancement is shown in the following matrix. From this relationship four types of knowledge-building can be identified.
<table>
<thead>
<tr>
<th>Symmetrical Knowledge Advances</th>
<th>Synchronous Instruction</th>
<th>Asynchronous Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type One</td>
<td></td>
<td>Type Two</td>
</tr>
<tr>
<td>Asymmetrical Knowledge Advances</td>
<td>Type Three</td>
<td>Type Four</td>
</tr>
</tbody>
</table>

**Type 1: Symmetric Knowledge Building in a Synchronous Learning Environment**
(Students primarily learning from other students simultaneously)

**Type 2: Symmetric Knowledge Building in an Asynchronous Learning Environment**
(Students primarily learning from other students in delayed time)

**Type 3: Asymmetric Knowledge Building in a Synchronous Learning Environment**
(Students primarily taking instruction from the teacher, simultaneously)

**Type 4: Asymmetric Knowledge Building in an Asynchronous Learning Environment.**
(Students primarily taking instruction from the teacher in delayed time).

This research can be considered in micro and macro terms as part of the preparation of Canadian students for a digital world (Information Highway Advisory Council, 1997). At the micro level pedagogical issues of the balance between synchronous and asynchronous teaching in digital intranets require teachers to evaluate the role of each mode of instruction in assisting students to build knowledge. At the macro level the policy issue of academically and administratively linking schools across dispersed sites has produced new educational structures that complement traditional schools. Teachers appointed to schools have been teaching across networks of interacting sites. There are resource as well as labour issues to be considered in the proliferation of this dimension of telelearning. Since the initial digital Intranet was created in Newfoundland and Labrador, other intranets in the province have been created and links between them are currently being extended. In the new telelearning environment schools are becoming sites within teaching and learning networks and teachers are being encouraged to collaborate between schools in ways that were not considered in the past. The next challenge is to adequately prepare teachers for life in virtual and collaborative environments as well as for traditional, face to face classrooms.

Expectations Of Technology For Learning Communities

Kaisa Still, SOLIDTECH, USA; Martha Russell, Clickin Research, Inc., USA

This theory paper analyses the role of technology in creating a space for shared knowledge and facilitating knowledge sharing in learning communities. All organizations need to be knowledge organizations managing knowledge across individual, group and organizational levels, and hence be learning communities.
Technology and educational changes force educational systems to modify their infrastructure to offer new teaching services to the learning community. The aim of this research paper is to present an infrastructure from a broader systems perspective that help educators understand the relationship between a web educational system and its environment. The outcomes of such an analysis should allow the readers of this research paper to assess the impact of the various supra-systems and sub-systems on a web educational learning environment. Furthermore, the results of the analysis should facilitate the identification of the particular functions of a web educational system.

Introduction

Educational institutions like other organizations in our society are faced with ineluctable changes brought on by new communication technologies. Various web educational models are developed and implemented to meet new demands in education and to survive in a highly competitive educational world. According to Salisbury (1996), transformational change can only be achieved when a systems view is applied appropriately to the specific institutional context and the interrelatedness of the various sub-systems is fully understood.

The conceptual frameworks provided by the writings of Salisbury (1996), Banathy (1992), and Moore and Kearsley (1996) allow the author of this article to examine a web-based educational setting from a systems point of view. The aim of this paper is to present a conceptual infrastructure, using a system approach, to describe the components of a web educational system that are affected by changes in the environment such as technology.

Educational Environment as a Supra-System

In education, the concept supra-system could be defined as an integrated framework that includes all the different education bodies and agencies seen as sub-systems. A system is an integrated entity that is focused on a set of objectives. Most systems accept inputs and transform them into outputs. The different sub-systems of a larger system can be perceived as environments with distinctive boundaries and at the same time multiple interrelationships. Each sub-system can be viewed as part of several supra-systems such as educational, technological, and economic, namely. Figure 1 shows the relationship between a web-based educational sub-system and the supra-system.

A closer look at a web-based educational environment reveals its elements generally identified as learners, instructional resources, behavioral objectives, goals of instruction, etc. (Salisbury, 1996). These new web educational system must present a system of instruction that provides for easy registration, access to relevant content, and the means to self-assess one's progress. This is accomplished primarily as the result of the Internet communication tools.

Figure 1 A Web-Based Educational Setting and the Supra-system
The emergence of these new technologies has forced many teachers to review their traditional perceptions of their roles in the teaching process and to engage themselves in a learning process that addresses the gap between their actual and expected technological competence. The fact that this gap also exists within society in general is another reason why educational organizations need to address this problem and enable their students to better cope with this new reality. Traditionally, educational institutions have seen themselves as a relatively closed environment. However, by analyzing how business organizations have reacted to changes within the supra-system, they have created inter-organizational systems to be able to survive and grow in a highly competitive environment.

**Systemic Environment and Systems Boundaries**

Figure 1 illustrates the relationship between the supra-system and its components, the sub-systems: learning community, schools system, classroom, and the learner. Figure 1 tries to represent the embeddedness of the learner within his/her educational environment. This diagram helps the web learning system designer to understand which components have to be taken into consideration if the web educational system is going to reach its intended goals.

**Figure 1** The interfaces in an educational setting and its relationship with the Educational Supra-system
When assessing the design of a web teaching system, the owner of the system has to determine whether the educational model has actually attained the goals it set out to reach. The system and its environment are separated by permeable boundaries. Inputs enter in the system through breaks on the boundaries and are then transformed into outputs. Another important aspect is the capacity of the system to adapt to change, i.e. to transform feedback from all stakeholders into the appropriate adjustments to the system itself.

The first consideration in the analysis of the various inputs from the educational environment is how the mission and goals of the organization are related to the instructional delivery. The mission should be closely aligned with the goals of the web-based educational system. The Functions/Structure lens (Banathy, 1992) allows to see the educational system at a given moment in time. It is a snapshot of what is happening in an educational program. Did the educational system, for example, begin with a careful formulation of the goals and missions of education and then work backwards from there to create alternative visions of systems that might be designed to perform the functions necessary to accomplish that purpose (Salisbury, 1996)?

The rising popularity of the Internet forces traditional educational institutions to offer new services to educators and learners. Rising education costs, emerging opportunities for new revenues for colleges and universities, and better services to students will compel these institutions to adopt an e-business strategy (Katz and Oblinger, 2000). Virtual and modern educational settings will emerge in this educational network infrastructure where educators and learners will expect a better educational product from the supra-system. Colleges and universities will have to reengineer their educational processes to adapt to new learners demands. Culture and change could be important factors to manage properly in order to assure educational growth in the
supra-system. They are more complicated to implement than technology. E-business technologies and media will provide improved and expedited benefits, increased process efficiencies, and competitive training to lifelong learning.

According to Moore and Kearsley (1996), typical components that constitute inputs in a web education system are students' characteristics, students' access to resources, response time, and institutional cooperation and support, etc. Instructional design should therefore start out with a thorough needs analysis of the potential learners, provide access to the appropriate technologies, and continually update the content and technologies used to deliver the instructional materials to the learners. In her book on creating a virtual classroom, Porter (1997) outlines criteria for determining the effect of instructional design and the kind of processes needed to make sure that inputs will result in effective outputs. For example, student characteristics, computer interaction, learning style, involvement, and participation should be part of the inputs the design team would have to consider before determining the instructional strategies of the educational program.

From a systems view, outputs can be viewed as functions of the system that achieve their purpose. Evidence of output functions that correlate with the statement of the intended learning goals will be investigated in order to determine whether the outputs actually relate to the inputs. Moore and Kearsley (1996) list several 'output' components in education systems that provide valuable information of the overall effectiveness of the system, e.g. student satisfaction ratings, student achievement scores, and completion rates. The question that the stakeholders of the educational system should ask: is the web-based educational system doing what it was intended to do? The learning should be structured in such a way that it delivers skill-based instruction in various processes to enhance learning outcomes.

Training programs and professional programs are essential to help teachers learn basic skills necessary to develop sound and effective web-based teaching systems (St-Pierre, 1999). If the educational organization realizes that, after all, the training participants do not put into practice the skills introduced in the training program, there should be an adjustment or adaptation in the system process with respect to the originally intended skills or knowledge (Salisbury, 1996). A thorough evaluation of output, i.e. what results from the transformation of input during the learning process, is obviously important to determine the overall effect of the training. The development of the appropriate strategies and tools to close the gaps between the current performance level of the training participant and the expected performance level should be the major focus in the development of any training necessary to promote learning outcomes in a web educational setting (Brethower, 1995).

The stakeholders of a web-based educational system, living in a supra-system, must identify instructional inputs and outputs from a traditional teaching perspective to transform them into a modern web teaching setting where new technology can help to design new instructional tools and media to promote learning outcomes. While the selection of new media allows for some learner control and also takes learner motivation into account, the instructional design has to expand outside its established boundaries and exploit deeper situational learning concepts that could be developed from a wider systems view. For example, a collaborative virtual learning community could be created through its web-based educational system to exchange ideas, knowledge and teaching products with its environment. St-Pierre, Bettin, Dillinger, and Ferraro (1999) present in their paper the components that an integrated community learning system should have while offering educational services to learners on the Internet.

Functions/Structure Analysis for a Web-Educational Sub-system
The main goal of this section is to describe briefly the functions/structure model for a web educational system as shown in Figure 3. This web educational system includes at least six main functions that are integrated to help educators develop web instructional models to promote learning outcomes.

**Web Registration Function**
Anyone who intends to take a course has to register by filling out a web-based registration form. The data entered in the registration function are processed through CGI-technology specifications and recorded into a database. The sub-system will produce a form displaying the UserID and the password required for accessing the teaching/learning component of the educational sub-system. There is a direct relationship between the registration and the teaching/learning components of the web educational system.

**Teaching/Learning Function**
The teaching/learning function includes learning modules that the student can choose from. The web learning modules, divided into numerous short lessons, provide contents that help the participants acquire the basic knowledge and develop technical skills. After having completed the learning modules, the participants may use the communication media to correspond with tutors and other participants or move on to the evaluation function. There is a direct relationship between the communication process and the teaching/learning function.

When computers are connected through the Internet, web media provide appropriate means for communicating and delivering instructional materials (Zellner, 1997). Well-designed web-based instruction provides an efficient delivery medium for the instructor and attractive course content delivery for the students in the classroom (St-Pierre, 1999). In addition, mediated forms of delivery using the web make it easy to update dynamic, constantly changing information; a very important aspect for a course that introduces to rapidly changing web.

**Figure 3 Functions/Structure Model for a Web educational Sub-system**
Teaching/Learning Function

The teaching/learning function includes learning modules that the student can choose from. The web learning modules, divided into numerous short lessons, provide contents that help the participants acquire the basic knowledge and develop technical skills. After having completed the learning modules, the participants may use the communication media to correspond with tutors and other participants or move on to the evaluation function. There is a direct relationship between the communication process and the teaching/learning function.

When computers are connected through the Internet, web media provide appropriate means for communicating and delivering instructional materials (Zellner, 1997). Well-designed web-based instruction provides an efficient delivery medium for the instructor and attractive course content delivery for the students in the classroom (St-Pierre, 1999). In addition, mediated forms of delivery using the web make it easy to update dynamic, constantly changing information, a very important aspect for a course that introduces to rapidly changing web.

Evaluation Function

Within each lesson, the learners have the opportunity to complete the so-called “Try it” exercises. They have to use basic concepts, knowledge, and skills acquired from the teaching/learning function to be able to solve problems presented in these exercises. The participants can work on these exercises on-line or off-line. The evaluation function will monitor the lessons and exercises throughout the teaching process at different points in time. Every time the participants return to the web educational learning model, the Lesson Status page could display a report showing their progress and suggests which lessons to work on next. Also, at the end of each lesson, the participants may complete an evaluation form if they wish to give feedback to the teacher on the course content or other topics of concern to them. There is a direct relationship between the teaching/learning function and the evaluation function.

Communication Function

During the learning process, the participants can use web media such as E-mail and the bulletin board to communicate in an asynchronous manner with other participants. At any time during the learning process, the participants can create a conference room with the tutors to obtain explanations on concepts or skills presented in the teaching modules. There is a direct relationship between the communication function and the major components of the web educational system, such as web registration, teaching, evaluation, and support functions.

Support Function

The participant can click on the Help icon to access a list of FAQ that will answer questions about online procedures, navigational cues, or curriculum issues. Also, the participant may send an E-mail message to a tutor and will (allegedly) receive a quick response within 48 hours. There is a direct relationship between the support function and the teaching/learning function.

Web Materials Production Function

The teaching/learning model uses a web platform to deliver curriculum and instruction. This platform is easy to maintain and can be accessed by a large population of educators and learners.
The participant can display and/or print the web training contents in an HTML or Adobe format. There is a direct relationship between the web materials production and the teaching/learning function.

In conclusion, the analysis of the different functions of the web educational sub-system show that these functions are indeed all interrelated as suggested in Banathy’s Functions/Structure model. The web instructional teaching system has to be well designed from a technical point of view and present good design features (interface design, navigation, progress report, etc.) to motivate the potential participant to register and engage into an effective learning process.

**Conclusion**

The analysis of the systems environment, the functions/structure components of the web educational sub-system, and the processes involved in the transformation of inputs into the intended outputs brought to light the complexity of managing changes in a intricate educational system living in its supra-system (environment). This experience also underscores the necessity to look at change processes as an ongoing endeavor that continually attempts to improve the system’s capacity (web-based model) to adapt its goals to the changes in the environment.

The continuous progress of technology will have direct consequences on the educational setting that will have to be revised repeatedly. In addition, new teacher generations will no longer need basic Internet training because they will have already used the web extensively at home and in school. In addition, effective feedback systems should be implemented in educational settings to provide relevant information for the necessary adjustments of the system. Furthermore, educational changes should take place on a continuous basis to develop a competitive educational system in an open educational supra-system where major technological changes threatens its survival.

Abstract: A Computer-Managed Metric Instruction Program (CMIP) providing instructional units on basic metric concepts has been developed. A blending of Gagné, et al. (1992) and the developmental theories of Bruner (1966) provides the pedagogical basis for the instructional design. The instructional design model used to create each lesson utilizes a system of "branches" allowing a student who has difficulty with a specific lesson to be routed to appropriate remedial exercises. Results indicate that the use of concrete materials adds a learning dimension to those students who need a transition between the "hands-on" learning modality and the more abstract learning module presented in the CMIP.

Introduction

One of the new facets of the elementary science methods program at Idaho State University is the increase in the science and mathematics general education requirements. These additional science and mathematics requirements were spawned by a survey that indicated a serious deficiency in the science content knowledge of elementary school teachers (Strickland & Horejsi, 1999). One alarming feature found in the analysis of the survey data was the apparent lack of knowledge and understanding of the metric system within teacher work samples. A parallel survey was conducted of pre-service elementary students and the results were similar: Lack of science content knowledge and, of particular interest for this research, a serious lack of knowledge of the metric system. Two decades ago, Strickland (1980) reported a similar lack of science and metric system knowledge among pre-service teachers at Indiana University.

The solution at Indiana University was a computer-managed program using the PLATO computer-learning system. After using PLATO for five weeks (i.e., five 3-hour sessions on the system), the metric performance among pre-service elementary teachers increased by 86%, and there was a corresponding change in science content knowledge and science teaching in the elementary school classroom. Apparently, as evidenced by the survey data referred to earlier (Strickland & Horejsi, 1999), the issue of science and metric illiteracy has resurfaced.

Idaho State University has embarked on a much larger research effort focusing on the design and development of a Computer-Managed Metric Instruction Program (CMIP). The CMIP software comprises instructional units providing basic metric concepts for each of the following measures: Length, area, volume, mass, force, and...
temperature. Uniquely, this instructional package consistently uses a pedagogical model based on the behaviorist views of Gagné (1962, 1968, 1970), and Gagné, Briggs, and Wager (1992). While each of these theorists offers the premise that correct sequencing of conceptual knowledge in conjunction with a mastery approach leads to meaningful learning by the student, the design team for CMIP felt the most effective sequencing model would be a blending of Gagné, et al. (1992) and the developmental theories of Bruner (1967). Bruner (1967) stresses that the effective use of information is found only when the learner has successfully translated the information into a form the learner normally uses in problem solving. Without this translation, according to Bruner, “Though it is logically usable, it is psychologically useless” (p. 53). To this end Bruner has applied a multi-branching model to learning. This model is incorporated into the metric instructional units discussed in this research.

Additionally, Rodrigues (2000) highlighted several fundamental differences between behaviorist and constructivist views as they impact multimedia development. These views are expressed in the following excerpt:

> Some of the strengths of behaviorist tutorials – for example, repeat practice, reinforcement, and control – are almost the opposite to goals advocated by constructivist philosophies (Heinich, 1984), where the notions of reflection, active construction, personal relevance, and autonomy (Lebow, 1993) are considered crucial constructivist learning facets. (p.1)

The instructional design model used to create each metric lesson utilizes a system of “branches” (as opposed to linear programmed learning). For example, a student who has difficulty with a specific lesson, or who shows deficiencies in command of a subject (identified by pretest results), can be routed to a review section or to remedial exercises, meanwhile all other students progress through increasingly more difficult exercises. Thus, the system is simultaneously a "Tutor, Tool and Tutee" (Taylor, 1980). As a result, this research concentrated on the design and development of the metric area module as the first module of the entire metric system course (and to act as a prototype for the remainder of the modules).

This selection, based on metric pretest data (see Table 1), indicated a serious deficiency among the students’ ability to perform calculations in determining area (mean score = 4.620) and volume (mean score = 4.440).

Table 1: Metric Unit Pre-Test Data

Metric area was selected instead of metric volume since the skills and concepts needed for the volume module were subsumed by the area module. The wide variation (SD = 2.30) in score on the metric area was an additional rationale for selecting this module to be first.

Computer-Managed Metric Instruction Package (CMIP): Unit Design

The CMIP software package (Fig. 1), has four primary elements; (1) the introduction to metrics module, (2) the pretest and skill assessment module, (3) the metric instructional module, and (4) the posttest and analysis of results module.

The introduction to metrics module is composed of an overview of the CMIP metric instruction. The student is guided through an array of examples which depict the metric system being used to measure length, area, volume, mass, force, and temperature.

The pretest and skill assessment module is designed to access the students preknowledge of the metric system, rudimentary mathematics skills and selected learner aptitudes.
Figure 1: Computer-Managed Metric Instruction Package (CMIP) flow chart outlining the elements of the metric instruction. If the student does not meet acceptable level of performance they are returned to the first unit that was below the acceptable level.

The metric instructional module consists of six metric instructional units (Fig. 2): Length, area, volume, mass, force, and temperature. Each unit describes the basic unit of measurement and explores units, which are smaller and larger than the base units.
Figure 2: Expanded flow chart of the Metric Instructional Module of CMIP. The Metric Instruction Module uses data from the pre-test module to determine the appropriate lessons for the student.

The posttest and analysis of results module is designed to measure the performance level of each student. If the performance level is acceptable then the student passes the metric course, if weakness (low performance) exists in any unit the student is guided back through that unit until an acceptable performance level is reached.
Formative Evaluation of the Metric Area Module

The metric area unit consisted of four segments (Fig. 3): (1) An introduction to the module, (2) the base unit module (square meters), (3) three modules with measurements smaller than the base unit (square decimeters, square centimeters, and square millimeters), and (4) one module with measurements larger than the base unit (square kilometers).

Figure 3: Metric Area Unit flow chart. After a brief introduction (2.1) the unit begins with the base unit of area and ends in a review and post-test (2.R) of the area unit.
The pre-test data for the metric area module consisted of 15 questions, 3 each on the following square unit segments: Kilometer, meter, decimeter, centimeter, and millimeter. The mean of the square kilometer was lowest (X = .20, SD = .09; out of 3); thus, this module was selected to be the initial module segment to be tested. The square kilometer segment (Fig. 2) consisted of several large regular shaped objects (scaled to fit on a standard monitor), such as New York’s Central Park. Central Park is rectangular in shape and made a good first example of the area calculations for large objects. After several similar examples, the instruction moved forward to irregular shaped large objects, such as a large reservoir in the geographical area. A scaled one-square kilometer area was used with the technique of summing whole and partial grid squares. The instruction produced a significant change in the performance on the module segment (X = 1.35, SD = .57; out of 3).

Summary

The analysis of the data collected during pilot test of the Metric Area module: Square Kilometer segment was critical in determining alterations needed to this module segment and additional components. This data analysis has shaped the instructional process for each of the remaining modules. While observing the students participating in the computer-managed module segment on square kilometers, it became apparent that each module must be constructed with some use of a manipulative, as well as the computer software. Apparently, the use of concrete materials adds a learning dimension to those students who need a transition between the “hands-on” learning modality and the more abstract learning module presented in the computer software.

Abstract: A doctoral level Instructional Technology course was delivered to 48 Taiwanese students in their country via WebCT. This was the first course developed by our College for complete on-line delivery and the first one taken by many of the students. The design consisted of 7 components and engaged U.S. doctoral students from an Instructional Technology cohort group two years ahead of the Taiwanese in the terminal degree program. The design, development, delivery, and evaluation of the course will be discussed in this presentation and paper.

Introduction

The College of Education at Idaho State University offers a required core course within its Educational Leadership doctoral program entitled, Instructional Technology (EDLP707). This class is designed for all levels of technology users.

The College accepted 48 Taiwanese students into the Educational Leadership program in the summer of 2000. All of these students enrolled in this course from their homeland of Taiwan during the fall 2000 semester. This added an extra dimension to the inaugural on-line delivery of EDLP707: The design needed to consider students whose second language was English.

Review of Literature

In many ways, the use of the World Wide Web for delivering instruction is still in its "pioneer" days. For users who choose, for whatever reason, to engage in this learning style, the technology is not ubiquitous in today's environment.

Foshay and Bergeron (2000) hold the view that web applications must be designed for a 28.8 Kbps modem. They caution developers to remember that today's world, particularly in the home, is a slower connect situation and will remain so for some time. A developer, then, should design for the 28.8 Kbps environment, or look toward a specialized clientele that will have faster connectivity.

As many course developers have discovered when adapting to a technological delivery mode, presenting content through a computerized system is not the same as instruction. Merrill (1994) cautions developers to remember that classroom (face-to-face) learning includes feedback and practice, and this must be brought into the computer-based world, as well. The author also warned that the technology driven training should not be just electronic pages, but there should be ways for the learner to interact with the technology to increase their knowledge base and interest in the scholarly pursuit.
Course Design

Idaho State University has adopted WebCT as its on-line course development tool. The on-campus students who selected Instructional Technology as their program concentration helped in the development of the components. This doctoral cohort group were approximately two years ahead of the targeted students in this course. The development group met on a weekly basis to receive final feedback and proceed with the uploading of materials.

The curriculum for the Instructional Technology course examined seven elements within each chapter of the text:

1. An extensive Review of the chapter contents, including Review Questions for students to submit and receive feedback from their assigned "tutor-mentor."
2. Resources that provided expanded understanding of the principles as well as hypertexted web site addresses (URLs).
3. Extensions, designed to broaden the information beyond the textbook chapter.
4. Explorations could be considered peripheral, but meaningful. These "side trips" were also tied to the bulletin board discussions for the chapter content.
5. Bulletin Board discussion topics were initiated as the "participation" portion of the course and served as a communication device for intellectual discussion.
6. Quizzes was taken on-line and pertained to the textbook chapter, the Resources, Extensions, Review and Discussion. Since Review was provided, and the assigned tutor-mentors provided constructive feedback, one quiz attempt was considered appropriate.
7. Projects were included as synthesis of the student's knowledge. These were communicated through email attachments.

Discussion

The instructor and the development team feel the experience of producing and delivering an on-line course to doctoral students in Educational Leadership who are not native English speakers has been a moderate success. Students experienced average to above average success with the course materials. In addition, the instructional design process served as a practical grounding for doctoral level students in this specialty. These same students have been involved in the revision of the course materials and sequence.

Certainly, our doctoral program, and probably our master degrees, will include on-line courses, or supplemental on-line portions to classes taught in the traditional face-to-face mode. The College is carefully examining the EDLP707 fall 2000 course, including the support for continued development and evaluation. As the first course offered fully on-line within the college at the doctoral level, future offerings will benefit from this experience.

As our College of Education moves toward more course delivery via distance learning, methods for totally on-line components will be perfected. We do not anticipate that this teaching/learning method will replace all other forms of course delivery, but the College does see it as a means for expanding our offerings to students who do not reside either on, or close to, our physical campus.
Creating web-based programs for international delivery: Curriculum and faculty concerns

Abstract:
This paper addresses curriculum and logistical issues which have arisen during the first year of Idaho State University's international doctoral program in Educational Leadership. Currently there are 54 Taiwanese students in the program, 48 of whom are taking classes from Taiwan on-line; six are taking classes at ISU. As the capabilities of the World-Wide Web make international on-line classes not only possible, but more common, the experiences of ISU's College of Education are timely and relevant.

Planning and delivering a program of on-line courses to foreign countries touches upon such issues as administration, hypermedia systems, multicultural instruction, instructional design, and the creation of on-line communities.

Introduction
Idaho State University's College of Education offers a doctorate in Educational Leadership to graduate students within its service area of 40,000 square miles. The College of Education recently accepted a large contingent of Taiwanese students into the doctoral program. Currently there are 48 Taiwanese students in the program who are taking a core (required) Instructional Technology (EDLP707) course from their homeland of Taiwan. An additional six Taiwanese students remained in Idaho to take courses. These groups are divided into three sections (one based in the United States and two in Taiwan). The College of Education is working to ensure an outstanding doctoral program for these students, both in Idaho and overseas.

As the capabilities of the World-Wide Web make international on-line classes not only possible, but more common, the experiences of ISU's College of Education are
timely and relevant. Planning and delivering a program of on-line courses to foreign countries touches upon such issues as multimedia and hypermedia systems, virtual universities, design principles (cf. Eastmond, et al., 2000), and the creation of on-line communities.

Several key issues have risen during this first year of the “international” doctoral program. These issues can be sorted into four major categories, each one of which will serve as a topic for discussion for the panel and the audience. These categories include design, logistics, administration, and community.

**Design**

This panel will address the particular issues in developing a doctoral level course that is a core element in a terminal degree program. The design of the course — textbook, on-line features, and projects — will be discussed, as well as future implications for this type of course delivery to students for whom English is not the primary language. It is hoped this panel discussion will lead to greater dialogue among international colleagues who are delivering similar courses at the advanced post-secondary level. The merits of timing, communication, and scholarly discussion opportunities are all components for consideration when attempting to replicate the same teaching/learning environment enjoyed in a traditional (e.g., not on-line) environment.

In addition to the design considerations cited above, design elements vary from culture to culture, and the design of instruction and the medium of instruction in any international program must take these cultural differences into account (Heaton, 1998). This panel will also touch upon cross-cultural differences as one of several factors to consider in instructional and multimedia design.

**Logistics**
Weston (et al., 1999) identify nine important components of on-line learning which must be considered when evaluating the success of the delivery. These nine components include: impact on learning, student computer literacy, student computer access, infrastructure, interactivity, navigation, evaluation, accuracy and recency, and loading speed and bandwidth. A logistical challenge for the international doctoral program has been to assess each of these components, especially those dealing with practical considerations, such as student computer competence, bandwidth, loading speed and access between the United States and Taiwan, and time differences. The panel will discuss practical, logistical constraints on the international program's on-line offerings.

Administration

The Doctoral Program is administered from the College of Education Dean's Office. The Assistant Dean for the College has primary oversight responsibility for assuring that the program meets its goals and provides a positive learning environment for all students. Separate funding for the program serving the Taiwanese students was secured to provide the resources to meet the demands of this program. In addition, new faculty positions were added to meet the needs of the program. The Dean, the Associate Dean, and the Assistant Dean have all assumed roles, including teaching, in helping to ensure success. Among these roles have been budget management, all-campus coordination for student services, planning, developing non-academic programming, providing resources, and others.

The panel will provide opportunities to discuss administrative challenges and solutions with colleagues involved in similar programs.

Community
An on-going challenge in any computer-mediated communication is to develop a sense of community among the users. It has been noted that listservs, emails groups, news groups, and chat rooms create small groups of people with similar interests, essentially “virtual communities” (see Jones, 1997, for an excellent overview of the concept of virtual communities). ISU’s Taiwanese doctoral program has also sought to create a virtual community, not only among the Taiwanese students, but also between the Taiwanese students and their faculty, and their American counterparts. The panel will discuss how the enlistment of American doctoral students as mentors for the Taiwanese has helped to create a coherent doctoral cohort that communicates through a variety of computer media. The panel will also address means of drawing experts from around the world into the students’ virtual community.

Abstract: The goal of this research study was to increase achievement elementary school mathematics through the application of an instructional model designed to emphasize all aspects of mathematics instruction, one which utilized technology where appropriate. Over 430 fourth grade students participated in the year-long effort. The primary conclusion of the study was that student achievement showed a marked increase in achievement.

Introduction

Concurrent publication of two texts in 1989, Everybody Counts (NRC) and The Curriculum and Evaluation Standards for School Mathematics (NCTM), launched a reform movement in school mathematics in the United States. Carlson (1992), describes this latest in a line of reform movements as part of the continuing tug of war between a "back to basics" or "drill and practice" orientation versus an approach based on "understanding mathematics" and "problem solving." A basic imbalance is always present when "meaning" and "skills" compete within the mathematics curriculum. Neither makes a complete math program. To teach all required skills, an instructional model must emphasize computational skills, conceptual skills, and problem solving skills. Students need them all in order to use mathematics.

Research Goal and Plan

The research goal was to raise math achievement by testing an instructional model designed to cover all aspects of mathematics instruction. The population selected for this demonstration project included fourth grade students in SE Idaho. Since Idaho gives benchmark ITBS tests to 5th graders in October, it was determined that fourth grade students should receive the year-long instructional program in order to prepare them for the fifth grade testing.
The treatment group teacher sample included 19 teachers in eight schools from six different school districts spread over 200 miles in SE Idaho. The control group included 15 teachers from the same geographical area. Students included in the sample were in these teachers’ classrooms. The treatment group began with 512 students, but fell to 434 students by the end. The control group had nearly the same rate of attrition, falling from 428 to 364 students.

Since the purpose of the study was to raise achievement in mathematics for Idaho’s testing program, The Iowa Test of Basic Skills (ITBS), mathematics section, given by the State, was the only achievement test that could be used for the final evaluation. The choice of a test for the diagnostic portion of the project was the Stanford Diagnostic Mathematics Test (SDMT).

Methodology

Treatment group teachers were provided with (1) diagnostic test results for their students to use in planning; (2) math manipulatives to be used in teaching math skills; and (3) five computers and the appropriate software to integrate technology into the daily math instruction. Teachers were trained to use these materials during two three-credit semester classes, one in the fall and one in the spring. The teachers were asked to provide “seamless integration” of technology into instruction.

Computer efforts utilized several different types of software. Children did computations on the screen as the computer checked every step of every problem. Students worked routine word problems on the computer. They were asked to identify the operation needed to solve a word problem, to enter the numbers into an algorithm, and if that work was correct, they completed the computational work on the screen to obtain the answer. Finally, students solved non-routine problem situations including interesting “game-like” activities.

Data collection consisted of collecting ITBS scores as pre- and post-test measures, as well as the SDMT pre- and post-test measures. Observations were made in all classrooms over the entire course of the year, as the researchers visited classrooms, worked with students on the computers, and examined the data stored in the computers on students’ work and achievement records.

Means and standard deviations were calculated for the pre- and post-test results of both the Stanford Test and the Iowa Test of Basic Skills. These were calculated for the total sample as well as the individual schools. In addition, the basic percentile rankings for each school and for the total sample were calculated for both tests. These percentile rankings can be used for a quick overview of the scores for the total sample and for each school.

Statistics were calculated, the entire set of scores were subjected to an ANOVA test to see if there were significant differences between the pre- and post-test scores on both the SDMT and the ITBS. Finally, if the “F” test was significant, the Tukey test for differences between means was used to determine which results differed from what would be expected by chance.

Findings and Conclusions:

Student scores increased on the SDMT from a mean percentile level of 35.1 on the pre-test to a mean of 63.4 on the post-test for the total math battery. On the ITBS the mean for all students increased from a national percentile rank of 40.3 to 58.9 for the total math score. This shows an increase on the Stanford of 28.3 percentile points and on the ITBS an increase of 18.6 percentile points. Both of these were statistically significant changes in student performance. Control group students showed no such gains.

The major conclusion is singular: Given an instructional model incorporating precision teaching, manipulatives, and technology, Idaho children can and did increase performance in mathematics. The teacher-training model implemented was a low-impact model; the researchers did not force an instructional plan upon all teachers. But the differences between classroom achievement test gains are clearly explained by each teacher’s level of implementation. Therefore, higher test score gains are directly tied to the teacher’s use of the total model.
Using metadata for re-using material and providing user support tools

Abstract: The reuse of learning content in educational technology attracts much attention. This is mainly caused by recent initiatives for standardization of learning technology, but also by the necessity of a more efficient usage of valuable learning resources and development time. Standards for reuse can provide uniform specifications for exchange of learning content. To make reuse efficient, metadata is needed to find and select relevant content. Metadata, information about data, describes this data on a higher level, so that material can be identified, ordered, categorized and selected. However, adding metadata can be very time-consuming. This paper describes a support system for users, like educational developers, teachers and learners, to add metadata to existing learning content and courses.

Introduction
The faculty of Educational Science and Technology started a faculty wide implementation of Teleleaming with the TeleTOP project in 1997. The aim of the project was to support teachers and students with a web based database driven environment. In three years time educational designers created a very large quantity of learning content stored in more then 600 courses. It is very beneficial if this set of learning content could be reused in different courses.

Metadata
Metadata can be seen as descriptive information; description as in providing more information about data. This is analog to the information such as found in a card index in the library, where information can be found about the stored books. Metadata is used to structure the collection of books. The better the material is organized, the better and faster a useful selection can be made. The themes used in a library (Nature, Science, Sports) are standardized and very easy to understand, even for non-experienced readers. So, these themes are used to guide the library visitor trough the large collections of books. Returning to educational technology, using metadata can guide non-experienced users trough a large collection of useful learning material. Presently, in the TeleTOP system metadata is already added to the content to structure learning content a within a course. The set of metadata was kept minimal because filling in a data set of metadata is often a boring and time-consuming task. Beside that, creating metadata is not considered important or useful by the users, as it is not direct beneficial for them.

Standards
Standards for reuse can provide exchange specifications. For instance, the Advanced Distributed Learning (ADL)\(^1\) developed the Sharable Content Object Reference Model (SCORM) that applies state-of-the-art technological developments from groups such as the Instructional Management Systems project (IMS)\(^2\), Global Learning Consortium, Inc., Aviation Industry CBT (Computer-Based Training) Committee (AICC)\(^3\) and the Institute of Electrical and Electronic Engineers (IEEE) Learning Technology Standards Committee (LTSC)\(^4\) to a specific content model to produce recommendations for different target groups. The recommendations can be used to structure learning material in a consistent format so that different learning management systems can make use of the material.

4 LTSC: http://ltsc.ieee.org/
A support tool for metadata application

SCORM can be used as a basis to specify the metadata within the TeleTOP system. However, only a small part of the metadata that is needed to be SCORM ‘compliant’ is currently available within the present TeleTOP system. Additional metadata that is needed is available in the general administrative databases. For this purpose, we developed a tool that offers support in adding metadata that makes use of different data sources. The TeleTOP system users (the teachers) that are involved in the reuse process of material, and therefore in the metadata creation process, have to deal with 4 aspects: 1) adding metadata, 2) finding material based on metadata, 3) selecting useful content and 4) making the content available for use. The application of these 4 aspects should be as easy as possible for the users. One way to do this is to automate the creation of metadata as much as possible. This automation promotes the usability of the system and the acceptance of the users.

The support tool guides the user in retrieving data from the administrative and educational system and combines the data in a SCORM compliant metadata set that is stored in a database. This database can be used to search for relevant learning content. Because of the structured storage of the metadata, the user can also search on categories, authors or dates. Search engines are provided to make full-text searches on the metadata available. Relevant hits can be previewed and selected immediately for reuse. An software agent makes reuse available for the users. After selecting material, the software agent copies the needed material to a new target learning environment. Users do not have to make links themselves; the database generates needed links on the fly. The tool makes it possible to add metadata to existing material and using for these process external data sources.

Challenge, future plans

Research is necessary for the use of metadata in different situations in learning and for different users. Research should focus on the different support tools needed for this settings and if a general metadata set can be extracted that is useful for most situations.
E-Learning for Corporate Training:
A Review of the Literature

Judith B. Strother, Ph.D.
Randall L. Alford, Ph.D.
Florida Institute of Technology
Humanities and Communication Department
Melbourne, Florida, USA
strother@fit.edu; rlalford@fit.edu

Abstract: Few people debate the advantages of e-learning — accessibility from any place at any time, significant cost savings, standardization of content delivered to large groups, and control of content quality. The levels of interactivity available through much web-based training increases these advantages. Although managers’ enthusiasm for online training runs high, most have not measured the effectiveness of their net-based programs. Systematic research is needed to confirm that learners are actually acquiring and using the skills that are being taught online, and that this is the best way to get to these outcomes. This paper provides an overview of successful e-learning programs.

Corporations are constantly looking for more cost-effective ways to deliver training to their employees. E-learning is inexpensive compared with traditional classroom instruction. In addition, many expenses — travel costs for employees or trainers plus employee time away from the job — are greatly reduced. The other advantages, such as convenience, standardized delivery, self-paced learning, and variety of available content, have made e-learning a high priority for corporations. It is still early to find conclusive results about the measurement of actual learning that takes place as a result of e-learning, but we can analyze the somewhat controversial results that have come out of mainly academic-based distance learning programs.

How Do e-Learning Instructors Feel?

A number of studies have clearly supported the value of e-learning across a number of fields. For example, in a recent survey conducted by eCollege.com, 85% of the faculty said their students learned equally effectively online as on campus. Some said their students did even better online than in traditional classroom settings. A California State University at Northridge study shows that students in a virtual classroom tested 20% better than did students who learned in a traditional classroom. Sixty-two percent of 130 faculty respondents in another study said their students learned equally effectively in the online environment; 23 percent of faculty stated that their students learned better online; while 90 percent indicated that they were satisfied with online teaching. One faculty comment was: “Online students participate more, perform slightly better than, and are at least as satisfied as their on-campus counterparts. From that I conclude that online education appears to be very effective!” (TeleEducation, 2000).

How Do Learners Feel?

The majority of 1,002 students who were enrolled in online university courses responded to a survey, saying they chose the online format because of the flexibility and convenience of the program. Comments included: “I love that I have the flexibility to continue to hold a full-time job, . . . and study any time that best suits my busy schedule; I travel extensively and . . . I was able to work with my instructor, receive tremendous technical support at all hours of the night, and gain the same quality content and evaluation as my peers taking the same class on campus.” The survey reports that 75% of those students online were employed and 68% of the learners worked more than 30 hours per week (Survey Finds Online Education, 1999). This fact makes this study particularly relevant for corporate trainers who have to fit e-learning into an already demanding work schedule.
Differences Between e-Learning and Traditional Instruction

Bates (1996) pointed out that “the potential for developing higher order skills relevant to a knowledge-based society is a key driver in developing computer-based distance education courses.” Examining how learners engage higher order thinking is the topic of a recent research study at Massey University in New Zealand. White (1998) examined strategies of 420 foreign language learners at the university. White reports that distance learners made greater use of metacognitive strategies — what individuals know about their own thinking — compared to classroom learners, most notably with regard to the strategies of self-management and advance organization and, to a lesser extent, revision.

A comprehensive research bibliography on e-learning has received much attention. Compiled by T. L. Russell (1999), The No Significance Difference Phenomenon may provide one of the most quoted rationales for the power of e-learning. This body of research demonstrates no significant difference no matter what media you use for learning. In many of these studies, the model is asynchronous learning delivered to the learner on demand. The findings demonstrate that even with no instructor or face-to-face interaction, there are no significant differences in the amount of content learned. A related website includes extracts from more than 355 research reports, summaries and papers supporting the No Significant Difference phenomenon. This is one time that a finding of no significant differences is actually a compelling advantage. If corporations can get all of the advantages of e-learning with the same level of results as an instructor-led classroom situation, the economic element becomes even stronger.

The research results continue to improve for e-learning in general. Nettles, et al., (1999) report that, while the majority of the 49 studies they examined reported no significant difference between e-learning and traditional classroom education, “nearly 30% of the studies report favorable outcomes based on student preference, better grades, cost-effectiveness, and greater homework completion.” An alternate website features comparative studies that do show significant differences, most of which report positive results. For example, Maki, et al., (2000) evaluated a Web-based Psychology course and reported that content knowledge, use of the WWW, and use of computers for academic purposes increased while computer anxiety decreased. Navarro and Shoemaker (1999) reported “... that Cyberlearners performed significantly better than Traditional Learners.”

In a study of corporate learners, Redding and Rotzien (1999) report that “the online group is the most successful at cognitive learning as measured by the end of course examinations. . . . The results of the study do provide strong support for the conclusion that online instruction for individuals entering the insurance field is highly effective, and can be more effective than traditional classroom delivered instruction.”

Content Quality Measures

In addition to the need for more research about e-learning results, more attention is being paid to the quality of the online education product itself. The National Education Association and Blackboard, Inc., examined case studies of six higher education institutions that provide Internet-based degree programs “... to ascertain the degree to which various measures of quality identified in previous studies are actually being incorporated into the policies, procedures, and practices of institutions that are e-learning learners. The final outcome is a list of 24 benchmarks that are essential to ensure quality in Internet-based distance education” (Forrester Research, 2000).

New e-learning evaluation guidelines were tested at 20 organizations by first determining an e-learning course’s relevance toward an organization’s needs, then analyzing content quality, usability, and instructional design methodology. These guidelines “… provide a robust and comprehensive set of quality criteria shaped by experts in the field” (ASTD, 2000) and have been adopted by the Canadian government.

Corporate Feedback on e-learning

Few people debate the overwhelming advantages of e-learning. Until a more solid research methodology is developed for e-learning results, however, we must rely on the feedback from corporations that have been using e-learning to deliver their training. Firms praise online training as a cost-effective and convenient way to deliver corporate education. Early studies seem to demonstrate that e-learning is a win-win proposition for all—the learner, the instructor, as well as the corporate world.

The Faculty Development Center as a Means of Cultivation of Needed Skills
in interface Design, Multimedia and Hypermedia

Andrei V. Strukov
The University of Maine
108 East Annex
Orono, ME 04469
Andrei@umit.maine.edu

Abstract: Information Technologies at the University of Maine established The Faculty Development Center as a direct response to the growing need to develop UM faculty skills in multimedia, hypermedia and interface design. The Faculty Development Center supercedes the simple act of making available electronic and multimedia resources by actively fostering, even encouraging among faculty members the necessary skill-sets in properly and effectively utilizing these resources. The following paper outlines how the Faculty Development Center achieves these goals through innovative and multi-level strategies.

Introduction

The Problem: Clearly the integration of new technology into the classroom, especially that of a higher education institution, is no longer just an academic advantage, but a necessary step to align education with the needs of a wired society. However, use of new technology in the University has been typically limited to trained students, and specialized staff and IT organizations on campus. The philosophy of "well do it for you" leads many unskilled faculty members to believe that adding online or multimedia content lies outside their own capabilities and time restraints. Despite the growing ease of use of relevant software and availability of hardware, the resulting atmosphere of "technological intimidation" has faculty still operating in what has been aptly called a "pre-Gutenberg" skill-set. Given the growing expectations of the academic community for multimedia and hypermedia course content and supplements, university faculty must be easily brought up to speed with the information age and its demands.

The Solution: In response to these demands, the Faculty Development Center was created at the University of Maine to specifically provide comprehensive technical education and support to faculty and staff. The key to performing these functions has been to replace intimidation with encouragement, and the notion of "we,II do it for you" with "let us show you how." Specifically, the Center has approached its mission with the following multilevel strategies: providing education and support in all areas of multimedia, hypermedia and interface design; acting as a working liaison between faculty and other technological administrative and support services; and providing Faculty Stipends for academic projects that utilize electronic media.

Education and Support

Providing education and support to faculty is, itself, a multilevel task. Any person who calls or enters the doors of the Faculty Development Center will have a differing level of familiarity with technology and specific needs than the next. Therefore, the staff at the Faculty Development Center must have a firm understanding of all levels of multimedia and hypermedia and current trends in design and function of those media forms. This is imperative. Through this expertise, the staff of the Faculty Development Center is capable of assisting faculty with needs ranging from preparing graphics for a PowerPoint presentation to digitizing and streaming audio and video from their course Web sites. While there are organizations on campus that can help with any one of these problems
specifically, the unique centralized nature of the Faculty Development Center ensures that faculty can access support on a horizontal level as well as vertical.

Education also exists on multiple levels. At the most basic level, the Center offers workshops covering everything from PowerPoint to web-editing skills using Dreamweaver, or online course builders like WebCT or BlackBoard (CourseInfo). On a functional level, these workshops provide an introduction both to the skills and program being used, and to the center itself. Alternative or more in-depth instruction is offered more or less on each faculty member’s own terms. Assistance may be arranged individually or by group covering any needs within electronic media.

As a Liaison

Despite the wide range of skills and services offered by the Faculty Development Center, there are certain functions that it cannot provide. Therefore the second variety of support offered comes in the form of providing liaisons between faculty members and appropriate campus technical or administrative organizations. This is key to eliminating the intimidation factor inherent in technology. Within the University there are various administrative levels having to do, for instance, with either creating appropriate access to resources (for instance, creating WebCT accounts) or having information stored on an appropriate server for online viewing. Having a knowledgeable go-between operating on behalf of the faculty member removes a great deal of confusion and misdirection, while initiating the faculty member in the processes necessary for enhancing their course content.

Stipend Awards

Finally, the Faculty Development Center is actively involved in offering Faculty Stipends sponsored by Information Technologies for work done on course-related projects presented in part or in full through electronic means. The award is offered essentially as a compensation for time and resources spent outside of regular duties on these projects. However, the projects produced are also made highly visible to the campus community and are ultimately presented to the University at large though a Faculty Technology Fair.

Last year’s Faculty Technology Fair, set for November 9th of 2000 has already received a great deal of response from the University community and is expected to be a great promotion of faculty involvement in multimedia and hypermedia course supplementation. Through this process the Faculty Development Center actively encourages use of technology through direct reward, while simultaneously creating a highly visible front to the University’s new technology projects.

Summary

It is the University of Maine’s belief that the university system, as a center for higher learning, should be a leader in using technological resources to foster the highest level of academic enhancement. From inception to present the Faculty Development Center has been a working experiment in not only supporting but also encouraging that same enhancement. Providing support and education, active liaisons between faculty and staff, and even monetary reward within a centralized location has been our means to the end. The end, simply put, is making high technology accessible and used effectively by our educators. The resources are there and the academic community certainly recognizes the need. The Faculty Development Center is best described ultimately as a catalyst in building enhanced course content, ensuring that available hypermedia, multimedia and corresponding interface design of such are effectively used to the benefit of the University and its students.
The Use of Hypermedia and Multimedia in course related projects at the University of Maine

Andrei V. Strukov

Hypermedia and multimedia course content serve so many purposes that indeed it is a necessary movement. Throughout their academic careers students are taught how to analytically judge traditional print resources and how to use those to back up their own critical thought. Simultaneously they are taught how to intelligently use those sources. In a world saturated with new media, the appropriate and responsible thing for higher education to do is to teach these students to judge and learn from these new media sources. As this proposal begins to outline, the use of hyper- and multimedia course content is fast becoming a necessary part in the students, learning process in becoming responsible and useful members of the wired world.
Abstract

This paper describes the early phases of an examination of the role played by Internet-based teacher professional development for K-12 teachers in the implementation of an innovation. The cases developed describe the effect of this professional development intervention on the teacher implementation of the knowledge construction tools in the *StageStruck* CD-ROM.

The current phase of the research has established the most appropriate web site design for on-line professional development to be the online community of practice. The hallmarks of an effective on-line community were determined from literature and available cases. These hallmarks have guided the web site network’s technical development and continue to inform the study as it seeks to gauge the critical factors in building and sustaining the social interaction for on-line community.

A web site portal or hub (http://www.stagestruck.uow.edu.au) has been designed specifically to build and support a community of practice. The web site development continues to be an iterative process informed by review of the literature, practice in the field and the contributions and ongoing evaluation of the community members.

Background To The Study

*StageStruck*, produced by Wollongong University and National Institute for Dramatic Art (NIDA), was one of ten CD-ROM titles produced in the *Australia on CD*, a Creative Nation* federal* funded Cultural program. Despite widespread distribution of *StageStruck*, across Australia (free to every school) and International acclaim for the teaching tool, preliminary discussions with educators indicated that most were unaware of *StageStruck*’s existence let alone its educational benefit. This suspicion was borne out when in a state-wide promotion many teachers replied to find out where to obtain copies of something already distributed to their school. It became evident that a mechanism was required to both promote the program and support performing arts K-12 teachers in their professional development. In broader educational contexts, reviews of traditional professional development (as part of widespread educational reform) have proffered Internet technologies as possible cost-effective and efficient training and development delivery mechanisms. This research sought to explore the issues lessons to be learnt in such Internet-based solutions.

*Creative Nation Australia’s Cultural Network http://www.acn.net.au/articles/1998/05/ozcd.htm*
Questions Addressed In This First Phase Of Research

1. Which professional development experiences/resources will assist teachers in their implementation of technological innovation (StageStruck)?

2. What Internet technologies and architectures best support those teacher needs?

3. What are the hallmarks of an effective on-line community?

4. How can Internet activities/resources be designed and developed to attract and sustain a community of users? What cases exist to guide this development?

The Related Bodies Of Theory And Literature

This research draws from three critical areas of literature; innovation and change, professional development and on-line communities. There is a thread emerging from between these seemingly disparate bodies of research. For innovation it is critical that change begins with teachers and their professional development. In professional development there are well researched hallmarks of best practice which describe opportunities for teachers teaching teachers. And in on-line learning heterogeneous communities have been shown through participant activity and leadership to support teacher directed just-in-time learning. The connecting thread is the teacher centred community of practice as the hub of the professional development experience.

A central tenet of professional development and school reform is the creation of an enabling participant-driven environment for students and teachers alike. Web technology shares and promotes this same imperative. The key dynamics of the World Wide Web and school reform are exactly the same. (Tenenbaum 1997 p485)

Traditional professional development has been criticised as being fragmented, unrelated to classroom practice and lacking in the focus and the follow-up that teachers require. The 1996 National Commission on Teaching and America's Future report What Matters: Teaching for America's Future (NCTAF, 1996) raised as one of it's five major recommendations to “Reinvent teacher preparation and professional development” to ensure “continuous high quality learning opportunities” for all teachers. This reinvention and continuation is supported in the locally produced Ramsey Report (NSW DET 2000) into revitalising teaching in critical times and choices. There is clearly an imperative for new professional development strategies and for teachers themselves to take more control of their personal professional development.

Principles of effective professional development (Bull et al 1994, ACOT 1995, US Dept Education 1996, Grant 1996, Loucks-Horsley & Hewson 1998, Stager 1998) define ongoing activity that builds on current practices, in a climate where teachers can take risks as part of a learning community. This “learning community” is a place or space where teachers support and learn from each other and take the time to reflect on the effectiveness of change. Joyce, Weil & Showers (Joyce et. al., 1992) reported that the most effective teacher professional development activities are those that combine theory, modelling, practice, feedback and coaching for application, particularly peer coaching. Novices in a community may collaborate with peers, work alongside experts, share, explore and learn as part of a network. Learners can be given opportunities through the community for ‘reciprocal teaching’ (Vygotsky, 1978). Teachers teaching teachers and teachers as learners are both concepts integral to this idea of reciprocal teaching and reform in professional development. For the contemporary social constructivist the “zone of proximal development” (ZPD) may be established through the community of novices and expert practitioners enabled in their social interactions by appropriate Internet-based activities, resources, opportunities and practices, beyond the physicality of being together in the same place at the same time. There is a body of practical work to indicate that the Internet does have more than just the potential to effectively facilitate teacher professional development. One example is an international on-line project EdNet@UMass (Reilly, 1999) that has shown evidence of the value of educational Internet communities. EdNet@UMass involves educators from the USA and 29 other countries in what is described as a forum for “promising practices” and exploring possibilities. The value lies in the networks both technological and social.

Educators are “islands of excellence” with no ferry service to connect them to each other or to groups of their peers. (Reilly, 1999, p60)
Defining this on-line community

Community is a much-argued concept. Long before the "community" went on-line social scientists had disagreed about what a community was. Thousands of print and web pages are now devoted to trying to adequately define, refine and finesse what an on-line community is.

These definitions vary from:

- In 1992 Howard Reingold (p1) said ...virtual communities are cultural aggregations that emerge when enough people bump into each other often enough in cyberspace.
- Palloff and Pratt (1999 p21) describe People seeking commonality and shared interests formed groups and communities in order to pursue the interests that distinguished them from other groups.
- Amy Jo Kim (2000 p28) suggests that A community is a group of people with shared interest, purpose, or goal, who get to know each other better over time.
- Wellman and Giulia (1997) define two types of community, personal and group. The group community most relevant to this research. A group community is a social network of people who interact with each other regularly to provide sociability and support.

In order to design and build an on-line community, we may be better served by identifying the essentials for on-line community rather than bogging down in the semantics. As quoted by Nancy White (1999) a federal judge said Community is like pornography, I don't know how to define it, but I sure know it when I see it.

It is evident from the literature that when the community as a concept is no longer confined to place and space, discussion has been sidetracked by arguing whether a listserv, a discussion space or a chat is a learning community. We would not argue whether the meeting hall or a telephone were a community. They are enablers to the activity of the community. In support Joseph Cothrel (1999 p52) writes ... "community" is about something more fundamental than location or mode of interaction, though we may not all agree what that 'something more is'. It is therefore meaningful to aggregate the attributes or hallmarks of communities, as suggested by the theorists and practitioners across education, edutainment and enterprise and distil from those attributes some essential qualities for, or hallmarks of on-line community.

What follows is table of attributes proposed by a sample of theorists and researchers (Table 1) and the subsequent distillation of these attributes for the on-line community for StageStruck.

                              • Integration of content and communications  
                              • Openness to competitive information/access  
                              • Commercial orientation  
                              • Valuing of member generated content |
| Reece (2000)     | • Clear purpose for the community  
                   • Help to create social policies that guide not stifle  
                   • Support social interaction  
                   • Sociability built through trust, collaboration and appropriate styles of communication |
| Galston (1999)   | • Limited membership  
                   • Shared norms  
                   • Affective ties  
                   • Sense of mutual obligation |

The attributes of community across all the appropriate sectors (school, tertiary and corporate) were examined and commonality began to emerge that could be synthesised into a few succinct hallmarks for community. These hallmarks are:

• Clear focus driven by the members (ownership)
• Employ appropriate technologies and styles of communication
• Members feel part of a social network where their expertise, leadership, content and contributions are valued
• Provides ongoing discussion, sharing of, and collaboration on, commonly valued things.

Designing for online community

So it was that this research embarked on the design of this online community to support the use of StageStruck. However it very quickly became evident that there were four distinct stages in working toward this true online community. Community might be the end product of this four step process, it was not the result of any one. Each of these stages is vital and does in turn inform the development and understanding of the next stage toward development of an online or web-based community for professional development:

1. Decide on the goals of the professional development and the needs of the teachers.
2. Design and build a web site architecture to support the goals and needs.
3. Establish a network of people as members in the interest group.
4. Build up the trust and ownership of the members as a community.

The StageStruck On-line Community Web Site [http://www.stagestruck.uow.edu.au](http://www.stagestruck.uow.edu.au) was developed after a year of research into teacher needs and on-line community-based web sites. The site was launch at the end of 2000 and the first participants joined the net work in February of 2001. The site is now between the third and fourth stages of the development process towards community. Members have registered and begun to contribute and share resources.
Diagram 1 The Initial StageStruck On-line Community Web Site Design

The StageStruck On-line Community will over the next two years test Tenenbaum’s tenet. The data will be collected from the network or community (depending whether community is achieved) and its members in various ways. The Concerns Based Adoption Model, CBAM (Hall et al 1973) instruments will be used to gauge levels of implementation of StageStruck from chosen community members. As a key instrument the CBAM Innovation Configuration Map will be developed over 2001 in consultation with teachers in the community to describe practices that are the variations of implementation into the curriculum. This map will be used to define teacher
implementation and to feed back into the professional development process as a self-assessment and planning tool for teachers. Quantitative measures will be used to review the website activity in terms of access, paths taken, time spent, numbers of contributions and statistical data from system logs. This data will track member activity as well as activity in specific areas and for all the Internet technologies employed by the community. Data collection for these cases will involve qualitative practices such as observation of teaching, interviews and focus groups, work samples, text analysis of web site contributions and documentation for units of work. The research program will run into 2002 with final data presentation to be as a series of cases of adoption of Stagstruck and data (qualitative and quantitative) will be analysed for trends in general levels of activity and individual involvement in the community over the two years.

Abstract: This paper examines chat room interactions in an on-line course given at Teachers College, Columbia University for their power to construct the traditional class frame in the on-line environment. Utilizing the framework of conversational analysis, I explore the effect of the affordances and constraints of synchronous communications devices on interactional sequences. The paper culminates in suggestions for practice in expanding the on-line course experience beyond traditional modes of text-based classroom discourse.

Introduction

In this paper I will focus on the ways in which my students and I attempted to construct the on-line classroom through interactional sequences in the synchronous chat room. I will investigate the ways in which the synchronous chat is akin to a face-to-face conversation, and how the constraints and affordances of this communications technology influenced the nature of the interactional sequences.

Description of the Class

The class that I taught was Instructional Design of Educational Technology offered through the Distance Learning Project at Teachers College, Columbia University in the spring 2000 semester. The class had 28 students and was conducted completely on-line, except for an optional last class meeting. The students had the choice of joining either the synchronous chat sessions or the asynchronous discussion boards. There were a total of 14 synchronous chats held during the semester. The chats were held on Saturday afternoons at 4pm and Monday evenings at 5pm. An average of six students attended each chat. All of the 28 students attended at least one chat, though many attended only one chat, several attended the majority of the chats. The students showed a clear preference for either synchronous or asynchronous communication.

In the transcript I will use for analysis purposes, an alphanumeric code is substituted for the participant's name and a symbol is used to delineate between a participant logging on and making a comment. The transcript shows the exact time (hour/minute/second) of any activity by an individual occurring in the chat room.

Establishing the Frame

On-line synchronous communication comes closest to establishing the traditional classroom frame in distance education. Synchronous communication allows the participants to jointly occupy temporal space and to create the illusion of physical proximity through spontaneous conversation and the sharing and contributing to the contents of one screen of information. The fact that each participant is using the same software and is therefore seeing the same thing visually adds to this illusion of a shared physical space. Varenne and McDermott (1998) describe the “well-specified interactional sequences” which signal the beginning of a class: “...a class cannot start in the absence of specific acts (reorganization of focus, synchronization, greetings, etc.).” (p.184). A transcript of a chat conducted in my class shows the above patterning of interaction in establishing the class frame:

04:01:41 PM: as130 > Hello...
04:02:31 PM: lb818 > Hi, Adrienne. I thought maybe I had the wrong day....
04:03:03 PM: as130 > I was thinking the same exact thing...
04:03:25 PM: as130 > How is your group project going?
04:03:53 PM: lb818 > We're done. But there were only two of us in my group. Groups with more members will obviously take longer. How's yours?
04:04:19 PM: as130 > We're a little delinquent in getting our initial paragraph handed in.
04:04:36 PM: lb818 > Is it due this Wednesday or last?
04:04:55 PM: mf914 logged in
04:05:00 PM: as130 > This past Wednesday - Florence sent me a note saying it was supposed to be handed in already.
04:05:08 PM: as130 > Hi Michelle.
04:05:17 PM: mf914 > Hi everyone :)
04:05:19 PM: as130 > Adult Learning
04:05:29 PM: lb818 > Good topic. Lots of stuff involved.
04:06:29 PM: as130 > We're going to do a site on the benefits of using bulletin board systems for adult learning. We can definitely hand in a paragraph, but I don't want to do it without consulting with the other 3 group members
04:06:43 PM: as130 > What are the two of you doing?
04:07:03 PM: mf914 > I thought the assignment due wed was the proposal for the final individual project..
04:07:22 PM: fs184 logged in
04:07:36 PM: lb818 > I didn't think we were allowed to do a whole site. You may want to check on that. I thought it had to be one page.
04:07:37 PM: mf914 > Hi Florence
04:07:42 PM: lb818 > Hi, Florence
04:08:01 PM: as130 > Hi Florence

In this chat, three students arrived before I did and began having a discussion about the assignments. When I arrived the students stopped interacting with each other and began interacting with me. This pattern can be seen as the re-organization of focus away from each other and to the teacher. This re-organization also occurs in the traditional classroom when the teacher enters the room, or when the teacher begins to verbally address the class. The cultural patterning of deferring to the teacher so that the 'beginning of class' interactional sequence can occur is played out in the chat environment.

The Phatic Function

Establishing verbal communication between teacher and students is a key component to the beginning of class interactional sequence. This establishment of verbal communication is termed the 'phatic function' by linguists. The phatic function in face-to-face conversations may be checked through visual cues. If the teacher is establishing verbal communication with the students, he is able to verify this by making eye contact with selected students. The phatic function plays a key role in the execution of interactional sequences and in the construction of a traditional class. The phatic function in the on-line chat room is equally important to the construction of the class. As aforementioned, the chat software used in the course allowed chat participants to hyper-link to a list of people in the chat room. However, many students either did not know about this function, or did not trust it to be accurate.

04:01:37 PM: rw684 logged in
04:03:30 PM: mf914 logged in
04:04:02 PM: rw684 > Hi Michelle
04:04:05 PM: mf914 > hello?
04:04:17 PM: mf914 > Hi Rob, I thought I was all alone :-)

1888
In this exchange, Rob logged in approximately two minutes before Michelle did. When Michelle arrived, she did not realize that Rob was there. After about 1/2 minute Rob says hello to Michelle, who is somewhat surprised by his presence. The only visual cue available to Michelle in the chat room is the hyper-linked list, which she apparently was not aware of.

Since eye contact cannot be made in a chat room, directing a comment to an individual could only occur through the use of the individual's first name. In a discussion of emerging conventions in Internet Relay Chat (IRC) environments, Werry (1996) states "...it has become entirely conventional for speakers to indicate the intended addressee by putting the person's name at the start of an utterance...Such a high degree of addressivity is imperative on IRC, since the addressee's attention must be recaptured anew with each utterance." (p.52). The use of the first name in the chat room was not only important for executing the phatic function, but also for delineating conversational threads, which I will soon discuss. In the first half of the semester we used the convention of typing the entire first name of the individual being addressed.

04:24:53 PM: fs184 > Adrienne, I lost the thread, what would be very complicated to create?
04:25:02 PM: mf914 > Florence, what do you think of logo/microworlds?
04:25:08 PM: nk762 > Robert, I agree. Adapting instructional design to individual learners means realizing that students need different degrees of structure.

By the second half of the semester we had switched to just using the first initial of the individual being addressed followed by a slash:

04:31:17 PM: fs184 > R/ perhaps the objectivists are right regarding natural laws and the constructivist are right about the best way to learn a natural law?
04:32:08 PM: rw684 > A/ I think the shared understandings are more in question for novice learners then experts.

While the phatic function was still being executed through using a participant's name, the convention evolved from the full name to the first initial over the semester. There are two reasons why this convention evolved. First, only typing the first initial saved space on the text line, allowing the participants to see more of the substance of his/her own comments before submitting it. Second, it allowed for a more rapid response time permitting the chat to flow at a rate closer to face-to-face interaction. According to Werry (1996), “On IRC, a combination of spatial, temporal and social constraints act as important limiting conditions that influence the size and shape of communication in roughly analogous ways...In order to keep up with the flow of conversation it is often necessary to respond quickly and this means that unless one can type very rapidly, messages must be kept short.” (p. 53).

What is perhaps most interesting about executing the phatic function on-line is the ease with which one can be ignored. As there is no physical means of insuring that one has established communication, there is also no means of insuring a response to a direct query. Twice during the semester I directly posed a question to a student in the chat room, which the student chose to ignore. The student did this by simply not responding at all. While I could have continued to query the student, doing so would have negatively disrupted the flow of the chat. Also, when I directly query a student, others may feel they cannot respond and this slows the overall flow of the chat. I did continue to directly query students when I thought a further explication of a previous comment would benefit the conversation as a whole, but I was also conscious of the other students and I would sometimes generalize the query to all of the students.

Finally, a note on a technological constraint in regards to the phatic function. Occasionally, a participant will be involuntarily logged off the chat room. This is a technical malfunction beyond the control of the participant. The biggest problem with this particular malfunction is that the only way to know that the malfunction has occurred is through the lapse in the conversational flow appearing on the screen. However, it is not uncommon for a lapse in the conversation to occur in the on-line environment. I was involuntarily logged out of the chat room only once during the semester, but it took me quite awhile to realize that his was the case. At first I thought that a conversational lapse was occurring, so I made several content related queries in an attempt to rouse the student's interests; when no one answered, I asked people to confirm that they could read my comments. There was no response. At this point I realized I had been logged out of the chat room, so I initiated the log in sequence, which takes approximately three minutes to accomplish. By the time I arrived back at the chat, the students had ended it and left.
04:47:20 PM: fs184 logged out  (Involuntarily)
04:56:02 PM: mf914 > great! it seemed to go so fast! do you think Florence is coming back?
04:56:24 PM: as130 > I think the chat went pretty smoothly other than some technological problems.
However, I just realized that Florence isn't in the chat.
04:56:35 PM: lb818 > I'm not sure. She's been gone a while. It did go fast, though.

I was involuntarily logged off at 04:47:20 PM. It is interesting that the students carried on the conversation for several minutes before realizing that I was no longer in the chat. The first mention in the chat of my absence occurs at 4:56:02 PM. The chat then ends at 04:58:58 PM. The role of the teacher in the chat room is clearly decentralized in this example. My presence was not necessary for the class to continue. It is highly unlikely that in a traditional classroom a teacher could, without comment, leave the room and have the class continue without interruption.

**Turn-Taking and Participant Roles**

This decentralization of the role of the teacher is an affordance of the technology. In traditional classrooms, the classroom discourse typically centers on the teacher’s contribution, either through lecture or what researchers have termed the IRF (Initiation, Response, Follow-up) communication pattern. According to Warschauer (1999) “Numerous studies have shown that this pattern [IRF] is the dominant structure of classroom discourse in the United States and other countries (Cazden, 1988; Lemke, 1990; Mehan, 1985; Poole, 1990).” (p.64).

My experience with the chat is that everyone who came to the chat also contributed to the conversation. However, participation was not equal, and students who speak English as their second language tended to contribute less to the dialog and tended to attend the chats infrequently. Since there was the discussion board option, the ESL students could contribute in that forum and most seemed to prefer it.

Sacks, Schegloff and Jefferson (1974) enumerate two methods of turn taking in face-to-face conversations: current speaker selects next and self-selection. (p. 705). Both methods occurred in the chat room discussions. In general, I would begin the chat discussion by posing a question to the students. Usually, some combination of students would self select and respond to the first query. I found that in the beginning of the chat I would need to employ the current speaker selects next method in order to propel the conversation. So, I would follow-up with a prompting question to a given student; sometimes I would contribute several prompting questions to several students. Soon, however, the students would be responding directly to each other’s comments and self-selection would become the more dominant mode of turn taking in the chat room.

Sacks, Schegloff and Jefferson (1974) also discuss turn size in face-to-face conversations: “Turn size is not fixed, but varies.” (p. 708). However as Werry (1996) pointed out, the technological constraints of the chat room system cause the turn size to be relatively brief. The shortness of the text line and the relatively rapid flow of the conversation combine to contribute to brevity in comments. One of my students found a way around this particular limitation by rapidly entering and sending a few words of her comment, followed quickly by the next few words, effectively controlling the chat room.
This individual through her method of rapidly sending a series of five to six word phrases to the chat room was essentially able to hold the floor for three minutes while she made her point. As one can easily see from reading the other transcripts in this paper, this student’s method was highly unconventional.

Schism

Sacks, Schegloff and Jefferson (1974) note that when more than four parties are involved in a conversation there is a possibility that a second conversation will begin within the group. They term this phenomenon “schism.”

Schism occurred regularly within my classroom chats. Related but distinct strands of the initial conversation were routine features of the twice-weekly chats. When one is reading the comments posted by others, it is an after-the-fact action. One does not see the comment as it is being typed, but rather one sees the comment in its entirety once it has been posted. This technological feature allows many people to post comments at once, something that is not possible in a face-to-face conversation. I encouraged the practice of schism through my prompts and queries to students as a method of furthering the conversation:

04:12:06 PM: fs184 > Is every content area ripe for the discovery learning method?
04:12:11 PM: mf914 > giving up control of a learning situation is, I think, difficult for many teachers
04:12:19 PM: rw684 > I know I thrive in this environment, but I wonder if all students comfortable with discovery learning.
04:12:22 PM: as130 > Florence, guiding a discovery isn't really the discovery method, but I think that it would be more beneficial and more acceptable to many people than a true discovery method.
04:12:46 PM: fs184 > Adrienne, why would it be more beneficial?
04:13:10 PM: sg439 > I think that it can work in all areas, but often some elementary knowledge is needed
04:13:18 PM: fs184 > Michelle, is one really ever in control of a learning situation?
04:13:34 PM: mf914 > we had a discussion about this in computer mediated communication...I think many adult learners are uncomfortable with this area because most of us were taught in a very traditional way
04:13:42 PM: mf914 > no, I don't think so
04:14:03 PM: mf914 > I think you can have a plan, and hope that things will go in the directions you hope
04:14:06 PM: as130 > Florence, I was thinking it would be more beneficial than the traditional method of instruction where everything is focused and directed and tuned towards standards.
04:14:11 PM: fs184 > It's hard to break free of the ways we all were taught.
04:14:18 PM: rh810 > Very hard....
04:14:25 PM: mf914 > but, as teachers I think we are often required to "tap dance" or go with the flow
04:14:46 PM: rh810 > and time is a major force in choosing what process we use.....
04:14:47 PM: mf914 > (I tap dance often, because our hardware is old
04:14:52 PM: fs184 > Michelle, is this due to school or community politics?
04:14:52 PM: sg439 > Good point ,Michelle, I taught some adult classes and many people were upset when I wouldn't give THE right answer
04:15:29 PM: as130 > But don't we start off as discovery learners as children? It seems like when we enter school that we learn the "traditional" method of learning, which is more artificial.
04:15:40 PM: mf914 > school departmental politics
04:16:14 PM: mf914 > need to beg for every dollar
04:16:18 PM: rh810 > I would tend to think it's community based.....our schools reflect the society and communities around us.....
04:16:18 PM: fs184 > Adrienne, excellent point! I agree this is exactly how we learn as children, it seems much more natural.
04:16:44 PM: mf914 > ADrienne, I agree
04:17:23 PM: mf914 > although, with children going to school at such young ages, that may change
04:17:36 PM: fs184 > Can designers be effective in creating electronic discovery learning environments?
04:17:56 PM: rw684 > Adrienne: But the things we learn as young children tend to be more open ended then those we learn as older students.
The above sequence is a good example of two strands of a conversation about discovery learning taking place at the same time. The first strand revolves around teacher control of the learning experience vs. student control. The second strand revolves around the benefits of guided discovery learning. Both strands are occurring at the same time. The teacher vs. student control discussion is the primary focus of mf914, rh810 and sg439, all of whom contribute to the discussion. The second strand is primarily pursued by as130 and fs184, but eventually they are joined by rw684, andjw914. This interactional sequence is lifted from an ongoing conversation. There are several examples in this exchange where I used a query to act as a prompt to a particular student or to the group as a whole (04:12:06 PM, 04:12:46 PM, 04:13:18 PM, 04:14:52 PM, 04:17:36 PM). Since the students are responding to my queries at the same time without virtue of knowing what each other is saying, the opportunity for schism increases. Utilizing the IRF technique, I followed up two of the student responses with more questions, thereby reinforcing the multi-threaded nature of the conversation.

Conclusion

Does the chat room constitute a class experience? Did my students and I construct a classroom through our interactional sequences? The chat room session is certainly an event that is constructed by a number of people, and, in the context of discussing texts and ideas, it is educational. The interaction and temporal sections of the class frame are present, and the virtual space shared could be considered a stand-in for the physical school building. The student participants and I both brought our previous cultural experiences of ‘class’ with us to the chat room, and we interacted in ways that are typical teacher-student interactions. As a group we followed some of the well-specified interactional sequences discussed by Varenne and McDermott. For the most part, I began and concluded each chat session. Students waited for me to open the discussion with a prompting question and they waited for me to signal the end of the chat before exiting the chat room.

Yet, the very nature of the technology itself allowed for something other than the traditional class experience to occur. As Warschauer indicates: “Student-centered discussion tends to be the norm in synchronous computer-assisted classroom discussion.” (p. 65). I have never witnessed a traditional face-to-face class that afforded equal time and space for all class participants to ask questions and make comments. The chat format allows for and requires the student’s participation. It encourages and allows the students to converse directly with one another and, as Warschauer (1999) has termed it, socially construct knowledge. The interactional sequences that took place in the chats for my class always included insightful comments from students and a great amount of give and take among the students themselves and with me. The technology itself affords a qualitatively different class experience. It seems to me that a class can be constructed on-line, but the question is, do we want to try to re-create the traditional class frame? Or do we wish to dream of new ways to learn, interact and educate in the technological environment?

Abstract: Recent developments in Internet technologies have enabled new, more flexible forms of telematic simulation and have raised issues that were not considered in the early days of networked learning. Ultimately, these questions revolve around (1) the learning cost-effectiveness of telematic simulation (quality and quantity of learning as opposed to development, technology and specialised training costs), (2) the necessary rethinking of learner and teacher roles, on the one hand, and institutional commitment to change, on the other, and (3) a variety of issues related to access. The panel members discuss Project IDEELS telematic simulations in terms of enabling interdisciplinary learning, matching learner needs with technologies, supporting learner independence and responsibility, evolving teacher/facilitator roles, and balancing research, evaluation and validation needs without compromising the quality of the simulation experience.

Introduction

Project IDEELS is a Socrates/ERASMUS-funded curriculum development project (CDI) that brings together a diverse group of educators and researchers from five tertiary institutions in four European countries who share a common interest in using simulations and games in educational settings. The Project team develops, tests, implements and evaluates simulation scenarios and provides a range of accompanying materials (language practice,
team-building, cross-cultural awareness-building, cognitive and thematic activities as well as glossaries and other information resources) to meet the increasingly diverse needs of an expanding user base.

IDEELS owes much to its direct predecessor and inspirational role model, Project IDEALS, a US-based, FIPSE and NSF-funded telematic simulation project directed in the early 1990s by David Crookall at the University of Alabama, and to ICONS, an outstanding telematic simulation program with an International Relations focus directed by Jonathan Wilkenfeld at the University of Maryland. We have learned a great deal from both programs, but rather than trying to repeat a successful project like IDEALS or compete with an established, ongoing program like ICONS, IDEELS looks for ways to learn from their experience and build on their successes.

The diversity of the current project group has allowed us to benefit from the insights of an unusually rich mix of disciplinary perspectives in all phases of our work. Over the first 3½years of the project, members have developed and implemented a series of simulation packages with a distinctively European flavour. The thematic focus of the scenarios varies: education (November 1998 & November 1999), immigration (November 2000 & March 2001), the impact of technology (September 2001), water (November 2001). Participants so far have been students at tertiary institutions in five European countries; at least ten different academic fields and as many different nationalities have been represented. Throughout the project, recursive evaluation of all aspects of the project has played an important role; two

**Supporting Interdisciplinary, International, Collaborative Learning**

**Learning Objectives**

A combination of broadly defined shared and class- or discipline-specific and individual learning objectives allows participants to focus on their own learning needs while maintaining some common ground. The shared learning objectives fall into three main areas: co-operation/collaboration, socio-affective, and interdisciplinary/cross-cultural.

![Figure 1: Learning Objectives](image)

Each group is expected to incorporate the shared learning objectives into its preparatory and debriefing activities; in addition, teacher-facilitators develop learning objectives consistent with their class' content and objectives, and students, in turn, are encouraged to set personal learning goals for themselves. The only constraint on the latter two sets of learning objectives is that they must not conflict with the shared learning objectives. This multi-tiered approach ensures a necessary degree of continuity while providing a highly adaptable learning opportunity for students from a wide range of disciplines. It also formalizes a commitment to learning in several areas not taught in most traditional educational settings: working in a team, taking responsibility for one's own learning and for one's part in the group's success, and becoming more aware of interdisciplinary and cross-cultural factors affecting successful communication.
Meeting Learners’ Needs with Appropriate Learning Technologies and Situations

Possible Role of Personality Factors in the Use of Educational Technology

Since the early 1990’s computer systems have supported computer mediated communication in ways which permit relatively naturalistic communication styles (e.g., e-mail, IRC, e-discussion lists), although this did not include video or audio conferencing except in rare research settings.

There appears to be little doubt among researchers that personality factors are of great importance in determining the successful use of information technology in educational settings (Clements, 1995; Hartley, 1998; Calvert, 1999; Harris, 1999 and Shavinia, 1999). Anecdotal evidence from composition and ESL/EFL teachers (including IDEELS project members) suggests that some students who rarely contribute to class discussions become quite outgoing when communicating via e-mail or in chat rooms. On the other hand, participants in IDEELS simulations rarely choose to communicate with other members of their own team via the software provided, preferring face to face communication, telephoning (or “SMS-ing”), chatting and e-mail using their regular accounts. Clearly, this is an area of human-computer interaction in the IDEELS context that deserves further investigation.

Appropriate Use of Technology

Computer conferencing systems are usually designed to support asynchronous transfer of text, pictures, and sometimes sound and, less frequently, live video signals. These facilities have led some to propose that the medium of computer conferencing might have potential as an environment for the teaching of language (Warschauer, 1997), since the supported features match those thought to be vital in language acquisition.

The OPUSi conferencing platform used in IDEELS simulations supports both intra- and inter-team asynchronous conferencing, synchronous teleconferencing, and — to a limited extent — collaborative writing. So-called “awareness tools” are almost entirely lacking, but there is a facility that allows for the creation of a “virtual library” of links to external web-based resources, including the IDEELS web site.

As about half the IDEELS project members are language teachers, language- and communication-related factors have played a role in several of the decisions taken regarding further development of OPUSi. A conscious decision was made, for example, not to incorporate video conferencing capabilities; it was felt that by using text-based conferencing, participants would respond to others’ use of language rather than to other factors revealed in video conferencing (e.g. age, gender, physical appearance). This has interesting implications for language learning, as the likelihood of mis-communication — both of misunderstanding and of being misunderstood — increases when the usually available visual or auditory clues are missing; often a kind of information gap results that 1) spurs learners on to further attempts at communicating, 2) that can encourage analysis of the unsuccessful communication, and 3) that can encourage learners to consider how they might prevent a recurrence — all of which are useful activities that support language acquisition.

It is equally important to recognise and respect that many students and educators will not wish to experience electronic conferencing systems — at least not initially — regardless of any bells, whistles, or ergonomic qualities they may offer. Moreover, some recent research has indicated that relying exclusively on cyber interactions may be psychologically harmful for some users (Brenner, 1997; Kraut, et al, 1998; Sleek, 1998). An important issue we have tried to address is the challenge of providing adequate opportunities for such learners in the context of telematic simulation. One possible solution involves encouraging students in a group to organize themselves to allow each individual to “play to his or her strengths” — at least at the outset.

Personality Factors in Collaborative Work

Students’ communication when working in groups is strongly predicted by those students’ Myers-Briggs personality Type Inventory (MBTI) scores (Kagan et al., 1987). Modern computer-based teaching systems place an emphasis on collaboration, and the overall activity and types of interactions undertaken by a group are known to be also under the
influence of MBTI types such that the overall combined MBTI types of the individuals in a group accurately describe and predict that group's behaviour (Stever, 1995). This means that it is possible for an educator to accurately gauge the overall MBTI types of a particular cohort of students before formal educational practices begin. The potential for allowing modification of teaching style or learning environment to match individual MBTI types or even group MBTI types is enormous. For example, it has been found that most professors at universities teach in an MBTI type I (introverted) manner while students generally prefer an MBTI type S manner of teaching (Cooper & Miller, 1991), yet when professors deliberately teach in the manner matching their students’ MBTI scores, student satisfaction ratings and overall grade performance are significantly enhanced (Provost, 1987; Cooper & Miller, 1991; McCutcheon et al., 1991; Fisher et al., 1998).

Currently, participants in IDEELS simulations are encouraged to complete an online MBTI questionnaire to become more aware of their own learning styles and needs. With our work investigating the links between personality types and student performance and attitudes in the IDEELS project we hope to be able to provide future educators using computer-supported learning environments with concrete data on the preferences they are likely to find amongst students with particular MBTI types.

Not Teaching, but Facilitating Learning

One of most important factors in making technology-enhanced learning environments successful is the presence of an adequately trained and resourced human facilitator. In other words, the most successful application of computer- and Internet-supported learning is as a complement to face-to-face classroom learning, not as a less expensive substitute. Project IDEELS resources for new group facilitators include manuals on facilitating and debriefing, facilitator training workshops, a facilitators’ community in OPUSi, teaching suggestions and answer keys for many of the preparatory activities, one-on-one mentoring by experienced facilitators in the area, and a facilitator-training CD.

Issues for Distance Education

A short-term study of the use of DLE for the teaching of negotiation theory (McKersie & Fonstad, 1997) reported that there were major differences between the pedagogical methods that are suitable for normal teaching and those suitable for computer-based distance education. The major advantage noted for DLE was that it gives students access to educational resources that they might otherwise be unable to use because of time limitations or geographical location. This potential for greater access to higher and more specialized learning is of great interest to a wide group of potential students, including those whose physical or mental disabilities might have otherwise prevented them from such educational opportunities (Gay, 1996).

However these same factors also place a great responsibility on the designers and facilitators of DLE systems. The systems of strict deadlines for assignments or exercises becomes very problematic for students who may be pursuing distance education because they have insufficient time to devote themselves to traditional full-time education or because of some other factor in their lives. Another issue that is closely linked to this deadline problem is that of providing support in the course for students who fall behind in the course progression because of some legitimate reason. Many distance based instruction systems simply rely on the student working through the course modules more quickly on their own. When many students fall behind it is because other external factors have introduced considerable additional stresses into their schedules. It may be inappropriate to expect these students to adapt by increasing their academic work load, instead a more student centered approach may be to provide alternative credit accumulation schedules, with delayed examinations and class graduations away from a fixed academic calendar.

Meeting research, evaluation and validation needs without compromising the quality of the simulation experience

In Project Ideels we have implemented what we feel constitute unobtrusive measures of the participants’ backgrounds and attitudes and of the effects of the simulation, in part through an on-line survey administered before
and after the simulation period. The on-line survey consists of web-based questionnaires (HTML documents) that the participants can respond to at their convenience, either at the university / college or at home.

The pre- and post-simulation questionnaires measure the following (Fig. 2):

<table>
<thead>
<tr>
<th>Pre-simulation questionnaire</th>
<th>Post-simulation questionnaire</th>

<tr>
<td></td>
<td>User Interface Satisfaction: evaluation of OPUSi software for teleconference within Project IDEELS</td>
</tr>
</tbody>
</table>

Figure 2: Comparison of Pre- and Post-Simulation Surveys

Since 1998 Project IDEELS have utilized this design of a pre- and post-simulation on-line survey of participants in four different simulations where the focus has been:

1998: Designing the Eutropolis Education System
1999: Tertiary Education and Training in Eutropolis and Eutropia
2000: Human Rights in Eutropia
2001: Immigration Policy in the Eutropian Federation

The questionnaires used across these four points in time have a common core of questions (both pre- and post-simulation questions), which allows for an analysis of effects across different scenarios.

Results from the Project IDEELS pre- and post-simulation surveys may be found at:

http://www.hint.no/~kne/ideels/results/

KnixSOM Method for Information Resource Management

Tomi Suuronen, Espoo-Vantaa Institute of Technology, Finland; Harri Airaksinen, Espoo-Vantaa Institute of Technology, Finland; Matti Hämäläinen, Espoo-Vantaa Institute of Technology, Finland;

KnixSOM is an alternative method for information resource management. KnixSOM is a method for organizing metadata based documents into a meaningful maps for exploration and search. KnixSOM is based on the SOM (Self-Organizing Map) algorithm that is used to automatically organize the documents onto a plane so that contently related documents appear close to each other.

Document maps are constructed by using SOM_PAK, a non-commercial software package developed at Helsinki University of Technology in Laboratory of Computer and Information Science. An interface written in JAVA2 applets is used to control the programs in the SOM_PAK. Document map is automatically created and converted into generic XML format and into SVG for visual presentation.

KnixSOM is connected to a Knixmas database (part of Knixmas project, EU-Inco N 977113), which is a relational model database implemented in Oracle SQL server. The database contains metadata instances about research documents, so that each document is processed as an independent entity that has no relation to other document metadata instances. The document metadata is organized into groups and elements according to the Dublin Core document metadata specification.
Development and Evaluation of Introductory IT Self-training System for Life-long Learners

Katsuaki SUZUKI, Iwate Prefectual Univ., Japan; Masahumi DEGUCHI, Iwate Prefectual Univ., Japan; Hiroshi TAKAHASHI, Iwate Prefectual Univ., Japan; Tetsuo KATO, Sendai-Miyagi NPO Support Center, Japan; Ryo OIKAWA, Iwate NPO-NET Support, Japan

As a contract research trusted by Digital Communities Promotion Office (DCs), a set of self-instructional materials for beginning users of computers and network has been designed, developed, and pilot-tested. The materials cover such basics as Introduction to PC, the Internet (Web browsing), E-mail, Word, Excel, and Power Point, all of which are introduced using clear and useful examples from everyday life. Clear checkpoints are given so that the beginners can proceed their training by themselves at their speed. A three-day training program was designed and carried out with those interested in involving in local community activities to be a licensed IT teacher. Characteristics of both instructional materials and training program will be summarized as to how this new set of life-long educational opportunity is different from traditional learning materials which can be seen in Japan. The process of material development and the results from field studies will also be reported.
A Navigation Path Planning Assistant for Web-based Learning

Abstract: The main topic addressed in this paper is how to help learners navigate in existing web-based learning resources. In order to resolve this issue, we propose a learner-centered navigation path planning. The key idea is to provide learners with a path planning space, in which they can see through hyperspace to plan a navigation path. This paper describes an assistant system called Planning Assistant (PA for short), which is composed of the resource map, page previewer, and path previewer. The page previewer generates an overview of each web page in the map by extracting representative information from the html file. The path previewer helps learners make a sequence of the pages previewed as navigation path plan. These facilities help learners decide which pages to visit and plan a navigation path without visiting web pages. This paper also describes an evaluation of learner-centered navigation path planning with PA. The results indicate that PA facilitates learners’ navigation in hyperspace, particularly in more complicated hyperspace.

Introduction

An increasing number of hypermedia-based resources on the web have been available, which are designed from an educational point of view, or which are worth learning (Brusilovsky, 1996). Learning with such existing web-based learning resources has accordingly become important, particularly as the realization of lifelong and distance learning (Kashihara, 1998).

Web-based learning resources provide learners with hyperspace where they can explore domain concepts in a self-directed way by following the links among web pages to achieve a learning goal. Such self-directed learning (Fischer, 1998, Dee-Lucas, 1996) could produce good results. On the other hand, learners often fail in making the navigation path since they do not know which link to follow for achieving their learning goal due to the complexity of hyperspace. They may alternatively make diverse cognitive efforts at comprehending the contents of pages, setting up global or local learning goals, making a path called navigation path attaining their goals etc., in the exploratory learning. How to facilitate learners’ navigation and learning has consequently become a major issue in educational hypermedia systems (Conklin, 1987).

The main topic addressed here is how to help learners navigate in existing web-based learning resources. Current work on educational hypermedia systems has provided a number of navigational aids such as spatial/concept maps and adaptive navigation (Domel, 1994, Heiling Huai, 1997). These representative navigational aids would generally work well in educational hypermedia whose semantic structure has given or analyzed. However, it is doubtful whether they apply to web-based learning resources. Existing web-based learning resources mostly have no concept maps. It is also hard to identify semantic structure of domain concepts embedded in the learning resources. Although there exist web-based learning resources with site maps, the information included in the maps do not always allow learners to foresee the contents of the web pages. In addition, adaptive navigational aids are not always applicable since existing web-based learning resources generally have no clear description of semantic relationships among web pages, which is indispensable for executing the adaptation.

Towards this issue, we introduce a learner-centered navigation path planning. The key idea is to provide learners with a planning space, in which they can see through web-based learning resources to make a navigation path plan, apart from hyperspace. Such planning space is also expected to facilitate their learning since they can focus mainly on comprehending the contents of the learning resources in hyperspace. We have accordingly developed an assistant system for the navigation path planning, which is called Planning Assistant or PA for short. PA provides learners with some facilities that help learners decide which page to visit and plan a navigation path without visiting hyperspace.

This paper also describes an evaluation of learner-centered navigation path planning with PA. The results indicate that PA facilitates learners’ navigation particularly in more complicated hyperspace.
Navigation Path Planning

Problems of Navigation in Hyperspace

In hyperspace, learners can explore the web pages in a self-directed way by following links among the pages to learn domain concepts embedded in the explored pages. The self-directed learning involves making a navigation path, which consists of pages that the learners decide to explore. However, they often fail in making the navigation path and reach an impasse. There are two main causes as follows.

- The learners cannot foresee what they should explore next from the current page for achieving their learning goal due to the complexity of hyperspace.
- The learners need to concurrently make diverse cognitive efforts not only at making a navigation path but also at setting up global/local learning goals, comprehending the contents explored, and so on.

Framework of Navigation Path Planning

Let us now introduce a framework for learner-centered navigation path planning in order to resolve the above navigation problems. There are two key points of the learner-centered navigation path planning. The first one is to divide learning process into navigation path planning and exploration (plan execution) phases as shown in Figure 1. In the planning phase, learners decide which page to visit and the sequence of pages visited. In the exploration phase, on the other hand, they are expected to explore hyperspace according to their navigation path plan. These phases are repeated during learning in hyperspace.

The second key point is to provide learners with planning and exploration spaces. In the planning space, learners can see through hyperspace provided by a learning resource to plan a navigation path. In the exploration space, on the other hand, they are expected to execute their navigation path plan. Such distinction allows the learners to focus mainly on cognitive efforts that are related to each phase.

We next discuss how to support learner-centered navigation path planning with some essential facilities for each phase.

![Figure 1: Learning process](image)

Support for Planning Phase

In order to plan a navigation path successfully, it is first important to get information for setting up global/local learning goals. Some existing educational hypermedia systems have provided the resource map, which represents hyperspace as network of nodes corresponding to web pages. Although the resource map provides learners with information for considering navigation path, the map alone may not always allow them to sufficiently foresee the contents of the web pages. Therefore, some additional information is required. However, planning with the full contents of the web pages causes the same navigation problem as hyperspace usually produces. This suggests the necessity to give learners an informative overview of the contents. In this paper, we introduce page previewer that tries to extract keywords, sentences, or images to be considered representative from a web page to display them as the preview of the page. The resource map with the page previewer enables learners to grasp not only the whole structure of web-based learning resource but also an overview of each web page. Referring to this information, the learners can consequently set up learning goals easily.
In addition, the navigation path planning involves considering the relationships among web pages explored, changing the plan, and replanning over again. We accordingly introduce the path previewer, which makes a sequence of the previewed pages that are put in order by learners. The path previewer enables learners to compare neighboring pages and to plan a navigation path for achieving their learning goal without visiting hyperspace. Since the navigation path also gives learners an overview of the contents to be learned as advanced organizer before exploring hyperspace, their learning in hyperspace can be improved (Ausubel, 1961).

Support for Exploration Phase

After the planning phase, learners are expected to follow their navigation path plans during the exploration phase. We accordingly introduce the navigation controller that enables them to explore along their navigation path plan in a simple way. However, the learners do not always need to follow the navigation path. They can explore pages that are not included in the navigation path with a web browser. When they want to change or cancel the navigation path during the exploration, they can return to the planning phase.

Planning Assistant

Let us next demonstrate PA. Figure 2 shows the user interface of PA, which consists of the resource map, the page previewer, the path previewer and the navigation controller. PA has been implemented with Microsoft Visual Basic 6.0 as plug-in tool for Microsoft Internet Explorer 4.0 (IE for short) or higher.

Figure 2: User Interface

Resource Map

The resource map represents hyperspace of a web-based learning resource selected by learners as a network of nodes corresponding to the web pages. It is automatically generated and displayed in the map window when they select the learning resource. The resource map represents the web pages only within the same web site where the homepage selected by the learners is located. The links from the site to others are omitted. Nodes in the resource map are tagged with page titles indicated by title tags in the HTML files. In addition, we added a title list of all pages in the web site. These facilities enable learners to decide from which page to start their navigation path planning. In selecting a node or title, they can have an overview of the web page with the page previewer.

Page Previewer

The page previewer extracts key information such as words, sentences of images attached to some HTML tags in a page selected and displays it as an overview of the page. Table 1 shows the HTML tags that can be considered representative of the page, and Figure 3 shows an example of the page previewer. The right
window displays the preview of a web page shown in the left window. As for the links out of the page, the page previewer searches for `<A href>` tags in the html file, and displays all titles of the linked pages in the drop-down menu as link list at the lower part of the page previewer. In planning a navigation path, the learners can start the path previewer by pushing the 'Path' button in the page previewer.

**Table 1: Html tags**

<table>
<thead>
<tr>
<th>Tag</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;a&gt;</code></td>
<td>Hyperlink</td>
</tr>
<tr>
<td><code>&lt;img&gt;</code></td>
<td>Image</td>
</tr>
<tr>
<td><code>&lt;h1&gt;</code></td>
<td>Header</td>
</tr>
</tbody>
</table>

**Figure 3: An example of the page previewed**

**Path Previewer**

The path previewer makes a sequence of pages learners have previewed, which pages are put in order by learners. The order of the previewed pages accordingly represents a navigation path plan. How to plan a navigation path is as follow, (i) learners select a next page from the link list which displays titles of the pages directly linked to the current page, (ii) the path previewer displays an overview of the page selected next to the current page, (iii) if they want to add the page into the sequence, push the “Add” button and return to (i), and (iv) if they do not want to add the page selected, return to (i) and select a next page again. In this way, the path previewer helps them plan (add, delete and branch), change, and replan their navigation path.

**Navigation Controller**

The navigation controller enables learners to explore along their navigation path plan in a simple way. Pushing 'Next' button, the learners can explore the next page on their navigation path plan. They can also explore pages that are not along their navigation path plan. When the page explored by them is not along their plan, the navigation controller puts a warning icon and shows ‘Return’ button in order to come back on their navigation path plan. When they also want to change or cancel the navigation path during the exploration, they can return to the page previewer and the path previewer from the node corresponding to the current page on web browser.

In this way, learners are expected to repeat the planning and exploration to accomplish their learning in a self-directed way.

**Evaluation**

**Purpose**

In order to evaluate the effectiveness of PA, we conducted an experiment. The main purpose of this experiment was to ascertain if PA facilitates navigation in hyperspace compared to navigation without PA. We prepared two learning resources, which had comparatively simple and complicated hyperspace, and ascertained for which resource PA supports navigation more effectively.

**Domain and Subjects**

Table 2 shows the two learning resources ([1], [2]). It describes the number of pages, the number of links per page, which was calculated except for navigation links such as Next, Back, and Top, and the longest distance from the homepage to terminal page that has no link. These can be viewed as the indicator of the
complexity of hyperspace each learning resource provides. The learning resource 1 accordingly had a more complicated hyperspace. Subjects were 32 graduate and undergraduate students in science and technology who were not familiar with the domain of the learning resources.

We set four conditions, which were (1) planning and execution with PA in learning resource 1 (Complicated-With), (2) exploration in learning resource 1 without PA (Complicated-Without), (3) planning and execution with PA in learning resource 2 (Simple-With), (4) exploration in the learning resource 2 without PA (Simple-Without). Subjects were provided with IE as web browser under each condition. In this experiment, each subject learned one learning resource without PA and learned the other with PA. Moreover, we assigned the subjects into four groups in order to counterbalance these conditions.

**Procedure**

The procedure of the experiment with each subject was as follows:

1. He/she was given the explanation about how to use PA.
2. He/she was given several problems as learning goals for learning resource 1 (or resource 2). The problems were classified into (a) single problem whose answer could be found within one web page, and (b) compound problem whose answers could be found in the relationships among two or three pages.
3. He/she was required to explore answers to the single problems and compound problems within 15 minutes each with PA (or without PA), and to copy and paste the URLs of the web pages considered as the answer.
4. When he/she finished finding out the answers or 30 minutes passed, he/she was given several problems for another resource and was required to repeat the same way with another condition.
5. Comparing the scores and the behavior of subjects under Simple-With and Simple-Without or under Complicated-With and Complicated-Without, we evaluated the effectiveness of PA.

We measured three criteria that were ‘achievement’, ‘accuracy’, and ‘efficiency’ of navigation, which were calculated from the scores. ‘Achievement’ was calculated from the number of questions they answered within time limit (15 minutes for each condition). ‘Accuracy’ was the percentage of correct answers per the answered questions. ‘Efficiency’ was calculated by multiplying ‘achievement’ and ‘accuracy’.

We also measured the influence on navigation in hyperspace by the number of revisited pages and a number of visited pages per all pages included in the learning resources, which were indicated from the behavior of subjects.

**Results and Discussion**

Table 3 shows the average of the ‘achievement’, the ‘accuracy’, and the ‘efficiency’ on each condition. As for the compound problems, the average of the ‘accuracy’ on Complicated-With was significantly higher than that on Complicated-Without (F=11.14, p<0.01). The average of the ‘efficiency’ on Complicated-With was also higher than that on Complicated-Without (F=21.34, p<0.01). From these results, it was ascertained that PA enabled learners to plan a good navigation path for achieving their learning goals especially such as
relating web pages each other in more complicated hyperspace. In a simpler hyperspace, on the other hand, PA could not be so effective since it was able to easily see through the learning resource even without PA.

Table 4 shows the average number of revisit per page explored on each condition. The results indicate that there is a significant difference between the average number of Simple-With and Simple-Without (F=29.10, P<0.01). There is also a significant difference between Complicated-With and Complicated-Without (F=63.83, P<0.01). These results indicate that PA reduces learners' behavior of revisiting the pages that have been visited both in simple and complicated hyperspace. In other words, PA enables learners to see through learning resources.

Table 5 shows the average number of visited pages per all pages on each condition. There was a significant difference between Simple-With and Simple-Without (F=46.19, P<0.01). There is also a significant difference between Complicated-With and Complicated-Without (F=183.18, P<0.01). These results indicate that PA makes exploration in hyperspace intensive. In addition, the average of 'efficiency' on Complicated-With was very high as shown in Table 3. These results indicate that PA enables learners to more efficiently direct their attention to pages, which fulfill their learning goals, particularly in a complicated hyperspace. From the above results, we can say that PA has a potential for facilitating navigation in a more complicated hyperspace.

**Conclusion**

This paper has proposed a learner-centered navigation path planning for learning with existing web-based resources. The important point is to provide learners with a planning space where they can see through the web pages to plan a navigation path. As the advantages, learning in hyperspace can be improved since the distinction between planning phase and exploration phase allows learners to focus mainly on comprehending the contents of the learning resources in hyperspace. The navigation path can also give learners an overview of the contents to be learned before exploring hyperspace.

This paper has also demonstrated a support system called PA including the resource map, the page previewer, the path previewer, and the navigation controller. These facilities allow learners to plan and explore a navigation path plan in a simple way. In addition, this paper has described an evaluation of PA. The results indicate that the system produces good effects on navigation in a complicated hyperspace.

In the future, we need a more detailed evaluation of the learner-centered navigation path planning. We would also like to provide more adaptive aids in the page and the path previewer.

Abstract: A CD-ROM based In-service ICT Training Program for schoolteachers was planned,
developed, and delivered to all of 40,000 schools throughout Japan. The training program
was designed to guide self-regulated workshops within an elementary or secondary school
with little experience of using ICT in their instruction. The design and development was
carried out by a group of researchers and teachers leading ICT application in school education,
organized by the Center of Educational Computing and sponsored by the Information-technology Promotion Agency foundation (IPA). The pilot studies were carried
out while the training program was being developed. Observations and questionnaire
revealed that this new approach of self-regulated training package was welcomed by the
participants. Characteristics of In-service training programs in Japan and importance of this
study for preparing Japanese teachers for ICT utilization in everyday classes are discussed.

Introduction

A CD-ROM based In-service Training Program for schoolteachers to obtain practical skills in designing
lessons with ICT was planned and developed, which has been delivered to all of 40,000 schools
throughout Japan. The training program was designed to guide self-regulated workshops by school
teachers within an elementary or secondary school who have little experience of using ICT in their
instruction. The design and development was carried out by a group of researchers and school teachers
leading ICT application in school education, organized by the Center of Educational Computing and
sponsored by the Information-technology Promotion Agency foundation (IPA).

The Training Program

The training program consists of a CD-ROM, two Video programs, and a workshop text (See Fig.1).
The contents of the training program include the followings:

1. How to overcome fear of ICT
2. ICT workshop beyond skill training
3. Procedures for Self-regulated workshop
4. Forms for planning ICT instruction
5. Introductory exercises for ICT instruction, and
6. Sample workshop outcomes from pilot studies
Evaluation of the Program

The pilot studies were carried out while the training program was being developed. Observations and questionnaire revealed that the participants welcomed this new approach of self-regulated training package. Further studies are needed to verify how this program are in fact utilized at each of school sites and how much it has been effective to create more ICT applications in classroom, as well as more positive thinking toward ICT in teachers mind.

Contributions of the Program

Integration of ICT technology into everyday classes requires reconsideration of instructor-led lecture style chalk-and-talk approach that has been the main methodology found in Japanese classrooms. This can be an opportunity to make school lessons more student-centered and self-directed learning. In order this change to take place, teachers need to be trained for a major change of their roles.

Contrary, typical teacher training programs in Japan have been instructor-led chalk-and-talk style. Teachers themselves need to experience how to learn in a self-regulatory manner, when they are learning something new, such as ICT and its application to classroom. In this respect, this program should give the teachers an opportunity to learn new skills in a suitable learning style.
The Information Revolution and The Future Role of Educators

Michael Szabo, Ph.D.
Department of Educational Psychology and Technology
University of Alberta
Canada
mike.szabo@ualberta.ca

Abstract: The purpose of this paper is to identify trends which are likely to come to fruition in the near term future and generate implications for the educational professional. The trends focus upon the information communications revolution and one subset, the coming Instructional Technology (IT) revolution. Ideas have been abstracted from a forthcoming chapter in the International Handbook on Information Systems. (In Press). H. Adelsberger, Collis, B., & Pawlowski, J. (Eds.). Berlin: Springer-Verlag.

The Scenario Approach

Predicting the future beyond lunch can be at once frustrating and unrealistic. An alternative is to consider different plausible scenarios of what might happen, develop a plan for each scenario and monitor events to decide which plan to implement. This scenario strategy has been used extensively in various business-futures planning (e.g., Schwartz, 1996).

The first scenario, at one extreme, is that nothing will change significantly from the current state of affairs. A teacher from the early 1900s who was magically transported to a current classroom would feel quite at home. The appropriate strategy might be to maintain a low profile in the trenches, keep your helmet pressed down around your ears and keep your head low. It is regularly practiced by many who are either within a few years of retirement or view their role as stewards of the institution who will turn it over to their successors in the same fine shape they received it. Some have suggested the lack of wisdom of this approach.

Universities won't survive...higher education is in deep crisis. Already we are beginning to deliver more lectures and classes off-campus via satellite or two-way video at a fraction of the cost [of traditional courses]. Today's [campus] buildings are hopelessly unsuited and totally unneeded. (Drucker, quoted in Green, 1999, p 15).

In a series of studies of campus computing in the USA, Green paints a somewhat dismal picture of the preparedness for this change when he says "the evidence suggests that as an "enterprise," higher education remains mostly unprepared for the consequences of this coming convergence." (1999, p. 11).

The other extreme end of the scenario spectrum is that the ICT revolution will dramatically effect how instruction is delivered in a major and revolutionary fashion. A teacher of today, transported into this new future, would be bewildered, out of place, and find difficulty determining what to do or say. The viability of this scenario of the future of education is based on machine and intellectual technologies which have been promised and are being tested at this time, plus successful experiences on smaller or non-educational scales than proposed in the following scenario.

Below are some guidelines to prepare educators for the IT society based on a review of current and projected technological and sociological developments.
Specialize in Change and Reform

If IT is not "rocket science" and can be implemented by any educator with proper support, particularly that which is provided in the context of the interdisciplinary team (see below), why has it been so little used? One answer whose credibility is growing is that IT represents a major innovation and the diffusion of innovation involves change. Bates has argued that

New technologies are associated with postindustrial forms of organization based on highly skilled and flexible workers with a good degree of autonomy organized into relatively small and flexible operational units. In contrast, universities and colleges have been characterized by a mixture of agrarian and industrial forms of organization, with hierarchical, bureaucratic, and relatively inflexible organizational structures and procedures...the introduction of new technologies for teaching will require a major shift toward postindustrial forms of organization for universities and colleges." (Bates, 2000, pp. 1, 2).

It behooves us to learn all we can about the process of diffusion of innovation (change), whether it comes from a managerial, administrative higher education framework (e.g., Bates, 2000), a business leadership framework (Kotter, 1996; Senge & Roth, 1999), a sociological, psychological framework (Rogers, 1995), or an educational technology framework (Fullan, 1991, 1992, Szabo et al, 1999). This leads directly to the second role.

Understand Innovation Rules and How They Apply to IT

IT must be respected as an innovation and its diffusion (Rogers, 1995: Szabo, 1996; Szabo & Anderson, 1997; Szabo, Anderson & Fuchs, 1999). This approach begins with an examination of those factors which characterize successful and unsuccessful innovation diffusion, from a variety of fields of human endeavor. It then constructs a system to optimize the effects of those factors. This paper looks at eleven characteristics of innovation and implications for the IT educator.

Focus on the Intellectual Technology, as Well as the Machine Technology

It is often stated that IT is too expensive. Exploring this notion further results in the conclusion that in education, machine technology costs are quantifiable and add-on, while the supposed benefits (increased achievement, effectiveness, attitude and access) are neither 1) easily quantified nor 2) valued in a practical, applied sense in education (which faculty member's increments or other rewards are based on how much their students achieve or how quickly)?

While it may be true that it is a zero-sum game for machine technology (money spent on IT must come from some other part of the budget), the intellectual technology represented in the employees of the university or college is a rich, renewable and expandable resource. And it is this technology which creates the programs which drive the learning process which is presented by the machine technology.

Predict Directions Computing is Going and the Implications for Education Networking

The global network of interconnected servers and clients will enable every educator (and student) to not only obtain resources from any location in the world, it will also enable every educator to contribute resources where they have expertise.

Broadband Transmission

The first infrastructure technology element is broadband communication which will enable the transmission of interactive and multimedia computer files significantly larger than anything we have today outside the research laboratory. At the time of this writing, governments are selling expensive licenses (average cost in
Britain of $7B per license) for third generation (3G) broadband frequencies which will significantly increase the ability to transmit large (e.g., full motion, full color video) files using wireless technology.

**Wireless Communication**

Wireless communication will permit full access to all educational services we now have and more, from any place in the world without a physical connection. On the day everyone has a single access number and full multimedia capability on a portable wireless device, we will have to rethink how, when and why we communicate with students, colleagues, administrators, suppliers, and experts.

**Internet Appliances**

Internet appliances are consumer electronics which incorporate elements of wireless phones, audio-visual entertainment devices and traditional PCs into useful devices. One such device resembles a 20 by 29 cm notepad with a digital screen, pencil-like pointing device and wireless connectivity. This prototype handheld device and presumably its successors (1) are made possible by microchips with high power but low power consumption, (2) will enable complete, interactive, multimedia-based courses of instruction to be received anywhere, and (3) will become relatively inexpensive if the forecast high volume consumer demand drives down prices. One implication is that the costs of distance education compared with conventional learning will become exceedingly attractive, especially when one considers the tradeoffs of the time and inconvenience and lost opportunity costs of relocating to an institution of higher education.

**Databases**

The third technology is also currently available as exemplified by the VISA credit card phenomenon which operates with vast interconnected server-driven databases which collect, store, quickly analyze and regurgitate on demand, information requested by authorized users, clients, and administrators in report format which they specify and control. Imagine the existence of master, world wide educational databases which contain detailed information about every conceivable aspect of educational life everywhere on the globe. Educators will have to create, maintain, and use these databases for the benefit of their students.

**New Models of Operation Infrastructure**

The fourth infrastructure component is a function of the human rather than technological concepts. This involves a major reconstruction of the educational systems of the world.

> The advent of the Internet is a massive, even unprecedented exercise in managing change... Success requires changing the model for how to organise the work and lead the organisation. It requires challenging traditional assumptions about organization, communication, decision-making, operating style, managerial behavior -- and then defining a new way. That is a human problem, not a technological one." [emphasis added].

Indeed it will require a major cultural change (Bates, 2000; Szabo, 1996).

CMC may result in a major leap forward in the development of the global brain, discussed elsewhere in this paper. It certainly seems to be playing a role in the development of the operating system called Linux. Anyone can change the code to improve or extend its functionality, but the changes must be made available to other users. Theories of learning which place high value on knowledge construction through dialogue with others and reflection may benefit from enhanced CMC in the forms of computer conferencing, e-mail, list-servs and other facilities which have yet to be developed.

**Preserve conditions of intellectual freedom and open political institutions**
The Post Industrial Society and its current incarnation, informationalism, promise men and women greater control of their social destinies. "But this is only possible under conditions of intellectual freedom and open political institutions, the freedom to pursue truth against those who wish to restrict it. This is the alpha and omega of the alphabet of knowledge." (Bell, 1999, lxxxiv). But this requires action and reflective thinking. "In times of rapid technological change, reflective practice is virtually an occupational necessity for everyone (Guiton, 1999, p. 52).

Respond to Changes in Educational and Social Goals

Increased demand for intellectual education and training for service, professional and managerial employment, coupled with decreased but nevertheless existing demands for skilled and semi-skilled workers. These latter will be reduced by such technologies as performance support systems and expert systems, which in turn will require building. There will also be a growing need to retrain and re-orient workers displaced by informationalism and provide entry into the market.

Another area of concern to educators is a somewhat uncomfortable concept—market share and competition with other educational institutions, commercial firms, and international alliances. Does your institution want a market share of the education and training industry, and if so how much? In the early days of the Internet, it will be easy for institutions to capture a nice share of the student market, but there are signs that will change as competition heats up.

Develop and Use Technology to Communicate

Computers aren't just for number-crunching anymore. They have become powerful but limited tools to support a wide range of communications. Consider the role of reflection and expertise among members of a class and how those elements can be used to enhance and enrich the educational experience of the whole class.

Break Free From Conventional Bonds, Thinking

The term horseless carriage was used to define the first automobiles—a blend of the old and new. But retaining the old, while providing some level of comfort, may have hindered the appearance of the new. Perhaps the term distance education will conjure up images of the classroom in different regions and have a stifling effect on the culture change necessary.

One way to break from conventional bonds is the look at things from a different perspective. It has been said that a chicken can be defined as a device which an egg uses to reproduce itself.

There are myriad details of how this could or should take shape; too many to include here. An extensive review of immersive instruction through virtual reality technology may be found in McLellan (1996). The outcome, however, is that any student can access the best education in the world from any location in the world in any time zone. The global brain will be strengthened. Now if we could just make similar progress and expand results like these into the arena of ethics, morals, and the realm of spirituality.

Change is guaranteed but what that future will look like must wait until it happens. It is likely however that change will continue at a rapid, even accelerating pace. Several other conjectures come to mind. First, unlike most of the rest of our economic, social and cultural environment, education has to date been largely untouched by the sweeping changes arising from the ICT revolution. It seems likely that this will change; that ICT will ultimately have a transforming effect upon the way we conceive of and deliver educational services.

An Evaluation of TIES (Training, Infrastructure & Empowerment System):
Evaluating Learning Technology Initiatives in Continuing Professional Development

Michael Szabo, Univ. of Alberta, Canada; Daylene Lauman, Univ. of Alberta, Canada; Sonia Sobon, University of Alberta, Canada

TIES is a system of professional development for educators in the process of change through instructional technology. It is built on the twin assumptions that instructional technology is an innovation, and educators fail to recognize the implications in terms of innovation diffusion. The TIES foundation is derived from a distillation of characteristics of successful and unsuccessful innovations. The outcome is a multi-faceted approach in which senior academics are encouraged to set a vision for the institution, and strategically-located and constructed leadership teams work to interpret and make that vision become a reality. This session describes TIES, its implementation in a research university, and results of interview-based research of a cross-section of TIES participants.
Constructivist Approach Towards Designing IT-based Constructivist Learning Activities

Seng Chee Tan
sctan@nie.edu.sg

Wong Siew Koon, Philip
skpwong@nie.edu.sg

Instructional Science Academic Group
National Institute of Education
Nanyang Technological University, Singapore

Abstract: A nation-wide Masterplan for IT in education was implemented in Singapore since 1997. To help overcome the shortage of instructional programs, an innovative approach, called microLESSONSTM, was devised to help teachers develop their own IT based instructional materials using MS PowerpointTM. In addition, it is also a way to help teachers to adopt a more constructivist approach by engaging them in designing constructivist learning activities.

Background

To meet the challenges of the 21st century, the Ministry of Education in Singapore has launched the Master Plan for Information Technology (IT) in Education in 1997. IT based teaching and learning was identified as one of the key strategies to equip our young with skills to think, to learn independently and to communicate effectively. Teacher training plays a vital role in the successful implementation of the IT Master Plan. However, there remained a few thorny issues that could present great barriers to the successful implementation of IT Masterplan. These problems could undermine the effects of integration IT in instruction, rendering the multimillion-dollar investment to waste.

Problems

One of the problems we faced was the availability of instructional software. While there are commercially produced pre-packaged materials, many of these software were not relevant for the local curriculum. Though the Ministry of Education and some local software developers are producing materials tailored to our local needs, it takes time to produce quality materials. In addition, such effort is hampered by the limited market in this island nation with a population of only 3.9 millions people.

Many of the existing instructional software were designed based on traditional didactic approach in which the instructor assumes the role of the fountain of knowledge. Instruction is focused on what information the learner needs to know or must know and then take the actions to provide the learner with the necessary information. While such didactic approach can be very efficient in disseminating information, the students are often not engaged in higher order thinking. The problem is aggravated in the learning of ill-structured knowledge domains, in which acquisition of simplified and compartmentalized knowledge often occurs (Spiro et al., 1992); students cannot handle complex, ill-structured problems in real-life situations.

The above problems might lead to another problem – perpetuation of the traditional instructional paradigm. Teachers using the available software, which are designed based on didactic pedagogy, might regard them as the model of IT-based instruction and such approach becomes more deeply entrenched in classroom practices. This is evident from the difficulty student teachers have in designing constructivist learning activities in our courses. Even after some discussion and feedback, some student teachers still revert to the show-and-tell method of instruction that they are familiar with.
Introduction to microLESSONSTM

The microLESSONSTM project started in 1998 by Philip Wong, the head of Instructional Science academic group, as a research project funded by the National Institute of Education. In Jan 2000, Ednovation, a software company in Singapore, joined in to provide further financial and technical support for the development of microLESSONSTM. MicroLESSONSTM as the name implies, are small units of learning activities with specific learning objectives as opposed to most commercial learning materials that cover a complete topic or curriculum. They are student-centered materials that incorporate various hypermedia features (e.g. hyperlinks, animation, graphics, sound, interactivity) to enhance the learning process. To facilitate the process, a user-friendly hypermedia tool should be chosen so as to facilitate rather than hamper the production process. MS PowerpointTM is chosen as the multimedia tool for this reason.

Potential Benefits of microLESSONSTM

Creating a microLESSONSTM is an active learning of constructivist approach of instruction: the MS PowerpointTM is used as a Mindtool (Jonassen, 2000) to engage the teachers in active construction of their knowledge about constructivist learning through design and development of something concrete and sharable. From our experience in conducting microLESSONSTM course, even after the initial exposure to microLESSONSTM, many student teachers still start with traditional didactic approach. But through discussions and feedback, these student teachers could better understand the constructivist approach and become more receptive towards this alternative approach of instruction.

Once the teachers have mastered the skills of creating microLESSONSTM, they have in fact been empowered to create their own IT-based learning materials. They are able to create materials customized to their needs instead of being totally dependent on commercially available software. The time needed to identify, evaluate, purchase and adapt existing materials is salvaged for more productive designing activities.

While the process of creating microLESSONSTM can benefit the teachers, the products, i.e. the microLESSONSTM will benefit the students. They are designed to engage the students with learning activities that emphasize active, intentional learning. These activities often encourage higher order thinking -based cognitive tools like simulations can also be included to enhance thinking skills.

One of the advantages of microLESSONSTM is the adaptability and transportability of the products. Each microLESSONSTM is a small unit of instruction that is easily adapted by the instructor. A teacher may use one or a few microLESSONSTM units in complement to non-IT based instruction to cover a topic. A teacher may also customize a microLESSONSTM unit by modifying the hyperlinks to other websites or programs. The small file size of microLESSONSTM facilitates transportability and they can be easily exchanged through floppy diskettes, CD-ROMs or the Internet.

Image Analysis and Teaching the Concept of Function

Steven L. Tanimoto
University of Washington
Department of Computer Science and Engineering
Box 352350
Seattle, WA 98195, USA
tanimoto@cs.washington.edu

Abstract: The concept of function is key for understanding algebra and all higher mathematics. Using digital images and image processing, it is possible to introduce the concept of function in new ways which has the potential to be more compelling and effective for some students and which can better reflect the spirit in which functions can be applied in contemporary technology. We describe how two programs for PCs and Macintoshes, called the Pixel Calculator and the Image Warper, can support the exploration of function from a variety of viewpoints. While a digital image itself can be considered as a function, the many other kinds of functions which arise in image analysis support discussions of invertibility, composition, and design of functions for specific purposes. This approach encompasses an important aspect of functions: that they are objects to be designed and applied as well as objects to be contemplated and manipulated with formalisms. The materials and suggestions reported here represent one aspect of an ongoing project that explores applications of image processing in mathematics education.

Introduction

This paper presents an aspect of applying image analysis in education. Some issues related to teaching the concept of function are discussed. Particular materials developed by the project, “Mathematics Experiences Through Image Processing” at the University of Washington are described and their applicability to the teaching of functions described along with possible additional activities using image-analysis algorithm design.

As part of an effort to improve mathematics education in the United States and in other countries (NCTM, 1989), our project has been developing materials that permit mathematical ideas to be learned in a context of connections to the real world, relevance to students, use of computer technology, and rich visual representations (Tanimoto, 1994). This project focuses on middle-school and high-school students (ages 10-18); the age of 14 is a critical one in that more students leak out of the mathematics pipeline at that age than any other.

A key mathematics concept in the middle-school/high-school curriculum is the concept of function. This concept is crucial for understanding algebra, the differential calculus, and most higher mathematics (Eisenberg, 1991). While the notion of function is extremely simple, the representations, terminology, and diverse examples of functions often lead to confusion for students. Functions are typically introduced using set theory, formal descriptions of numerical domains or other notation which may complicate the teaching of the basic concept itself. The use of graphs helps some students but may confuse others (Goldenberg, 1988).

An advantage of using computer-based image processing to teach about functions is that functions can be seen as operational. When a function is applied to an image, the function “comes alive” in a certain sense. This can have a positive motivational effect on students. At the same time, the computational context provides additional richness for the study of functions. The distinction between mathematical functions and computational functions is typically not made in grades K-12, and students who begin their formal study of computing in college must overcome this confusion at the same time that they are learning a programming language.

Images as Functions

Let's begin by considering images themselves as functions. One often thinks of a function as a rule for answering questions. The function \( f(x) = x + 1 \) can thus be considered as a scheme for answering questions such as “If you give me the number 2, what number will I give you back?” Another representation of such a rule is a table of values such as that shown below.

<table>
<thead>
<tr>
<th>x</th>
<th>f(x)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

1917
Page 1867
In this way a function may be viewed as a type of correspondence between questions and answers.

**Mapping to and from Coordinate Pairs**

By considering a digital image as a slightly more elaborate table, which provides a way to give answers to questions of the form “What value is at \( x = 153, y = 39 \)?” students can come to understand that a digital image may be used as a function and that it actually is a function. A consequence of this is that an image can be used as the key to a code. Provided that the image contains pixels with enough distinct values, a pair of coordinates can be used to represent a character of an alphabet. A student decodes a pair of coordinates by looking up the pixel value for that pair of coordinates in the image, and taking the \( k \)th character of the alphabet, where \( k \) is the value of the pixel. The use of codes is a standard approach to involving students in mathematical activities in an informal way.

**The Application of a Function**

Once the student understands the concept of function as a rule for answering questions, it is important to distinguish the *application* of a function from the function itself. Where the function provides a way to answer questions, the application of the function is the actual *answering* of such a question. This point can be confusing, as the answer to a question could itself be an image and thus a function. An example of such a question is this: “What image results if we subtract each pixel value from 255?” (answer: a photographic negative of the original).

**Pixel Calculator Operations as Functions**

**The Pixel Calculator**

The Pixel Calculator is a program for displaying and manipulating digital images on personal computers. While its principal intended use is to introduce students to the digital representation of images, it may also be used to support discussions and exercises about the mathematical concept of function. The Pixel Calculator is first of all a display tool. As the user zooms into the image using the magnifier tool, the pixels of the image appear as gray squares, and when the squares are large enough, the numerical pixel values are overlaid upon them. In this way, the display shows both the visual and numerical aspects of digital images, and therefore it portrays a digital image as both a visual object and a mathematical object. Figure 1 shows two displays of a toad image to illustrate the combination of visual and numerical views afforded by the Pixel Calculator.
Operations on Single Pixels and on Multiple Pixels

One possibility when using the rectangle-selection tool is that the user clicks once without dragging and thereby selects only a single pixel. Performing calculator operations then affects only this one pixel. For example, entering \# + 50 would cause the selected pixel to take on the value 50 plus its current value or 255, whichever is smaller. In this mode of use, the user is specifying a function and applying it to a single argument at the same time.

When the user has selected a rectangle containing more than one pixel, the operations entered into the calculator are applied to all the selected pixels. If the selection rectangle includes all the pixels of the image, then the user is causing the function to be applied to the entire image. One may consider this to be a multiple application of a pixel-oriented function or to be a single application of a different kind of function --- one that takes as its input argument an entire image rather than a single pixel value.

The Concept of Variable

A concept that is closely associated with functions and with algebra more generally is that of “variable.” Mathematicians use variables for a variety of different purposes, and when variables are introduced to students for the first time, it is important to be clear on which purpose is intended. A variable may be an independent variable in a function definition. It may represent an unknown quantity to be established (in an algebra problem). A free variable may also indicate implicit universal quantification as in F(x,y) = 0. It has been pointed out (Kline, 1972), (Philipp, 1992) that the concepts of function and variable have been linked ever since they were introduced by Leibniz.

Related numbers that change together, like x and y in the above equation, are called variables. When one variable depends on another for its value, we say that it is a function of the other. (Upton 1936, in Philipp, 1992, p.239)

The most important interpretation of variable is “varying quantity.” This concept is specifically designed into the Pixel Calculator. The Pixel Calculator uses the symbol “\#” to mean “the current value of the pixel.” The operation “\# + 50” corresponds to the function \( f(x) = x + 50 \). Thus \# represents a quantity that generally varies from one pixel to another, and it plays the role of independent variable in formulating functions with the Pixel Calculator. The symbol #, which looks like a pixel, is preferable in this context to the symbol x, which not only has nothing obvious to do with the value of a pixel, but which can easily be confused with the x-coordinate of the pixel.

The same symbol can represent an unknown in an algebra problem without difficulty. Consider the following question: “If the user applied the function \# + 10 to a pixel and the result was 25, what was the pixel value?” Expressed with the equation \# + 10 = 25, the problem can be solved in the conventional way by subtracting 10 from each side to yield \# = 15. The Pixel Calculator implements an arithmetic calculus that we have named “pixel arithmetic.” Among other properties, pixel arithmetic obeys truncation semantics. Thus 255 + 1 produces 255 and 0 - 1 produces 0. Therefore, the next algebra problem has a multiplicity of solutions: “If the user applied the function \# + 10 to a pixel and the result was 255, what was the pixel value?” The answer is “one of the values 245, 246, ..., 255.” This sort of algebra problem, where the function as well as the result are given, and where it is required to find the starting pixel value, can be called “doing Pixel Calculator operations backwards.”

Geometric Transformations with the Image Warper

While the Pixel Calculator supports the exploration of functions as operations on pixel values, another sort of function takes entire images as input values and produces transformed images as outputs where each output pixel may depend on the values of one or more input pixels in different locations.

The Image Warper is a program for personal computers which permits the user to specify geometric transformations on images using sets of line segments called “control lines.” The program uses an algorithm reported in the SIGGRAPH'92 conference (Beier and Neely, 1992) which is part of a “functions on images effected by the Pixel Calculator are specified in terms of operations on individual pixels. The pixel-wise function operates on each pixel independently and independent of the pixel’s x and y coordinates. The Image Warper, on the other hand, transforms an image according to geometry—that is, according to the x and y coordinates of the pixels. After a student has warped an image by defining a set of control lines and their displacements, one may ask her/him the question, “Where is the function?” A student unfamiliar with functions as methods for transforming images may be tempted to say that the resulting image is the function, or that the pair consisting of the source and destination images represents the function. Once it is clear that the function is something that can be applied to any image of given dimensions, they may be able to realize that the function is
represented by the set of control lines and their displacements. In order to save the function, one saves the control lines (together with their displacements). The lines (and displacements), together with the algorithm implemented in the program, provide a specification of the function.

Invertibility of Functions

A useful property of functions that can be easily introduced through the image-processing context is invertibility. As mentioned above, doing Pixel Calculator operations backwards provides a simple way to pose algebra problems using the variable symbol #. The multiplicity of answers to the second problem above indicates, that it is not always possible to get back to precisely the value one started with when applying a function and then trying to go backwards. Such a discussion leads naturally into the concept of invertibility of functions.

While the concept of undoing the effect of a function is a natural one, the concept of inverse of a function is more subtle. The inverse of a function is also a function, and it must undo what the original function did to any element of the domain (e.g., any image, in the case of an image transformation). Strictly speaking, the inverse of a function must always produce the original element from the transformed element exactly.

When one considers an image itself to be a function $F: X \times Y \rightarrow \{0, 1, \ldots, 255\}$, the question arises whether such an image can have an inverse. If the image were a bijection (which would imply that the image has precisely 256 pixels), then the image would have an actual inverse, a mapping that assigns to each pixel value in the range a unique coordinate pair where that value occurs in the image. Since such images that might have inverses are so restricted and unlikely to occur if one were to use a commercial digital camera or scanner in the normal fashion, it is natural to ask whether there is some other way in which an image can have an inverse. The answer is "yes." It is common in image analysis algorithms to require answers to questions such as "Where in the image does the value set of coordinate pairs. If the number 73 is not the value of any pixel in the image, then the answer set is the empty set. Otherwise, it is a set consisting of all the (x,y) locations where the pixel value is 73. This kind of inverse is sometimes called the "relational inverse" of the image. Traditional lessons on invertibility of geometric transformations such as rotation, reflection, and scaling are implicitly based on a pure notion of invertibility. Applying a transformation to an image and then applying the inverse transformation to the image must reproduce the original image exactly.

In the discrete world of digital image processing, we can also identify different kinds of partial invertibility. For example, a translation of an image to the left by k pixels causes data to "fall off the edge" of the image and brings in potentially undefined at the right border of the image. The subsequent translation of the image to the right by k pixels is a partial inverse for the left translation, because some of the pixels are restored to their exact original values, but values in the leftmost k columns of the image are either undefined or set to a "padding" value. In the case of rotation around the center of the image by $\pi / 4$ followed by rotation by $-\pi / 4$, there is a similar loss of data due to pixels at the corners again "falling off" the image. However, there is an additional source of information loss. The resampling that must be performed in computing the rotated image in the discrete space of pixel samples causes a loss of detail. If the original image happened to be extremely detailed, this loss might not be noticeable. However, close inspection of the pixel values is likely to indicate that the pixels are not always brought precisely back to their original values. Therefore, this illustrates a second kind of partial invertibility.

![An original image, its rotation by $\pi/4$, and the result of rotating it back.](image)

The rotation transformation has a "partial inverse."
These transformations which are at least partially invertible can be contrasted with image mappings that contain singularities. Such a mapping is easily specified with the Image Warper by drawing two line segments in the shape of a cross, and then rotating one of the segments by \( \pi \) in the destination window. The resulting transformation has a drastic effect on the images it warps.

Illustration of warping with the “cross” transformation (non-invertible).

Functions as Processes

In presenting functions as process, one must note that unlike purely mathematical functions, computational functions have additional aspects such as temporal behavior and consumption of memory resources. The temporal behavior may depend upon not only the way in which the function is programmed, but the presence and behavior of other processes running on the same computer, the particular input values given, and the particular hardware that the program is running on. Computational functions are also different in that their domains and ranges are generally not the same as those of purely mathematical functions. Whereas mathematical functions often take as their domain the real numbers or vectors of real numbers, computational functions must usually limit themselves to finite representations such as double-precision floating-point values. Integers are often restricted to 32 or fewer bits.

Construction of Functions (or Functions as Designable Objects)

Mathematical functions are often conceived of as Platonic, pre-existing ideas that we may discover but not create. While it is indeed likely that any function that we can describe very simply (such as \( f(x) = 2 \sin x \)) has been “created” before and therefore is not “original,” there is no reason not to consider functions as objects to be designed or created, and in image analysis and other areas of applied mathematics this is commonplace.

In order that students develop a sense that functions are objects to be designed, they need a means of expressing those designs. The basic building blocks of complicated functions are themselves functions, though they are simpler. Transformations on images may be built out of simpler transformations. Simple ones include translations, rotations, scale changes, and arithmetic operations on pixel values. Geometric distortions can be expressed in terms of mathematical functions applied to the coordinates of pixels.

Students can explore the design of functions from either the bottom-up or the top-down approach. Bottom-up creation of functions begins with some available functions and involves combining them in various ways, exploring the effects of the resulting composite functions. Top-down design is encouraged when a student is given a precise goal and asked to create a function that achieves that goal. The goal may be to correctly classify some objects or images.

In a traditional image understanding framework, the recognition process begins with the sensing of an image, its preprocessing, segmentation, feature extraction, and classification or description. If students are provided with a suitably rich vocabulary of functional building blocks, it should be possible for them to construct working image analysis systems. Two good activities in this realm are segmentation and measuring faces. The process of separating the pixels of an object (such as a person) from those of the background provides a suitable challenge for students to design a function. Working with primitives such as a thresholder, a mean-pixel-value function, a central
region selector, and various parameters, a student can develop a segmentation function that will extract the shape of the person from the background, at least under appropriate conditions.

Another challenge for the student is to design a function that takes an outline of a person’s face, expressed as a binary image, and comes up with a value that can be used to discriminate correctly among the faces in a given set. The aspect ratio of the face is one straightforward possibility.

**Pedagogical Issues**

The approach to teaching about functions outlined here may have the following benefits: an apparent relevance to students, because they can understand how functions are needed for generating special effects and for automatic pattern recognition; an aura of excitement because the functions often have striking visual effects; and an authenticity in terms of design and construction of functions, which is something very real in the engineering community. While functions have been traditionally taught in terms of correspondences and other recent approaches that have considered co-variational approaches and rates of change (Confrey and Smith, 1994), the teaching of functions as designable objects and/or as process objects with computational properties is a new approach that fits well in the context of image analysis techniques.

**Software Availability**

The Pixel Calculator and the Image Warper are available for download free of charge for educational purposes. For more information, see http://www.cs.washington.edu/research/metip/.

**Acknowledgements**

This project has been supported in part by National Science Foundation Grant MDR-9155709. Programmers involved in writing the Pixel Calculator and the Image Warper include James Ahrens, Jeremy Baer, Lauren Bricker, Dennis Lee, Evan McLain, and Alex Rothenberg. Abstract: Previous research has demonstrated that the uneven nature of students’ participation is one notable challenge of Computer-Supported Learning. In this study we analyzed the relations between elementary school students’ motivational orientation and their engagement in computer-supported inquiry learning within a networked learning environment. The investigation was a case study in nature; one classroom’s study project was examined across two terms. The participants were the teacher and 30 students of one fifth-grade class. The technical infrastructure was provided by Virtual Web School (VWS) developed by Helsinki City Department of Education. A self-report questionnaire was used to assess students’ motivational orientation. Students’ discourse interaction in the database was investigated through social network analysis. The results of the study indicated that mainly the high learning-oriented students actively engaged in CSCL. It was encouraging, however, that there was moderate reciprocal interaction across gender and motivational orientation groups. Implications for educational practices are discussed.

Introduction

The emergence of a knowledge society is transforming educational practices in many ways. In international assessments, innovative learning technology, based on the new information and communication technology (ICT), is seen to lead to a new decade of the learning revolution (Pea et al. 1999). Computer-supported Collaborative Learning (CSCL) is expected to increase the quality of education by engaging students and teachers in coordinated efforts to build new knowledge and to solve problems together (Dillenbourg, Baker, Blaye & O’Malley 1996).

One of the starting points of the present study is the progressive inquiry model of learning developed by Hakkarainen (1998) and his colleagues in the context of CSCL. Characteristic of progressive inquiry is to go beyond conventional learning by pursuing students’ own questions and problems of understanding; generating and discussing their own conceptions and explanations for the problems being addressed. The model implies that students themselves should develop functions of monitoring and controlling learning (e.g., Bereiter & Scardamalia 1987).

It can be stated that the above-presented elements of progressive inquiry impose rather demanding challenges for an individual student’s cognitive capacity. In addition, any learning or performance situation can, from a student’s point of view, be seen as a ‘coping situation’ with many other, e.g. socioemotional and motivational, demands (Boekaerts 1993). The goals students pursue in a given learning situation depend partly on each student’s interpretation of these demands. Learning may not be seen by the student as the most crucial (or even
worth (Covington 1992) or some other issues present in the learning environment engage students' attention (e.g. chatting with friends).

From a motivational point of view students' personal goals represent the energizing and directing force of activity (Pintrich & Schunk 1996). In classroom studies it has been found that the learning-oriented students (those who seek to increase their knowledge and skills) show more active cognitive engagement in learning activities (Meece, Blumenfeld & Hoyle 1988; Lehtinen et al. 1995) and tend to choose more challenging tasks than other students (Dweck 1999). Moreover there is evidence that when working with computer supported learning environments, learning-oriented students are more active, creating new knowledge and commenting on other students' inquiries in the database (Järvelä et al. 1999). These findings are also in accordance with investigations of students' preferences regarding different instructional practices. It has been reported that while learning-oriented students prefer autonomy and possibilities for challenging work, there seem to be students who are not so willing to participate and 'be active' during learning situations (Niemivirta, 1998; Peltonen & Niemivirta 1999).

Further, there are certain indications that rather than helping to overcome motivational, cultural or knowledge-related differences between students, computer-supported learning leads to increasing learning difficulties and performance differences - without strong teacher guidance (Venezky 1999). Therefore, the uneven nature of students' participation can be considered to be one of the current problems of Computer-Supported Learning.

On the other hand, the promise of the new computer supported learning environments has been partly based on the pedagogical assumption that they include elements, which can be regarded as inherently motivating (e.g. possibilities to solve complex, authentic tasks) despite students' individual differences and prior experiences (CTGV, 1992; Lin et al., 1995; Savery & Duffy 1995). A few studies have even demonstrated promising results: that, in some cases, students who have problems in adapting to an ordinary school tasks, may find CSCL very motivating and intriguing (Hakkarainen, Lipponen, Järvelä & Niemivirta 1999). Consequently, there seems to be a need for a more detailed analysis of the patterns and intensity of students' participation and of the individual differences behind these phenomena.

The present study focused on uncovering the patterns of students' participation by applying methods of social network analysis, which provides statistical tools for examining networking relations among students (Wasserman & Faust, 1995; Scott 1991). The problem we addressed was whether high learning-oriented students who are engaged in conventional educational practices would also be most active in the context of CSCL. Palonen and Hakkarainen (2000) found out that there may be substantial gender differences involved in participation in CSCL. Thus, gender was included in the study design to test for similar differences on this data.

The questions addressed were a) how intensively do elementary school students representing both genders and different levels of learning orientation participate in discourse interaction within a networked learning environment; b) is the students' discourse interaction dominated by some student groups.

Methods

Participants

The study was conducted in a fifth-grade classroom in an ordinary urban elementary school. Altogether, 30 students and one teacher participated in the study, which focused on analyzing the students' activities in two study projects in history. To support collaborative building of knowledge, the students used collaborative software called Virtual Web School (VWS) designed by the Media Center of the Helsinki City Department of Education. The VWS was designed to help students share information and construct learners' joint knowledge. There were four networked computers within the classroom that were used for conducting the project.

Data analysis

The students were administered a self-report questionnaire to identify their motivational orientation at the beginning of the learning project (Niemivirta 1996). The self-report questionnaire included several subscales, but
only the scale for learning orientation was used in this study. The scale contained five items for assessing a student’s focus on learning new things and gaining knowledge (e.g. “The most important goal for me in school is to acquire new knowledge”). Items of this scale were used to create a composite score (Cronbach’s alpha coefficient for this scale was .87). In order to make comparisons between students representing different levels of learning orientation, students were divided into two groups on the basis of a median split on this scale. Students with above-median scores were classified in ‘high learning orientation’, and remaining students in ‘low learning orientation’ groups. Both genders were equally distributed across the two groups.

Patterns of students’ participation within the VWS were examined by applying social network analysis for written discourse interactions between the students (Wasserman & Faust, 1995; Scott 1991). Characteristics of the students' social network were analyzed by examining the amount of direct connections among members of a learning community (density), patterns of interaction in the community as a whole (centralization), and the extent of each student group’s participation (centrality).

Measuring the density is a simple way to assess characteristics of a network: the more actors have connections with one another, the denser will be the network. The density of a (binary) network is the number of observed ties divided by the number of all possible ties (Borgatti, Everett & Freeman 1996b, p. 78; Scott 1991, p. 74). Density of a binary matrix varies between 0 and 1, and it is 1 in cases where everyone is directly interacting with everyone else. Centralization describes how tightly interaction within a network is organized around particular focal points. A centrality value is calculated for each student in order to find the most active and visible persons in the community, and it was assessed using Freeman’s degree (i.e., number of sent and received comments).

The data consisted of the links between students' notes: who interacted with whom by constructing VWS comments. The information was examined as a weighted and directed graph representing the structure of communication, in which the teacher and the pupils were viewed as nodes and the comments as vertices. The dataset was dichotomized in the analyses (cut-off point = 0). All analyses were performed by using the Ucinet program (Borgatti, Everett & Freeman 1999).

Results

Density of Participation

The analysis indicated that the students' network of interaction was not very dense; the density was 0.26 (SD =0.44) for symmetrized data (direction of commenting ignored). In the case of the asymmetric graph based both on sent and received comments, the measure was 0.16 (SD =0.37) of the possible ties. From the relatively high standard deviations, we may infer that there were subgroups of students that engaged in denser interaction than their fellow students. Therefore, we examined density of students’ interaction as a function of gender and levels of learning orientation. The network was partitioned into blocks the density of which was examined separately on the basis of gender and motivational orientation (low vs. high learning orientation) (see Tab. 1). In addition, the teacher of the classroom formed her own blocks. However, the densities of blocks with varying sizes are not directly comparable; i.e., larger graphs have lower densities than smaller graphs because only so many ties can, in reality, be maintained by an individual (Scott 1991, p. 77).

An examination of Table 1 reveals that there were differences between the students’ participation patterns as a function of their gender and motivational orientation. Density of between-student interaction in the case of low learning-oriented students appeared to be lower than that of high learning-oriented students. There were not, however, the same kind of drastic gender-related differences in intensity of participation found in some other studies (Palonen & Hakkarainen 2000). Table 1 indicates, further, that a substantial part of the discourse interaction took place between the high learning-oriented students. It is encouraging, though, that there was also interaction across the borders of gender groups as well as across students representing different levels of learning orientation. In many cases low learning-oriented students’ were in connection with the high learning-oriented students although interaction between the low learning-oriented students themselves was not very dense.

Finally, it can be seen that the teacher, who sent 9 messages and received 21 messages from 13 students, interacted with the both gender groups with an equal intensity. It is particularly noticeable, that she engaged in rather intensive interaction with low learning-oriented boys apparently trying to get them involved in CSCL. She was also interacting with high learning-oriented boys and girls. This is to be expected because active participation of these groups provides many opportunities for her to respond and provide support. An open question is why she did not make a corresponding effort in the case of low learning-oriented girls. It is also to be noticed that interaction between the students and the teacher was bi-directional. In many cases teachers are only commenting on students' productions, but there is no any real dialogue involved.

The Centralization and Centrality of Participation

We also examined the extent to which a whole graph representing VWS students' interaction had a centralized structure (Scott 1991, pp. 92-93). The results of the analysis indicated that students' interaction was not very centralized (0.24 and 0.35 in the case of sent and received comments, respectively). It follows that the students' communicative efforts were distributed among a relatively large number of persons.

The participating students, taken together, produced 280 written notes. On average, they sent 8.9 (SD = 7.9) comments. All students either sent or received a comment but two students did not send any comments and two did not receive even a single comment. Table 2 reveals, however, that there were between-student differences in the intensity of engagement in VWS-mediated peer interaction. The most active students could be found among the high learning-oriented girls in the cases of both sent and received comments. Also high learning-oriented boys participated actively, but high learning-oriented girls produced approximately twice as many comments as the corresponding boys. The girls contacted a much larger group of fellow students through their comments than any group of boys. However, where the number of actual dialogue partners is concerned (i.e., number of students that one was interacting bi-directionally), learning orientation appeared to be a more important factor than gender.

*Groups with same letters differ from each other at p<.05 (Nonparametric, MW-test for comparing two groups of cases on one variable). ¹ Dialogue partners refer to number of fellow students that a student both sent and received comments so that the interaction was bi-directional.
Because of the small sample size and abnormal distribution of measures, the statistical significance of these differences was examined using nonparametric versions of the t-test and analysis of variance. The findings revealed significant differences (p<.01) on all measures between high learning-oriented and low learning-oriented students (Mann-Whitney test). There were no significant differences between boys and girls at the general level. However, several differences were found across the four groups. Both low learning-oriented boys and girls differed significantly (p<.05) from the high learning-oriented girls' group on all measures. Low learning-oriented girls differed also from high learning-oriented boys (p<.05), while there were no significant differences between boys' groups.

Discussion

The results of the study indicate that the level of students' learning orientation was closely associated with the intensity of their participation in CSCL. In other words, the high learning-oriented students, and most girls, engaged in a rather intensive process of inquiry within the VWS. The low learning-oriented students, in contrast, produced fewer comments or pieces of knowledge during the projects examined. These phenomena revealed by the study might appear to be expected or trivial because, in a sense, a disposition to engage in active learning is what we expect from learning-oriented students. However, it is important to remember that the motivational orientation was assessed by using a self-report questionnaire that addressed the students' general motivational tendencies notwithstanding CSCL.

Moreover, it is not self-evident that students who are learning-oriented would also be the ones who engage in CSCL with the highest intensity. Our earlier studies indicate that for pupils with performance or avoidance orientation in relation to traditional school tasks, CSCL may open up an alternative way of participating in schoolwork (Lipponen & Hakkarainen 1997; Hakkarainen et al. 1999).

The results of this study indicate that the students' participation was not equal. It was, however, encouraging that students representing both genders were involved in CSCL inquiry. Students' participation was not centralized to the extent that only a few students produced most of the knowledge. Further, the results indicate that interaction across boundaries of gender or motivational orientation was rather active. This appears to be a very valuable and encouraging aspect of networked learning that would not have been revealed without the methods of social network analysis.

However, these results point out the importance of acknowledging students' individual differences in the context prevailing motivational basis and gender do 'make a difference' as far as their participation is concerned. One possible explanation might be students' different skills in regulating their goal directed activity. Further, it is possible that, on the basis of their goal preferences, students interpret the characteristics of the learning environment differently. For students with strong learning orientation, the new learning environment may seem to provide possibilities to challenge one's cognitive capacities and promise new knowledge. Instead, some students may experience these elements as new obstacles and demands that they have no interest in or prerequisites to encounter. In both cases, the importance of teacher guidance and support is highlighted. It seems evident that students with motivational problems need more structured instruction and encouragement during computer supported study projects. On the other hand, students with strong learning orientation may also need guidance in their inquiry practices. In-depth learning is demanding for everyone facing the new challenges of CSCL, regardless of students' enthusiasm or personal goals.

Certain limitations of the study are important to note. First, because of the small sample size, the findings of the study need further testing with larger populations. Second, the methods used covered only a part of the actual interaction during the projects. Observational data are needed to supplement the results obtained through database analysis.

Abstract: The current American education system is vastly different from the institutions of twenty years ago. The pervasive influence of technology is changing the way we teach, the way we conduct research, and the way we seek to provide increased educational opportunities to students from all walks of life. Many departments of Information Technology are beginning to develop programs to offer courses using on-line or web-based delivery, i.e. via the “virtual classroom”. In this paper, we offer a list of “do’s and don’ts” that provide background and insight into the decisions involved with creating a virtual classroom and the activities associated with the development of an online Information Technology course. In conclusion, we present some of our observations concerning the impact of the online paradigm based on our own experience.

INTRODUCTION

In the past, students who were unable to attend college in the traditional way used correspondence courses to earn a degree. Now the trend in higher education is to offer courses, and in many cases, entire degree programs via distance education, the most notable being Internet or web-based instruction. One result of this trend is an increase in the number of adults attending college for the first time, returning to finish a degree, or to get additional training in a specific area. Institutions of higher learning are scrambling to take advantage of this new development. A recent survey by the U.S. Department of Education’s National Center for Education Statistics (NCES) shows that the number of distance education programs increased by 72 percent from 1995 to 1997-98. Moreover, an additional 20 percent of the institutions surveyed planned to implement distance education programs within the next three years. Those institutions also reported that they planned to start using or increase the use of Internet-based technology and two-way interactive video technology more than any other type of technology. (3) These results suggest that online course delivery is dramatically on the rise. Although the effectiveness of distance education is under current debate (4), institutions are rushing to jump on the “e-learning” bandwagon. In turn, faculties are being asked to develop web-based enhancements for traditional courses or an entire course to be delivered online. In this paper, we propose practical suggestions (do’s and don’ts) for a faculty member who is considering or facing that challenge.

OUR ON-LINE CURRICULUM

Northwestern State University (NSU) is a 4-year public university of about 9,000 students that serves a mostly rural population in northwest Louisiana. Given the large geographical service area, NSU has become a leader in the state in online education. It was one of the first institutions to have courses included in the Southern Regional Electronic Campus of the Southern Regional Education Board (7). Our institution currently offers approximately 60 online courses to over 2000 students. Others are being developed and plans are underway for the development of complete online associate degrees in Computer Information Systems (CIS) and Business Administration (BUAD).
We have been involved with the development and delivering of online courses for approximately three years. We have organized our suggestions into two broad categories: (1) course development, i.e. that which takes place from initiation of the project up to actual course delivery, and (2) course facilitation, i.e. that which takes place while the course is underway.

**DO'S AND DON'TS OF COURSE DEVELOPMENT**

**DO...**

- Allow more time to develop materials for an online class.
- Work with your administrators as much as possible. (8)
- State instructions and other information about the class as explicitly as possible.
- Keep course integrity in mind at all times.

**DON'T...**

- Use existing course materials just because they are readily available and worked in a traditional classroom environment. (5)
- Try to re-invent the wheel.
- Think all courses can be delivered effectively online.

**DO'S AND DON'TS OF COURSE FACILITATION**

**DO...**

- Provide some type of orientation so that students can practice using the technology.
- Make your first quiz over the orientation. This forces the student to take a close look at the course documents.
- Provide each student with timely feedback. Student surveys show that prompt response from the instructor is very important to student satisfaction with the online experience. (2)
- Treat students courteously and with respect. The written word can appear harsher than the spoken word.
- Be prepared to handle technical questions and problems. Know where to refer the student.
- Evaluate and revise.
- Maintain a course portfolio to help organize your course, remember what you did, and provide a source of information when it comes to teaching evaluations. (6)

**DON'T...**

- Isolate your students or yourself. If anyone feels over your head, then ask for help.
- Allow your class size to become too large.

**CONCLUSION**

The trend in higher education is to develop electronic delivery of individual courses or entire degree programs. The successful development of any distance education program rests squarely on the shoulders of the institution's faculty. Therefore, faculty members must break away from old paradigms and adopt new techniques for teaching and learning. We have presented a list of suggestions, "do's and don'ts" for an educator who is interested in or facing the challenge of developing an online course or enhancing a traditional course with an online component.

Case Study: The Translation of Archive Materials into an Interactive Medium

Jason Taylor, Jane Wood, Simon Robertshaw

Abstract: This paper documents and explores the methodology employed by the developers of the Euro.Network.Hats project - a CD-ROM and web site exploring the hatting and millinery industry in Europe, particularly the development and decline of European felt hat manufacture. It will provide an insight into an approach to the translation of diverse archive materials into an interactive digital format. The paper will illustrate the process of content development: from the elicitation of content knowledge to the developer's response in terms of information, visual and interaction design.

Introduction

Stockport Hat Museum initially approached the Learning Methods Unit (now a core element of the International Centre for Digital Content) in 1998 with regard to the development of multimedia materials for their new museum site. The success of this relationship led the Museum to approach the ICDC for support on a bid for transnational funding under the European Community's Raphael programme.

The aim of this programme is to encourage co-operation between the Member States in the area of cultural heritage with a European dimension. It is intended to support and complement Member States' action aimed at representing national culture, highlighting the shared cultural heritage while respecting national and regional diversity. This action seeks to encourage operations to promote European cultural heritage, especially through new information technology and multilingualism.

The bid was successful and funding amounting to 144.328 EUR was awarded in September 1999, the project being scheduled to run from September 1999 to September 2001. The ICDC acts as technology partner for the project, which will explore the hatting and millinery industry in Europe and maximise public access to a significant aspect of social and industrial heritage. The final product will be an interactive CD-ROM, available in English, French, Dutch and German, exploring the hatting and millinery industry in at least three European countries.

The Project

The Museum came to the ICDC with certain key pre-requisites. The product was to explore the hatting and millinery industry in Europe using content supplied by the European partners. The content had to be equally accessible in four languages (English, French, Dutch and German) and to three distinct user groups (researcher, school child and casual browser).

The Players

There are three major stakeholders in this production: the content specialist (the Museum), the developer (ICDC) and the user.

The lead partner in this project is the Stockport Hat Museum; they represent the bid partners: Museé du Chapeau, France and Historisch Museum, Netherlands. Together they are the content specialists. They hold a wealth of information about the hatting and millinery industry. However they lack knowledge of the creative technology they wish to be developed. They are unlikely to be aware of the potential of specific content.
The ICDC developers have a good understanding of the management of rich information and its presentation in an interactive fashion but nothing beyond surface knowledge of the subject matter to be presented.

In any multimedia production it is the user who is the ultimate arbiter of quality, not the developer or the content specialist. Therefore an awareness of the needs of the user are crucial to the development of coherent and usable content. We anticipate that each type of user will have a variety of different needs.

The researcher has prior knowledge of the subject - we assume that they will approach the product searching for particular information rather than casual browsing. The child will have a range of needs too. Activities within the CD-ROM may need to be classroom focused (whether teacher guided or self-directed study or just fun). It is understood that the gatekeepers (teachers, parents) needs must be acknowledged in responding to the child’s needs. We anticipate that the general browser has a level of curiosity about the content and therefore needs an environment that is easy to explore.

The Process of Content Development

In attempting to present complex information it is crucial that the presenter is knowledgeable in their field. When the medium is written this shouldn't be a problem - here the author has complete control over the means of communicating their ideas. The intent of the author is only impeded by their ability to express their ideas. Interactive forms however demand a different process. Two distinct roles emerge: content specialist and multimedia producer. Here, author and means of communication are divorced. If the information to be conveyed is to retain its original quality and meaning, great care must be taken. The content specialist and multimedia producer must work together to share their knowledge. Either working alone will dilute their skills and therefore the end product.

Figure 1. Content Development Process
Knowledge Elicitation

The model above (figure 1) represents the content development process. This process is iterative and continues throughout the development of the project. The content specialists hold the knowledge within their own context; this knowledge needs to be extracted. Here the need is to break down the knowledge accumulated by the content specialist into distinct areas to aid understanding first for the developer and then for the user.

To start this process several brainstorms were needed to break down the large content area into definite themes. It became clear that the content area to be included was extensive and the relationship between themes was complex.

There seemed no natural order or hierarchy of information. Sub sections of the six areas identified overlapped resulting in potentially confusing or unnecessarily duplicated information.

Having a greater understanding of navigational structures and the structure/editing of content for a multimedia context, the developers independently refined and removed sections to make the content more coherent and manageable.

Even with further refinement it was difficult to find a clear organisation of information that would not artificially compartmentalise the content. However, we recognise that a fragmented body of information need not be a divided one. There is a balance between chunking information for easy explanation and retaining the mosaic of information. We came to understand that the structure of the information was largely arbitrary. The way in which we made the content accessible would be crucial.

Information Design

Any structuring of information is artificial - information has no natural underlying order. But by categorising content we transform data to information - by supplying a context within which the content can be accessed we give the user a greater chance of assimilating the information into knowledge.

After establishing the content areas we went on to develop a metaphor to represent the content. It was clear that the holistic nature of the information couldn't and shouldn't be avoided - it should instead be embraced. The metaphor provides a map of the interactive environment. Information exists within the information space of the model - altering the position of a point on any axis allows a meaningful movement between content areas. Using this metaphor allows you to see the development of certain processes over several hundred years. It allows you to see these processes as they differ between country and also allows you experience other categories of information from the same time and place.

Figure 2. Content Metaphor
Structuring information by time, location and category allows us to separate the information into bite size chunks. As we are dealing with historical information largely provided by a museum, each photo, artifact etc. already has a date and geographical location associated with it. In addition, the categories defined in collaboration with the Museum staff provide the final element of the metaphor. This model allows for an easily understood and accessible division of content areas i.e. 1850, France, Architecture. It should be noted that all content is to be available in four languages (English, French, Dutch and German). This adds a fourth dimension to the model where any content can instantly be viewed in another language.

The model was developed before we had access to the content. It was an abstract approach to content about to be delivered. Resources were provided as a mass of information (text, image, and video) and it soon became apparent that the materials supplied were much too dense for easy assimilation by the developers. The developers had a basic understanding of the content, which was insufficient to develop the rich, coherent content required for the CD-ROM. At this point the developers decided upon the range of content to be covered in the CD-ROM. This made it clear that the content specialists had to edit the content to match these requirements. The developers and content specialists later met to collaborate in the gathering and formulation of resources. This enabled the developer to identify material that had potential for development in multimedia context that may have been overlooked by museum staff as their knowledge of multimedia was limited.

For instance, this simple line drawing had been discounted by museum staff as being of no value to the development. By chance the developers became aware of this and knew immediately that this resource was ripe for inclusion in the CD-ROM.

Figure 3. Technical drawing of fur-former

The developer's lack of specific knowledge was useful in this instance. Previous video selected for inclusion in the CD-ROM included footage of the process illustrated above. However the age and quality of the film reduced the clarity of the footage. The footage would have offered an incomplete view of the process to a layperson whereas a content specialist would tap in to their content knowledge to fill in the gaps. Our role as layperson allowed us to see through the eyes of the user. We therefore knew we had to provide a more comprehensive breakdown of the fur-forming process.
Figure 4. Stills from animated sequence of Fur-forming machine

This example shows the importance of collaboration between client and designer to exchange individual subject knowledge thus providing a richer more comprehensive set of content for the user. The ideal situation would be to work together in the same location to develop content. Ideas the designer has trigger 'hidden' information from the client and vice versa.

**Visual and Interaction Design**

The visual and interaction design is an expression of the information design. Once the metaphor had been developed a 2D representation of this was designed for screen use. All the elements from the metaphor had to be included: category, time, space and language. This enabled the content specialist to visualise the development and the way in which the content they were to provide would be accessed. This early treatment is flexible and evolves through consultation with the client. Our primary consideration was to create an environment where a diverse range of content could be presented with the focus upon the content rather than the interface. The generous use of space and muted colour scheme were intended to draw the user to the content.

Please visit [http://www.icdc.org.uk](http://www.icdc.org.uk) to link to the project web site to view examples of the interface design.

The central element of the screen was devoted to content allowing us to use the top and bottom of the screen as areas for interface/navigation control. This wide screen layout gives an uncluttered and consistent feel to whatever content is presented. The interface design gives a crucial sense of orientation to the user. When the user selects a different area of content to visit the desired effect is that of the content coming to the user rather than vice versa. The user feels safe/comfortable and ensures the design meets their needs rather than the user fitting to the system's needs. We build upon the sense of orientation by the use of perspective within the screen. Multimedia does not have to be a 2-dimensional form and the screen design used should express that. The distinction between the content itself and the icons used to control or navigate are clearly separated by the use of perspective. Incorporating perspective into the design was intended to aid the understanding of the content and acts as a visual representation of the layering of information.

The process of content editing and processing is time consuming and continues throughout the development period. As a result the developers aren't always aware of the nature of the content for inclusion. Therefore the interface had to be readily adaptable to new content to prevent costly redesigns every time new content was received. In addition, all content can be viewed in four languages. This has an immediate knock-on effect to screen design. A passage written in one language will not be the same size in another language. The flexibility of the interface was key. The use of layers of information allow the developers to build screens using a basic tool set without knowing the content in advance.

**Types of Interaction**

The interface has four types of interaction available - content navigation, interface control, context and the content itself.
Content Navigation

The means by which the user navigates through the content is crucial to their creation of a mental model of the content available. Successful navigation involves actively using the metaphor used by the developers to map the content. Time, space, category and language are all equally accessible from any point within the content. Changing any one will present the user with different content.

Interface Control

The user must be given support in using the developed product and have control over the underlying system.

Context

We anticipate that the environment created is easy to use and to explore. However we appreciate from are own experience that frustration can occur when the user feels confined to the metaphor in place. As the needs of the user are diverse we allow the user to step outside of the metaphor. Rather than following prescribed routes, users can jump to different points in the interactive environments according to their needs. The researcher can search for a particular keyword and/or media type and move straight to that point rather than intuiting where certain content will occur within the model. Children will have access to interactive worksheets. Here users will be prompted to answer questions relating to the content in the CD-ROM. This is anticipated to be used by school children where use of the CD-ROM may need to be teacher guided. As the questions may be curriculum based the user will be guided to specific areas of content - again this allows immediate direction to content without explicit use of the metaphor. Not all activities will be curriculum based. Users will be able to reorganise content to meet their own needs by capturing media and storing it for their own purpose i.e. school projects.

Content

Within the framework supplied by the consistent interface rules there is room for flexible content. The interaction within each content area will be developed using the interface tool set developed.

Conclusion

This paper has sought to illustrate the methodology employed in a particular CD-ROM production and to indicate the value of that approach. At the time of this conference the production phase will be complete and the CD-ROM will be undergoing testing prior to release. The developers will be preparing to demonstrate this to the transnational partners and testing will begin. We will soon to discover whether the approach taken has been successful.

When the project began the content seemed extensive and complex. The development of a metaphor to understand the organisation of this information has been key. Though the scale and complexity of the information has not changed, the means by which we can understand it has. The metaphor began as a model for the developers to map the information to be addressed. It evolved into a means of navigation and a way of looking at content development.

Creating a set of parameters for the information to be incorporated into the production will, we anticipate, prove invaluable. Giving the user the opportunity to choose a context for the information they access, and to follow the links between strands of information, will improve their understanding and appreciation of the holistic nature of any body of knowledge. However, giving the opportunity for users to create their own paths, to step outside our rules and to create their own order will, we hope, prove equally invaluable.
On Paper or Hypermedia? the Effect of Procedural Information in Digital Video Format in the Learning of a Music Score Editor Program by Novice Users

Abstract
In this study, and by means of an experimental contrast design, we have tried to determine whether the use of an electronic manual is more effective and efficient than a print manual for the training of novice users with a score editor program. We also looked for differences in access to the two types and for information on users' perceptions regarding the materials they used. Were developed a minimalist print manual, an hypermedia manual and two questionnaires. The most prominent difference between the two manuals was the use of digital video to present procedural information in the electronic version. The rest of the information remained the same for the two manuals, as did the training strategy based on guided exploration. The research findings show an effect of the hypermedia manual in learning outcomes, access to manuals and users' perceptions. This effect might have been due to the confluence of several factors differentiating the manuals: the procedural information in the video format and the design of the interface - with limited control elements, fast access to information and a low complementary interaction between presentation modalities - minimized the potential cognitive overload and allowed the user to start working rapidly.

Keywords: novice user training, training materials, hypermedia, minimalism, music technology.

1. Introduction
Research related to technical documentation, understood as an instructional resource, investigates design and elaboration strategies that are especially important because of their impact on learning. Educational research is deficient on empirical studies comparing novice users' learning outcomes in working with different types of documentation. This deficiency extends to a lack of contrasting on presentation modalities. It is widely expected that computers will increasingly play an important role as normal working tools in different knowledge domains, musical disciplines included (Tejada, 1998). At least in academic environments, a considerable amount of time will certainly be devoted to learning computer programs and controlling machines. Educators will need to expand their knowledge of methodologies and materials to include this type of learning.

2. Literature and hypothesis

2.1 Minimalist training materials
Carroll et al. (1987) observed the novice users' behavior and they found problems on the program documentation: it was extensive and exhaustive and did not have either a task-based approach or a system for
error detection and correction. In their empirical studies, the model was a learner focused to act, interested principally in doing real tasks, trying to make sense of all, he/she sees, hears, reads and does; someone that uses their own hypothesis even when the evidence contradicts them; a learner with a tendency to access technical documentation in a non-linear way (Carroll, 1990). Conventional manuals do not address this novice user's needs. This explains why only a small percentage of users read technical documentation (Lazonder & van der Meij, 1993). Novice users, focused on their goals, generally explore program functions by means of a trial-and-error strategy, which technical writers try to avoid in the manuals. Furthermore, while users explore, they make many errors, which explain the high amount of time devoted to correct them—about 25% to 50% of training time (Lazonder & van der Meij, 1994, 1995). The minimalism, a model of training heavily user centered, takes on two key principles from cognitive psychology: active learning and constructivism. Users can learn more and better if they are actively involved; when they are doing something. Users do not learn so much if they follow instructions like a script. Secondly, the user builds up their own mental models combining their past experiences with new information; hence, their mental models, already constructed, are modified. It makes explicit the user's goals and involves them in real tasks. It reduces the need for extended training materials and supports error recognition and correction. Its aims are to maintain motivation, promote active learning and make the learning environment user-friendly, that is, it enables exploration that users can do without feeling frustrated by their errors. Several authors define principles for the minimalist model (Carroll 1990, 1998; Van der Meij & Carroll, 1995). These share some characteristics with cognitive psychology: focus on real tasks; active learning; documentation structure based on users' real needs; brevity of materials; error recognition and correction; modularity; screen-documentation coordination system; iterative documentation design. Empirical research contrasting minimal materials and conventional ones has shown the superiority of the minimalist approach in developing training materials.¹

2.2 Problems of non-linear information access

Interacting with information in a hypermedia structure is a complex cognitive activity. Total freedom in the choice of the pathway into a hypermedia system may mean that the user's orientation abilities decrease (Dede, 1992) and a cognitive overload can arise. The term cognitive overload refers to the additional cognitive effort and concentration needed to simultaneously perform certain tasks. This demand for additional effort is due not only to the user taking decisions about what path to follow, but also to being forced to remember his/her situation in the net and the nodes that he/she has visited. Sciarone and Meijer (1993) have shown that the freedom provided in navigating through a hypertext system provoked users' inability to do the tasks required of them and that they preferred finding the responses through the system's help rather than learning the system itself. Several authors have tried to overcome this problem by providing navigational help, such as maps, indexes or pathway restrictions (Gay, Trumbull, & Mazur, 1991). Some useful techniques in facilitating navigation and avoiding disorientation are guided tours, maps, backtracks, bookmarks, overview diagrams, search engines and fisheye views (see Nielsen, 1995).

2.3 Contrast of print and electronic materials

Empirical contrast studies of educative print and electronic materials have shown contradictory results, due to the heterogeneity of research goals, subjects and type of materials used. Some studies show positive results for print materials.² There are two studies on comparing still and dynamic images in hypermedia materials. The video information included in both was declarative. Christel (1994) compared two courseware versions. A software engineering course included several records of meetings and other methodological aspects in which students could interact with simulated participants. One version included video at 30 fps and the other version presented the same contents (V) with slides which were replaced every 4 seconds (S). In test sessions, group V

recalled 89% of the required information while group S recalled 71%. Pane (1994) assessed a multimedia-
learning environment in the biology domain. The study measured the summative effect on students' performance and their satisfaction with the material. Instructional material containing video and simulations (V) was compared with other material containing static graphics (G); the results showed that group V spent more time working through it and scored better than group G. The author speculates that the time difference was probably due to group V projecting the video and simulations more often. These studies suggest that video information can enhance learning in a computer-based environment.

2.4 Hypothesis

Expressed in negative form, the hypothesis are (dependent variables between parenthesis):

Hypothesis 1 (H1): When carrying out tasks, there are no significant differences between users of the hypermedia manual and users of the print manual (voluntary exercises -time and number- near transfer tasks -time and accuracy-, and far transfer tasks-time and accuracy-).

Hypothesis 2 (H2): There are no significant differences in manual access between users of the hypermedia manual and users of the print manual (frequency of access, number of jumps, access time).

Hypothesis 3 (H3): There are no significant differences of opinion about the materials between users of hypermedia manual and users of print manual (ease of use, usefulness, satisfaction, structure and organization, speed of information search and the preference for the other manual).

3 Methodology

3.1 Previous work

We gathered data from users over two academic years through verbal protocols, which showed the most frequent problems users had with the music score editor, the "impasses" or errors they made, methodologies they used to solve problems and whether they needed external help to resolve the impasses. These data allowed us to make a task analysis, task selection and an error-recognizing and correction system to include in the manuals.

Our model of user was one with the following profile: low skills in computer use, a moderate level of motivation in learning with computers, high motivation in learning music programs and a low-moderate level of previous music knowledge. On the basis of this profile and the type of learning intended, we adopted the features of the minimalist model.

3.2 Materials

Before building the two manuals, we translated the music score editor into Spanish in order to: a) make the user's work environment more accessible; and b) eliminate a potential nuisance variable during the experiment.

A task analysis was carried out to determine the tasks to include. In the print manual, the procedural information was presented in text, while in the hypermedia manual it was presented in a digital video format. The hypermedia manual did not display video with other complementary information (textual or graphic) in order to avoid both dividing attention and the appearance of cognitive overload (Sweller, 1994). The manuals consisted mainly of procedural information, except for the first unit, which was devoted to the conceptual, specific terminology used. This unit was a still graphic without text. The structure of both manual contents was logical, sequential and chronological with respect to the task. Contents were split up into twenty units; the unit titles made up the Table of Contents and were used as organizers. The interface was quite straightforward, with a reduced number of control elements that allowed users to run a complete navigation. The hypermedia manual included a help system in order to facilitate operations and minimize the potential cognitive overload Ebersole, 1997).
According to minimalist model, a section called "Posibles Errores" (Possible Errors) for diagnosing and correcting errors was included in eleven units of both manuals, which were most susceptible to syntactic and semantic errors (Carroll, 1990; Lazonder & Van der Meij, 1995). The system consisted of a description of most frequent error and its general or specific corrections. Also, other section termed "Por ti mismo" (On Your Own) was included in order to stimulate user guided exploration and production. With this section, we expected users to do voluntary tasks (see Carroll et al., 1987; Van der Meij, 1993).

Usability tests were carried out with novice users that allowed us to gather data for redesigning the manuals. A pilot test was carried out in order to: a) assess the time necessary to accomplish near and far transfer tasks in experiment; and b) modify the observers' score card. The final version of the print manual was a fifteen-page booklet, whereas the original manual was a 256-page book. The final version of the hypermedia manual was an auto executable (4 Mb.) made using Macromedia's Director with links to 6.4 Mb. of video clips.

3.2 Subjects

To test the fifteen sub hypotheses, we used inter-subject contrast design with volunteer undergraduates on the Music Education Teacher course at the University of La Rioja -Spain. An initial questionnaire about previous experience of use of computers filtered out thirty subjects (11 males and 19 females) with an age range between 17-26 years. This sample was regrouped in sub samples corresponding to nuisance variables (age, course and sex) and assigned randomly to each of the experimental conditions to balance the groups. The subjects were provided with a consent form for participation and received one extra credit.

3.3 Control of variables

The documentation to train with a music score editor program (Encore) was the independent variable; it had two levels: hypermedia manual (HM) and print manual (PM). To balance the experimental conditions, the subjects were grouped in sex, age and course sub samples. They were then randomly assigned to each experimental condition. The program that subjects were to learn was translated into Spanish. The researcher was neither an observer nor an evaluator. The experimental environment was constant: place, hour and computers.

Each of the fifteen observers recorded measurements on two subjects, one of each experimental condition: study time for each instructional unit, time of voluntary exercises and time of transfer tasks in the test stage. Observers also recorded the current unit number and problems expressed by subjects "thinking aloud".

Variables related to the users' perceptions were measured with a questionnaire working on a seven-point scale. An external evaluator scored the test files by an evaluation form provided by the experimenter, which indicated scores based on the absence/presence of items required for transfer tasks.

3.4 Experimental environment and procedures

The experiment was carried out in a computer classroom at the University of La Rioja with fifteen Macintosh PowerMac 6230; it took three training sessions of ninety minutes and one test session (one week between each). The print manual was a booklet with fifteen pages of text and graphics. All the subjects in each experimental condition were told that the research aim was to study how a user learns a music score editor program. They were not informed about the other manual. Based on the data obtained in the pilot test, subjects were assigned thirty minutes to do nine near transfer tasks. These included fifteen different operations to be undertaken out of context. Subjects were assigned fifteen minutes to do one far transfer task. This consisted of replicating a music score and involved the application of knowledge to novel situations and the application of non-explicit information from the manuals. Subjects were not allowed to consult their manual while performing the transfer tasks (test session). When finished with the test session, subjects were provided with a final questionnaire, model A or B depending on the experimental condition, to test the dependent variables on users' perceptions.

4. Results
4.1 Training and learning

Three PM subjects and four HM subjects did not finish all the near transfer tasks. This difference was not significant (means: HM=8.66; PM=8.46).

Analysis of the data related to learning outcomes with the U-Mann-Whitney test showed significant variance (Table 1). A T test for non-related samples was run, which confirmed the significance. According to these results, the HM group scored better in near and far transfer tasks than the PM group.

4.2 Access to documentation

This variable was operationalized as a) number of accesses; b) jumps between non-consecutive units; and c) time of access. The results for number and time of accesses showed statistical significance with the U-Mann-Whitney test (Table 2). A T test for non-related samples confirmed the significance. Group HM consulted the manual less and consumed 33% less time than their counterpart.

4.3 Users' perceptions

The item 13 of the final questionnaire asked subjects to evaluate their preferences for the prominent information modality included in the other manual, the one they don't used (Table 3). The users of print manual would have preferred to use the hypermedia manual to a greater extent than the HM users the print manual.

5. Conclusions

The research findings show an effect of the hypermedia manual in learning outcomes; access to manuals and users' perceptions. This effect might have been due to the confluence of several factors that differentiate the manuals. First, the procedural information in the hypermedia manual was exclusively video. The hypermedia manual approached a modeling of the student using a presentation modality that fitted better with the type of learning sought; it produced extra time during training and a better assimilation of task procedures by users. Secondly, the design of the interface -with limited control elements, fast access to information and a low complementary interaction between presentation modalities- minimized the potential cognitive overload and allowed the user to start working rapidly. Designers of educational software materials for novice users should cover users' information needs -focus on user- rather than follow a systemic approach, for example by making a list of what the software is capable of doing. With the incorporation of novice users to learning situations, electronic training materials should be conceived so that the user can quickly build a suitable mental model of the software by explicit wordings from domain knowledge, program features and capabilities, through a real task approach and the presentation of procedural information in the video format.

Further investigations could offer users the freedom to access both types of documentation in order to study the relationships between use frequency and the variables measured. This will help in understanding the reasons why a particular user (expert, intermediate, novice) chooses one or another type of documentation and therefore knowing more on the user's information search strategies. Two variables not studied in this work are the type and number of errors during training. These ones might be important to explain the effect of materials. Though this would require highly trained observers, these two variables and error correction time should be studied to relate them to access to materials and learning outcomes.

This study made a moderate attempt to measure the effectiveness and efficiency of two types of auto instructive learning software materials through a guided exploration by novice users. It left at the margins important matters like learning style influences, degree of learning directivity, training strategies or type of users, which deserve to be investigated.

Learning on the Move: Vocabulary Study via Email and Mobile Phone SMS

Patricia Thornton thornton@kinjo-u.ac.jp  Chris Houser chris@houser.cc
Kinjo Gakuin University Omori 2-1723 Moriyama-ku Nagoya 463-8521 Japan

Abstract: Vocabulary acquisition is an important element of foreign language learning. Research on memory suggests that vocabulary can be learned most efficiently by elaboratively rehearsing each word at spaced intervals. We propose that push media—such as short email and text messages sent to student's mobile phones—can encourage study at regular intervals. We developed a series of concise, informal mini lessons and sent students three each day. Students reported that the push media and friendly writing style were enjoyable and promoted regular study.

Introduction
Cognitive science provides educators with insights into learning, challenging us to help students learn more efficiently. In foreign language acquisition, one challenge is memorizing a large vocabulary. Effective vocabulary study includes practice at spaced intervals (Bjork 1979; Dempster 1996) employing elaborative rehearsal leading to deeper mental processing (Craik & Lockhart 1972). However, Japanese university classes meet once a week, making spaced practice difficult. Students need to be unusually self-disciplined to space their studies. Instead of relying on discipline, we help students study outside the classroom by sending email to their mobile phones.

Vocabulary Study
Acquiring a large foreign language vocabulary daunts adult learners. They need 5,000 words to read non-specialized English texts (Nation 1990). Applying research on learning, they should review words at spaced intervals; their review should incorporate elaborative rehearsal in various contexts rather than simple repetitions. Foreign language students acquire vocabulary both by intentional learning through explicit instruction (Nation 1990) and by incidental learning through reading (Nagy et al. 1987). Experts recommend combining these methods (Wood 2001) but existing teaching materials provide inadequate exposure to many of the 5000 essential words (Groot 2000). Thus, students need a program facilitating long-term memory storage of vocabulary.

Push Media
The educational materials normally used outside of class—texts, web pages, even homework assignments—are pull media, in that students must willfully pick them up to use them. But imagine if students used push media—email or SMS (mobile phone email, so-called Short Message Service)—media that prompted them to immediately study. Push media seem ideal for the repeated exposures needed to efficiently learn foreign-language vocabulary. Compared to students only occasionally admonished to study in intervals, students receiving spaced email vocabulary lessons would be more likely to do so.

Although many articles advocate email in teaching foreign languages, most describe student-generated email exchanges or written assignments submitted via email (Warschauer 1995). We found no research using email as educational push media. But some websites offer push learning. EnglishTown.com, a web-based commercial language school, emails English lessons containing readings, vocabulary lists, practice sentences, and review quizzes. They also promise English lessons for WAP phones. Another site, EigoTown.com, provides daily idiom lessons and monthly hypertext fiction. However, no research describes the effectiveness of any of these programs.

We propose facilitating learning by emailing new vocabulary in spaced intervals to mobile phones. We present vocabulary in several contexts to encourage elaborative rehearsal. We investigate the use of SMS as a tool for learning, specifically the learning of foreign language vocabulary.

We chose mobile phones because of their popularity in Japan. Nearly 60 million Japanese (half the population) constantly carry mobile phones (Mobile Media 2001). In contrast, only 20% have occasional access to desktop PCs. Ubiquitous internet-capable mobile phones can encourage structured practice outside of class.

Experiment
We introduced five words each week, sending students short mini lessons three times a day. Individual lessons defined a single word, taught some facet of a word, gave new contexts and examples, or reviewed words previously introduced. This variety of messages provided students with elaborative rehearsal, likely leading to deeper processing than that provided by methods such as bilingual word lists.

In the spirit of email, and accommodating the limitations of SMS, we wrote concise lessons (under 100 words) in an informal, friendly style. We also devoted the last lesson of each day to a story episode. We hoped that students would anticipate our lessons as they anticipated personal messages from their friends.
Hypotheses
In this first phase of our study, we investigated usability issues, considering these hypotheses:

H1. Push media will prompt students to study vocabulary.
H2. The story episodes, and concise, informal writing style will appeal to students.
H3. Push will be sufficient: students will be content to read their lessons without interaction (just as they've read their texts and studied their paper vocabulary lists without interaction).
H4. Students will read our short appealing messages soon after they arrive. (If students read lessons when they arrive, we could control their study intervals simply by controlling the time we send messages.)

Procedure
To test these hypotheses we gathered eight volunteer students of English as a foreign language (EFL) and Japanese as a foreign language (JFL). Pre-tests determined sets of words unknown to all the volunteers. We wrote the fifteen mini lessons required for each week of study, and then constructed a computer program that would automatically send lessons at 9:00, 12:30, and 16:00 each day. For example, here are the second day's EFL lessons:

Hello. Hi everyone. I hope you are enjoying learning English words. Learning is lifelong, not temporary. Today's word is reluctant. If you're reluctant to do something, you're unwilling to do it. You might do it slowly and without enthusiasm because you're afraid or shy about doing it. Many people are reluctant to speak to large groups. They feel afraid or shy about talking in front of many people. How about you? Is there something that you are reluctant to do?

Hello again. Do you remember the words we studied yesterday and this morning? Ignorant? Temporary? Reluctant? Sometimes people who live deep in the mountains of North America are called ignorant. Many of those people do not go to high school. They stop going to school after 6th grade. The government hopes this is a temporary problem. But parents are reluctant to let their children go to high school because they need them to work.

Maggie was tall, almost as tall as Tom. (Tom was the young man's name.) Maggie had purple hair. Tom had never seen anyone with purple hair. He thought it was strange but beautiful. It made him want to talk to her to ask why she had purple hair. But Tom was very shy and he was reluctant to begin a conversation with her. He kept hoping that she would talk to him. Finally, one day...

One student read the lessons using SMS on a mobile phone; the other students read their lessons using email on their PCs. At the conclusion of the experiment, the students took post-tests and responded to a questionnaire.

Results
H1 was supported: 88% of our volunteers studied the lessons every day. 75% mentally reviewed. H2 was supported: Students found the lessons "very enjoyable" and 88% desired to continue studying using this method. Most praised the brevity and informal writing style. All enjoyed the stories most.
H3 was partially supported: 75% of the students were content to merely read their lessons. But one student desired quizzes; another wished to ask questions.
H4 was supported only by the student reading the lessons via SMS on her mobile phone. The students reading email on their PCs were often unable to soon read incoming lessons; many could read only once or twice a day.
Only for the student using a mobile phone were we able to evenly distribute our three lessons throughout the day.

Future Work
Our informal, bite-sized lessons were well received, but our experiments have only just begun. We plan to
• Add interaction (quizzes and hypertext).
• Compare mobile phones to PC email (for convenience, coolness, and disruption).
• Prepare even terser (100 character) micro lessons (for use on less endowed mobile phones).
• Study learning effects (finding optimal review intervals and number of words studied per week).

Abstract: Changing demographics at many colleges has led to an increasing demand for distance education programs based on emerging network and multi-media workstation technologies. This paper describes middleware that personalizes asynchronous Internet courses featuring 1) Use of a database of related material, which differs in difficulty, assumed background and delivery modes. 2) Use of knowledge base in which the instructional material is organized as a dependency graph between the instructional topics 3) Management of the student's progress through the material based on demonstrated preparation in the prerequisite material 4) Uses of Artificial Intelligence techniques to assist in the creative process of learning concepts in discrete mathematics. We report on status of this project and plans to utilize this system for teaching two leveling courses in discrete mathematics and programming for transfer student into our computer science program. (This work supported by NSF DUE-9981039)

1. Introduction

The changing mission of institutes of higher education has led to increased interest in the use of emerging network technologies to support distance education programs. These changes have been brought about by the need for life long education in fast moving industries, desire for second career choices [Thomas91], and the spiraling costs of higher education. Aside from perceived cost advantages of utilizing computer and communications technologies for education and training, distance education claims to offer self-paced just-in-time learning which provides the efficient delivery of information to the students as they need that information. However to realize its potential, distance education requires new learning models and new methods of organizing, delivering and managing instructional material [Benyon 1997]. These models should support efficient learning (in terms of the amount of effort expended to realize goal) and they should be compatible with the life styles of prospective students, many of whom will continue to work while furthering their education. This paper describes a middleware infrastructure for asynchronous internet-based course delivery that features personalization to student progress and background.

The organization of this paper is as follows. The background section describes the motivation for this work as well as related work in the area. The next section covers the overall system architecture. This is followed by discussion of the state of the prototyping efforts. The final section gives conclusions and directions for future work.

2. Background

Of specific interest to Old Dominion University is the critical need for information technologists. One study done by the Virginia Business Higher Education Council in Virginia First 2000 (released October 1997) identifies a critical shortage of information technologists for an ever-increasing job market. Part of this need will be met by retraining non-traditional students who may already be working in a related field. These students tend to be more mature and better motivated than traditional college students. In many cases they are impatient with unnecessary obstacles that are often placed in the way of an education by traditional approaches (one size fits all lecture for instance).

Because of convenience and cost, many students choose to start their (re-) education in community colleges and then transfer to a four-year program. Recently the Department of Computer Science has initiated the TechEd program which will provide transfer students or those with an Associates Degree from a Community College with the ability...
to finish a four year degree through a variety of distance education media including broadcast TV, synchronous interactive instruction delivered over an INTRANET to the desktop, and asynchronous Web-based delivery of course material. In order for this program to be a success, it will be necessary for these students to make the (sometimes difficult) transition into our program. Because of rapid advances in information technology and a lack of uniform requirements in the introductory courses, students are not always adequately prepared for our upper level courses. Based on our experience with transfer students, we anticipate that the students enrolling in this program will have a wide variety of backgrounds, from professional programmers to students fresh out of community college. In particular their backgrounds in programming, problem solving and theoretical computer science will vary widely. In order to deal with any deficiencies; we believe it will be necessary to provide certain "leveling" courses that address any weaknesses in the student's background. Furthermore these "leveling" course will need to be personalized to the student background, learning media preferences and life styles (e.g. adapt to the student's work schedule). This will in turn require a course structure, technological infrastructure and sophisticated evaluation services that support an any-time, any-place personalized education.

One of the earlier computer based instruction systems is LISP Tutor [Anderson 1985], It helps students to learn LISP programming by detecting and analyzing mistakes. There are also systems which tailor their responses to user questions, such as UNIX Consultant (UC) [Wilensky 1988], [So 1994], Eurohelp [Breuker 1990][Winkels 1992], E-Help [Ohyama 1993], and Intelligent Help for IPS [Mallen 1996]. UC and So and Travis's system are for helping UNIX operating system users, Eurohelp deals with an e-mail system, E-Help is concerned with a text editor, and Mallen's system provides assistance to information processing system users using the designer's description of the system. Today there are a number of Web based adaptive educational systems such as ELM-ART [Brusilovsky 1996], PAT-InterBook [Brusilovsky 1997] and WITS [Okazaki 1996] to name a few. These systems except WITS have adaptive sequencing capability of knowledge units and they all do intelligent solution analysis. There is a comprehensive review paper by Brusilovsky [Brusilovsky 1998]. There is also a system CIRCSIM-Tutor [Evans] that uses natural language dialog to communicate with students.

Another application of artificial intelligence research comes from the work on automatic theorem provers. There are numerous automatic theorem-proving systems today such as HOL [Gordon 1987], Otter [McCune 1994], and TPS [Nesmith 1998] just to name a few. Of these TPS is an automatic theorem prover for high order logic. Since it is relatively easy to install and use, we have adapted it to diagnose student's answers to exercise questions in logic.

Needless to say appropriate and timely feedback through an analysis of the students' answers is very desirable. But there are many problems for which it is not trivial to even verify the correctness of the student's answers. For example when translating English into a formula of predicate logic, there are infinitely many correct answers. Even simple properties of logic, such as commutativity and associativity of and and or operators, create many variations. It is therefore necessary to have some kind of intelligence in checking the correctness of students' answers. In this project existing artificial intelligence technologies are investigated for possible use in providing solution checking and analysis. Currently TPS automatic theorem proving system [Nesmith 1998] and symbolic computation of MAPLE are used in providing solution checking.

3. Architecture

The work described in this paper is focused on providing the technological infrastructure to support two cornerstone courses for the TechEd program. These cornerstone courses will be taken for credit and are intended to provide the necessary theoretical (CS381) and practical programming (CS333) background for students entering the TechEd program. Because of the diversity in student backgrounds and the varying time commitment to complete the material, these courses will be self-paced using web technology for instructional delivery and monitoring.

The main objective of the proposed courses is to adapt to the diversity of backgrounds of entering students. Their key features are: a) Use of a database of related material, which differs in difficulty, assumed background and delivery modes. b) Use of knowledge base in which the instructional material is organized as a dependency graph between the instructional topics. c) Control by students to explore any material for which they have the prerequisites. At each stage, the student can be evaluated to determine their preparation for more advanced material. d) Management of the student's progress through the material based on demonstrated preparation in the prerequisite...
material. e) Uses of Artificial Intelligence techniques to assist in the creative process of learning concepts in discrete mathematics.

In this section, we describe the architecture to support the proposed adaptive tutoring system. We describe the course description and students profile structure followed by the overall architecture.

3.2 Course Description

The course description including the prerequisite information and requirements is represented using XML, and is similar to the proposed IEEE course description markup language

3.3 Profile Description

The student profile consists of two parts: static and dynamic. The static profile is set up at the registration time, and the dynamic profile tracks the student's progress in the course.

3.4 Software Architecture

The proposed architecture is partitioned into three tiers as shown in Figure 1. The first tier consists of student and instructor interfaces, which are realized using Java applets. The second tier consists of HTTP server along with other major components for handling student and instructor requests. The third tier consists of AI system to support automatic evaluation and databases for storing course content, structure, and student profile.

4. Status of Prototype

We have built a prototype system that implements most of the major components of our architecture and have tested the functionality of the system with the CS 381 course. The prototype system is implemented using Java and servlet technology to maintain the portability of the code. We have implemented the basic Navigation and Evaluation applets. In the second tier we have implemented all the components except the Instructor related components. For testing purposes, we have created the course description and entered into the system manually. In the third tier, we are using Unix based file system for the content repository. The Oracle database is being used to store the course description and student profile.

This prototype is the result of several previous prototyping efforts that have been used in the past three years to teach various aspects of CS333 and CS381.

Utilizing AI techniques

Learning by doing is an important strategy in developing and reinforcing the student's understanding of the material. An ideal web course would provide students with opportunities to work on exercise questions and to get feedback on their work just as they do from their human instructors or tutors. With the current technology, however, it is not possible even to accept and evaluate students' answers unless they are in multiple-choice or other restricted forms. Diagnosing student performance and giving appropriate feedback is also difficult. The discrete math exercise analyzer utilizes theorem proving techniques and symbolic mathematics to take a first step toward achieving the goal.

At this time our system is capable of doing the following automatically on Web through the use of an automatic theorem prover TPS and a symbolic computation system MAPLE:

1. Answer checking for English to logic translation
   Given an English sentence, a universe and predicates to use, students are asked to type in a logical formula that represents the sentence. The system accepts any answer as correct if it is equivalent to the stored correct answer. This equivalence is checked by an automatic theorem prover TPS.

2. Checking simple inferences
   Students type in logical formulas representing premises and a conclusion. The system then checks whether or not the conclusion can be deduced from the premises. The inference is checked by TPS.

3. Checking correctness of simple set theory theorems
Students can type in a simple theorem of set theory. The system then checks whether or not it is correct. TPS is used for proving theorems.

4. Checking proofs by mathematical induction
For example, a proof by mathematical induction of $1+2+...+n = n(n+1)/2$ is checked automatically by this system. Statements involving equalities and inequalities can be proven. Symbolic computation of MAPLE through MATLAB has been extended to provide this capability.

5. Checking converse, contrapositive and negation of statements in English
Students are asked to type in English the converse, contrapositive and negation of simple English sentences. Their answers are checked and the result is displayed.
Here simple natural language processing is used.

Currently work is under way on a system which accepts a simple English sentence and its translation into logical formula and which checks the correctness of the translation. This involves the automatic translation of English into logic and checking of equivalence between student's translation and system generated translation by TPS. Our goal is to handle the range of exercises found in a typical book on discrete mathematics.

5. Conclusions and Future Work
This architecture and the current prototype described in this paper is the result of previous systems that have been built over the past several years to support CS333 (which has been offered three times) and CS381 (which has been offered twice). Both these courses are successful and attract an increasing number of non-traditional students each offering. The development of an appropriate middleware infrastructure to support personalized progress through asynchronous Internet courses will provide a firm foundation for developing new approaches to learning. Providing alternate content presentations and utilizing the information in the dynamic profile will allow the system to adapt to the learning style, interests and background of the student. Providing sophisticated analysis of student answers using AI techniques will broaden the range of material that can be adapted to Internet presentation and evaluation.

Once completed, the new system will allow the exploration of several new areas of research. For instance, the protocol between a browser and a web server is essentially episodic. Each access to the web site is a separate episode with limited state information kept between episodes. The current implementation attempts to inject a degree of continuity by recording and reporting progress. However more sophisticated methods of dialog management would be desirable. We plan to investigate how current research in dialog management can be adapted to a web-based course.

Another area in which we have begun investigation is the use of user input capture during a problem solving session and the subsequent replay of this input by the instructor who can analyze the problem solving strategies of the student by virtually "looking over the shoulder" of the student (this may be computer assisted).

We believe that the proposed middleware infrastructure will provide the basis for a truly adaptive self-paced Internet course delivery system.

Do Gender Differences in Computer Efficacy Affect Course Grade Performance in Interactive Technology Courses?

Holly Traver, Rensselaer Polytechnic Inst., USA; Bianca Dupuis, Rensselaer Polytechnic Inst., USA

Previous research has shown that self-efficacy is related to task performance. The purpose of this research was to examine the effect of gender differences in efficacy beliefs (general, computer, and confidence) on expected course grade performance in interactive technology courses. As expected, males reported higher computer efficacy beliefs and greater confidence to do well in the course than did females. However, the interactions between gender and efficacy beliefs were unrelated to expected course grade. In other words, even though males and females reported different efficacy beliefs, males and females reported similar expected grades at the end of the semester.
Student individual differences, reactions, and learning in a molecular biochemistry course using web technology

Holly Traver, Rensselaer Polytechnic Inst., USA; Joyce Diwan, Rensselaer Polytechnic Inst., USA

Student individual differences, reactions, and learning were examined in a course that incorporates student collaboration and web technology. As expected, attitudes toward interactive technology positively impacted learning, and males reported higher levels of computer efficacy than did females. Gender differences in computer efficacy were unrelated to differences in learning gain. In addition, self-monitoring interacted with gender to influence learning gain, such that male learning gain tended to decrease as levels of self-monitoring increased; female learning gain was unrelated to self-monitoring.
Abstract: Recent cognition research has provided new tools for analyzing priority allocation for revisions and innovations in teaching, such as the development of educational multimedia. This paper introduces a methodology for seeking information about the learning difficulty (element interactivity), the students’ level of expertise and schema development, and the students’ engagement with the content (germane cognitive load) which can then be used to guide the revision and innovation. An example is provided showing how a relative cognitive demand estimates obtained from staff and students may be used as a guide to prioritizing multimedia development. The method is shown to be very easy to use, providing all educators a new method, based on recent cognition research, for systematically organizing educational innovations.

Relative Cognitive Demand

After taking over from Gil Amelio as an interim Apple CEO, Steve Jobs faced some tough questions at a public presentation about why Apple had killed off some projects, such as the Newton. His answer was that in order for Apple to do some things well the company had to focus on those things by cutting out other activities. The argument of this paper is that in order to produce the strategic innovation benefits expected in educational development and revision projects, such as multimedia or online projects, the most pressing student learning needs have to be identified and prioritized for action. Then the effort, time and funds invested to address the greatest needs will produce the best improvements for educational programs.

How might we identify the priority areas for action in the current subjects? The usual answer is to carry out a needs analysis (Reigeluth, 1999), learner analysis (Heinich, Molenda, Russell, & Smaldino, 1999), context analysis (Tessmer & Richey, 1997) or task analysis (Jonassen, Tessmer, & Hannum, 1999; Tennyson & Schott, 1997). Although some existing analysis methods already provide useful information helping to prioritize the development of learning materials for new courses or existing ones during revision (Jonassen et al., 1999, p. 17-22) it is argued in this paper that results derived in the Cognitive Load Theory framework (Sweller, van Merrienboer, & Paas, 1998) can be used to produce a cognitive demand based guide for priority allocation. A number of sources of information are incorporated and can be used to set priorities. Three major interacting factors have been identified in the Cognitive Load Theory framework, which may be used as the basis for focusing improvement efforts in innovation programs. These are: (a) element interactivity of learning content, (b) expertise level of the learner, and (c) germane cognitive load of the content.

Element Interactivity

A major finding in Cognitive Load Theory has been to recognize that the characteristics of the learning content significantly affect the mental processing demand during learning. This is an important consideration since the human working memory, the portion of our minds used for conscious problem solving and mental processing, can only deal with very few items, or chunks, simultaneously (Miller, 1956; Richardson, 1996). Thus an important consideration is how many elements does a learning task present to be processed and related to each other simultaneously, i.e. its element interactivity? For example, learning individual reserved words in a computer programming language is a lower element interactivity task than learning the procedure for a recursive process.
Each of the reserved words can be learned independently, but to create a recursive procedure the programmer needs to take into account its place in the program, the variables involved, the scope of the recursion, mechanisms for detecting the end conditions for the recursion, appropriate syntax for writing the recursion end operation, etc. Thus to create an effective recursion procedure many elements need to be identified, and their interactions considered, resulting in a large number of individual items to be processed in working memory.

The element interactivity of a given task may be analyzed by examining the number of sub-tasks and their relationships to each other (Tuovinen, 1999). For example, Sweller and Chandler (1994) analyzed the elements of locating a point on coordinate axis and identified seven items or steps in the process.

Expertise and Schema Development

This is exactly the difficulty level a new learner trying to find a point on x-y axis has to face. If the element interactivity is too great, the learner will not be able to cope with the processing demands and the learning is faulty. However, we also know that once people have located many points on coordinate axis they will be able to combine, or chunk, many of these steps together and their working memories treat these seven distinct items as smaller groups. Eventually the whole process may be treated as a single item in the working memory. The chunking of basic items for more effective processing is called schema development, and it takes place as the learners become more expert in the field. Thus a task with many interacting elements, identified as discussed above, may not pose a very large demand on learners’ working memories, and would be considered appropriate for them.

This argues for the identification of the learners’ level of prior knowledge and capability in a given area, so that appropriate instruction may be provided to them. This may be achieved by surveying students about their prior experience with content, e.g. databases (Tuovinen & Sweller, 1999). Alternatively the students’ prior schema or mental model may be evaluated, as shown by (Marshall, 1995) and (Cosgrove, 1994).

These approaches have a similar flavor to the task analysis stage in instructional design (Redding, 1995; Taylor, 1994). The earlier approaches to task analysis were based on the behaviorism, but the later approaches described in the above sources, are grounded in cognitive science. In these instructional design approaches the function of task analysis is to identify what the learner needs to be able to do after an educational or training program.

The differences between the conventional task analysis and the approach advocated in this paper are that the current approach is closely related to a robust theoretical structure which integrates human information processing, learning and instructional implications. The approach of this paper also systematically links task element interactivity and expertise, which is often vaguely, if at all, connected in conventional task analysis. This new approach incorporates analysis approaches which have been developed and tested in empirical research over more than a decade (Sweller, 1999; Sweller et al., 1998).

Germane Cognitive Load

Van Merriënboer (1999, personal communication) (Sweller et al., 1998) found that some students were not able to make the most effective use of their learning materials, not because the tasks posed too high processing demands on their working memories, but rather the opposite. The students did not adequately engage with the learning material. Thus a number of ways have been identified to ensure the students engage adequately with the material they need to understand, e.g. completion exercises (Tuovinen & Ross, 1997; Van Merriënboer, 1990), or employing a system for generalized encoding of information learned by analogy (Pirolli & Anderson, 1985).

Thus the processing demand of the learning content for students with a given level of prior knowledge must not be too high, or learning is impaired, and the students must engage sufficiently with the material for it to be beneficial. How then do we identify the relative cognitive demand in a given subject and how do we relate it to the students’ prior learning? It is the hypothesis of this paper that it is possible to obtain useful estimates of the relative cognitive demand for particular subject content.
Estimation of Relative Cognitive Demand

Expert Estimates

Many people have a good knowledge of a given course content. If these people were asked to rank the relative effort or cognitive processing demands of the various content components, a composite ranking from the most to the least demanding content can be derived by computing the medians of their rankings for each subject component (Argyrous, 1996, p. 41). If some people are judged to have a better understanding of student learning in this subject, their estimates may be appropriately weighed. Some of the possible people who could be consulted to give these rankings are: subject designers, i.e. lecturers, responsible for designing current or previous versions of the subject, educational and instructional designers involved in the subject design, authors of relevant textbooks, authors of relevant educational software, and tutors/lecturers who have previously taught the course. The data may be sought using a very simple survey form, which lists the subject components and asks the informants to rank or rate the components according to their relative cognitive demand.

Novice Estimates

Despite the best efforts of the teachers or lecturers, they are often not very good judges of the learning requirements of students. This was borne out in experimental studies on software evaluation where teachers were asked to judge the educational value of software and then their judgments were examined in light of the students' performance (Reiser & Kegelmann, 1994). Thus it is important to obtain information from the students themselves. The students are a vital source of information about the relative cognitive demand of their subject's components. Students who have recently studied a subject can rank the relative cognitive demand and give estimates of their prior knowledge of the subject parts. Their consolidated reports can form the second major category for determining the innovation priorities. A survey form, such as shown in Appendix 1, can be used.

Unfortunately the students often forget the earlier difficulties where they had to expend considerable mental energies in comparison to problems they face currently, or have met most recently. Thus their end-of-subject ratings are not as valuable as data sought immediately after they have worked on particular content components. For this reason in the evaluation of the strategic innovations student data on cognitive effort/demand should be gathered throughout their engagement with the subject.

Once these two sets of rankings of the cognitive demand of the subject have been developed they may be compared to gain estimates of the cognitive demand as shown in the following example. The cognitive demand estimates may then be used to establish priorities for educational innovation and development.

Example

The following learning analysis was carried out to find out what aspects of a current first-year university subject most urgently needed additional multimedia resources. Both staff and student data was obtained from a small number of people. Thus this is a simplified example dealing only with a small number of data sources. However, even this limited analysis helps to illustrate the process. 2 staff and 22 students in an on-campus class were surveyed (student survey instrument attached as an Appendix 1) and the following results were obtained.

Cognitive Effort and Prior Learning Estimates

The lecturers were asked to rank the relative cognitive demand of the subject objectives (see list in Appendix 1) from 1 (least demanding) to 9 (most demanding) using a simple table. Using a similar ranking scale the survey instrument shown in Appendix 1 was used to gain estimates of the cognitive effort in student learning in this subject.

The medians of the staff relative cognitive demand estimates were obtained (see ‘Lecturer Cogn. Demand’ values on Graph 1). The medians of the mental effort estimates provided by the students were computed for each objective category (see ‘Student Effort’ on Graph 1). Estimates of the students’ relevant prior knowledge were also obtained.
The medians for the prior learning survey results for each objective category were computed. These medians are shown on Graph 1.

**Graph 1: Student Estimates of Cognitive Effort and Prior Knowledge, and Lecturer Estimates of Cognitive Demand**

The greatest learning needs occur in the areas where the students have the least prior knowledge and require the greatest effort to process the new learning material. In contrast, areas where students already possess good knowledge and require minimal effort to master the work comprise the lowest learning needs, in terms of further learning process improvement. In fact, the student effort and prior knowledge graphs suggest that the greatest learning difficulties are indicated by the greatest differences between effort and prior knowledge. Alternatively, when the knowledge and effort estimates are close, the learning difficulties are reduced.

To help to identify the greatest group differences between the mental effort and prior knowledge required by the subject objectives, the median differences were computed. These were then graphed (Graph 2). The greatest differences indicate the areas that need the most educational design attention.

**Graph 2: Median Differences: Student Mental Effort – Prior Knowledge, and Lecturer Estimates of Cognitive Demand**

Priority

The median differences between the student estimates of the mental effort and the prior knowledge and the median lecturer cognitive demand estimates may be used as a basis for arranging a priority order for development effort in this subject. As noted previously, the lecturers and students do not necessarily agree in their learning difficulty...
estimates. For example, the lecturers rated objectives 2, 4, 5 and 6 as more cognitively demanding than the students. However, where they do agree, such as in rating objectives 7, 8 and 9 as highly demanding or difficult, we can be reasonably confident that we have found high priority areas for further educational development.

**Conclusion**

It is possible to gain significant information about students' prior knowledge and cognitive effort during a course of study. This information may be used to set priorities for subject revision. The technique used is relatively simple and speedy, in contrast to the more comprehensive conventional learning needs and task analysis methods and may be profitably employed by educators alongside other needs and task analysis methods.

Abstract: MeduLearning studies essential multimedia learning skills against the background of new 'literacies'. Literacy is increasingly evolving into a plural concept comprising not only traditional and visual literacy, but also general media and digital literacy on the one hand and more specific electronic and multimedia literacy on the other hand. MeduLearning envisages to trace specific skills that account for successful interaction with a multimedia programme. Two empirical studies were carried out with a multimedia strip story ('Operation Teddy Bear') about World War II. The first study (OT 1) with last-grade primary school pupils forwarded evidence for a competition of cognitive load build up by multimedia layers in the story with the linear succession of pictures in accessing historical background information. The results of a second study (OT 2) with pupils suffering from learning difficulties are now being analysed. An assumption of OT 2 is that disadvantaged children will cling on to visual cues in the strip story. The implications of this assumption for curriculum development are mentioned.

Introduction

MeduLearning is a line of thought explicitly stressing the insufficiency of the traditional classroom in meeting the need of children for skills to learn and work with educational multimedia. Therefore, essential multimedia learning skills have to be studied and a strategy for implementing the outcome of research in school curricula has to be developed. A useful starting point of research in this domain is the study of literacy, both in its traditional and new forms. Literacy is a powerful theoretical background for research into the interaction of learners with educational multimedia.

Traditional literacy and visual literacy

1962
The skill to comprehend and handle printed course materials is essential, both in school and in broader society. The International Adult Literacy Survey (IALS) describes literacy as a broad range of information processing skills in relation to written or printed language and defines traditional literacy as follows (Van Damme et al., 1997):

"Using printed and written information to function in society, to achieve one's goal and to develop one's knowledge and potential."

However, literacy is increasingly evolving into a plural literacy (Erstad, 1998) due to the growing importance of images in communication. Visual literacy complements traditional literacy and claims a unique position in today's school curriculum. Children should acquire skills to work effectively and efficiently with educational multimedia. Undoubtedly, it is indispensable to analyse the nature of the skills children need to take full advantage of today's new learning opportunities.

Still more 'literacies'

Debes (1969) first mentioned 'visual literacy'. Like traditional 'verbal' language, a specific 'image' language supports communication. Visual literacy may not only be a means of communication, but also a way of thinking (Hortin, 1983). Thinking visually, then, means the ability to think and learn in terms of images.

During the last decade, a panoply of 'literacies' related to new technologies surfaced: media literacy (Hobbs, 1998; Potter, 1998), electronic literacy (Maylah, 1993), multimedia literacy (Kellner, 1998), computer literacy (Guthrie & Richardson, 1995; Peha, 1995), and digital literacy (Gilster, 1997). Media literacy pertains to communication through printed media; digital literacy is the ability to navigate both effectively and efficiently and to keep track of position in electronic media, while 'criss-crossing the landscape' (Spiro, et al., 1991). Computer literacy is the ability to integrate information and build an own knowledge base, subsuming both electronic literacy (e-mail reading skills) and multimedia literacy (technical multimedia skills). Reading hypertext is cared for by both electronic and multimedia literacy. When comparing the different 'literacies', two observations are important. First, critical analysis, interpretation, and processing of information are attributed to media literacy and digital literacy. The processing and integration of information (computer literacy) and technical skills (electronic and multimedia literacy) have to be critically evaluated by tutees. Secondly, without the notion of traditional and visual literacy, none of the newer forms of literacy can be understood.

MeduLearning: research questions

Departing from the 'literacies' debate, MeduLearning envisaged to trace specific skills that account for successful interaction with a multimedia programme. These skills have to be integrated in the school curriculum and treated as abilities underlying new 'literacies'. The primary research question concerns the relationship between 'operational skills' (searching, clicking, and dragging objects) and content comprehension in a multimedia programme. Is retrieval of information influenced by the mastery of operational skills?

Information can be presented textually, visually, or spoken. Does the integration of different types of information in a multimedia software package breaks the typical linearity of user's interaction with the interface? This research question addresses conditions that facilitate 'switching subjects' in a multimedia programme fitted out with 'clickable' hotspots and hyperlinks. Different subjects in a single multimedia package can range for instance from an adventure game with hyperlinks to an illustrated and spoken encyclopaedia supporting the game with relevant background information. A related question points to the relationship between switching subjects and retrieving or remembering information afterwards. Is switching subjects detrimental to retrieval of information or does it on the contrary support memory?

Research studies

Platform and method
Two research studies into MeduLearning were conducted. In both studies, the platform used was an educational CD-ROM, called ‘Operatie Teddybeer’ (‘Operation Teddy Bear’ or OT). The CD-ROM presents a multimedia strip about the adventures of a 12 years old boy, Paul, during the invasion of France by allied troops in June 1944. Paul smuggles important documents stolen from the Germans and hidden in his teddy bear to Paris, where his mother waits for him. The strip story is 73 pages long. The story is animated by the addition of sounds, motion, and more. The conversations within the different pictures making up the whole strip are textual: speech bubbles flash on and off according to actions undertaken by the user. Typical actions to be performed include searching, clicking, and dragging objects. Apart from the strip story, a huge amount of background information concerning World War II is included in the CD-ROM. This multimedia encyclopaedia is accessible through so-called hotspots in the story; a fighter aircraft for instance, highlighted in the strip story, leads into background information about allied air superiority in the second half of World War II.

Both in research study 1 (OT 1) and research study 2 (OT 2) children are observed while working through the CD-ROM’s content materials. Observation data were recorded in a log-book. Afterwards, children were asked to reconstruct the story line of OT in an essay and to recall as much of the story as they still remembered. Finally, they were interviewed and attended on specific episodes in the strip where a decision to search, to click, or to drag was requested. We were interested if some sort of strategy hides behind searching for objects in the strip’s pictures, clicking them, and/or dragging them to other pictures.

The observation of children and the recording of data were executed by master students taking a course in educational technology. They were credited for their involvement. Each student observed and interviewed a primary school pupil aged 11 or 12. This age group was chosen for the first research study, OT 1, since its more explorative nature demanded pupils who were good readers with sufficient computer expertise. It could not be allowed that the exploration of operational skills would be hampered by insufficient traditional and/or multimedia literacy. In all, 63 last-graders of Flemish primary schools participated in OT 1.

Results and discussion OT 1

The primary research question that addressed the influence of mastering and executing operational skills on the reconstruction of the story-line suggested a negative relationship. While pupils’ essays were insufficient, even weak, the operational skills searching, clicking, and dragging were acquired effortlessly. Additionally, it turned out that an essay representing a story-line of a strip is a too demanding assignment for last-grade pupils after several hours in front of the computer.

The qualitative data analysis software package ‘Etnograph’ supported the analysis of data gathered. Essays and interview excerpts are coded and searched for utterances that support raw logbook data. The logbook recorded the fluency of searching, clicking, and dragging in OT, the accessing of background information, and the thoroughness of reading conversation bubbles.

Multimedia effects such as the combination of pictures, text, motion, and sound do not contribute to breaking the linearity of pictures’ succession in the multimedia OT strip. Accessing background information through hotspots and hyperlinks is limited.

An explanation for pupils’ clinging on to operational skills in a semi-linear adventure game quite like the OT story-line may reside in the ‘cognitive load’ phenomenon (Kalyuga, Chandler, & Sweller, 1999). The integration of pictures, text, motion, and sound heightens cognitive load. Meanwhile, task tension pertaining to the involvement in the rousing OT story successfully competes with the attractiveness of hotspots, opening a way to background information.

A last research question pertained to mutual support of the story-line and the background information in OT. Generally, the pupils’ essays do not contain any reference to background topics at all. Strenuous effort to keep up with the speed of the story line’s evolutions throughout OT seems to dissociate the story line and background information in the experience of children.

Finally, OT 1 produced 4 navigation patterns: (1) apathetic navigators, (2) selective readers, (3) information meeters, and (4) information explorers. Apathetic navigators pass through OT in a linear way and fully concentrate on the story-line. They ignore all hotspots giving access to background information.

Selective readers are rightly interested in background information, but often due to time pressures, they prefer first to work through the OT story line. They access background information that appeals them most.

A third group of pupils are ‘information meeters’: hotspots that are exceptionally striking are selected for further exploration. However, hotspots that are hidden in the background of the strip’s pictures are ignored and there is no active soliciting of additional information.
‘Information explorers’ learn most of the CD-ROM’s content. They consult all possible additional information and make good use of hotspots and hyperlinks, both in the actual OT story and the background information encyclopaedia.

Testing new insights

The results of OT 1 suggest that children pre-eminently view OT as a strip story. This view does not alter substantially while reading OT. Initially, the presence of sounds, speech excerpts, music, and motion in the story adds ‘movie’ features to OT. As the story progresses, children more readily anticipate story events: they look for objects in pictures that most probably will play a role in the next few pictures. Mere reactions to audio-visual events in pictures lessen. Searching, clicking, and dragging objects become increasingly well-considered. Throughout OT, visual literacy progressively changes from visual reagibility to ideational comprehension. Visual literacy is an essential condition for meeting OT’s requirements. Multimedia literacy skills are effortlessly acquired on the spot: clicking and dragging objects are no problem. Originally, visual literacy is narrowed to multimedia skills like clicking and dragging, but gradually visual literacy opens up again to more thoughtful, content driven interaction with OT.

Working with OT proved to be a strenuous activity demanding high levels of persistent concentration. Since there are some good reasons to question the essay as a criterion to measure story line recall, recall should be orally in new studies, giving more spontaneous and exhaustive output of what remains stuck in memory.

Taking into account OT 1 results a new research study was set up featuring oral recall of the story line. At this moment, we are analysing data gathered by students, credited for their participation in observing and interviewing pupils. OT 2 was designed to be less explorative and explicitly investigates the added value of OT in opening up media skills to first grade pupils of polytechnic schools, aged 12 and 13. All of the pupils selected, 27 in number, follow a special preparatory year that copes with learning deficits incurred in primary school. Main interest are performances of children with learning difficulties in OT. OT 2 questions the evolution of cognitive activity in first graders with learning difficulties. Is the assumption that children with learning difficulties will cling on to visual cues in the OT story justified? A profound analysis of log-books has to yield conditions that trigger access of background information in disadvantaged pupils.

Implications of the studies

Both research studies provide input for implementing MeduLearning in school curriculum. OT 1 drew attention to an important shift from superficial reactions to visual stimuli toward anticipation of events in the story line. Pupils seem to encounter difficulties to cope with the different layers of multimedia information: text, pictures, motion, music, sounds. The linear nature of the story-line is hardly broken: background information is scarcely accessed. Processing and integrating information from different sources is a computer literacy skill that may acquire a place in school curriculum in due time.

OT 2 will make clear if pupils with learning difficulties perceive OT as a linear story-line that is better not broken by accessing background information via hotspots. If pupils hold on to visual cues, they should be more prone to access background information and OT may be a select platform for disadvantaged pupils. In conjunction with traditional reading and writing training, computer literate pupils may cope successfully with learning difficulties. Computer literacy in disadvantaged pupils comprises technical computer skills (searching, clicking, and dragging) and cue awareness that triggers reading and deepened understanding of information content.

Networked Educational Management: 
Transforming Educational Management in a Networked Institute

ABSTRACT: Transformation of academic, student and administrative management are key elements in the institutionalisation of Internet/intranet-based (networked) education in higher education. The distributed nature of networked education demands distributed models of academic, student and administrative management. This precept is based on the writer's doctorate research, implementation of networked education at Massey University, New Zealand as well as on consulting assignments over the last six years including a five-month consulting engagement at Cape Technikon, South Africa. Some argue that networked education is essentially an alternative delivery mode and its management is thus no different than that of other modes. Others posit that networked education is a new educational paradigm and a response to the educational needs of the emerging information society, in the same way as the traditional class was a response to the educational needs of the industrial society. Management of networked education is therefore fundamentally different from conventional educational management and correlates with new forms of private enterprise management including management of the learning organization, the information-based organisation and the networked organisation. The writer proposes a new form of higher educational management for the operations of networked education: networked educational management. The following dimensions of networked educational management are discussed: its distributed nature, managing convergence, its adaptability and transitory character.

Introduction

The widespread implementation of Internet and intranet-based education (networked education) in tertiary education globally necessitates a careful consideration of appropriate corresponding academic, administrative and student management approaches. Drucker (1998, p. 100) argues that “…as soon as a company takes the first tentative steps from data to information, its decision processes, management structure, and even the way it gets its work done begin to be transformed.”

Networked education are being implemented on an exponential scale due to its flexibility, its links to the emerging culture of postmodernism (Hartley, 1995), potential to increase the cost-effectiveness of delivery (Romiszowski, 1993, June) and quality of learning (Uys, 1998) and its pertinence as an appropriate educational response to globalisation and in addressing the increase in the world demand for tertiary education (Daniel, 1998). Tiffin (1996, November) believes that the “…concept of the virtual class is the kernel of a new educational paradigm that matches the needs of an information society” (p. 1).

This paper presents some aspects of the writer's doctorate research of the last four years (Uys, 2000). It is primarily based on the action research findings of the hydi Educational New Media Centre (Uys, April 1998; Uys, July 1999) in implementing networked education since September 1995 at Massey University, New Zealand. It also draws on case studies in other countries including a five-month consultancy in 2000 at the Cape Technikon, South Africa to start the wide implementation of e-Learning.

The term "management" is used in a broad sense to describe planning, organising, leading and control (Boone and Kurtz, 1984; Newman, Warren and McGill, 1987; Schultheis and Sumner, 1989) on all levels of a tertiary educational institute. There has been a clear and consistent call from prominent writers on management and organisational design like Drucker (1989, 1995), Senge (1990), Peters (1988), Marquard (1996), Tapscott (1996), Limerick and Cunnington (1993) that these functions of management are to be practiced in an entirely new way in the context of the emerging global information or knowledge society.

A networked institute is one in which networked education has been implemented widely and strategically. Paul (1990) posits that an institution that is dedicated to the values and practice of open learning needs to have an “open management style” (p. 72). Thomas, Carswell, Price and Petre (1998) argues for the “…transformation of practices (both teaching and administrative) to take advantage of technology in order to provide needed functions, rather than superficial translation of existing practices”. Bates (1999) contends that the introduction of networked education "...will mean a thorough re-examination of the core practices of the organisation, from
advertising to registration to design and delivery of materials to student support to assessment of students, in order to analyse the most effective way of providing these services in a networked, multimedia environment."

**Conventional educational management**

The management structures of universities has remained largely similar through the ages as Patterson (1997, p. 7) points out "The historic continuity of the institution is unbroken, and many of the medieval university’s unique features remain characteristic of ample, such as ... structures of governance, such as the division of major branches of learning into faculties, and the hierarchical positions such as deans, chancellor and rector”. Over the years Higher education grew in size and complexity and "...bureaucracies became the controlling mechanism” (Garrison, 1989, p. 38). In contrast to the institutional management structures, the teaching and research functions of academic staff as professionals are typically more client oriented, less formal and less concerned with hierarchy (Paul, 1990). While institutional conventional educational management operates on a largely bureaucratic model, academic staff operate on a “collegial model” (Paul, 1990. p. 32). The anarchic model (Cohen and March, 1974) depicts the modern university as an organised anarchy which, according to Paul (1990) illustrates such ambiguities and uncertainties that it renders the traditional forms of management meaningless or inept (p. 37).

The management model on organisational level in conventional tertiary education is therefore one of tension between a centralised administrative approach and a decentralised academic approach in which the centralised, bureaucratic and hierarchical dimensions seem to be pre-eminent. The generic conventional management paradigm in tertiary education can therefore be described as being often mechanistic, formal, centralised, focussing predominantly on the local environment, insular, inflexible, rigid, bureaucratised, with strong institutional control and segmented, with a high degree of division of labour, variable participation, and often politicised.

**New forms of educational management**

In view of the new technologies and the emergence of the information age, education “...is experiencing a shift from formal, centralised, and segmented operations to increasingly complex, decentralised, and integrated levels of organisation” (Garrison, 1989, p. 38). Rumble (1992) refers to the operations of distance education as a “highly distributed system” which “looks very different to the residential or non-residential campus-based university” (p. 95). Peters (1993) contends that in the post-industrial society there will be in distance teaching institutions a “departure from a highly centralized organisation of the teaching-learning process and a move to small decentralized units which can be made transparent by the means of new technology” (p. 53). Use of such communication systems is seen as part of a large learning system that may well be a network of institutions” (p. 60).

Paul (1990) suggests that a value-driven leadership approach can address the different models of educational management and that in this approach, leadership is committed to ensure that people find meaning in life through their work by creating things of value (p. 68). Paul argues that an institution that is dedicated to the values and practice of open learning needs to have an “open management style” (p. 72) and that “those responsible for the leadership and management of these institutions must emulate the principles they espouse in the performance of their day-to-day activities” (p.22).

**New forms of private enterprise management**

Aspects like the globalisation of education, the role of private enterprise in tertiary education and pressures on the funding base impel tertiary institutes to increasingly operate in ways that closely resemble private enterprise. At the same time private enterprise is concerned with, and heavily involved in education (Drucker, 1989, p. 243; Garrison, 1989, p. 38). Organizational structures in private enterprise are becoming increasingly distributed. Drucker (1998) asserts that the “...need to organize for change also requires a high degree of decentralization” in the structure of the “new society” (p. 60). Beare and Slaughter (1993) contend that “... a business which operates on bureaucratic lines cannot compete in a post-industrial economy...” (p. 35). Marquardt (1996) describes the learning organisation as being “boundaryless” (p. 83). Two major transformations (or megatrends) in society are a transformation from centralisation to decentralisation (in effect distribution) and from hierarchies to networking (Naisbitt, 1982, p. 1).

Marquardt (1996) contends that in this “...faster, information-thick atmosphere of the new millennium... ‘old’ companies [cannot] compete with more agile and creative learning organisations” (p. xv). A learning organisation has a streamlined, flat hierarchy and is..."
seamless and boundaryless (p. 83). It is further built on networking and "...realize the need to collaborate, share, and synergize with resources both inside and outside the company... they provide a company with a form and style that is fluid, flexible, and adaptable" (p. 84).

**Networked educational management**

The writer proposes a new educational management paradigm for managing the operations of networked education: networked educational management. Networked educational management incorporates the key elements of the new forms of private enterprise and educational management. This term is chosen since a central aspect of education in networked education and the management thereof seems to be the connectivity or networking that it facilitates often across the boundaries of space and time. This term correlates with "network management" (Limerick and Cunningham, 1993) and terms that writers like Tapscott (1996) ("internetworked organisation"), Beare and Slaughter (1993) ("network organisation"), Limerick and Cunningham (1993), ("network organisation"), and Tapscott and Caston (1993) ("open networked organisation") use when describing the organisational model for the emerging information age.

Networked educational management has twelve dimensions: networking, student focussed, globalisation, transitory, adaptability, transcending time, market orientation, computer mediation, collaboration, convergence, boundary orientation and being information based. Its distributed nature and the dimensions of convergence, its adaptability and transitory character are discussed in this paper.

**Distributed nature**

Networked educational management postulates that a distributed model of management is appropriate for networked education on both learning and institutional level. The distributed nature of networked educational management is based on the new connectivity within networked education, the distribution of learning and control, the distributed nature of the Internet and intranets, and the globalisation of education.

Networked educational management has its control, power and resources distributed throughout the organisation.

Managing the connectivity that networked education facilitates is a key difference between managing the conventional class and managing the operations of networked education. The learning control as well as on-line learning and teaching materials are distributed to both local and distance students using the same interface (ie a Web browser) because of the convergence of learning modes which traditionally have been called “distance education”-campus education through networked education. This implies that the management of learning is no longer linked to physical locality (on-campus/off-campus) but distributed to study networks comprising local, distance, national and international students, that operate as virtual teams (Jarvenpaa and Leidner, 1998; Lipnack and Stamps, 1997).

Bates (2000) acknowledges the challenge to create a congruity between centralised and decentralised management aspirations in tertiary education: “When it comes to organisational structures, the challenge is to develop a system that encourages teaching units to be innovative and able to respond quickly to changes in subject matter, student needs, and technology. At the same time, redundancy and conflicting standards and policies across the institution must be avoided” (p. 181). A similar tension within the organisation of information systems activities and communications has been transcended in computer and communication systems using distributed approaches. Networked educational management can ensure conformity to central principles and standards as Evans and Nation (1993) contends, and simultaneously encourages diversity (Frederick, 1993; Negroponte, 1997 June).

**Convergence**

The convergence that networked educational management need to address finds expression on the institution level as well as the more detailed learning levels. On institutional level this convergence is increasingly occurring among educational institutions, enterprise, entertainment and the like (Evans and Nation, 1993).

The convergence that networked educational management needs to address is related to it being computer mediated. ICT is fundamental to the operations of networked education. Bates (1995) points to the convergence of telecommunications, television and computing as an important technology trend for the distance-teaching organisation (p. 45), while Tapscott (1996) highlights
convergence of computing, communications, and content industries as one of the themes of the new economy. Networked educational management needs to manage a new integration or convergence of computing, communications, and educational content.

Networked educational management deals with a new convergence of on-campus and distance learning which has been made possible through networked education particularly with the advent of Intranets and the Internet. Garrison (1989:117) notes that this convergence is "...blurring the boundaries between conventional and distance education". This is due to an increase in the ease and feasibility of simultaneously offering a networked course to on-campus students as well as to distance students. Berge and Schrum (1998:31) contends that "it is important to recognize that on-campus programs and courses may often use the same resources and infrastructure as those delivered to students at a distance".

The convergence on macro- and micro-level does not necessarily mean conformity. Networked educational management is based on a distributed or networked model (described in 9.1 above) and can therefore couple centralised (strengthening conformity) and decentralised (encouraging divergence) management approaches.

Adaptability

The turbulent and dynamic internal and external environment calls for networked educational management to be highly adaptive. It connects to the concept of learning organisations (Marquardt, 1996) in which management needs to be highly adaptive. Networked educational management is organised along a flat hierarchy and is seamless and boundaryless like learning organisations (Marquardt, 1996).

There is also a requirement for flexibility within the software and hardware for developing on-line materials itself due to the inherent flexibility of web based materials. Management of networked education also needs to be flexible in the approach to acquiring and discarding ICT in order to grow with the continuing developments in the undergirding ICT.

An adaptive approach is also required in managing the learning environment through instructional design. Adaptive hypermedia systems achieve personalised presentation (Brusilovsky, 1996). This means that educational material is presented in an individualised and possibly unique way to students on the basis of mapping systems that are created for each individual student.

JIT teaching that is teaching that can change rapidly and immediately based on the needs of students and is available when students need it (Tiffin and Rajasingham, 1995; Marquard, 1996; Mason, 1998) calls for the management of teaching to be particularly adaptive.

Transitory

Control is an integral part of management (Newman, Warren, McGill, 1987) that is directly impacted by the transitory nature of the operations of the virtual class. Networked educational management acknowledges a decrease in control, more uncertainty and therefore an increased risk in the management of digitised education (Tapscott, 1996). The central position of the student as described above (under 9.2) and the changing nature of the student body contributes to an uncontrollability of huge proportions, which challenges the essence of conventional educational management and have to be addressed in networked educational management. Networked education further provides students with the flexibility of studying at their own pace and also at their choice of place. Networked education also allows students to either study independently in a more flexible mode or as part of a group in a more structured manner.

The transitory nature of networked educational management is linked to both the transitory nature of the technological environment and that of the change process. The environment in which networked education in tertiary education occurs at the beginning of the new millennium has been described as exceptionally dynamic and volatile (Tapscott, 1996). The introduction of computers in education is seen in revolutionary terms by some (Drucker, 1989). Even the nature of the change process from conventional to networked education itself is not stable (Morrison, 1995).

The global dimension of networked educational management furthermore increases the boundaries of the institutes using networked education and exposes them to be impacted by more factors and influences from a turbulent international environment.

In the emerging information or knowledge society, education has to further contend with an exponential growth of the amount of new information available for use by organisations, governments, and businesses and people (Nugent, 1996). The growth in the Internet continues to be exponential while there are furthermore sustained, revolutionary changes in the ICT that undergird networked
education (Bates, 1995:45; Szabo et al., 1997). In the increasingly digitised environment of networked education, networked educational management needs to allow for less control and more risk-taking (Tapscott, 1996).

Web-based materials are further especially fluid due to the ease of publication and the state of continuity of Web-based materials. In networked education the materials and teaching process is in a state of continuity which is in contrast to the state of discontinuity of materials in conventional tertiary education. Once a course is on the WWW, it remains available and no special arrangements are needed to keep it continually available - special arrangements however have to be made to discontinue its availability.

Conclusion

Transformation has become a key descriptor for the environment in which educational institutes operate. Conventional tertiary educational management has struggled with a dichotomy between its centralised administrative processes and its more fluid academic processes and has been criticised for its bureaucratic and unresponsive management structures. Institutes wishing to widely implement networked education will encounter the need to also transform its management processes. Networked educational management is proposed as an appropriate objective for this transformation.

"In a time of drastic change it is the learners who survive; the 'learned' find themselves fully equipped to live in a world that no longer exists"

Challenges in Designing Communal Web-Based Learning Environments

University of Helsinki, Finland
teeum.masalin@helsinki.fi

Abstract: In this paper we will discuss the key issues of designing communal and experiential web-based learning. When designing web-based learning we focus particularly on the community of learners and the learning situation on the users' viewpoint. We see web environments as the physical and virtual environments of action, in which learners can authentically meet and act. Our thinking is strongly based on the socio-constructivist idea of learning, on communalism in learning and studying, and on the importance of physical surroundings and context in all of our learning activities. We argue that communal learning and experientiality are meaningful didactic principles when designing web-based environments. Finally we introduce a pedagogically-potential designing model for web-based learning. Our considerations and findings have arisen from the research and development project TriO (Teaching, Studying and Learning Materials in a Network-Based Learning Environment. An Evaluation and Development Project of Network-Based Learning 1999–2000), which has been undertaken in the Media Education Centre of the Helsinki University in 1999–2000.

Keywords: Communal learning; experientiality; web-based learning; learning environments; designing model; uses of information and communication technologies (ICT).

Introduction

The work of the teacher is partly changing into designing learning environments. Information and communication technologies (ICT), especially the developments in multimedia, increased communications and web-based environments, have speeded up this change. In designing these new learning environments the challenge is to find didactically reasonable designing principles for their basis.

As a learning environment, the web clearly seems to be something that we have never experienced before (Hein 1999; Vahtivuori 1999; 2000; Vahtivuori & Masalin 2000). What do we mean by the web or a network then? These concepts themselves are quite problematic when learning and teaching are concerned. There are a number of different definitions and interpretations. The web or a net can be defined, for example, as a conceptual and cultural historical artefact or a technical platform (Lintula 1999). In this paper, the web is seen as a combination of different media, ICT tools and learning practices, which can be used for obtaining information, acting and communicating. The practices are understood as established ways of human actions. These ways of acting are created and they formulate when tools, such as e-mail, the web or a groupware are used together during the learning process. (Vahtivuori 1999; 2000; Vahtivuori & Masalin 2000)

Our idea about the concept of learning environment is based on Vahtivuori, Wager & Passi's definition (1999, 266–267) that the learning environment is formed by a physical, virtual or mediated and telematic space (see also Tella 1998, 4–18), which is created for an active learning process and enhances and supports learners' possibilities for learning. The special needs and interests of the learners are highlighted. A functional learning environment offers practical ICT tools, different working methods, possibilities for interaction and dialogue, and guidance and support for the learners. We see the learning environment essentially as a community of learners where communal learning and communal culture may become real. This concept of a learning environment also arises from Uljens (1997) model of school didactics. In line with Uljens (1997), we emphasise the teaching–studying–learning process (TSL), in which studying in particular refers to the active process of the learner.
Challenges of Designing Communal Web-Based Learning Environments

According to Duffy & Jonassen (1992), the most functional learning environments are those which concentrate on the users, their needs and which emphasise a problem-based approach to learning and which take the social aspects of studying and learning into account. Our experiences and findings in different web-based learning environments strongly support Duffy & Jonassen's ideas. We see that the key issues in designing these environments and materials are: 1) paying attention to and focusing on the users; teachers and learners, as well as on the social aspects of studying and learning on the web and, 3) understanding the characteristics of time and space in learning and studying on the web. Finally, we emphasise that, in designing and exploring web-based learning environments, the whole context of action as well as different ICT tools and the uses of these, should be considered. The web very seldom creates a catchall learning and studying environment. We would rather see the web as one tool out of a large selection of mixed media, also including conventional tools and physical space, which are a vital part of this context.

Users as Designers

One key principle in designing didactically meaningful web-based learning environments is to study and understand the user's viewpoint. By user we mean the teacher and the learner who are interacting, teaching and studying in these environments and using related materials. The producers, such as manufacturers and system designers, who design the environments and materials, always have lots of preconceptions about the user. These preconceptions may be explicit, but they may also be implicit within the producers' organisational culture. The dominant producer's preconceptions of the user become embodied in the learning' environment or material. These preconceptions might not always be very relevant or reasonable in the users' viewpoint. They may even mislead the designer to create an environment which does not support the users' needs, when they are studying or teaching. That is why the social relations and discussions between the users and producers of the environment seem to be more important on the web than in conventional classroom-based learning environments. Good communicative relations and active dialogue between different participants provide a practical and also effective way of developing and creating web-based environments and materials (see e.g. Woolgar 1996). When designing these environments, the co-development of the user and the designer seems to be one of the most crucial prerequisites, when the aim is to create communal, functional and experiential learning environments in which the users willingly and effectively act and learn.

In Quest of Experiences

Hands-on sessions, experiments and learning-by-doing are often seen as important components of meaningful learning (Ackermann 1994; Jonassen 1995). Face-to-face teaching lecturers and traditional classroom-based learning are commonly supported by physical demonstrations and hands-on sessions. We argue that this should also be an objective when designing web-based learning. We see that multimedia, video, sound, animation, modelling and interactivity, especially in computer games (e.g. different edutainment software) and simulations, can create experiential and problem-based learning contexts and make virtual “hands-on” sessions possible more and more in the web-based learning environments (See Jasinski & Thiagarajan 2000). According to Gell & Cochrane (1996), the multimedia and the web, as well as other ICT innovations, can enhance learning by producing experiences. This means that, with the help of ICT, new kinds of experiential learning environments can be created. At the moment the learning materials are expanding step-by-step into a virtual “hyper- or cyberspace” in which new immersive visuality comes more and more important and documents can be flexibly cross-linked (see e.g. Aarseth 1999; Tella in preparation). The new technologies of virtual reality in interactive web-based environments will introduce in the near future the richness needed to move from the world of information to “the world of experiences” (Gell & Cochrane 1996; Vahtivuori 2000; Vahtivuori & Masalin 2000).

Understanding Time and Space

The concepts of time and space become very problematic when designing teaching and learning on the web. Learning and teaching do not necessarily have to take place in real-time, nevertheless studying and learning always take place in a physical context, in a classroom, in an office or at home. (Matikainen 2000; Vahtivuori 2000; Vahtivuori & Masalin 2000) When analysing the web as a learning environment, it should be understood as a vital part of the context used. The web cannot be detached from the physical environment and activities. We always belong to a certain time and space and culture with their limitations and opportunities. Learning and studying, like all physical and cognitive activities, are always somehow contextualised. The physical
surroundings and cultural context define and change the nature and way of our activity. This relation is dialogic and exists in both ways: when the context affects us and changes our activities, our activities produce that context.

The conclusions drawn from the observations and reflections on web-based environments, clearly support the idea that the role and specific features of the web, in a particular learning context, are important to take into account. Therefore, we see that the analysis of a physical learning environment is still a functional starting point when designing web-based environments.

In addition to the emphasised significance of physical context, the web-based learning, where the interaction and activities are primarily situated on the web, is exemplified by a lack of physical presence. This does not necessarily prove to be a barrier between learners. The feeling of presence and being on the web can sometimes be almost as real as in real life, or even more real (see e.g. Kynäslähti 1999; Welsch 2000). Slevin (2000) emphasises that this virtual rendezvous is something tangible and refers to Latour’s (1998) idea of virtuality: "... not as something which is disembodied, but something which is more material than real." Interaction and activities can be very rich and meaningful, even if all the learning activities are mediated. Even emotions, which are a crucial part of the communal learning process, can be delivered through media. How the community of learners will succeed in this, depends a great deal on the teacher’s ability to give guidance and support for collaboration. If a comfortable and good atmosphere is created, and good ICT tools are given for communicating and acting, learners can talk and exchange their ideas the same way as in real life. New kinds of learning communities can be built in which learners can participate with people who have common learning interests. It is essential for the successful communal learning and the effective learning community on the web to aim at creating the kind of learning situation and context, which supports the dialogue, and the social dimensions of learning.

Supporting Web-Based Learning Environments through the Use of ICT

Information and communications technologies can enhance and facilitate the learning process in many different ways. We outline here some aspects of learning and technology. Our thinking is based on Goldsworthy’s (1999; 2000) thoughts of how technology can support and facilitate learning. We use here the term “technology” to refer to information and communication technologies (ICT). Here we briefly present our model which includes four overlapping categories describing the different uses of technology facilitating learning. (See fig. 1) We also analyse how the communal modes of studying are taken into account in each of these categories. (Vahtivuori 1999; 2000)

Figure 1: Different uses of ICT in Web-Based Learning Environment (Vahtivuori 2000)

Pedagogical Use of ICT
This category describes that learning can be facilitated by having content explicitly taught by a technical application or software package, with the learning material embedded in the technical appliance or software package itself (Goldsworthy 1999). Knowledge and skills are often mediated through the activities arranged in the software environment. It should be considered that this kind of use of ICT can be defined as pedagogical use merely on the condition that material or software used are didactically reasonable. This requires high professionalism and pedagogical skills from the teacher. In our viewpoint, this facilitation category does not support communal learning directly, but it is an essential and commonly used part of the learning process and offers possibilities for problem-based learning with some elements of communal learning, e.g. especially when using simulations, games and entertainment software.

**Instrumental Use of ICT**

This use of ICT represents a common way of understanding the meaning and the use of technology in learning. It describes how technology enhances an individual's capability and efficiency when working on learning materials (Goldsworthy 1999, 59). Technology is considered a tool, in a way, as for instance a book, a leaflet or a pen in a more traditional learning environment. The instructional use of ICT can also support communal learning activities, but its ethos is mainly individual: one student working and interacting with the ICT tool.

**Communal Use of ICT**

This situation represents a more communal way of learning. Skills and content are learned through the structuring of the situation, where a group of students shares a number of computers housed in a common place. Activity and interaction are informal and improvised. Affective changes related to computer use and motivation, as well as the attributes of particular computer applications, could affect how students learn around technology. Co-operative and collaborative learning tasks are very effective and usable ways of structuring computer environments, in which students often learn as much from their interactions around the computers as they do from their interactions with them, as is described in the “pedagogical use of ICT” category (Goldsworthy 1999, 59; Vahtivuori 1999; 2000). In the communal use of ICT, students can share physical and virtual working space at the same time. Students, for instance, can solve problems; write reports and investigate together. This way of using technology supports communal modes of studying and learning and enforces the interaction and dialogue between students and teachers in a technology-generated situation.

The interaction between technology and learning may vary, depending on the way it is explored. One way is to investigate whether there is an improvement in performance on computer-based tasks, as a result of group co-operation and communal learning. The other is to investigate whether certain types of software actually facilitate the co-operative and social behaviours of learners. In all likelihood, this is a complex reciprocal relationship dependent upon the nature of the task, the attributes of the software, the physical and social surroundings, the teacher's pedagogical thinking and choices and composition and cohesion of the group. (Goldsworthy 1999, 59–62) We see that the this facilitation category is the most promising and fruitful way to organise communal learning situations in a web-based learning environment.

**Communicative Use of ICT**

Time learning occurs primarily through the interaction of learners at a distance, as mediated by computer technology, the learning may be considered as facilitated through technology (Goldsworthy 1999, 59–60). We called this here the communicative use of ICT. This use of ICT describes the situation in which the social organisation and interaction are mediated. This is the classical distance education (DE) situation (see e.g. Tella 1998). The key here is that participants are learning more from one another than from the computer itself; the computer is acting as a conduit for their interactions, enabling students to become separated in time and space. According to our experiences, this can easily cross over with the "communal use of ICT" facilitation category. For instance, the groupware may help the communicants through structuring the participants' interactions and other learning activities.

We find the described model and these described distinctions useful because they remind us of the complex role of ICT in communal learning. They help us to identify the different uses better and to find the key aspects and principles when designing communal web-based learning environments, and also to make reasonable choices. In these environments, it really seems to be vital to understand technologies as tools to think and act with. If we are aware of these various uses of technology as designers and teachers, we can support the students' process of learning in the best possible way and design communal web-based learning environments.
Conclusions

One of the main objectives of this article has been to understand the characteristics of the teaching–studying context of web-based learning environments and to outline the complex role and significance of the technological tools in a learning community, when designing web-based learning environments. Our reflections and findings are based on experiences on developing web-based learning environments (see Tri0 project http://www.edu.helsinki.fi/media/trio/english.html)

The first aspect that is important to take into account is the role of the user. We argue that the user should play an active role in the designing process for the environments and materials to be effective, to help the studying community in the learning process and to help to choose from the available tools those whose use would be most conducive to learning. The designers and users should collaborate in designing these environments. The web can give new opportunities for students and teachers to act, to teach and to learn.

The second design principle is highlighting and understanding the nature of hands-on experiences on the web. When seeking experiences, we see problem-based learning, with web-based games and role-plays and simulations as functional and promising examples. In interactive games and simulations we can regard the social and communal aspects of learning as real and authentic. Games and simulations are also immersive, so emotions are taken into account along with cognitive and intellectual aspects of learning.

One of our arguments is that the web very seldom constitutes itself a catchall learning environment. The web should always be used and understood as a part of some broader context of learning and activity. For the teacher, it is important to analyse what the role of the web is in a particular learning context and what makes it possible or not. According to our experiences, the web seems to work at its best, when it is specifically chosen for a particular task, from a larger selection of tools. So, the third designing principle in communal web-based learning environments according to our reflections is to consider not only the activities and context in the web and virtual world, but also the physical and cultural context of learning where the web is used. We argue that all the other designing principles of web-based environments can be built on physical learning environments.

Especially when designing communal web-based learning environments, it is essential to analyse the specific features of each tool used and the different uses and strengths of the technological tools. How does each tool supports dialogue and communal activities and how can it be used in the learning community? Where and how a particular tool is used and best suited seems mostly to depend on the user, the physical context and the particular culture of the learning community. The designing models, such as the one we described, can help the teacher design and organise a learning environment in practice. They can also help to understand and to synthesise the roles of the different tools and also their strengths.

When considering these points in designing web-based environments and materials, we can gain deeper understanding about web as the context of learning, studying and teaching and also get closer to environments which really support communal learning, while meeting the community needs for meaningful learning on the web.

Experienced Teachers as Novice Knowledge Builders in Online and Face-to-Face Environments: Informing Professional Development

Jan van Aalst and Cher M. Hill
Faculty of Education, Simon Fraser University
8888 University Drive, Burnaby, BC, V5A 1S6 CANADA
{vanaalst, chill}@sfu.ca, http://www.sfu.ca/~vanaalst/edmedi1.pdf

Introduction

The goal of our research is to understand better how to provide professional development to teachers who are beginning to use Bereiter and Scardamalia's (1996) knowledge building theory in their classrooms. The study is a response to several calls for more attention to what the teacher must learn to be able to support an inquiry-based classroom culture (e.g., Keys & Bryan, 1999). We interviewed eight experienced teachers (experience range: 4-24 years) after they had taken a course on inquiry-based approaches to teaching and learning science (total enrollment: 18 teachers). The teachers used an online discussion environment, Web Knowledge Forum™, to discuss classroom activities and readings between class meetings. (Because the course was located in a Northern Canadian community, the class met on alternating weekends for two 4-hour classes.)

A section of the course focused on knowledge building. The teachers were first introduced to some video-based examples of knowledge building in elementary schools, and read an article (Scardamalia & Bereiter, 1996). Following this, they began to contribute their questions and theories about electricity to the online database and read an article on benchmark lessons (diSessa & Minstrell, 1998). During the following weekend, they completed a series of simple activities with batteries and bulbs, and began to develop conceptual models for the phenomena they had explored, using concept maps. In the following weeks, they discussed questions left open by this work. As the discussion evolved, the teachers had an opportunity to experience a dialectical interaction between contributions to the database and classroom activities. For example, experiments were tried in class as a result of contributions to the on-line discussion, and reading material was taken to a subsequent class in order to shed new light on one or two conceptual issues.

In the study we analyzed statistical data of online interactions, their quality, reflections on the course, written after each class, and verbatim transcripts of one-time interviews. This paper focuses on the interviews. Teachers were asked about their educational and professional histories, pedagogical beliefs, experiences in the course, understanding of knowledge building, and ideas about implementing it in their own classrooms. The interview questions and initial codes were informed by the knowledge building principles and a content analysis of the Knowledge Forum™ database. We report the main themes of what proved to be difficult for these teachers in relating the underpinnings of knowledge building theory to their beliefs about teaching and learning.

Results

Understanding limited to surface features of knowledge building

Although the teachers accepted that collaboration can enhance what an individual is able to learn, they were less open to some key aspects of knowledge building—metacognition, knowledge as improved over time, and knowledge as communal. For example, no teacher referred to the progressive nature of the knowledge building process: when a problem is understood at one level, learning resources are reinvested into understanding the problem at deeper levels (Bereiter & Scardamalia, 1993). Some teachers who understood the emergent nature of learning goals in knowledge building, were concerned about the fate of misconceptions. Such concerns usually were connected to the need to cover a prescribed curriculum and a fear of how misconceptions might hinder future learning. Statements made by some teachers indicated a belief in certain knowledge, the idea that knowledge is absolute and unambiguous (Schommer, 1990). This limited understanding of the core principles of knowledge building may have contributed to the erroneous belief of some of the teachers that knowledge building is something that “happens all the time naturally” (DR, 192) or that “educators are using (knowledge building) but not calling it that” (RC, 165-166).

Face-to-face and online discourse

1980

Page 1930
The teachers saw the value of the online environment primarily in the possibility to comment on each other’s ideas and to communicate with distant classrooms. Most teachers saw the online discourse as the characteristic feature of knowledge building, but did not recognize that each medium provided different affordances. (Asynchronous discourse can be more intentional and more reflective than synchronous discourse.) Some teachers stated a personal preference for a particular medium or raised issues about which they were passionate. For example, one teacher felt strongly that children spent too much time in front of screens (TVs and computers) and therefore did not support the use of computers to have children share ideas; she stated her personal preference for face-to-face interaction versus interaction with others via a computer screen.

Individual differences

We observed several individual differences among the participants in the study. (1) Preference for different discourse modalities (face-to-face versus online). (2) Experience and comfort level with computers. And (3), interest in the topic – a principled understanding of electricity. One teacher noted that she was motivated to contribute to the online discussion as part of the electricity inquiry, in which she was interested, but not to follow up on other class activities, in which she was less interested. Further, most teachers could see that knowledge building could work for some of their students, but did not believe that any given topic could hold the interest of all of their students. One teacher was concerned about a substantial number of her students with “behavior problems”, and students who had low prior achievement, especially in reading and writing.

Conclusions

The study allowed us to gain some insights into how to provide professional development for teachers interesting in knowledge building. First, our findings suggest that there may be a hierarchy to the ideas underpinning knowledge building. For example, the idea of collaboration was less problematic for teachers than some other aspects like progressive problem solving. Thus early in the life of a knowledge building community we may find only some aspects of knowledge building represented (van Aalst & Chan, 2001). Examples of progressively more sophisticated knowledge building discourses may give teachers a better sense of what to expect in the early phases of implementation. Second, the mutual roles of the face-to-face and online discourses is easily misunderstood and should be examined explicitly in working with teachers. (This also applies to the role of hands-on activities.) Finally, it appears that teachers could benefit from empirical evidence that shows how students of diverse interests and abilities can participate in and benefit from knowledge building, especially in light of external expectations such as the prescribed curriculum.

Abstract: One of the central notions of the ARIADNE learning platform is a share-and-reuse approach towards the development of digital course material. The ARIADNE infrastructure includes a distributed database, called the Knowledge Pool System (KPS), which acts as a repository of pedagogical material, described with standardized IEEE LTSC Learning Object Metadata (LOM). Web-based tools enable content developers to describe their material, course builders to search for appropriate material to include in their courses, and course managers to develop, maintain and distribute computer-supported courses. It is important that a learning platform such as ARIADNE is open to external components, so that dedicated tools for the specific needs of a particular audience can be added to the generic toolset. In this paper, we will discuss several modules we have added to the general ARIADNE infrastructure. These modules include template-based delivery of web courses, a workspace application for sharing documents, a discussion platform for asynchronous communication, and an online questionnaire system. Based on our experiences, we have further refined these components, so that they can be applied more widely in the future.

1. Introduction

The concept of share-and-reuse for educational resources is obvious when one considers how hard it is to produce good quality digital material for education. In order to promote this collaborative approach to computer-supported learning, the ARIADNE Foundation provides a distributed infrastructure for the production of reusable learning content, its description, storage and discovery, and its exploitation in well-structured courses [Forte 1997]. The core of the ARIADNE infrastructure is a digital library of reusable educational components, called the Knowledge Pool System (KPS) [Duval 2001].

2. Knowledge Pool System

In ARIADNE, the term Knowledge Pool System refers to a large store of electronic pedagogical material. The KPS is in essence a distributed database of multimedia pedagogical documents (the data) and their descriptions (the metadata) [Cardinaels 1998]. It is important to note that the KPS can include any digital material. There are no restrictions on the format. As such, the term document should be interpreted in a very wide sense, including educational applications like simulations.

ARIADNE metadata are compatible with the IEEE LTSC Learning Object Metadata standard (which is in fact based on earlier ARIADNE work). They can be regrouped under several categories [Duval 2000]:

- General information (title, authors, language, etc).
- Semantics of the underlying pedagogical document (discipline, concepts, etc).
- Pedagogical attributes (end-user type, document type and format, difficulty, etc).
- Technical information (size, platform requirements, etc).
- Conditions for use (usage, price, etc).
- Meta-metadata or information about the description rather than the resource (indexer, validator, etc).

In order to describe documents (i.e. to generate metadata for them), an indexation tool that interacts with the KPS has been developed. This tool basically prompts the indexer to provide values for the elements in the ARIADNE educational metadata set. Document type specific ARIADNE authoring and segmentation tools can even generate some of these values automatically. ARIADNE also provides a query tool for searching the KPS, so that the rich set of metadata really becomes useful to an end-user. The latest version of this tool has a web-based interface [Verhoeven 2001].
At the moment, the KPS contains about 3000 documents. Roughly 25% of these documents can be considered as active, i.e. they require a reasoned action by the learner (an exercise for instance). The remainder of the documents is expositive, i.e. they require the learner to listen, read or watch (a video clip for instance). Most expositive documents are text documents.

3. Web-Based Learning

Within ARIADNE, a Web-Based Learning Environment (WBLE) has been developed for the creation, maintenance and distribution of courses [Macowicz 2000]. Using the ARIADNE WBLE, an educator can

* create and maintain pedagogical curricula, incorporating learning objects from the KPS, and
* distribute these curricula to students with minimal follow-up.

The ARIADNE Management Interface (AMI) allows educators to edit courses, to transform them into web sites, and to maintain and deploy them. Once deployed, a course is available to students for computer-based training through the ARIADNE Learner Interface (ALI). Using a normal web browser, students are guided towards relevant material and information.

An ARIADNE course description includes general course information (title, summary), and an overview of all sessions within the course. References to internal (within the KPS) or external (not within the KPS) documents can be linked to one session or all sessions. The translation of a Course Description File (CDF) into a web-site is done automatically.

4. Extending The ARIADNE Web-Based Learning Environment

4.1. Template-based Look & Feel

In the current version of the AMI, the translation of a course description into HTML always looks the same. Some teachers however may want to change the look & feel of the generated web site for the specific context of their users. A solution towards this problem consists of integrating a template-based generation system within the AMI. Several approaches are possible. One could imagine dynamic generation of pages using some web server extensions. Another approach could consist of using XML and XSL for transforming a CDF into a web course. Because the current AMI implementation generates the necessary pages once (no on-the-fly content), another approach was taken. Using Freemarker [http://freemarker.sourceforge.net], an open-source implementation of a template-based HTML system, an extension or plug-in for the AMI was constructed.
Within Freemaker, the source code for a template is an HTML document that contains special directives for including dynamically generated data. Software has been developed for mapping a CDF to a data tree structure. Figure 4 illustrates this mapping for a course with 4 sessions. Figure 5 illustrates how a template uses this tree to generate the appropriate HTML.

### 4.2. Forum

The ARIADNE infrastructure, focused on share and reuse of pedagogical documents, does not include interaction facilities for communication from students towards educators, or between students themselves. In order to support these additional interaction facilities, the ARIADNE learning platform has been extended with external components or modules. We have developed a discussion platform for asynchronous communication between students and educators. The use of an online discussion system has some obvious advantages like public availability on a twenty-four hour basis, the ability to reuse an answer when the same or a similar question is asked, and the possibility to post questions as they arise during study. Because most existing implementations have too much/few functionalities and they can’t be customized easily, we implemented our own web-based threaded discussion system.

Students as well as educators can participate in online discussions from within the generated web site of a course. Our Forum implementation, based on MySQL [http://www.mysql.org] and PHP [http://www.php.net], provides some interesting features, like:

- email notification of authors if a reply article is posted,
- email notification of moderators if an article requires their attention (students can enable this option when posting a question),
- attachment support (articles can be augmented with several file attachments),
- relevance indication for threads (moderators can mark certain threads within a forum as especially interesting; it is possible to define several levels of relevance within a configuration file),
- generation of an all-in-one version for a discussion group, which can be distributed as a FAQ (Frequently Asked Question) afterwards, and
- GUI customisation through the use of cascading style sheets [http://www.w3.org/Style/CSS].

```
<email notification>
</email notification>
```

```
<attachment support>
</attachment support>
```

```
<relevance indication>
</relevance indication>
```

```
<all-in-one version>
</all-in-one version>
```
A recent add-on consists of the possibility to post mathematical articles within a discussion group. Using MATHML [http://www.w3.org/Math], an XML-based language for expressing mathematical content, several formulas can be included within a post. Based on a commercially available system [http://www.webeq.com], we developed a server script capable of transforming a MATHML string into a picture. We integrated this script within our Forum system.

4.3. Workspace

In a collaborative learning setting, students work together on an assignment, discuss the content of a course session, or share insights to solve a problem. Electronic aids like document sharing systems can help students perform these tasks. Our Workspace application enables students to upload and structure documents using a web interface.

As it may be difficult for educators to keep track of who has done what, or whether some students need help (either technical expertise, or with their planning), a matrix add-on with annotation and deadline support has been developed. For instance, if a course requires students to perform several group assignments, a matrix can be used to show the relevant documents for each assignment for all student groups. Besides a deadline, an educator can associate annotations with a solution for an assignment (a cell within the matrix overview). Public annotations are visible for everyone and typically used for scheduling meetings. Private annotations are visible for educators only and typically used for grading.

Figure 9 illustrates the matrix concept. For a course called IPS, two assignments (columns) have to be made by three student groups (rows). There is a public annotation for the first assignment of the second group (a meeting); the third
group failed to reach the deadline for the second assignment (the number of uploaded files is zero, that is why the title is coloured red).

4.4. Questionnaire

Online tests are an interesting tool for helping students auto-evaluate their progress and knowledge. ARIADNE supports this type of self-assessment with the QuizCode toolset [http://www.codeonline.com]. Using a simple authoring environment, educators can create and distribute quizzes. Students can try to solve these quizzes online; they immediately receive appropriate feedback. Finally, educators can interpret the different answers using an analyser tool. The current implementation of QuizCode is XML based, which enables us to develop an additional component to overcome some important limitations. For instance, formatting of questions is difficult, there is no support for mathematical formulas, and it is not possible to associate metadata with a question. The solution towards this problem consists of a lightweight web implementation of the QuizCode viewer for solving quizzes.

![QuizCode Author - Questionnaire - QuizCode Viewer - QuizCode Analyzer](image)

**Figure 10: Questionnaire**

Our Questionnaire application has some interesting features as opposed to the original QuizCode viewer software. These include ...

- Full HTML formatting of questions.
- MATHML support for the inclusion of mathematical formulas within questions.
- Regular expressions as answers:
  The answer can be expressed as a pattern rather than a case-(in)sensitive string. For example, if the answer to a geographical question is the USA, then also United States of America should be considered as correct.
- Metadata for questions:
  Students use this metadata for generating a quiz based on their selection needs. If for instance the metadata includes a topic and a difficulty indicator, a student can compose a quiz with easy questions on topic X and Y.
- GUI customisation of the student web-interface through the use of cascading style sheets [http://www.w3.org/Style/CSS].

*Questionnaire* is compatible with the QuizCode authoring environment and most features of the analyser tool. There is support for 8 types of questions: multiple choice, radio button (a multiple choice question with only one correct choice), word, essay (this type of question cannot be graded automatically), graphical, numerical, fill-in, and true/false. For the moment, the inclusion of the extra features is done by hand.

5. Experiences

The extended ARIADNE infrastructure was used during the academic year 1998-1999 within the Electronic Student Counselling project sponsored by the K.U.Leuven [Van Duren 1999]. The aim of this project was to create a virtual guidance environment for first year students. The experiences gained from this experiment led to the development and refinement of several ARIADNE add-ons. In 1999 another project sponsored by the K.U.Leuven started. The aim of this project was to construct an electronic environment supporting guided self-study, demonstrating that online collaboration and online learning communities can impact and enhance the learning process. During the academic year 2000-2001, several courses use our ARIADNE-based environment. These include a first year
programming course, a course on information and programming constructs, and a course on human computer interaction.

We will evaluate the quality of our ARIADNE-based guidance environment at the end of this semester through doing a study for mainly examining the functions, interface, content, and learning experiences by means of questionnaires that embrace specific questions. We can now already observe that …

- **It is sometimes hard to involve educators.**
  
  The Internet is all about sharing and cooperation. A good number of educators are clearly prepared to integrate this spirit within their teaching. Others however are rather reluctant towards this idea. They complain that, after an initial effort, an educator is forever in a continuous process of assessment, modification, learning modern techniques, and implementation. We believe that this has in fact always been the case. The web has just introduced different details and a new medium to stimulate learning in a more effective manner than before.

- **It is sometimes hard to (actively) involve students.**
  
  Our computer science students have almost no trouble in taking full advantage of the power of our web-based guidance environment. A recent experiment with students from another department showed that, although the Internet is very popular today, not all students are willing to interact within a virtual environment.

- **A tighter integration of several plugins with the existing ARIADNE toolset might be useful.**
  
  Students and educators interacting with the different modules within our guidance environment often need to authenticate themselves. For the moment, most modules have their own authentication mechanism. A shared authentication service would be appropriate to solve this peculiarity. Work is being done for integrating LDAP-based authentication [http://www.innosoft.com/ldapworld/] within ARIADNE.

ARIADNE supports multilingualism both in the KPS and the WBLE. Within the AMI, a course manager can select the language for a web site to be generated. Our components however provide an interface in one specific language. Thus, making these components multilingual is also on our to-do list.

6. **Conclusion**

Using the extended ARIADNE infrastructure enables educators as well as students to work together within a virtual environment. Educators can share pedagogical material using the Knowledge Pool System. A web-based learning and guidance environment enables them to stimulate students creatively. Students interact with multimedia material, discuss within several fora, try to solve some quizzes, and share documents with each other. An ongoing extensive evaluation including user inquiries (students as well as educators) will provide us with the necessary insights for further developing, extending and promoting our virtual environment.

Abstract: The theme of this paper is the problems associated with pedagogy of initial computer literacy education for adult learners in South Africa, and more specifically the learners' interpretation of iconic symbols of the Microsoft applications. In a first phase of a study of 21 students in such a course we found that it was not, as we had assumed, the language of learning (English, which is a third or a fourth language for them) or experience with electronic technology, which posed a problem. The major obstacle for these learners was the lack of knowledge of the root metaphor of the Windows and Microsoft Office GUI interface. They had little, if any, everyday experience of life in an office, and therefore the ostensibly simple and straightforward icons that were derived from the physical space of 'the office', were not known to them. The icons were thus mostly used as 'semantically limited' tools.

Context and Framework

In this paper we will argue that a first encounter with computer technology reveals person-technology dynamics that vary in different contexts, and that the notion of the 'office' as root metaphor for Microsoft applications can in itself be a marginalizing agent. In a developed world setting, adult learners often experience typical difficulties in becoming competent as e-learners and communicators. These may be navigational problems and the general clumsiness and apprehension with which first-time adult learners approach the interface. However, in a developing country, such as South Africa, with its unique socio-political history, the majority of the present generation of adult learners did not receive exposure to environments such as the 'office' as workplace. Students that were earmarked by policy of the state for manual labour or for a service vocation, do not have the everyday knowledge of the mechanisms of 'the office', a place that was known to an elite in the corporate world and to selected whites who formed the civil service. If learners with this type of background then learn to apply symbols linked to this metaphor, they do so with limited semantic backup¹, or by means of a rerouting of the analogy, both of which take up more time and slow down their learning process.

With this phenomenon in mind, we have set out to capture more detail about the activity at the interface in a longitudinal study of three years, the first findings of which will feature in this paper. The focus of this paper will thus be the data emanating from a thick description (Merriam, 1998) of a very first encounter. We approach this study not only from the position of what Nardi (1999) refers to as 'information ecologies' (an approach that we find essential in teaching computers to what has been until recently a predominantly oral culture with many students being first generation literates), or from a general Human Computer-Interaction (HCI) perspective (Preece et al. 1994). We also approach the inquiry from the specific position of cultural linguistics as propounded by Palmer especially (1996), with emphasis on the use of metaphor and the activation of relevant schemata in learning new procedures and skills. Palmer (1996) refers to Lakoff and Johnson (1980), who use the phrase "experiential gestalts", by which they meant "ways of organising [multidimensional experiences] into

¹ We use this term with some care, meaning that the symbols do have meaning, but only superficial operational meaning.
structured wholes". Single acts, especially using metaphors as organising principle, invoke a whole array of life experiences and coherence-making mechanisms, which invoke networked images (also linguistic images) that are used to frame and to found new knowledge construction. Palmer argues (1996):

> We have the cognitive ability selectively to focus attention on different components of complex mental images, to consider them from different perspectives, to zoom in and zoom out mentally, to trace paths through them, to turn them over in our minds, and to experience them as processes, that is, to play them back in our minds and view them at different phases, This sort of construal and reconstrual probably applies to all kinds of imagery, from complex social scenarios to elementary special schemas, such as container, link, and source-path-goal. The relations that arise between various construals of image-schemas have been called "Image-Schema-Transformations" (Lakoff, 1987:440 – 444; 1998: 144 – 149).

The recognition of a metaphor, or any other sign or symbol for that matter, does not mean a linear recall of meaning. The meaning is reconstructed through many processes of reconfiguration of images and other knowledge schemas. Viewing learning of the interface at the interface, although epistemologically radically constructivist, at the same time also invokes a social constructivist and sociocultural view, because of the role of life experience in the reconstructions. A perspective that focuses on individual learning, but against the backdrop of a broader sociocultural perspective, is of activity theory, which we also use in our interpretation and framing. Nardi (1996), who proposes that activity theory is a viable analytical and descriptive tool for HCI research, maintains that it has been recognised that "technology use is not a mechanical input-output relation between a person and a machine; a much richer depiction of the user’s situation is needed for design and furthermore says that it is not clear how to render this portrayal that is not simply ad hoc. She proposes that activity theory can be used as tool to study the interface and to explore HCI in rich matrices of understanding.

Two other activity theorists (Cole & Engeström, 1993) argue that language, as mediation tool, is the ‘master tool’ of learning. We add to that, that the linguistic imagery which Palmer (1996) uses as central concept to propound the theory of cultural linguistics, captures the role of language as major constituent of the reconstrual of imagery, which Lakoff speaks of (Palmer, 1996). For the purposes of this inquiry this means that ‘office’-like analogies will presuppose schemata for office life (as well as the language to label this) from which to draw the reconstrued procedural knowledge that is needed to perform certain functions at the interface. Whether these are in the representational form of concrete objects or of abstract symbols (Preece et al. 1994) is not really the issue here, and whether the original symbol was presented in linguistic form or not is not of primary importance – the reconfiguration of images and the reconfiguration of meaning are the issue and that, we claim, is networked and fuzzy. Without a clear root metaphor the fuzziness can become a major obstacle in cognitive functioning, because the organising tool is not known (well enough). From this position we argue that during encounters at the interface, and more so with specific reference to first encounters, that the learning of skills and the mastering of tools are only part of the human activity that constitutes consciousness, and that human consciousness includes a socio-historical and cultural matrix (Nardi, 1996) in which activity is embedded. If the analogies used are too strange, the cognitive burden becomes heavier, and progress is retarded.

Additionally, we argue that consciousness is expressed and communicated mainly through human language. Thus, when African teachers, who use English as a third or a fourth language, meet with computers for the first time, they do not meet with a tool or instrument only, they also meet with a way of life that has been constructed in the think-tanks of societies that they do not know very well, and which can appear hegemonic, managing their knowledge construction and access to information, and using the powerful world language. Their first encounter may again affirm what these learners were made to believe in a life of indoctrination – cognitive and personal autonomy is not within their reach. Warschauer (1999) addresses this issue of equity (and equality) and refers to the renowned scholar, Manuel Castells, who has investigated the role of e-equity and who has concluded that the "global village" consists of "customized cottages". Disempowered inhabitants of the "cottages" in Africa (where only 0,6% are connected to the "village", 98% of which reside in South Africa) cannot appropriate a "village" discourse if they do not comprehend the basic tool of the interface in an emancipated fashion. Unless they do, they will continue to ‘copy’ and execute orders and ‘commands’. They may, also therefore, from the very beginning, believe that computers are used as instruments and are not extensions or prostheses of the personal and the communal mind, or networking agents in distributed cognition (Di Sessa, 2000 & Brown, 2000). We argue that this type of appropriation could perpetuate the knowledge and information hegemony, with the knowledge economy functioning at the table of the ‘e-lite’, the first generation of e-literates, and thus also the inhabitants of the ‘first’ world. Initial contact with computers, we believe, should thus send a clear message that personal autonomy is valued and that understanding is empowering.
As we have become aware of the complexities involved in first encounters through many years of education and training with African adult learners who were educated for the most part of their lives in the educational system of apartheid, we wished to capture the detail of this encounter, trying to give a thick description of activities, events and qualities of a group of teachers’ first interaction with the computer. Our aim was not only to describe their interpretation and use of signs and symbols on screen and in communication, but also ultimately to try to assist them by designing a training package that follows a different and culturally-experientially more effective route, using additional analogies as supportive analytical tools where necessary. We also wished to capture their personal interpretation, their perceptions and experiences upon this first encounter as possible evidence for the claim that, according to activity theorists, consciousness “is not a set of discrete, disembodied cognitive acts (decision making, classification, remembering), and certainly it is not the brain: rather consciousness is located in every practice: you are what you do. And what you do is firmly and inextricably embedded in the social matrix of which every person is an organic part. This social matrix is composed of people and artefacts” (Nardi, 1996). The social matrix of the designers of the interface can hardly be a universal template in which different matrices can be placed or forced, especially if the matrices of those who need advancement and access most are delayed in their progress, due to the exclusivity of the metaphor. Designers in the think-tanks of the great IT companies, spending vast amounts of money and resources on research and development, construct products that address an audience who will decode their registers and who will interpret their genres successfully, otherwise their profit margins will shrink. For the masses that need to still join the knowledge economy the decoding of the interface and the interpretation of its genres need to be made more ‘affordance-able’, assessing their ‘zone of proximal development’ or ZPD (Vygotsky’s term for the cognitive space that is eligible for learning with scaffolding [Newman & Holzman, 1993]). Our inquiry looked at the way novice computer users respond at the interface - how their social matrices fit the templates of Silicon Valley, the systems from Seattle and the machines from Dublin, and how the tuition addresses their ZPD.

The Inquiry

We identified a group of 21 practising teachers who are enrolled to participate in a basic computer literacy course. They entered the course as novices, and in a typical two-day program we investigated their experiences. We worked with the whole group of 21 students for in-depth description and analysis of what they said and did during these workshop sessions, using a number of research activities:

1. Upon entry they completed a battery of English language proficiency tests that assess speaking, listening, reading and writing. The texts contained many of the linguistic terms associated with icons and other signs and symbols that feature in the introductory course on computer literacy. The aim of this assessment was to evaluate students’ language use for communicative purposes generally, but also in the register of the GUI and of MS Word. These ‘tests’ were analysed for general language competence, focusing on coherence, range of vocabulary, syntactical appropriateness, and authenticity. The reading exercises were geared to capture typical information texts on computer and the listening tests were engineered to check for communication understanding in English in a course context.

2. Students also wrote short paragraphs about their experiences with technology, both electronic and otherwise. They included early childhood learning experiences. In this activity the aim was twofold; on the one hand we wished to assess their free writing composition and on the other hand we wished to find out to what extent they use technology, and are able to write about it, while getting a picture of their learning background. We also conducted a “complete the following sentence...” data collection exercise in which they had to present information about their use of technological devices and their reading and writing habits.

3. The group was asked to “make sense” of MS Word icons, and other MS Windows symbols before their first-time introduction to the computer. The icons and other symbols were printed and they responded by writing their interpretation.

4. Two focus group interviews were conducted with this group prior to the course, the topic being their anticipation about the course, and their experiences that led them to enrolling.

5. During the course, individual students from the sample were interviewed about their experiences in the course.

6. Individual students from the sample were video-recorded during their interaction in the course, with all the other students’ included in the background of the video shots.
7. Towards the end of the course individual students were interviewed about specific difficulties that they had.

Analysis of data and summary of findings

The verbal data obtained from the interviews, the paragraphs, and the sentences were transcribed (where needed, such as in the case of the interviews) and coded, then clustered and analysed for content, but also for discourse indicators. The language proficiency tests were analysed for competence, applying error analysis techniques and assessing the coherence and the syntax for clarity. During the first phase cluster (or primary categorisation) the data from a single collection source, such as the completion of sentences or the interviews, were condensed in clusters. Subsequently the clusters were grouped together across sources, emanating in the final categories or themes (Silverman, 2000; Flick, 1998 & Merriam, 1999):

- We found that they had, firstly, appropriated the electronic world with confidence, with most of them using cellular phones and other electronic devices frequently and intelligently.
- They also seemed to read and write adequately, in terms of quantity and quality. Their English proficiency was certainly sufficient for the needs of the course.
- The students' definitions of icons were probably the most revealing of their conceptions of the interface. The most prominent aspect of the analysis of these data was that, although there was little direct link between the symbols and the concrete representational objects (Preece et al. 1994) of the 'office' root metaphor and their individual interpretations of these symbols, the students logically deduced meaning from icons and would probably make a secondary link to the function of the icons when learning to use them in the context of the course and later on. However, although their own analogies were sophisticated in some cases, using tangible objects as starting point and then trying to explain the possible use of the symbols at the interface, the conceptual link between these would be contrived. We identified this as a crucial component of the findings. The absence of real office experience and knowledge could deprive the students of authentic analogical links and the operation at the interface would therefore be based on mnemonics or a non-conceptual retrieval from memory, which we labelled as 'non-semantic'. We believe that this could slow down their progress. The example of the "copy" icon explains this: the symbol of the "two pages" was described as objects from their lives, such as "two barrels". Although the link is there, in that the 'containers' (the barrels) would have to be 'filled' with something, the analogy makes for a cumbersome transfer to the interface meaning of making a copy of an existing text. If too many of these associations were to function at the interface the cognitive load would be heavier and proceduralisation would be slower. Another example was the interpretation of the "paste" symbol, which was described by many as 'luggage', with one student referring to it as "the suitcase of a man who went home to his family after working in the city" (this is not an uncommon practice in South Africa where many men and women work far away from their homes in rural areas and then commute a few times per year). There was an abundance of these types of analogies that were 'non-office' in character and that were therefore also not coherent, as they did not share the same root metaphor and did not fit the organising metaphor of the desktop as originally conceived by the Xerox company. Some more examples are as follows:

The "open file" icon: dustbin, refuse bin, bookshelf, ships in the water, it means there is enough information; it even pushes the door open, it means the information has to be stored.
The "save" icon: entertainment unit, a reflection of the TV on the computer, a screen of audio-visual apparatus, an object that looks like a screen with part shaded, this means that you have to pause while writing, incinerator/furnace.
The "view" icon: faulty page, a magnifying glass, a battery, a projector, cutter of some fruit with the fruit.
The "copy" icon: computer symbols of houses, typed pages, two printers, two pitcher(s), two written pages that are folded on top right.

- In the interviews the main theme was that they were motivated to master the computer and to access the Internet, but that they were very apprehensive.
- Although students were apprehensive, and although some of them remained tentative, they said that they tried to work through all the activities, even though the majority were hyper careful and also extremely...
slow in moving from thought to keyboard and mouse and to and from the screen, with continuous
refocusing of vision. It was evident that the pace of the activities was too fast for them, and that a great
deal of in-between thinking and processing had to take place, especially to decode the icons. The
affirmed this in almost all the interviews.

- Throughout the introductory course, they all felt that they had made a start and that they would come to
  the university computer centres as often as possible (the centres are open 24/7).

In the video data the verbal data were born out.

- Seven of the participants were indeed far slower in their reactions and found the use of the mouse
daunting.
- The students also found it difficult to switch from listening to the instructor, keeping an eye on the
  instructor’s projected screen image and working on the keyboard. The shifting of vision, the
  simultaneous use of keyboard and mouse, while listening to fast paced explanatory instruction, caused
  some discomfort.
- Five people in the group struggled with clicking the mouse, exacerbating the problem by what appeared
  to be left-right confusion.
- Students tried to assist each other, which is also not uncommon in this socio-cultural matrix, and were
  surprised that the instructor prohibited them from continuing to “lean over to a neighbour”, as one
  student put it. During these working interludes there was also laughter (often to release tension, but also
  because some of the things that happened and were said were truly humorous).
- When students focused on the keyboard only they worked quite harmoniously, although very slowly.
  When they switched to the screen, the rhythm stopped and each time there was great consternation to
  decide which icon to use.

Discussion

It is evident from the data that the social and educational background of the students impacted their participation.
In their school careers they would hardly have learned to type, or to use instruments, including musical
instruments. They never experienced instruction in which they learned to work with an instrument or device,
except for pens and pencils and sometimes paint brushes. Their science education, for example, was usually only
theoretical. In a few instances they may have had some practical training in woodwork. Consequently, this
course could have been, in most instances, their very first encounter with a ‘machine’. It was, therefore, not so
much a question of not being able to learn at a faster pace, but more a question of being unaccustomed to
learning in this mode, functioning in this type of educational culture (Bruner, 1996). The set-up, in a computer
centre, with an instructor showing examples on the ‘big screen’ and having to translate those messages into
working on a keyboard and on the ‘small screen’, was, for most of them, a completely new experience. Coupled
with their lack of experience or knowledge of “office’ life, the learning burden was indeed heavy during the first
encounter with computers.

Another aspect of their first experience of this learning environment was that they spontaneously wanted to assist
each other. The notion of working completely individually was upsetting for some of them. The instructor had
experienced through many years that novice users of computers transfer their own misunderstandings and faulty
use to others and has therefore drawn up a ‘code of conduct’ that prohibits too much collaboration. Although this
may be beneficial in a limited sense, the disadvantages seem to outweigh the single advantage of making only
‘your own mistakes’. In the spirit of social constructivism and the impact that the theory of situated cognition
and apprenticeship has had on education (Rogoff & Lave, 1994 and Brown, 2000), suffice to say that there are
always moments in learning events that are shared, and that the spontaneous assistance of adult learners for each
other could be used as a learning management tool in a learning environment that is ecological.

Important aspects of the findings now have to be engineered into the design of the learning programme. The
designers will have to craft a curriculum that uses their socio-cultural matrix as a resource and not see it as a
deficiency. In other words, if the ‘consciousness’ of the students requires a learning ecology that celebrates joint
efforts and joint failures, then the curriculum should take cognisance of this. There should really be no code of
computer centre conduct that inhibits cooperation and social learning where it is suitable. The instructor, and the
course, should guide and scaffold the learners, without disturbing the emergent learning ecology.

1992

Page 1942
In addition, the world of 'the office' needs to be explored with real experience, before the interface is introduced. Students need to see a number of offices in action and work with files, copiers, and sit at the desks of typical office workers in a conventional, not too high-tech environment. The genesis of metaphor of 'the office' would have to be explored, in order to give substance to the words and the iconic symbols that abound in the Microsoft platform and in hardware and software generally. This preparation would have to be done before the learning on computer commences, and should also be integrated into the initial literacy courses in a subtle way.

Furthermore, the programme that would probably best suit students who have not learned to 'use machines' in this way would have to be optimally engaging and would need to engender the development of procedural knowledge without too much obvious mechanical drilling. We therefore suggest an e-learning hypermedia-based programme, where only the steps needed to get to the first learning objective would be learned initially, and they would be repeated, with 'electronic rewards' featuring when the path of learning has been achieved. The learning units would be small (at present the students are bombarded with procedural and conceptual information at a very fast pace) and designed to scaffold competence and understanding. This means that the learning to use the computer will be happening through medium of the computer — a twofold curriculum that serves to teach e-learning while it teaches 'e'. The design would be simple to begin with, but as the skills of the learners increase, the complexity will increase. Discussion with fellow learners will be invited, both orally and via the e-learning mechanisms. We would aim for a truly empowering design that would lead to independent growth in competence, but especially in confidence. To develop critical use of the medium, we would later on introduce critical e-literacy as well, pointing out the power of the computer user over the computer and the contents of the Internet.

Conclusion

What set out to be an argument for culturally 'sensitive' instructional design and curriculum ended with a more than cautionary note about the need to understand the semiotics of the interface and preparing a course that will activate prior schema of the learners in a constructivist way, mediating the symbols. The inquiry thus also serves to illustrate that if the digital 'haves' are at all serious about crossing the divide and about creating opportunities for the knowledge economy to reach those who are eager to join, that they will have to consider the life-worlds of those who stand waiting for 'e-crumbs' from the table of the 'e-lite'. The organising metaphor of the desktop is not as universal as its originators and many authors may think (Preece et al. 1994).

Abstract: The paper describes the developed virtual laboratory that makes possible to play and learn static VA characteristics, ac behavior and important applications of basic semiconductor devices via standard Web browser. Virtual lab is implemented as Java-based applets embedded in HTML page. It permits student to arrange experiment and to obtain hands-on experience operating with virtual signal generator and dual channel oscilloscope in a way they do this in real lab.

Introduction

The technological development and the modern society continuously required more qualified and competent citizens. To maintain their innovative forces in the future, highly qualified experts with a multidisciplinary background, experimental skills and social attitude must be educated. The ever growing importance of knowledge and greater numbers of people being educated and trained at a high level have increased the responsibility of educational institutions, particularly universities which are under strong pressure to change (Donaval 1999). At the same time decreasing level of secondary school education and lack of student motivation, have led to great difficulties in the teaching situation and decline of exam results at the universities. Out-of-date laboratory equipment can’t support students’ skill obtaining and leads to financial problems for university budget. Obvious there is a need for change not only leading to better study results but also in finding a new infrastructure meeting the need for less expensive teaching localities.

To fulfil these requirements, the e-Learning tools should be developed and introduced into the educational scheme in general (Colleman 1998). Their wide use and dissemination is enhanced by rapid growth and use of the Internet and WWW, which have become the inevitable base for all type of life long and/or distance learning. To address these issues, we have developed a virtual lab, which allows students to enhance their experimental skills and interactively to study dc and ac behaviour of semiconductor devices via standard Web browser.

Structure of the Virtual Lab

The virtual lab consists of two basic facilities – one for obtaining static characteristics of semiconductor devices and second concerning ac applications. Virtual lab is implemented as Java-based applets embedded in HTML pages. Applets are designed as general tools permitting analysis of different semiconductor devices.
Static characteristic applet, shown in Fig.1 contains schematic field, characteristics display area, and control panel. The schematic field visualises the circuit required for VA characteristics measurement. Physical processes occurring inside the device can be observed in the same field. A control panel permits students to choose the device and the characteristic types, to set appropriate voltage value, and to start simulation. Family curves are automatically scaled and plotted in different colours in the applet’s display area. The parameter value is also visualised. Figure 1 shows output curves of an enhancement mode MOSFET. Using the same tool one can obtain transfer characteristics of an enhancement/depletion mode MOSFET. Diodes, Zener diodes, bipolar transistors and JFET can also be studied.

Figure 1. Interactive tool for VA characteristics

AC device behaviour can be studied interactively by virtual lab containing dual channel oscilloscope and signal generator. Both measuring devices, like in real life need first to be switched on before starting measurement. The signal generator permits setting of different signal types – sinusoidal, pulse or triangular. Students can choose voltage levels or frequency as well as pulse duty factor. Simple simulator calculates the output signal depending of current application. Both input and output signals are displayed by dual channel oscilloscope. Students can manipulate these signals like in real oscilloscope – move in x or y direction, change voltage levels or frequency.

Fig. 2 shows laboratory arrangement for analysing MOSFET amplifier. Observing simultaneously input and output ac signals student can examine differences in phase and voltage level between these signals as well as voltage gain.

Virtual lab can be used for studying typical applications of basic semiconductor devices as diode rectifiers, voltage limiters, bipolar, JFET and MOSFET amplifiers, CMOS inverters, multiplexers etc. It permits students to obtain hands-on experience operating with measurement devices, to achieve qualification in setting appropriate input signals and in analysing output signals as well as contributes to easier and deeper understanding of learning material.

Conclusions

We have developed a Web-based e-Learning tool, aimed to enhance practical training of the students. The developed virtual laboratory consists of Java based interactive modules, which permit students to arrange experiments and to study dc and ac behavior of semiconductor devices. All modules are directly accessible through the Web browser.

Interactive web-based tool is developed as a part of e-Learning material dedicated to self-learning as well as a complementary material to regular training. E-Learning allows university to start creating a better skilled, better performing workforce today. These tools can be used most effectively to leverage the teacher’s time and energy, so that the teacher spends the most time doing those things that add the most value to the learning process.

Abstract: The idea of creating virtual professional learning communities has been the starting point for a set of three online workshops that have been organised by the European Schoolnet and the Centre of Educational Innovation & Technology of Delft University of Technology. The results show a promising potential for online workshops in forming communities of professionals. With the workshops a total large group of 49 people all over the world have been reached who have actively participated in discussions with each other. Some of them have even participated in two or three workshops. Many evaluation respondents say that they have made contacts during the workshop that will last after the workshop. The results of this evaluation can be used to improve the workshops’ technology and organisation.

The idea of creating virtual professional learning communities has been the starting point for a set of three online workshops that have been organised by the European Schoolnet and the Centre of Educational Innovation & Technology of Delft University of Technology. The workshops aimed at:

• Creating a virtual community of practice in which participants can learn and work collaboratively on educational issues related to their work as teachers, researchers and policymakers
• Building expertise of new technologies for professional development at a European level.
• Constructing models for effective ways of collaborative learning in online learning.

The subjects of the three workshops were self-directed learning in secondary education, problem based learning, and the implementation of ICT in education. The online workshops are supported by a website, which can be found at: http://www.en.eun.org/menu/training/online-workshops.html. This website contains information about the workshops, BSCW workspaces for groups, streaming video, an electronic evaluation form, and an electronic application form. The organisation of the community of professionals during the workshops reflects the efforts of trying to create human networking and developing a sense of community among the participants through the use of native language groups, native moderators, personal presentations, live video, sharing of experiences, and the use of different roles. Participants apply themselves for one of three roles: attendee (participates actively), observer (just observes), and consultant (someone with expertise on the subject). Each workshop has been developed and conducted by an expert in the field of education who defines the learning content and activities of the workshop and presents the subject of the workshop in the video sessions. The workshops are co-ordinated by two overall staff members from Delft University of Technology.

Method
A fixed format was chosen for all three workshops, thus facilitating comparison of the results. The evaluation is performed at the level of each workshop, the language groups within a workshop, and the individual level. The workshops have been evaluated by means of an electronic evaluation form and through the analysis of the BSCW workspace. The workshops are open to everyone who is interested in the subject of the workshop. These can be teachers, educational specialists in the field or policy makers. A total of 222 persons applied for the workshops. These participants live in 31 countries, all over the world. 64 people applied for the first workshop, 120 for the second workshop, and 57 for the third workshop.

Results and Conclusions

Creating a Virtual Community of Practice

The results show a promising potential for online workshops in forming communities of professionals. During the workshops, this has really worked. With the workshops a total group of 49 people all over the world have been reached who have actively participated in discussions with each other. Some of them have even participated in two or three workshops. The evaluation respondents say that they have made contacts during the workshop, which will last after the workshop. They feel they have learned a lot from the workshops: mostly about the subject of the workshop but also about learning together in a virtual environment. The workshops are highly valued. The organisers have come across the following critical issues in the process of building a virtual community:

- High dropout rates are a well-known phenomenon in free online learning activities. Measures to motivate people to participate have to be developed.
- Some participants don’t write English well enough to function in a European group and therefore prefer to participate in a group of their native language. This helps to feel comfortable and fosters group cohesion.
- Participants also can have difficulties in exchanging resources because these resources are often written in their native language. There is no real solution for this problem at the moment, although the use of free automatic translation software can help to some extent.
- Moderators play an important role in the function of the groups. Finding moderators is hard because moderating is a time-consuming task. Payment of moderators could help in finding more experienced moderators. Clear instructions for moderators are compulsory as well as a manual describing measures they can take to enhance the discussion in the language group.
- Role specification of the consultant, the expert and the staff of the workshop should be worked out in more detail. This is crucial for their well functioning.
- A BSCW workspace in which participants can exchange ideas and documents with each other supports the functioning of the network. The BSCW environment, however, is not very user friendly for people who have little experience with computers.
- A database of professionals in which people could search for others with the same expertise or for someone who can answer a question has not been realised yet.

Professional Development

The online workshops facilitate both individual and group learning. Individual learning concerns the use of technology in education, online education, experiences of others, and the educational content of the workshop. Group learning outcomes relate to sharing knowledge with others, experience other ways of thinking, and meeting colleagues. This shows that the online workshops contribute to a professional identity in which the professional considers him or herself as part of a greater European-wide network of professionals from which much can be learned.

Models for Online Learning

The series of workshops started from a model on the organisation of the community of professionals during the workshops and a format for the content of the workshops.

- In the original plans for the workshop, participants were supposed to form local working groups. In reality, most participants subscribe individually and hardly form local groups. Learning activities should be designed in such a way that they can be done individually.
- The length of one week has appeared to be the most appropriate time length for the workshops. Although participants sometimes ask for a longer period of time, the experience with the second (and longer) workshop shows that participants lose their interest after one week.
• The live video sessions give the participants the feeling that they are connected to the expert and staff of the workshop. An important precondition for this is a good quality of video and audio. It has also been appreciated that the video sessions have been archived.

• The assignments guide the activities that take place within the workshop. Assignments that worked well, asked participants to write down their own experiences with the subject or asked participants to reflect on a case of practice of someone else. This case of practice should not be too advanced in order not to scare away participants who have little experience with the subject and feel overwhelmed by the case of practice.

• The resources are consulted very often. It was the intention to create a database in which resources can be stored and searched for by professionals. Such a database would be a strong instrument to enhance knowledge sharing among the community of interest. This has not been implemented yet.

• The target group of the workshops is very broadly defined: teachers, researchers and policy makers. Most of the participants appeared to work in secondary education. This is due to the context of the European Schoolnet in which the workshops are carried out. Although secondary education teachers should be the main target group of the workshops teacher educators should also be addressed.
Experiences with the ARIADNE pedagogical document repository

Abstract: The ARIADNE methodology and system exist since more than five years. A large amount of user feedback has been gathered. In this paper, we focus on what we learned from the feedback on two tools: 1. the ARIADNE Knowledge Pool System, a distributed database of reusable pedagogical documents and their associated descriptions (metadata), 2. the tools to store, search and retrieve such reusable learning objects.

1. Introduction on ARIADNE and IEEE Learning Objects Metadata
The main goal of ARIADNE, started in 1996, is to promote 'share and reuse' of educational resources. A distributed infrastructure has been developed for the production of reusable learning content, its description (metadata), storage and discovery, and its exploitation in well-structured courses [Forte et al. 1997a, Forte et al. 1997b]. The core of this infrastructure is a learning resource catalogue or digital library of reusable educational components, called the Knowledge Pool System (KPS).

Metadata are extremely important for the proper management and reuse of educational resources [Forte et al. 1999]. It should be easy to generate the metadata and to use them in order to identify relevant material.

As the KPS is a library, it requires 'traditional' metadata, such as title, authors, publication data, publisher, etc. Since the documents in the KPS are of a 'digital' nature, some extra metadata is needed: what software and hardware are necessary to view the document, does the document require a specific operating system etc. For the educational aspects of the resources, we include the categories document semantics and pedagogic attributes. We refer to section 2.2 for detailed information about the semantics category.

If we want the KPS to offer relevant documents for most users, it must hold a critical mass of good quality material. This is one of the reasons why we want to exchange metadata with other similar repositories (see also section 4). Therefor we have been deeply involved in the IEEE Learning Technology Standardization Committee (LTSC) Learning Object Metadata (LOM) Workgroup [LOM]. The LOM standard is based on earlier ARIADNE work, as captured in a submission made to the LOM workgroup in collaboration with the IMS consortium [Duval 1999a].

2. Enhancements gathered from experience and users
By now, the ARIADNE community represents 5 years of practical experience, from which valuable lessons can be learned (see for instance [Duval et al. 1999] for the evaluation in the context of one particular course). A large amount of useful feedback was collected by different means: mailing lists (separate ones for each of the different tools and general comments), SUMI (Software Usability Measurement Inventory) questionnaires [SUMI], evaluation reports and, last but not least, user and consortium meetings. This section discusses several enhancements we are currently finalizing, in response to that feedback.
2.1. Multilinguality
From the start of the ARIADNE project in 1996, numerous partners from different European countries were involved, and the project wanted to cope with the specific local needs of the different parties. Specifically, we want to respect and preserve the multilingual context of the users. We certainly do not want to enforce one specific language for the documents stored in the Knowledge Pool System. The same is true for the metadata: these can be inserted in any language. Note that the language of the document does not need to be the language the metadata are provided in.

Beside, multilinguality is also important for the tools. We want our tools to have a localizable interface. The latest ARIADNE core tools have the option to switch to another language during use. All the menus, attributes, buttons, etc. are presented in the preferred language, as shown in the figures below.

Multilinguality in the metadata has many consequences. On the one hand we want to support values in any language. On the other hand we want to provide translations for all values. This latter requirement can be met relatively easy for attributes with fixed lists of appropriate values, as these lists can be translated a priori. An example for such an attribute is the discipline of a document. ARIADNE defines a list of disciplines that can be used for cataloging the learning object. The name of each discipline is available in several languages. Free text attributes (e.g. installation remarks) can be inserted in a specified language with the option to manually insert multiple translations for those attributes: e.g. a description can contain an English entry for installation remarks ('You need a screencam viewer for this pedagogic document') as well as a Dutch translation ('Je moet over een screencam viewer beschikken om het pedagogische document te kunnen bezichtigen').

2.2. Structured navigation of document and concept space
An important part of the ARIADNE metadata is reserved for modeling the document semantics [Forte et al. 1999]. Initially a hierarchical structure was associated with each document. This structure indicated the main discipline, main concept, main concept synonyms and secondary concepts. The newly used metadata structure adds two extra levels to this hierarchy: science type (which becomes the new top-level) and sub-discipline, as illustrated in Figure 5.

Figure 2: The Query/Indexation tool in English
Figure 3: The Query/Indexation tool in Dutch
In previous versions of the indexation and query tools an overview of the available concepts was presented as an alphabetically ordered list. Still, it was very difficult for users to identify relevant concepts when creating new descriptions or when searching for interesting pedagogical documents.

In order to use the already (implicitly) available concept structure in a more effective way, we developed a concept navigator, which enables the user to browse through the concept space in a more intuitive and flexible manner. First of all, users can restrict the concepts to only those within a particular science type, main discipline and subdiscipline. For example, selecting 'Exact Sciences' as science type presents the user with a list of main disciplines defined within exact sciences. Selecting 'Informatics/Information Processing' updates the list of appropriate subdisciplines.

Figure 5 displays the relevant part of the concept navigator enabling the user to impose restrictions on concepts. In addition to the hierarchical structure, the language of the label of the concept and a pattern for the name of the concept can also be defined. In the example of Figure 5 the user is searching for concepts belonging to 'Exact Sciences' → 'Informatics/Information Processing' containing the word 'use'. Several concepts were found satisfying those restrictions: 'Clause Use', 'Design of User Interfaces', etc. For each concept presented in the resulting concept list, a number indicates how many descriptions this concept is used in: e.g. the concept 'Design of User Interfaces' is associated with 4 pedagogical documents.

An illustration of the relation between documents and concepts is displayed in Figure 4. This (greatly simplified) extract of the Knowledge Pool System displays 5 concepts, 5 documents and the relationship between concepts and documents. The figure can be read from top to bottom (concepts are related to certain documents: e.g. the concept 'Pedagogical Indexation' is the main concept of document 1 and a secondary concept of document 2) as well as from bottom to top (documents have an associated main concept and optional main concept synonyms and secondary concepts: e.g. document 2 mainly deals with 'Knowledge Pool', but also with 'Pedagogical Indexation').

The concept navigator provides the user with a more manageable overview of the concept space. Since the naming of concepts is subjective there should be some support for concept 'relatedness'. Still using the situation presented in Figure 4 a search on the concept 'Share and Reuse' will result in document 1. However, the user may also be interested in documents on 'Pedagogical Indexation', which would broaden its result outcome to documents 1 and 2.

Therefore, we introduced a degree of relatedness between different concepts. This relatedness is based on the concepts used within one specific description: e.g. the concepts 'Share and Reuse' and 'Pedagogical Indexation' are used within the same description (more concrete the metadata for document 1) and therefore are related at level 1. This relation is extended over different descriptions using the transitivity relation: e.g. since 'Share and Reuse' is related (at level 1) with 'Pedagogical Indexation' and 'Pedagogical Indexation' is (directly) related with 'Knowledge Pool', 'Search and Reuse' is related at level 2 with 'Knowledge Pool'. Using an extra level of indirection (more concrete the direct relation with 'Knowledge Pool') 'Indexation Tool' is related with 'Search and Reuse' at level 3. This is reflected in Figure 6 which displays the real overview of the concepts related to 'Share and Reuse' at a maximum level of 4.
3. Open problems

The experience we have with open and distance learning and the management of learning objects still leaves some issues unsolved. In this section we briefly discuss some of the problems we encountered.

- **Design for reuse**: By facilitating the process of identifying and retrieving appropriate learning objects, the ARiADNE system does make it easier to bridge this first hurdle to share and reuse. However, sometimes these objects can not be reused as such: learning objects may contain links to external web resources that may be inappropriate in a new context, or they may include information about people, locations or times that are not applicable, or they may use symbols that are different from those in other learning objects, etc. By following simple guidelines, many of these problems can be avoided. However, further research on 'design for reuse' is certainly needed. Also, granularity of the documents is important. A document stored in the knowledge pool should be an atomic element independent of other stored documents. This implicates that a document should be large enough to be reusable. On the other hand, the document should be small enough to fit in with other documents to make up a lesson. A precise definition for the size and granularity is difficult to state. In ARiADNE we leave it to the users to decide about this granularity of the documents: typically, the pedagogical elements stored in the KPS take between 15 and 120 minutes to study.

- **Quality assurance**: It is critical for widespread adoption of a learning resource catalogue like the Knowledge Pool to meet quality standards for both the learning material and the metadata that describe it. In ARiADNE, validators check the quality of the metadata. They are experts in a specific domain who can ensure the quality of the given description. It is their task to check for newly inserted elements and verify the quality of the metadata for those documents. ARiADNE does not formally check the quality of the learning material itself. Most users are experienced content developers that insert their documents in the knowledge pool for someone else to find and reuse it. Through annotations to stored documents (part of the metadata) other users can informally give feedback on their use of the documents.
• (Semi-)automatic description of documents: Because describing documents in some can be a tedious task, it would be beneficial to automate this description (partially) for some types of documents. Specific tools (like the video-capturing tool in the ARIADNE project) can fill in parts of the header automatically. Other more general tools could use plug-ins to generate metadata. Some of the metadata attributes (like document size, name, etc.) could even be filled in automatically by the knowledge pool system. When a batch of similar documents must be indexed, (description) templates can be used. Nevertheless, describing the pedagogical attributes of a document remains a manual task, which is rather time-consuming and is hard to automate.

• Information visualization: As the contents of the Knowledge Pool System increases, it gets more and more difficult to obtain a good overview of the available learning objects. Information visualization can be used to improve this situation, and to provide an alternative to querying based on an ‘electronic form’ approach [Schneiderman 1992]: e.g. a 2-dimensional representation of all descriptions whereby each field can be displayed on the X or Y-axis enables the users to search for commonalities and relations between different metadata fields. We have performed some experiments already as can be seen in Figure 7 which displays the ARIADNE metadata plotting the discipline (chemistry/biochemistry, civil engineering/architecture, economy/management, electricity/electrotechnics, electronics/microtechnics, informatics/information processing, life sciences/bio engineering, etc.) vs. their difficulty level (very easy, easy, normal, difficult and very difficult) on the axes. Squares are used to represent groups and their size is proportional to the number of descriptions. Selecting a square leads to zooming in on that group of descriptions. On the level of individual descriptions colors are used to denote the discipline of the pedagogical element: e.g. a brown block is used in Figure 7 to display the document belonging in chemistry/biochemistry of normal difficulty. The corresponding color legend is displayed in the bottom of the application window. This representation offers several insights that are difficult to conceive if you only use a form-based interface: e.g. most pedagogic documents (248) situate themselves in the informatics/information processing discipline and are of a normal difficulty level, the documents on life sciences/bio engineering are of a normal difficulty level, no very difficult documents are present, etc.

![Figure 7: Information Visualization displaying discipline (X-axis and color indication) and difficulty level (Y-axis)](image)

4. Related work

In [Koppi 2000] the authors write about the need for Learning Resource Catalogues (LRC) that must be implemented to enable share and reuse of learning objects. ARIADNE implements such an LRC in its Knowledge Pool System. This Knowledge Pool System stores the metadata about the learning objects, but also those learning objects themselves. In this way, a learning object will not be lost when the author decides to move or delete the object. This is a problem mentioned in [Currie 2000] for the IMS metadata project.
The ARIADNE Knowledge Pool System can be considered as a digital library of educational material. In this regard some digital libraries can be compared to it:

- The **Networked Digital Library of Theses and Dissertations** [NDLTD] is an initiative that shares some of ARIADNE’s goals, but restricts itself to theses and dissertations. Architecturally, it operates on a different model of loosely coupled sites.
- The **Computer Science Teaching Center** [CSTC] builds a digital library of computer science teaching resources. Little attention is paid to pedagogical metadata for the resources.
- **SMETE** is an initiative for a digital library for Science, Mathematics, Engineering and Technology Education [SMETE]. This project also supports the LOM metadata standard, so the contents of SMETE and ARIADNE should be relatively easy to exchange.

Other projects support (educational) metadata based on standards or through a self-defined set of attributes:

- **Education Network Australia** [EdNA] supports a limited set of Dublin Core elements, but only one of it is a real pedagogical attribute ("user level"). Also searching is rather limited: only five fields are searchable.
- The metadata structure of the **Gateway to Educational Materials** [GEM] is also based on the DC set, but it includes more attributes adopted from LOM for indexing (searching is also limited to five attributes).

5. Conclusion

The ARIADNE community has a lot of experience in the field of pedagogical document storage, query and retrieval. User feedback on the Knowledge Pool System, facilitating share and reuse of documents, and the tools to index and query its contents lead to important improvements in the new version of these tools.

Practice makes perfect: Preparing participants for an online conference

Dr. Jean Vermel, Mofet Institute and Beit Berl College, Israel

In February 2001, two simultaneous, three-day International Online Conferences, in English and in Hebrew, "Opening Gates in Teacher Education" were held. The target audience was teacher educators from all fields, not only those involved in information or educational technology.

For the vast majority of the participating 600+ teacher educators, it was their first experience taking part in an online conference as well as being their first true contact with authentic use of Internet communication technologies. In light of this situation, the participants were offered preparation - technological, pedagogical and psychological - for the totally online event.

This demonstration will illustrate the practice sessions, the real time technical help, the posted presentations before the conference, the psychological preparation, and the testing carried out by the participants before the conference began. Finally, it will look at the effect of these practice sessions and conclude with the belief that pre-conference practice sessions must become an integral part of an online conference to ensure its success. In addition, it will look at the ramifications of this success in terms of eventual integration of technology into the teacher education classroom.

The conference can be accessed at http://vcisrael.macam.ac.il/site
Collaborative knowledge construction in electronic forums and integrative scenario development as bridges between the socio-constructivist discourse and its application in educational practice: An exploratory research with pre-service teachers.

Abstract: This paper presents the preliminary results of our exploratory research concerning the impact of Information and Communication Technologies (ICTs) on students’ perceptions about their role as future elementary school teachers. More specifically, we are trying to identify instructional activities that are likely to facilitate the shift from a teacher-centred approach to a more genuine learner approach. We will shortly present a Web site providing scaffolding tools to help students and teachers through the whole process of scenario production. In order to stimulate metacognitive processes and collective knowledge construction about the new roles of teachers, we use telediscussions in an electronic forum. Although we believe that ICTs provide numerous opportunities to render students more autonomy over their learning, and despite the knowledge and experience gained over the past years, we have noticed that many students still have problems assuming more control and freedom over their own learning experience. Indeed, when they are facing a novel situation or when they encounter a difficult problem, students tend to fall back on their old ways of learning. They do the same when they plan a lesson for a specific class situation. We will present an instructional strategy that we foresee as a possible solution.

Introduction

The integration of information and communication technologies (ICTs) in classroom activities is strongly associated with the systemic education reforms taking place in many North American countries. National and international committees/associations (NCATE, 1997; ASCD, 1998; NETS, 2001) have been insisting on the need for teachers to adopt socio-constructivist strategies in order to take full advantage of ICTs and to prepare teachers for the emerging knowledge society. But, the use of socio-constructivist strategies (Brown, 1997; Wenger, 1998) in daily activities is complex and requires, from most of us, technological and pedagogical competencies that are not included in our culture of teaching, as well as a major shift in our vision of teachers’ roles, as it is the case for the adoption of the current systematic school reforms. Research on the adoption of innovations in education insists on the complexity of the adoption process and the time required to have the change to take place in practice in a deep and meaningful way (Laferrière, 1997; NETS, 2001). For example, in presenting the essential conditions for implementing National Educational Technology Standards, NCATE proposes ten issues going from a shared vision through school and university politics to support the integration of technology in learning. Once they have adopted a socio-constructivist vision of their role, teachers still face many problems before they can develop a rich and coherent socio-constructivist practice. A key issue seems to be what Schön (1983) called the espoused theory versus the applied theory problem. Even if teachers talk about and agree with socio-constructivist principles in their discourse they often stick to the traditional strategies to which they have been exposed. When they plan a lesson they often keep control over the learning process and pre-organise the access to information. We have observed this with pre-service and in-service teachers using ICTs. The emerging question is now how can we foster in parallel the
adoption of a new vision of teachers/learners’ roles and the adoption of new teaching strategies in lesson planning with ICTs?

Context of the study

Over the past six years, we have implemented a socio-constructivist approach in the two Information and Communication Technologies (ICTs) mandatory courses provided to students registered in the first and second year of the teacher education program at l'Université de Montréal. In the first course, students have to develop the basic technological competencies, a general culture of ICTs pedagogical uses and resources, a vision of ICTs impacts on society and education such as new roles and requirements for teachers and learners. The course’s pedagogical approach rapidly moves from teaching the basic pedagogical concepts and technological competencies in delivery mode during the first weeks towards a direct application of project based learning in a collaborative socio-constructivist approach. This allows students to be exposed and involved in a socio-constructivist learning experience. Working in teams of three to six students, they choose a classroom situation for which they have to develop a complete pedagogical scenario (detailed lesson plan). Since two years, a Web site, http://facvirtuelle.scedu.umontreal.ca/scenaristes, called "Les Scenaristes", provides scaffolding tools to help students through the complete (or entire) process of scenario production: analysis, development of the content, selection of a learning approach, formative evaluation and implementation of the lesson plan. Scenarios are interactively constructed and stored online so students can keep trace of the evolution of their work. Final products (scenarios and accompanying resources such as student guidelines or a complementary web site) can be shared among the community. Finally, collaborative reflection and metacognition is supported throughout the course by a mandatory participation in electronic forums focusing on issues of ICTs integration in education. The use of the electronic forums has shown to be a major tool to support the evolution of novice students’ perception of ICTs in education towards positive attitudes and vision (Viens & Rioux, submitted).

The second course, PED2000, is a full year course, mostly via the Web and open laboratory activities. It is fully project based, with tutoring in team meetings, Web resources, technology workshops and laboratory assistance. Teams of three to six students have to contact an in-service teacher who would be interested in implementing a scenario with his students, as well as collaborate with the students in the development of their project. Using the scaffolding approach and the Web site, students have to produce a more comprehensive scenario than the one they did in their first year. The field experiment allows the teams to experience a real life situation, while taking into consideration the constraints and realistic conditions of a classroom. This experimentation permits students to conduct a formative evaluation of their scenario and to develop experience in reflexive practice. PED2000 students also have access to electronic forums of discussion, with the difference that no themes have been pre-determined. It is the students and the tutor who create and launch topics of discussion as issues are emerging along the year.

The study

Goals

As we mentioned earlier, our goals are to understand better the perceptions that students might have about the impact of technology on their future role as elementary school teachers and to assess the impacts of these perceptions on their practice when they plan a lesson. Ultimately, the research results will be used to improve and to enrich our scaffolding approach, in order to help the students not only to discuss the socio-constructivist principles but also to adopt them in practice. To do so, we explored the links between the discourse held in the electronic forums and the application of the principles in the integrative scenarios.

2007
Sampling procedures

In order to reach our goals, we studied the work of first year (N=35) and second year (N=187) students registered in the K-6 pre-service teachers' program. We wanted to identify students demonstrating a socio-constructivist discourse in the forums and then study their scenario to establish relationships and ruptures between their talk and their practice. We used four basic pedagogical characteristics of socio-constructivist pedagogy, inspired by Brown, Collins & Duguid (1989), Brown (1997), Wenger (1998) and Viens (in press): 1- it requires a high degree of autonomy and cognitive investment of the learner; 2- learning occurs in communicating and collaborating with others; 3- project based learning anchored to society (milieu) and involving high level problems or questioning; 4- metacognition (critical reflection on one's knowledge and strategies).

Thus, the first selection step was the identification of students who appeared to hold a socio-constructivist discourse about the respective role of teachers and learners. Despite the relatively large number of contributions (N=632), we realised that the second year group did not discuss socio-constructivist principles sufficiently in order to provide an interesting basis for comparison. Indeed, most messages were oriented towards practical questions on the experiment to be held in class and on other course related issues. This is probably due to the fact that in this course, the topics of the forums are initiated mostly by the students who express their basic practical concerns instead of offering a reflexive stance on socio-constructivist issues. Consequently, we decided not to pursue our analysis of the second year student work. In contrast, approximately half the first year students were holding, at one point or another, a socio-constructivist discourse. Taking into consideration the object of research, we then decided to focus on two relevant themes of the forums: "perceptions of the teacher's roles and responsibilities" and "conditions for the use of ICTs". Since the scenarios are produced in teams of three to six students we had to take into consideration the messages produced by other team partners who were not necessarily holding a socio-constructivist discourse. We assumed that this decision would contribute to understand better group dynamics and its incidence on the socio-constructivist nature of the scenario. Finally, the selection process reduced our original sample to 18 students, divided into four teams. The total number of messages analysed for this study is 80.

Criteria for analysis

Beyond the identification of elements of the socio-constructivist discourse, we assessed the qualitative nature of the messages in terms of depth of elaboration and justification. Three levels were set: 1= superficial message (surface statement, no elaboration, shallow talk, name dropping); 2= opinion message (some elaboration but no justification); 3= (elaboration and justification of views and ideas). Our intent was to probe the student's capacity to reflect critically, that is if they were able to develop and support their thoughts rather than merely contributing an unsubstantiated opinion (Quellmaz, 1987; Ennis, 1987). Two researchers rated the messages and compared their results resolving the few rating differences in consensus.

For the analyses of the socio-constructivist nature of the scenario, we used the same criteria as for the analyses of the electronic forums to which we added a fifth criterium: interdisciplinarity of the scenario. Here we evaluated each aspect individually to obtain a better picture of the nature of the scenario.

Learning strategies (autonomy). Notwithstanding the specific learning strategy to be used, we assessed whether the learner's during the instructional strategy was « directed », « guided », « rather guided », or « free ». Levels went respectively from 1 to 4.

Team work (collaboration). We examined whether the students planned to have their learners work individually (1), in teams but to conduct a fragmented task (2), or in teams to conduct a collaborative and collective task (3).
Content (project based learning). Did the students scenario provides a specific and linear content (1), a multiple path content (2), a framework with certain freedom of the learner (3) or did they leave it completely opened for their learners to decide of their subject, as in project-based learning (4)?

Pedagogical goals (metacognition). Aside from the usual well-stipulated instructional goals, did the students add other learning objectives such as transversal competencies or metacognitive activities? No = 0, Yes = 1.

Interdisciplinary. Did the students focus on one subject matter or did they use the opportunity to integrate several disciplines? One subject = 1, More than one subject = 2.

Even though we used a Likert scale to evaluate each criterium our intention was not to cumulate frequencies but to guide our critical analysis of the constructivists aspects of each scenario. In this perspective, we considered the number of criteria with a rather positive level towards socio-constructivist principles as an indicator of the socio-constructivist nature of the scenario.

Results

Perceptions of the role of the teacher and critical thinking abilities

Although not all interventions under the theme « Perception of the role as teacher » referred directly to it, it is interesting to discover that the perception of the role is indeed changing. The students did mention that the ICTs will help shift from a traditional role of « content deliverer » to one that assumes more guidance, more facilitation. Terms such as « facilitator », « animator », « councillor », « advisor » were used relatively frequently. However, we discovered that many students limited their intervention at the opinion level. They only named or listed the role without providing an explanation or a definition of what they meant by « facilitator » for example. Furthermore, they did not establish a priori what they mean by « traditional role ». In other words, students talk about the changing role without defining their assumptions. No one proceeded to compare and contrast the two positions or provide an illustration to support their thought. Indeed, many participants merely identified keywords and did not attempt to engage in a more critical discussion.

Some interventions were also addressing the issue of the changing role, but indirectly. Some students talked about the fact, for example, that the ICTs will provide the opportunity for the pupils to be more active in their learning process. Here, the guiding role of the teacher is implied in the discussion. Participants mention the possibility that ICTs will encourage the active construction process and consequently, will contribute to a more significant learning experience. In fact, in those indirect interventions, the learners are considered to be at the centre of their learning, actively engaged in the construction of their own knowledge and experience. In sum, those students seem to think that ICTs can be used to favour collaboration between the learners as long as the learners’ needs are respected.

Furthermore, the same group of students also discussed a specific aspect of teaching that will be affected by the technology: the impact of broader access to information. Some students recognise the fact that a wider access to information will bring new tasks for their learners. One student mentioned that their pupils will have to « clarify their own research goals, define their information seeking strategy, make choices in the information, and sort the information ». This type of anticipation regarding « transversal » competencies was certainly an interesting finding.

Scenarios

As one can see in figure 1, only one team has scored positively on four of the five socio-constructivist criteria. Two scored positively on two criteria while the last team did not meet any
socio-constructivist criterion. Team 1 produced a scenario proposing learning strategies that were rather guided toward a collaborative project to be realised by the learners with objectives from multiple disciplines. Meanwhile, they did not propose specific metacognitive activities or activities oriented towards transversal competencies.

Team 2 produced a scenario with limited socio-constructivist features. They offered rather guided strategies and proposed metacognitive activities based on individual learning, close and predetermined content, and objectives from only one discipline. Team 3 produced a scenario with collaborative activities and multiple disciplines but offered rather directed learning strategies with a multiple-path pre-determined content. They made no mention of metacognition or transversal competencies. These two scenarios are rather traditional in essence. Finally, Team 4 produced a very traditional scenario.

Table 1. The score of each team's scenario according to the 5 socio-constructivist criteria.

Comparing scenarios and electronic forums

Table 2 presents the teams' description in terms of number of students, socio-constructivist criteria reached and number of students for each level of depth for the electronic messages. Two trends have been identified in this comparative analysis of the electronic forums and scenarios. First, the students who are better able to support their opinions by providing examples, using the literature, explaining their thoughts, seem to be more capable of producing a scenario that uses a genuine constructivist approach. In fact, if all the constructivist criteria are applied whenever it is reasonable to do so, the tone used to describe the learning activity is more opened, more respectful of both the freedom of the teacher and the learners. Here, we noticed that the team who produced a constructivist integrative scenario, was constituted of four members who demonstrated some critical thinking abilities, by elaborating and justifying their arguments or their position.

The second trend shows that the students who claim that the role of the teacher is changing but who do not support their opinion, do not apply their values and perceptions in their integrative scenarios. In other words, they claim to be constructivist in the telediscussions, but they fail to transfer their thoughts in practice. As we anticipated, the majority of the scenarios produced were meant to be constructivist. Some teams for example, will have their students work in teams but in a fragmented fashion (individual students will provide parts that will make a whole); the content will be determined and not opened for change; the learner will be rather guided in the learning process.

These teams' lessons plans tend to be very organised and directed as well. The outcomes, ensuing the instructional goals are well planned. In fact, the pre-service teachers, remain perfectly in control of the predetermined outcomes. Despite their good intentions, the students remain in control of the learning process. The steps are not only too well defined, they are also not flexible. The outcomes of the intervention using ICTs are still pre-determined and nothing else, that is no incidental learning is considered.
Table 2. Teams description in terms of number of students, socio-constructivist criteria reached and number of students for each level of depth for the electronic messages.

Conclusions

In this exploratory research we highlighted two trends. Students who demonstrate critical thinking abilities in electronic forums are more likely to apply successfully their values and beliefs in their productions of integrative scenarios. Secondly, students who do not support their opinion in the electronic forums will be less able to apply the socio-constructivist principles to their productions. They will remain in control of their pupils’ learning. The next logical step would be to combine the use of the electronic forums and of the scenario development in order to help students to identify rupture points between their discourse and their practice. Such activity would directly support the development of critical thinking skills in the telediscussions and hopefully encourage a better transfer of the socio-constructivist principles to the development of integrative scenarios.

**Abstract.** Fostering socio-constructivist practices with ICT in K-12 classroom activities is complex and requires numerous conditions to be met. In order to study these conditions and to develop a model of practices that take teachers’ concerns and classroom reality into consideration, we initiated a community of research on collaborative learning with ICT, called CRACTIC. Over the past three years, this research “community” has included University-based educational researchers from two institutions, teachers and pedagogical support staff from three school boards, and the collaboration of topic experts from an ecological museum.

Socio-constructivist principles provide the theoretical foundation for Information and Communication Technologies (ICT) uses in almost every recommendation plan delivered by national orientation committees in the United States (NCATE, 1997; ASCD, 1998; NETS, 2000) and in Canada (MEQ, 2000). At the same time, a gap exists between these underlying principles and their interpretation, their practical meanings, and their day-to-day application in schools. In order to develop powerful understandings of socio-constructivist practices, we initiated a community of research on collaborative learning with ICT, called CRACTIC, the acronym for an expression in French meaning “Research Community on Collaborative Learning with Information and Communication Technologies”.

The starting point of CRACTIC is the formation of a collaborative research community linking University-based educational researchers, grade school teachers and support staff, and domain experts, in order to implement a model of collaborative learning activities based on socio-constructivist principles. Teachers are selected to participate in the project based on their experience with project-based initiatives, access to adequate on-site technological infrastructure and support, and an interest in action-research about collaborative knowledge building. The project partnerships thus lays the foundation from which students in different schools embark on project-based learning activities integrating ICT tools. The main research objective is to understand how the classes are able to use collaborative technologies (Roschelle, 1995).

---

1 Funding for educational research within CRACTIC, beyond the resources and expertise offered by the participants, is provided by a team grant from FCAR (Fonds pour la formation de Chercheurs et l’Aide à la Recherche, Québec).
One important way of developing and documenting the use of collaborative technologies in the CRACTIC classes has been through the iterative design and implementation, over a period of four years, of project management guidelines. These guidelines support the coordination of teachers and students in the various CRACTIC schools to exchange questions based on their common research sub-themes (e.g., whales, pollution) so as to generate and share research and topic information by using Web-based collaborative tools (discussion forums, calendars, etc). For example, the guidelines indicate how teams of students from one class can be paired with a team from one other class, in a coordinated way to facilitate the establishment of stronger relationships between participants (both teachers and students). The St-Lawrence River was chosen as a general theme due to its historical, economic, social and geographical importance, and because of its many curriculum connections. Project activities consist mostly in students engaging in jointly formulating deep questions and working on providing rich answers to these questions, using collaborative technologies to achieve this across classroom contexts. This represents an attempt to carry out Brown’s (1997) FCL activities (e.g., modelling thinking and reflection, supporting statements with evidence, summarising) online in addition to in class. Finally, while the project guidelines suggest a minimum commitment of ten weeks, classroom exchanges and related activities often stretch over a number of months. The outcome of knowledge construction is an evolving collective Web site where each group posts their work.

Our methodology is based on on-site observations and analyses of multiple sources of information (e.g., meeting notes and reports; classroom observations; interviews with teachers, students and school administrators; student productions such as email messages, exchanges, and Web sites) to document the circumstances and outcomes of the CRACTIC practice.

Results are summarised in terms of an outline of the project management guidelines, patterns of classroom practices leading to collaborative exchanges online, the kind of support that has been observed as successful in achieving increasingly connected and collaborative practices within our community of inquiry, and the obstacles and impediments that we have encountered which are very similar to those observed by Zech & al. (2000) and Blumenfeld & al. (2000). Our discussion is mostly about how this project guides and fosters the emerging practices of a complex community that is targeting issues of teaching and research and wants to converge in increasingly successful ways.

Towards a Compromise Between Talking Heads & Interface Agents: A Web-based "Mentor" for Computer Assisted Language Learning (CALL)

Julie Voce, Marie-Josée Hamel
Centre for Computational Linguistics
UMIST
Manchester, UK
j.voce@umist.ac.uk, mjhamel@ccl.umist.ac.uk

Abstract: Animated agents are used to provide an interface between a human and a computer. Talking heads provide us with a realistic model of a face which, when combined with speech synthesis technology, can give us a tool that can aid audiovisual perception of speech. Our aim is to combine these two technologies to create a talking animated interface that will be used within the FreeText project, a Computer Assisted Language Learning environment under development, to act as both a "mentor" and as an aid to pronunciation and understanding of speech. By adapting and developing the FREDA project we hope to achieve this aim.

Introduction:

When learning a new language the most difficult part is understanding spoken communication; research has shown that this understanding is greatly diminished when background noise, i.e. people talking, music or traffic, interferes with the speech. The results of experiments concerning the intelligibility of speech (Sumby & Pollack 1954) concluded that 'visible speech' aids the listener's understanding because he/she employs visual perception to clarify that the phonemes/words heard match the facial movements of the lips and jaw. This is the motivation behind developing and adapting the FREDA project (Mumford 1998) to be used within a web-based CALL environment.

FREDA (French Real-time Educational Displayed Articulation) provides real-time visual support for FIPSVox (French Interactive Parsing System, Vocal) (Gaudinat & Wehrli 1997), a French text-to-speech synthesiser used in SAFRAN (Système d'Apprentissage du FRANçais) (Hamel 1998), a CALL application. FREDA uses a series of visemes to create real-time animation based upon the output of the text-to-speech synthesiser. The animation is then combined with the corresponding audio file to create a video file. This paper looks at the current research into agents, talking heads and facial animation and discusses the developments and adaptations that will be made to the FREDA project.

What is an Agent?

For the purposes of this paper we are interested in agents that provide an interface between a human user and a computer by means of an animated character which can be directly manipulated by the user. This type of agent is more commonly known as an interface agent and the definition we will use is that of Henry Lieberman (Lieberman 1997):

"An agent is any program that can be considered by the user to be acting as an assistant or helper, rather than as a tool in the manner of a conventional direct-manipulation interface"

Using the list of properties of an agent (Franklin & Graesser 1996) it is possible to produce a good definition for a specific class of agent. An animated interface agent can therefore be reactive, communicative and having character.
Talking Heads:

A "talking head" is a synthetic human head which has the ability to speak. More formally, a talking head is an audiovisual speech synthesiser and the current research combines knowledge from the fields of computer graphics/animation, facial movement and speech technology. The ideas are based upon the fact that visual perception of speech aids the auditory understanding. Using the advances in 3D graphics a dynamic model can be created that not only looks human but also mimics human behaviour and facial positions.

Facial Animation:

Animators discovered that the best way to make their characters more "alive" was to give them moving lips, when they speak, which match the phonemes being spoken. For each phoneme in a language, it is possible to define a viseme - the visual interpretation of the position of the articulatory organs during the pronunciation of a phoneme. The animators found that a number of phonemes could share the same lip viseme, as the position of the lips is identical. The articulatory difference between many phonemes is internal, so it is something that animators rarely need to display. For our agent we will define a set of French visemes that will be limited based upon methods used by animators and using the work of Benoît et al (Benoît et al. 1992), which identifies twenty-one mouth shapes that describe the structure of the lips and jaw gestures used in French.

Aims:

Our aim is to create a web-based talking interface agent that will be used within the FreeText project http://lismore.ccl.umist.ac.uk/freetext, a CALL application, as a mentor. The mentor will exhibit agent characteristics by giving the learner help, both when asked for directly and when the mentor thinks that the learner may need a bit of advice. We will use the technology behind talking heads used for speech reproduction in order to provide realistic facial movements. The aim of this is to allow the learner to use visual perception of speech to increase the intelligibility of the phrase being spoken. The other advantage of using facial animation, in the field of CALL, is that it can be used as an aid to pronunciation; learners can mimic the mouth movements of the mentor.

Empowering the citizen

Frank von Danwitz, Deutsches-Diabetes-Forschungsinstitut, Germany; Thomas Baehringer, Heinrich-Heine-Universitaet Duesseldorf, Germany; Werner A. Scherbaum, Deutsches-Diabetes-Forschungsinstitut, Germany

This paper carries the fundamental implications for healthy living and actual media concepts.

Introduction

Numerous initiatives and declarations have called for more support for public health, sickness prevention and increased self-empowerment for the public in the health services. The aim is to optimize the form, the intelligibility and the publication of publicly available health information within the health service for non-experts.

Study

Resulting from a representative telephone survey (n=2000) on health behavior and health empowerment and utilization of media answered the points: a) How does the citizen get information about health? b) How does the ordinary citizen use information? c) How does the layman judge the quality of health-related information?

Findings

Empowerment as a practical educational aim with regard to health includes the following factors: a) understanding health, b) asking questions, c) creating models, and d) implementing it in a social setting.

Conclusions

The conclusions of our study help us to create user oriented health information.
Extending the IEEE – LTSA

Dipl.-Ing. Jörg Voskamp

Fraunhofer-Institute for Computer Graphics, Division Rostock
Joachim-Jungius-Straße 11
D-18059 Rostock, Germany
{joerg.voskamp, sybille.hambach}@rostock.igd.fhg.de

Abstract The IEEE developed an architecture specification for learning technology systems (LTSA). This paper proposes an extension for the LTSA covering the learning cycle taking place between expert and learner. We describe a general production model to motivate the extension of the LTS architecture as described in [Farance and Tonkel, 1999].

Introduction

An Internet based course management system (CMS-W3) is being developed at Fraunhofer-Institute for Computer Graphics Rostock for the past five years. It is used by experts for distributing their courses via Internet and by students for learning with the material distributed. The “Course Management System for WWW – CMS-W3” (see [Voskamp, 1997,Voskamp, 1999,Hambach et al., 1999] supports self studies, group learning and communication among students and with the tutor.

There are various standardization processes on ICT (Information and Communication Technology)-based learning technologies running all over the world. One standard is developed in the IEEE 1484 Learning Technology Standards Committee (LTSC). The LTSC proposes the “Learning Technology Systems Architecture (LTSA)” [Farance and Tonkel, 1999].

Following these standardisation processes we tried to match the architecture of CMS-W3 and the LTSA. One important part of CMS-W3 was missing and was not described in the LTSA. Going back to underlying learning processes we found that the proposed LTSA is missing the part on how the knowledge is transferred through the system.

This article proposes an extension of the LTSA supplementing the process of knowledge transfer: from the expert to the resources of the system and back to the expert in form of experience.

IEEE - LTSA

The IEEE 1484 Learning Technology Standards Committee (LTSC) develops an architecture specification for learning technology systems, the “Learning Technology Systems Architecture (LTSA)”. The LTSA is

“... an architecture specification: the technical details can be used to specify or design systems as well as detailed systems components.” [Farance and Tonkel, 1999]

The specification is being developed in close collaboration with the Aviation Industry CBT Committee (AICC), the European Commission PROMETEUS initiative (EC/DGXIII), the European Union ARIADNE Project, the European CEN/ISSS Workshop on Learning Technologies (CEN/ISSS/LT); the IMS Project, and the US Department of Defense Advanced Distributed Learning (ADL) initiative.

The LTSA proposes a basic top-level architecture for system design and components. It covers a wide range of ICT-based learning methods and even non-ICT-based models.
Setting up such a specification architecture is a great idea. Using an existing architecture standardization process makes things much easier, for example defining the exchange of courseware (see [Dodds, 2000]) or student profiles. Figure 1 shows the LTSA system components. See [Farance and Tonkel, 1999] for a detailed description.

![Figure 1. LTSA system components model](image)

**Objectives of the LTSA**

The LTSA specification states to be

"... pedagogically neutral, content-neutral, culturally neutral, and platform-neutral. The LTSA specification is neither prescriptive nor exclusive."

Furthermore, it

"... does not address the development systems (e.g., programming languages, authoring tools, operating systems) necessary to create the LTSA components, and the management systems (e.g., learning material lifecycle, quality assurance, access control, user administration) necessary to manage a learning technology system."

Consequently, the LTSA is an architecture describing general learning processes. Anyway, in our opinion the learning process is not completely described.

**Missing points**

The LTSA covers only a closed learning process. However, the knowledge to be "produced" in the head of the student has a source. It is either the knowledge the expert has or it is the experience of the student in finding and solving problems.

If there is expert knowledge to be passed to the student, this knowledge has to be translated into some kind of information (data plus multi-modal presentation). In working with and studying this information the student may acquire his knowledge – he learns.

The process of learning produces a learning history and learning performance which can be used by the expert to improve his knowledge about the way the information has to be passed to the student. This process is missing in the LTSA.
Extending the LTS Architecture

We propose to extend the LTSA by an expert process. The purpose of the extension is not to deny the LTSA but to extend it by a process we think is essential.

The proposed extension is based on a production model which will be described in short in the following.

**Production model**

The relevant state $S$ of a student for the learning scenario bases on his actual knowledge $K_t$ and his mental state $M_t$. This state changes during one learning cycle $S_t \rightarrow S_{t+1}$. The student starts in state $S_t$, which bases on the knowledge $K_{Lt}$ and the mental state $M_t$ where $t$ defines the moment before the learning process starts.

$$ S_t = \{K_{Lt}; M_t\} $$

Let $I$ be a set of information objects $IO$. An information object contains the data which solely or in combination with other information objects is to be presented to the student.

$$ I = \{IO_1, \ldots, IO_n\} $$

$$ \forall i \forall j : IO_i = IO_j \Leftrightarrow i = j; n, i, j \in N $$

The student consumes an information $I_{t,t+1}$ during the learning process $l_{t,t+1}$ presented by a set of presentation types $P_{t,t+1}$ (described later) where

$$ I_{t,t+1} \subseteq I $$

A presentation can be a simple audio presentation, an interaction, an exercise, a test as well as a discussion forum or other learning tools. The learning process $l_{t,t+1}$ is a function depending on the information, the presentation types and the knowledge as well as on the mental state of the student.

$$ l_{t,t+1}(I_{t,t+1}, P_{t,t+1}, S_t) $$

For the transfer of information to the student it can be coded in different presentation types (see [Mengel, 1999]).

Information objects $IO$ are acquired out of the experts knowledge $K_e$ to be passed to the student as well as out of the knowledge of other students $K_{sg}$.

Experts are responsible not only for the information to be transferred to the student but for the type of presentation, too. They define a set of presentation types $P$. A presentation type $PT$ is one method to present an information object $IO$.

$$ P = \{PT_1, \ldots, PT_n\} $$

$$ \forall i \forall j : PT_i = PT_j \Leftrightarrow i = j; n, i, j \in N $$

As described in [Reinhardt et al., 2000] every presentation type contains attributes which allow a decision when to use this presentation type. The presentation function $p_{l_{t,t+1}}$ returns the necessary set of presentation types $P_{l_{t,t+1}}$ to be used for the current information $I_{t,t+1}$.
The aim is to maximize the learning function $I_{t,t+1}$. In order to maximize this function the best sets for $I_{t,t+1}$ and the best fitting set of presentation types $P_{t,t+1}$ has to be found. This is the task of the coach in LTSA.

However, $I_{t,t+1}$ depends on the learning function $I_{t,t+1}$. For this reason, it is necessary to optimize the presented information $I_{t,t+1}$, the information objects $lO$, the presentation function $p_{t,t+1}$ and the presentation types $PT$. This cannot be the task of a coach but has to be the task of an expert. For optimizing the information objects $lO$ and the presentation types $PT$ expert knowledge $K_e$ is definitely necessary.

Figure 2 gives an overview on the production model.

Figure 2. Production model

Reasons for the extention

The main reason for the extention is to find a system architecture for learning technology systems that covers all learning scenarios – as LTSA is dedicated to be. As shown in section "Production model" the learning process is not covered by only presenting information to the student and using the learning performance to let the coach find the next information to be presented.

The learning performance of a student is used by the expert to train the coach in didactics and to transfer the right knowledge into information object to be stored in the learning resources. For ICT-based learning environments this recursion is not done for every single learning step. However, it is necessary to bear in mind that it exists. Therefore it should be included in the LTSA.
Extended Architecture

We propose to expand the LTSA by an expert process. The expert process is responsible for transferring information into learning resources and for training the coach in didactics. After the first learning cycle the expert process learns from the learner performance how the coach has to be re-trained and which knowledge has to be re-transformed into information. Figure 3 shows the extension.

Following the description of the LTSA the coach can be an automatic process following predefined rules. This process is not able to define new didactic rules. It simply does not have the necessary knowledge.

The main reason for extending the architecture is that there is no knowledge-to-knowledge flow described in the LTSA as it exists in the real world. When trying to set up a learning specification it is important that this specification meets the daily learning business. Daily business in learning is a cyclic dependency between students and experts knowledge.

Review

The proposed extension for the LTSA adds an important part of the daily learning and teaching business. It says that the student does not only learn from the expert, but the expert learns from the student as well.

Background for the proposed extension are ICT-based learning environments. However, as stated in the LTSA specification the extended architecture covers daily learning processes like face to face learning, too, and much better.

The following list shows the steps during one learning cycle as proposed in the LTSA. The first and the last line are added due to the extension described.

1. Put expert knowledge into resources (knowledge to information) and didactic knowledge into the coach
2. Start with human sensory input: multimedia delivery to learner (similar to entertainment)
3. Add coaching/feedback loop for human “unreliability”
4. Add learner records for varying teachers, infer intelligently about learner capability
5. Add rich learning resources, search, and lookup to support diversity of humans
6. Add negotiated learning preferences for direct communication with learner
7. Add negotiated learning preferences to give feedback to expert
Conclusion

Using the extended learning technology systems architecture it is possible to describe the functionality of CMS-W3 and other ICT-based learning systems. We use it as a starting point for further research in technical support for transferring expert knowledge into information objects, in didactic support for the coach and in organizing the re-transformation of information objects according to the students learning process.

Abstract: This paper illustrates how the issue of providing user-friendly access-mechanism to learning resources has been addressed by UNIVERSAL, an open, pan-European brokerage platform for learning resources. The focus is devoted to catalogue design; its creation, development, structure and organization. More attention is also given to the automated categorization of learning resources within the category tree, creation and maintenance of the catalogue hierarchy. The described approach enables gradual automation of the categorization process: from manual to semi-automated and finally to a fully automated categorization process.

Introduction

The European project “UNIVERSAL - Universal Exchange for Pan-European Higher Education” is an attempt to demonstrate an open exchange of learning resources (LRs) between higher education institutions across Europe. The goal is to create and manage an open market of learning resources by introducing a brokerage platform with a standard way of describing the pedagogical, administrative and technical characteristics of learning resources. The system will enable institutions to enrich their curricula with remotely sourced material. It is intended to be compatible with a variety of similar models pursued by different institutions, including open universities and alliances between peer institutions. The business-to-business oriented brokerage platform will embrace offers, enquiries, booking and delivery of LRs.

Based on the IEEE Learning Objects Metadata (LOM) standard, four aggregation levels of LRs are introduced: course, unit, lesson, and fragment. A course is defined as a set of units or lessons contributing to one learning goal and lasting not longer than one semester or term. Courses can be organized in units, which in turn consist of individual lessons. A full course description does not always have to consist of units, it can also be based on lessons. A lesson is part of a course or a unit, which does not necessarily have to be offered in UNIVERSAL as well. Lessons can consist of multiple fragments, which are also referred to as supporting material (Guth et al. 2001).

The platform supports synchronous as well as asynchronous material. The following examples of LRs are taken from the preliminary version of the UNIVERSAL catalogue:
- A course dealing with Icelandic Sagas (aggregation level: course; delivery mode: synchronous);
- A web-based training application instructing ophthalmologists on how to diagnose patients (aggregation level: unit; delivery mode: asynchronous);
- A recorded session of a course in international marketing dealing with a Levi Strauss case study (aggregation level: lesson; delivery mode: asynchronous);
- PowerPoint slides, exercises, and a term project description supporting an introductory course in information technology (aggregation level: fragment; delivery mode: asynchronous).

LR metadata is maintained by the UNIVERSAL metadata engine combining the eXtended Markup Language (XML) and the Resource Description Frameworks (RDF) approach. The RDF Schemas used for describing LRs and LR related information such as authors, delivery systems, taxonomies, etc. are available at http://nm.wu-wien.ac.at/universal/metadata. The XML:RDF approach used ensures scalability and transferability of UNIVERSAL.
repository of LR metadata instances (Guth et al 2001), because mapping the Universal metadata schema with LOM or Dublin Core can easily be carried out by generating LOM compliant or Dublin Core compliant metadata instances.

A key innovation of the UNIVERSAL project is the tight integration of the LR catalogue and the delivery systems. A delivery management engine prepares the grounds for the delivery of LRs by granting access rights and verifies the availability of the content. A thin generic interface layer provides communication functionality between brokerage and delivery system, such as availability checks, authentication and authorization services, delivery negotiation and delivery supervision. UNIVERSAL will offer a fully implemented delivery interface to the following restricted set of delivery systems, but is also open to others by providing a generic delivery interface:
- Apache web server (asynchronous packaged content);
- Hyperwave's E-learning Suite (learning management system);
- RealNetwork's Realsuite (asynchronous streaming content);
- Isabel (synchronous collaboration tool and video conferencing system).

Requirements for Catalogue Design

The UNIVERSAL catalogue is an essential part of the system, since it brings demand and supply together and has direct implications on the costs of deploying the system. Considering the effected user groups (potential LR consumers, LR providers, and platform administrators), several issues arise. On the one hand catalogue design has to assure that potential LR consumers have efficient access to the LR they are interested in. It is essential for the potential consumer to find a desired LR quickly and with ease, since high search costs reduce the perceived net-value of a web-based information system (Kaukal & Simon 1999). On the other hand, platform hosts are interested in keeping the catalogue maintenance costs at a minimum level. Brin and Page argue that human maintained catalogues are expensive to build and maintain (Brin & Page 1998). In this paper we present a scalable approach that should make up this drawback.

The catalogue requirements from a LR provider's perspective are based on a qualitative survey at Austrian universities. Seven higher education experts, managers or pioneers in applying new media in the field of traditional higher education have been asked about potential obstacles for using systems such as UNIVERSAL. Concerning catalogue design the survey revealed that faculty members are reluctant to provide LRs of high quality when the quality of the listed LRs is not of a similar level. There is also a need of accessing LR-specific assessment and usage data in order to charge LRs depending on their quality.

A catalogue must have structured content of a well thought and well-defined standard set of fields that can be extended to all metadata elements to accommodate the uniqueness of the different types of resources as the number of catalogued resources increases and as the category tree expands.

The content of a catalogue must answer the following questions:
- What is available on the subject of user's area of interest (AOI)?
- What is the quality of available LRs and what do they look like?
- What is the procedure for the user to get a specific LR?

The Categorization Process

A hierarchical structure of a catalogue in the UNIVERSAL project will be presented in a multi-level hierarchy. The first level is a subject-centric level with main thematic categories which provide the subject structure of the catalogue content based on keywords from a selected classification schema, such as the Dutch Basic Classification (available at http://www.konbib.nl/88/kb/resources/frameset_kb.html?/kb/vak/basis/bc98-en.html). The top division of the classification schema is of particular importance, since it provides the first entry point to the catalogue and effects the organization of all the following categories. The second level is a title/authors/publication time/etc.-centric level where the structure is based on a certain elements of the LR metadata instances. These attributes are used for building categories (title/authors,...- the middle division). These elements (categories) are selected by the catalogue administrator. As the number of LRs grows the number of categories used in the middle division will expand. The second level may be repeated several times with a different category in each level (repeated middle division). The next level is a type-centric level with four types of LRs: course, unit, lesson and fragment (actually it is a specific type of middle division). The last (the bottom division) is for the actual links to
resources with all the important information for every resource, respectively. The top and middle division(s) are essential for navigation around the catalogue, and the bottom division holds information where the content of the catalogue is found.

The goal of the categorization process is to find the most appropriate categories under which every LR should be classified. The categorization process has two inputs. On the one hand, XML:RDF metadata instances of LRs are exploited and, on the other, the pre-existing category tree in a catalogue (let us assume that an initial version of catalogue exists) within which every LR must be categorized is taken under consideration (Fig. 1).

The category tree consists of a tree with a description for every node, which identifies the category and helps to properly categorize every new LR, which is to be added to the catalogue. The output of the categorization is a vector of weights associated to each node in the category tree. Each element of that vector represents the probability that the resource should belong to the category represented by each node. The vector of weights will be determined by using natural language processing tools, which will take advantage of a UNIVERSAL ontology.

The classification algorithm considers each node in the category tree as a context path. The weights from all context paths of the same resource are added (sum of weight vectors is performed) and if the normalized sum for a certain node is greater than a certain threshold, the resource is classified under that node. The mechanism allows classifying a resource under more than one node. However, the same resource could never be classified in nodes, which are descendant of one another. The title of a category is not sufficient to fully identify the category. The whole path (context path) is necessary to disambiguate among the categories.

The categorization algorithm works as follows: it first computes candidate context paths for classifying a resource, then it selects among candidates, and finally it updates the category tree and the entire catalogue. Every context path in a category tree (path from the root node to each node on every level in a category tree) is represented by a vector of weights $C_1, C_2, \ldots, C_n$, where $n$ is the number of levels in a context path. Each weight presents the probability that the resource should belong to the node. The initial value of every weight is 0. The values from the metadata instance are searched for an identifying description. If the value is found in node $j$ ($j = 1, 2, \ldots, n$), a certain discrimination weight is added to the weight $C_j$. Any path containing non-zero elements is considered as a potential candidate. The selection among these candidates is performed as follows. Any path with zeros in its leading fields should be discarded. This means that matches are found only in some subcategory, but not in the top-level categories. If more candidates remain then a candidate with longer path should be selected. This forces categorization under the most specific category. The selected candidate paths associated to the resource are stored in the database. If the same LR could be classified into different categories with different context paths (the same resource is reached from a different path), the categorization mechanism should either enforce the indication of the category for a resource or should suggest alternative categories for the resource (creation of a new category).

There are two possible cases when the categorization process should extend the categories in the catalogue. The first one is when the number of entries of a category exceeds a certain threshold (e.g. 40 entries). In this case the...
list of LRs would become too long for displaying it in a user-friendly manner. Re-classifying those LRs in new subcategories would significantly support finding desired LR effectively. The second case is when an alarming number of resources do not find a proper place in the catalogue hierarchy. Then a new category should be created.

To extend the categories, the context paths should be analysed further (Maarek & Shaul 1996). In both cases, the context path in a single large category should be searched for elements in the metadata, which produce partitions of the resources. All unused elements from the metadata instances of resources in that part of category tree should be considered as candidates for creating new categories.

Since several partitioning alternatives may arise, statistical or neural analysis techniques should be applied to rank the most promising alternatives and present them to the catalogue administrator who will decide which subcategories to add to the catalogue. The experienced catalogue administrator could do the selection of an adequate category instead of applying automated statistical or neural analysis techniques. However, we can already find products such as Autonomy and Vistabar on the market that are designed to automate the process of categorization. The choice between the manual or automated categorization lies in the decision of the level of automation of the whole cataloguing process (Salton et al. 1994).

User Interface Design of the UNIVERSAL Catalogue

Fig. 2 illustrates the two different types of user access to a repository of LRs: browsing and searching (Manber et al. 1996). A user starts browsing through catalogue and wants to discover what is available on his AOI. The top-level category (root node) is the starting point in his attempt to find a resource meeting his general idea of the item of interest. Then in the information discovery process user continues to browse and progresses to more and more details by refining the selection in every node moving from higher to lower level to the last possible selection. Browsing mechanisms enable users to locate and identify their AOI. At the same time a user can view relationships such as overlapping, intersecting and containment of the available resources with their AOI. A second way to explore the content of a catalogue is by defining an AOI with the search query. This process could be repeated several times and every time with a different function: search or browse. Therefore a list of resources from the search function must also contain information in which node of the category tree a resource can be found.

Catalogue Browsing Interface

The UNIVERSAL catalogue will provide a structured view on the LRs offered through the UNIVERSAL brokerage platform by introducing multiple levels of categories. For every node in a category tree index will be unique. An index is understood as a list of LRs sorted in a specific way (most common is descending alphabetical order) (Srihari 1995). Each index page should present its hierarchical location in the catalogue. The user interface should allow users to click on any node in the hierarchy (when a user is visiting certain node, the whole context path should be visible as array of hyperlinks) and when clicked it should send a user directly to that catalogue node. Which nodes (hyperlinks to nodes) should be visible (clickable) from certain node is a matter of discussion. However, the rule must be the same for all nodes (for example: all nodes in a context path and first descendant level to that node - if existing).

The catalogue in UNIVERSAL will use a hierarchical arrangement. In other words, users will be able to "drill down" from general to a more detailed level within the catalogue. Here a hierarchy may be presented as a triangle, with the root node at the top corner, and the lowest level of detail as the bottom edge of the triangle. If the hierarchical structure of this presentation is close to an equal-sided triangle then the hierarchy is assumed to be sensible and adequate. Smaller catalogues usually need only a few levels, while bigger may have a middle level of nodes between the root node and the lower level. As one same resource can be assigned to more than one catalogue node the same LR can be found also in several catalogue nodes of the category tree (if selected elements from the metadata instances allow categorization of the same resource into those nodes).

Search Interface

When search is performed the user searches a catalogue with a specific, focused goal. The search interface of the UNIVERSAL brokerage platform will provide the input dialog or selection fields to enter the specifics. The search could be performed "globally", i.e. within the complete repository of LRs. However also "local" search will be supported. Here only the content of that part of the catalogue, where the user is browsing will be subject of the search (this includes all nodes bellow a certain node). The search results are returned as a list of LRs. Then, the user
can explore the details of the returned matches through further selections, query refinements, and viewing of all information relevant to meet the initial specifications as closely as possible (Chalmers 1998). It is planned that the LR search engine will support previews and users will be able even to download a sample set of the resources to determine their match to the AOI.

**Figure 2:** A user may access resources in two ways: by browsing through the catalogue or by searching mechanism. Users are looking for offered resources meeting their Area of Interest (AOI). A link between the area of interest and the catalogue shows resources available in the catalogue meeting their AOI. The result of a Browse/Search activity is a list of resources (Browse/Search activity can be performed further on this list of resources). List of resources in every step is different moving from one position/size to another (dotted stop sign shape square) with goal to match with AOI square as much as possible.

The search engine of the UNIVERSAL brokerage platform will perform search based on the descriptions of resources (content of metadata instances) and will provide results as a linear list of resources. This is unsatisfactory because the list can be quite long, and indication of possible grouping of related material is essential. Splitting the list of resources into categories and displaying hits based on catalogue categories will significantly facilitate selecting those LRs the user is most likely interested in.

The scope of a search in a UNIVERSAL catalogue will be limited by the user's search location within the category tree. To search over one category a user should go to this category node. To search over whole catalogue (all LRs), he should simply go to the top-level node (root) and search from there. Therefore the user in order to broaden or narrow his search scope has to go to a more appropriate node in the catalogue.

When search will be performed a list of LRs will be displayed. A user is usually interested in how this list is near his AOI. The title of the LR is often not enough for a user to identify if a LR is on the subject of user's interest. The following information will be available: language, title, aggregation level, learning goals, educational aims, description, author, keywords, duration, costs, copyright restriction and categorization within the category tree. Depending on the LR aggregation, additional information is provided:
- For fragments: learning resources type (lecture, case study, exercise, simulation...), format, version, status (draft, final, revised);
- For lessons: instructional design (directed learning, self directed learning, collaborative work), starting time, ending time and time zone (for live lessons), delivery platform specifications;
- For units: pre-requisites (knowledge, experience), instructional design (see above);
- For courses: pre-requisites, program (undergraduate, graduate, postgraduate).
Conclusions

There are many approaches for building a catalogue hierarchy described in literature (Hahsler & Simon 2000). The proposed approach in this document is taking advantage of highly structured and highly flexible repository of metadata instances achieved by combining the advantages of XML and RDF (Guth et al. 2001) and enables full automation of a cataloguing process. This has an impact on fast and objective categorization of LRs into categories avoiding subjective estimation of the catalogue administrator or users in which category specific LR should be found (Cleverdon 1984). This approach also manages fully automated growth of catalogue and category tree as the number of LRs offered through UBP increases. Moreover, it facilitates a gradual automation of the whole categorization process. In an early stage of the project manual categorization will be done. Planned stages are:
- Fully manual categorization and manual managing of a catalogue (expansion of a category tree);
- Automated categorization in an already existing category tree and manual expansion of a category tree;
- Automated categorization of LRs and automated expansion of a category tree by applying analysis techniques of metadata for further partitioning of categories.

Is the Web Too Powerful?

Introduction

The Web has become a phenomenon in education, particularly in the Western world as Western nations are heavily industrialised and information technology occupies an important role in their development, economically and politically. The role of the Web in the so-called ‘global village’ has been endorsed by many and has also been critically questioned by others. Is the Web just a tool or is this tool too powerful? For those who question the impact of the Web in a global context, the Web in not just a tool as it also creates some social discrepancy and a paradigm shift. Paradigm shift refers to a meaningful change from one alternative to another. This can happen if current discourses are taken for granted and we are not critical of various aspects of our discourses, which include the Web culture. The Web is seen by many as a powerful tool for teaching and learning. The word “powerful” tends to designate usefulness to its users. However, if we view the Web in a critical discourse perspective, we start to wonder whether it could be ideologically free when it enters the educational discourse.

Tool and ideology

Recently, a new force under the names of Critical Theory, Critical Discourse Analysis, post-modernism, which promote debates social issues in the cultural and intellectual scene in many academic discourses. Advocates of these critical views aggressively criticized traditional culture, theory, and politics. They provide a critique of representation and hold the view of relativity which stresses that theories at best provide partial perspectives on their objects, and that all cognitive representations of the world are historically and linguistically mediated. From a sociologically perspective, they reject assumptions of social coherence and notions of causality in favour of multiplicity, plurality, fragmentation, and indeterminacy. They question the rational and unified subject postulated by much modern theory in favour of a socially and linguistically decentered and fragmented subject. The Internet has become another “battlefield”.

Ideology plays a crucial role in the development of critical theory. Interest in ideology leads to an understanding of, and sympathy for, the culture of the disadvantaged. Critical theory operates by empowering people from the coercion of ideology, by enabling them to recognise the reality of their situation and thereby giving them more control over their lives. From a critical theory viewpoint, educational practices are not themselves ideologically neutral, but reveals a context of cultural and political imposition. As Comber (1994) points out in reference to literacy education:

Literacy practices are not in themselves neutral, but work culturally and politically to privilege particular kinds of literacies and therefore particular kinds of literate students.

(Comber, 1994, p. 26)

As the Web is a powerful tool produced to serve a discourse, its neutrality in interaction and education can be questioned. Is the Web value-free from an ideology-loaded discourse? For those who consider the Web merely a tool, it is morally innocent and ideologically neutral. Like many other tools, it is a physical entity which is subjected to good use or abuse by human beings. However, it can be argued that the Web is a product and an instrument which cannot be divorced from its historical background and functioning. It was invented and has been maintained by a professional group or elite for serving their growing needs and reinforcing their
images and metaphors of their worldviews. The Web is there because it helps to maintain a system of social interaction. It is embedded in a social discourse and should not be treated as a separate entity.

According to Critical Discourse Analysis (CDA), a discourse can enhance some people and discriminate against others. CDA is a type of discourse analytical research that primarily studies the way social power abuse; dominance and inequality are enacted, reproduced and resisted by text and talk in the social and political context. With such dissident research, critical discourse analysts take explicit position, and thus want to understand, expose and ultimately to resist social inequality. The Internet is no longer "innocent" in their critical eyes. Metaphorically, the Internet is an international superhighway, which is not free from traffic. There are always carriers on the superhighway and cross different cultural territories. These carriers are not content-free and culturally neutral. They represent some powerful forces with explicit and implicit agenda.

The Web is exceptionally powerful as it can perform huge tasks with its electronic power. The newly introduced prefix e- such as e-mail, e-commerce, e-trade, e-banking, e-book, e-paper, etc. shows clearly the impact the Internet has in modern society. It empowers many institutions to revolutionize their old practices. The Internet and globalisation walk merrily together. However, this is not the way emancipation is perceived from a critical perspective. The dichotomy of empowerment and disempowerment is relative depending on a discourse community and external interference. It could be seen as disempowerment when the Internet brings along the gap between the e-people and those who cannot afford the Internet or those whose culture does not accept or worship the virtual reality. We all know when a highway runs across a village, its culture and environment are no longer the same.

According to Davison (1997) the importance of personal knowledge of the people involved in Internet-based learning is sometimes lost in a context of "globalisation". Education is a moral activity. It is concerned with people significantly affecting the lives of others and educators have a moral obligation to consider how their individual actions in the teaching/learning nexus might significantly affect the lives of those immersed in it. Education should seek to overcome false consciousness as individuals are caught up in a social context in which they are blind to inequities of their situation and can be exploited by the dominant class.

In order to seek students' views about the role of the Web in education, particularly from the Critical Theory and Critical Discourse Analysis perspectives, a Web-based discussion board was established to provide Education students at our university with a forum to express their views and attitudes toward the Web in general and its role in education in particular. The result indicated that the Web was considered as a resource for teaching and learning. However its usefulness depended a great deal on the theoretical orientations of course designers and instructors. Majority of students' comments tended to focus on the instrumental function of the Web in education, and little attention was given to the ideological aspects of the Web.

Conclusion

The challenge by Critical Discourse Analysis to the educational establishment is important for educators because it raises crucial questions regarding certain hegemonic aspects of modernism and by implication how these have affected the meaning and dynamics of present-day teaching and learning. Educators working in a Web-orientated cross-cultural discourse need to question how the master narratives become constructed and how they influence the thinking and living experience of others.

Abstract: A masters-level music analysis course was designed to introduce students to "real world" practice. All activities led to writing publication-quality articles, which were published in a peer reviewed and edited web journal. The students created an on-line community using the conferencing software, and posted the journal on a web server. The course was ranked very highly by the students for helping them to learn as well as being relevant to their future. The professor considered it a success in that most produced work that significantly exceeded his expectations.

The Case Study

For many students the transition from school to the working world is difficult. When a colleague shared this concern, I proposed a design experiment (see Collins 1992) to explore structuring his course to help bridge the gap. The framework was Legitimate Peripheral Participation (LPP) (Lave & Wenger 1991), in which the learner works as a novice professional (or apprentice) at the periphery of practice in their chosen field. Such a situated approach to learning builds on constructivism (see Honebein, Duffy, & Fishman 1993) and cognitive apprenticeship (see Collins, Brown, & Newman 1989) but stresses the socially constructed nature of knowledge as situated in communities of individuals working at similar practices. Rather than “learning facts” the learner addresses the practices and skills of the community. While students leave school with a wide array of knowledge, its application is often left for them to “pick up on the job.” Lave and Wenger argue that this knowledge is both valid and teachable.

Within the framework of LPP, the concept of communities of practice is crucial (see Brown & Duguid 2000). These groups working on similar activities can be as close-knit as a class of students or as diverse as an entire field of inquiry. One of the challenges for applying LPP to education is the identification of appropriate communities of practice. For graduate school, I assumed that writing articles was a valid activity of the students' communities of practice after graduation, since they were working toward a practical degree in music criticism. The professor agreed, and changed his original requirement for a final term paper to that of a journal article.

Qualitative methods of research have been shown effective in studying educational cases (see Merriam 1998) and design experiments (see Brown 1992). As this was an exploration, I chose case study as the methodology. With another person to actually teach the course, I was free to study the class as a participant-observer (see Spradley 1980) and take field notes during each of the class sessions as well as during on-line discussion. I also gave the students bi-weekly surveys about issues that they felt were important, and I triangulated all of this data with a 90-minute exit interview at the end of term.

Use of Computing for Learning

The class met once per week for a three-hour seminar. Computer conferencing allowed students to communicate between classes if they chose to. During the first half of the semester, the students used the system daily, only stopping when the system was unavailable. They credited the conferencing system with helping them become acquainted at the start of term, and they found that the mutual exchange of ideas benefited their learning. They cited being much better prepared for classes after discussion during the week, and their professor remarked that he had never had such intense discussions in class. The students also felt that they learned a great deal from seeing each others' working method, which demonstrated ways of thinking that they had not previously considered. They also found others' work to be useful working models, and felt that its very visibility held up a standard to strive for. The professor noted that this class produced the finest set of papers he had seen in the past decade.

The World Wide Web hosted the final articles in a student-edited journal. The students found this project enjoyable and worthwhile. All noted that they learned many computing skills that would be valuable for their future, and yet
this was not an explicit part of the course. Their concentration on such an ancillary skill is reminiscent of the concept of “stolen knowledge” (Brown & Duguid 1996) while their devotion of large amounts of time to their journal because of their enjoyment in creating it seems clearly related to the concept of “flow” (Csikszentmihalyi 1990). While web pages are fairly simple computer technology, they were critical to the success of the design. The mere existence of the journal on the web allowed its availability to a large proportion of “real-world” members of the academic community, and this in turn made the experience more real to the students. All students reported working much more carefully than on a “standard term paper” since this was their introduction to the professional community. The concept of the community of practice being “academics publishing in music analysis and criticism” came from the students, contradicting the professor’s initial notion that their audience be “fellow graduate students.”

**Educational Evaluation**

The success of the class was the result of the students’ engagement with the concept of starting their own careers by introducing themselves to their professional communities via the journal, and most worked long hours on the design and editing. Student enthusiasm for their own particular career and learning interests led to their synthesis of other work with the subject matter of this course, resulting in much richer and more interesting papers. The students were encouraged to contribute ideas, and many were implemented by the professor. As Lincoln (1995) has pointed out, there is surprisingly little research on learning from the perspective of the student, and this study suggests that there is a great deal of value to be learned from following the experience of students over an entire semester, or longer.

Merrill (2000) has identified five common traits of effective educational systems, which neatly sum up the experience of this course. Key to the experiment was that it was problem-based, rooted in the problem of the students starting their own career while still working toward their degree. To do this, we had to activate the students’ prior knowledge, challenging them to use all of their skills to write effectively. In teaching the new skills, the professor demonstrated how he wrote and critiqued, and the students had opportunity to write for each other and critique this writing, in a safe, supportive environment. This application of skills began with short, simple articles and led to the final one; the critiques increased in complexity at the same rate. Finally, all of the work of the course was integrated in the final journal article. The goal of the class had by this time become a personal goal of each of the students.

The class will be offered by the same professor in essentially the same way this year. Changes will include a more stable conferencing system and more tutorial assistance with computing. Also, although feedback from the professional community about the journal was extremely positive, this came after the semester had ended, and we are hoping to have an external reviewer to give the students feedback while the class is still in session.

Abstract: New technologies, like Multimedia Database Management Systems (MMDBMS), enable new possibilities for education. In the OMODIS-LoD project, we have developed a Lecture-on-Demand (LoD) prototype that is based on the Object-Oriented Database System ObjectStore and a new data model for multimedia data, called TOOMM. The prototype manages teaching material that has been originally used for CD-ROM based distance education of medical students at the University of Oslo. This paper describes the original CD-ROM based legacy application and the LoD system, as well as the experiences with the process of extracting teaching material from the legacy application and converting and integrating it into the LoD system.

1. Introduction and Motivation

There is a strong tradition to use new technologies for education. The development of multimedia technologies has enabled efforts in distance learning, both synchronous and asynchronous. Synchronous systems may be playout only, for example, a scheduled multicast of a recorded lesson, or live, with a student audience and a lecturer who manually controls presentation of slides and multimedia data. An example of a live synchronous system is the electronic classroom system$^2$ (Plagemann et al. 1999) that has been used between the University of Oslo and the Center for Technology at Kjeller for live distance teaching in graduate courses since 1994.

Asynchronous systems are implicitly Lecture on Demand (LoD) systems, where multimedia data are used for unscheduled playback (on demand). They tend to be interactive in the sense that the student controls the presentation sequence of different data elements, including following hypertext links and using “VCR-like” controls for play-rewind-reverse-forward. Asynchronous systems may differ as to how they handle questions and feedback, whether it is supported by the system or done offline (e.g., by email). Current asynchronous systems can be CD-ROM based or media server based. In a CD-ROM based system, (e.g., the Computer-Supported Learning Project$^3$), each student has his own copy of the read-only CD, so questions and answers must be handled offline through email or other mechanisms. An example of a media server based system that does not provide feedback mechanisms is the Cornell project (Mukhanpodhyay et al. 1999). Our project investigates moving from the static data of a CD-ROM to dynamic data of a Multimedia Database Management System.

---

$^1$ This work has been funded by the Norwegian Research Council in the Distributed IT Systems (DITS) program.
(MMDBMS), where content and questions are captured interactively, stored and updated online, and presented on demand. Additional reasons for the use of an online MMDBMS instead of CD-ROMs are data reuse as well as easy update and adaptation of learning material.

The OMODIS-LoD Project is working on a MMDBMS-based LoD prototype. The prototype is being done in the context of education for medical students on practical medical procedures. We have conducted a requirements elicitation (Eckland et al. 2001) for this context that also included more general telemedicine and other distance learning requirements. We found requirements for five functional areas: Element Production, Lecture Production, Question, View, and Core (select, setup environment, play). The Question functionality includes Ask Question, Answer Question, Notify (the teacher of new questions, the student of a new answer) and View (Question or Answer). Questions and Answers are themselves required to be supported as general multimedia data. The scope of interaction required by these applications (interactions such as interactive questions and answers, mentoring, and consultation) is best supported by an MMDBMS. We report our experiences with our first MMDBMS-based LoD prototype supporting learning of practical medical procedures.

2. The Legacy Learning System

The Multimedia-Supported Learning of Practical Procedures Project at the Medical Faculty of the University of Oslo developed, in cooperation with two university hospitals (National Hospital of Norway and Ullevål University Hospital) a CD-based set of teaching materials. The long-term project goal is "to capture actual procedures (e.g., surgery or diagnostic procedures) in the hospital and produce interactive multimedia lessons, delivered over the internet, that enable medical students to reinforce their learning of medical procedures" (Eckland et al. 2001). The CD-based system was the first step in achieving this goal. This legacy system will be replaced with a new interactive multimedia database system based on our prototype.

In the legacy system, each lesson covers one procedure, such as lumbar puncture, arterial blood sampling, pleural drainage, venous cannulation etc. Each procedure may contain one or more captured actual procedure video/audio sequences which are stored in RPZA-coded QuickTime Movie format. In addition to the captured video/audio clips, text, sound, pictures and animations are also used to illustrate each procedure.

For the legacy system, Macromedia Authorware was used to create an executable presentation program based on the above data materials. The executable integrates simple media data types such as text and images, and captured QuickTime movies are stored in separate files on the CD. At presentation time, the executable runs an external QuickTime player, which loads movie files and presents them in a specified area on the user's screen. Macromedia provides built-in mechanisms that work together with the QuickTime Player to support synchronized playback. The executable enables users to navigate the lesson in a stepwise way by providing users with Next, Previous, and Return button operations. Within each step, the executable recognizes the timing and spatial relationships among different media data associated with this step, and presents them in a synchronized way.

In the legacy system, each lesson is stored on a separate CD-ROM. A lesson includes the final executable and all associated movie files. The following section describes the Ellipse Biopsy lesson as presented by the legacy system.

An Example Demonstration

[3] For example, see The National Centre Of Telemedicine, The Regional Hospital of Tromso. Internet: http://www.telemed.rito.no
When the executable, Ellipse_Biopsy, is started, it brings up the main window shown in (Figure 1-A). The user can select among the option buttons: Introduction, Equipment, Procedure and Post-op care, to view different subtopics.

Suppose the user now clicks the Procedure button. The initial Procedure window is displayed as shown in (Figure 1-B). The window consists of a text area and an image and displays them simultaneously. The text serves to be a description or literal explanation of the image. The Next button (in right arrow shape) enables the user to go a step further into this section, while the Return button (in return key shape) will bring the user back to the main window.

Suppose the user presses the Next button now. The next window will come up with a text area and a movie panel shown in (Figure 1-C). The movie panel is ready for playback. The first frame of the video is initially displayed. The user clicks the Play button at the left-bottom corner of the movie panel to start playback. (Figure 1-D) is a snapshot of movie playback. An audio track explaining the video contents is played out in synchronization with the video. The Step Forward and Step Backward buttons at the right-bottom corner of the video panel allow the user to step through the video, if desired.

At anytime during the presentation, the user is allowed to return to the main window shown in Figure 1-A by pressing the Return button.

System Evaluation

The CD-based system did not meet the medical project goal of support for interactive questions and answers, online update of learning materials, and network-based or internet-based access to learning materials. Distribution of CDs and ensuring that students have the most recent version of learning materials was another undesirable side effect of the CD-based system. Pedagogically, the user-interface of the CD-based system was deemed to be sound. Hence, we have chosen to retain the look and feel of the legacy system interface.

The second-generation learning system, utilizing a multimedia database, enables support for interactive questions and answers, online update of learning materials, and flexible and consistent distribution of learning materials. Also the MMDBMS and its multimedia data model are extensible, allowing easy development of new user-visible features and services. We describe the multimedia database prototype in the following sections.

3. The LoD System

In this section, we take a closer look at how our LoD system is constructed. We start with a presentation of the overall architecture, then give in more detail a description of the two basic components in the architecture, the data model TOOMM and the database management system ObjectStore.

Overall Architecture

Figure 2 shows the general architecture of the LoD system. The architecture is based on a client-server model. The application on the client side interacts with users via a graphic user interface (GUI), interpreting user inputs,
retrieving multimedia data from the server if necessary, and presenting it to the user in a synchronized way. The client might also enable the user to use flexible multimedia data queries, e.g., retrieving a particular video clip of a particular lecture. On the server side, a multimedia database management system (MMDBMS) is responsible for the management of all the multimedia data pertaining to the lecture, such as storing lecture data to or retrieving it from the database. The MMDBMS consists of a data model and a database management system (DBMS). The data model serves to facilitate the access to the multimedia data objects managed by the underlying database management system.

In our first prototype LoD system, we have used commercial off-the-shelf technology largely. On the server side, we use ObjectStore (Lamb et al. 1991) as the DBS, while on the client side, we use Java applet to handle both the interactions with the user and with the server. We have also designed a new data model called TOOMM (Temporal Object-Oriented MultiMedia data model) (Goebel et al. 1999).

The TOOMM Data Model

TOOMM (Goebel et al. 1999) is a novel data model that integrates temporal concepts into an object-oriented multimedia data model. The three main elements of TOOMM are logical data model, presentation model and play time. Objects containing multimedia data are instances of object types from the logical data model. Objects instantiated from the presentation model specify how multimedia data should be presented. The play time places logical data units (LDUs), such as video frames or audio samples, into a temporal structure for multimedia presentations.

The logical data model differentiates between three main categories of object types: (1) play time dependent multimedia data types (PTD_MMDTs), (2) play time independent multimedia data types (PTI_MMDTs), and (3) components of PTD_MMDTs. The presentation model differentiates between two object types: APO (atomic presentation object) types and CPO (composite presentation object) types.

The OODBS: ObjectStore

ObjectStore is an object-oriented database management system (Lamb et al. 1991). It allows users to persistently store data, access data in the same format in which it exists in the application, and create and modify objects instead of tables, columns, rows, and tuples by using the ObjectStore C++, Java or ActiveX interfaces. In our LoD prototype, TOOMM data are stored and managed on the ObjectStore server machine. Multiple Java applets run on client systems and use the TOOMM model when retrieving and presenting multimedia presentations to an end user. Clients communicate with the server via the ObjectStore Java Interface (i.e., a set of Java classes and interfaces) for retrieving data and presenting data locally.

4. Conversion and Integration of Learning Material

In this section, we introduce the approach how we obtain from the original learning materials the data suitable for TOOMM and how we incorporate them into our LoD system.

Conversion of the Learning Material
The first step in populating the database is to extract the needed data from the medical learning material and store it as logical data objects in Object Store databases. By examining the original presentations created with Macromedia, we observed that the PTI_MMDT type data, such as texts, images or graphics, are small in size, and are therefore able to be copied either manually (for text) or by screen-shots (for images and graphics).

The movie data cannot be employed directly by the TOOMM data model, because both the Video and Audio objects implemented in TOOMM must be decomposed into LDU components Frame and Sample. Therefore, it is necessary to extract individual video frames and audio samples from the movie. We implemented a small extraction tool to recognize QuickTime RPZA format, and extract and convert each frame to either JPEG or GIF representation, which are codecs supported by Java. For our implementation, we use the JPEG codec. We did not extract individual audio samples because Java does not support fragmented audio playback. Hence, we extended the TOOMM Audio class to enable the playback of the audio clip as a whole.

Creating a Presentation

After the basic multimedia data elements were extracted from the medical data source and loaded into the Object Store database, we created our own LoD presentations using the extracted data and modeled it with the TOOMM data model. This phase includes: (1) creating a CPO graph, (2) defining temporal and spatial relationships, and (3) running the presentation as a Java applet.

Creating a CPO Graph : A large presentation usually can be partitioned into APOs and smaller CPOs which in turn might recursively contain other APOs and CPOs. In an example session of the interactive medical lesson shown in (Figure 1-A), when the user presses the Procedure button in the main window, a new interface is brought up where some text and a movie panel are displayed, as shown in (Figure 1-B). In turn, when the Play button under the movie panel is pressed, the movie which contains a video clip and an audio clip will be played in place, as shown in (Figure 1-C and Figure 1-D). It is natural to group all the presentation objects which are displayed in one interface (a window, for example) into one CPO. Therefore, the Procedure CPO object in this example can be regarded as being logically composed of a Text APO object and a Movie CPO object, and the Movie CPO object is further composed of a Video APO object and an Audio APO object. We can then create a CPO graph rooted from the Procedure CPO object as shown in (Figure 3).

Defining Temporal and Spatial Relationships: After the above CPO graph has been configured, part of the timing relationships between CPOs and their component APOs or sub-CPOs can be determined. For instance, in (Figure 3), Object P_Text will be displayed the same time as the CPO procedure is activated (i.e., the Procedure button is pressed). However, we cannot calculate the play time of the CPO_movie until the user presses the Play button in the movie panel. Therefore, the presentation must support a dynamic global start time setting for APOs and CPOs. Spatial relationships such as the position of the movie panel within the whole presentation region will also be determined in this stage of data construction.

Running the Presentation as a Java Applet: The final presentation is carried out in a Java applet running on the client system. The applet runs two threads concurrently. One thread is responsible for retrieving TOOMM objects from the ObjectStore server. The other thread captures user input and renders the retrieved multimedia data onto the GUI according to the specifications of their temporal and spatial constraints.

5. Experience and Lessons Learned

The current prototype of the Medical LoD system has been proved to be able to enable the stepwise interactive presentation to the end users. During the project we learned several significant lessons. First, data extraction and data loading is a time-consuming process and must be carefully planned. Second, selection of client software and server software is critical. We have two issues with client and server software.

1) There are restrictions on which Java-supplied classes can be made persistent, in particular Image and ImageIcon classes that we use cannot be persistent. An Image or ImageIcon object must be obtained for each frame before the frame can be displayed on the GUI, but the creation of Image or ImageIcon object can be very...
time-consuming. An obvious solution is to create these Image or ImageIcon objects in advance and store them into ObjectStore for faster retrieval later by the presentation. However, the fact that Image/ImageIcon classes cannot be made persistent has made us to seek other non-efficient workarounds.

2) The Java image drawing process is a major bottleneck. An individual image drawing would require a delay of about 100ms in a Sun Ultra 10 Station with 128M memory, much longer than the acceptable frame duration 33-40ms. Image strip and multithread image loading techniques have been tried to solve this problem, but they have not been entirely effective.

Our current work is concerned with performance improvements of the LoD prototype. In the long term, we aim to support user needs and requirements that are stated as Quality-of-Services specifications in the entire LoD-system.

Reference

Abstract: For teachers using Internet resources, weeding through a morass of Web sites, separating relevant from irrelevant, and ultimately locating useful resources that they can integrate in their instruction were such a daunting and time-consuming task. The need to minimize frivolous tasks in resource seeking and the demand for immediate access to relevant instructional resources gave rise to a new venture entitled "eThemes" - the Internet resource scouting service. To start with, three graduate assistants with library and education backgrounds were hired to staff the scout team. In addition, a database application was developed for managing and distributing Internet resources requested by teachers. Both the scout team and the database were perceived invaluable to teachers for saving their time and effort in finding appropriate Internet resources that can be quickly integrated in their instruction.

Introduction

The Panel on Educational Technology of the President's Committee of Advisors on Science and Technology (1997) reported "the real promise of technology in education lies in its potential to facilitate fundamental, qualitative changes in the nature of teaching and learning" (p. 13). Studies (Becker & Ravitz, 1999; Sandholtz, Ringstaff & Dwyer, 1997; Wilson, Teslow, Cyr, & Hamilton, 1994) affirmed that computer and Internet uses have positive impacts on teachers' pedagogical practices. Among these impacts is the shift of designing instructional systems from teaching to learning and from instructional objectives to facilitative environments. This also reflects the willingness of teachers to relinquish their authority in dictating the learning process and content in favor of giving students greater choice in learning tasks and resources.

To help Missouri teachers use technology to enhance teaching and learning, the School of Information Science and Learning Technologies (SISLT) at University of Missouri - Columbia began a project entitled "eThemes" (http://emints.more.net/ethemes/) in 1999. The goal of this project has been to support Missouri teachers in integrating valuable Internet resources in their instruction to create an active learning environment. This paper traces the background of the project and explores issues related to locating Internet resources that need to be addressed. The project is presented as a solution to explicate how these issues can be resolved. Project results are discussed while further improvements are proposed.

Background

To improve student performance as measured by the Missouri Assessment Program (MAP), teachers are learning new and different teaching and learning strategies with the addition of technology in their classrooms. One of the most successful state initiatives promoting this changes has been the MINTs (Multimedia Interactive Networked Technologies) project, which began with 13 teachers in six St. Louis schools in 1997. The MINTs project was designed to transform the teaching styles and techniques of teachers in an effort to improve student performance and enhance life skills preparation through the infusion of technology. By placing state-of-the-art technology in the hands of teachers and students with full technical support and training and by eliminating the technology barriers traditionally experienced by schools, this project has encouraged a new way of instruction - a way that engages students in their learning by making resources available in a learning environment that fosters cooperation, collaboration, problem solving and higher order thinking skills. The results of this project were so successful that it prompted the Missouri Commissioner of Education to launch a statewide initiative to change the way Missouri is educating its K-12 students. This new initiative is the enhancing Missouri's Instructional Networked Teaching Strategies (eMINTS) Project. The eMINTS project has spread across the state to include188 teachers in 88 school districts throughout Missouri.
Issues

After placing technology in eMINTS teachers' hands, a logical next step was for those teachers to integrate Internet resources in their instruction. However, providing teachers with the infrastructure for tapping into Internet resources has not proven to be a panacea. While teachers may be aware of the richness of content and resources on the Internet for teaching and learning, they are often hindered by lack of time and possibly the skills needed to locate these resources. In other words, teachers may know what resources they want but may have difficulty in finding them. Several issues contribute to this impediment.

First, the Internet is like a school library, only much more extensive. Internet resources are similar to all books in the library but not shelved and sorted in a familiar way. Accessing Internet resources becomes much more difficult because numerous Internet search engines utilize different cataloging and indexing systems. Each has its own underlying algorithm and requires a different searching technique. Without mastering such techniques, the user often gets unexpected or inconsistent searching results. This is why use of effective searching techniques is so important. Unfortunately, many teachers have not been trained in Internet searching. As a result, searching for Internet resources can be a frustrating task.

Second, the growth of Internet resources continues at a speed that no one can image. Searching for a resource can be like looking for a needle in a haystack. For example, a keyword search of "Missouri History" on the Yahoo site returned 19 matched categories and 204 matched sites. These numbers will significantly increase when this article goes to the print. While search engines are helpful, none is perfect. Users still have to sift through numerous search results to locate what they want. It can be a time-consuming task that most teachers are too busy to carry out.

Third, the hypermedia nature of the Internet keeps the location of Internet resources in flux. As authors and servers of Internet resources move, the links to these resources often become disconnected. Broken links become a dreary issue for many users. In fact, according to a Web user survey conducted by the Georgia Institute of Technology (1998), Web users ranked broken links as the second most frequently cited problem on the Web. This is particularly problematic for teachers who rely on Internet resources for instruction. Usually, they are not informed about the problem of broken links until they need to use these links. Instructional quality can suffer when students are struggling to figure out what is wrong. Even though teachers know this may be a problem, they do not necessarily have the time or energy to fix these broken links. Therefore, administering Internet resources can be a laborious task for teachers.

Fourth, the process of finding and maintaining Internet resources is often conducted by individual teachers. Those teachers who identify valuable resources may not know other teachers who may benefit from these resources or how to share the resources they have found. Consequently, teachers' efforts are often duplicated in locating common Internet resources.

The Solution: Internet Resource Scouting Service

For teachers using Internet resources, sifting through a morass of Web sites, separating relevant from irrelevant, and ultimately locating useful resources that can be integrated in their instruction can be a daunting and time-consuming task. The need to minimize frivolous tasks in resource seeking and the demand for immediate access to relevant instructional resources has given rise to a new venture - the Internet resource scouting service. This service for eMINTS teachers began in May 2000 when three SISLT graduate assistants with library and education backgrounds were hired to staff the service team. In addition, a database application entitled "eThemes" was developed by SISLT for managing and distributing Internet resources requested by teachers.

eThemes service

Figure 1 depicts the fundamental process flow of using eThemes to create and manage Internet resources. The process starts with a request by an eMINTS teacher. Once the service team receives a request, a resource scout is assigned to search Web sites that match the criteria of the request. Then, a resource record that contains the information of matched Internet resources is created and published in the eThemes database. Meanwhile, an e-mail notification is sent to the requester who then uses the resource in his/her instruction. Also, the requester can
provide feedback for the resource scout to revise the resource. Once a resource is published, other teachers can use the database and search for archived resources that can be used in their instruction.

**eThemes database**

eThemes is a Web-based database system that helps the service team to fill requests from teachers and provide them the needed functions to search and use Internet resources. It allows the service team to build a collection of Web sites with current, relevant content which are aligned with Missouri education standards. It also enables teachers to share their instructional resources using technology.

There are three primary modules in eThemes -- Request Fulfillment, Resource Search, and Resource Administration (see Figure 2 for the main menu). The Request Fulfillment module keeps track of the requests that eMINTS teachers make for resource scouting services. A request contains the information about the content and format of Web sites the requester wants. A resource is composed of a collection of resource links and associated information. A resource link contains the URL, title, and description of a Web site. The Resource Search module allows a teacher to use keywords, names, grade levels, and Missouri education standards to help teachers quickly find the resources they want. The search results can be sorted by their relevance to the search query or by alphabetical order. The Resource Administration module is the place where the service team manages its services. This module contains the functions for a scout to create and revise a resource based on a request. It tells which requests are new, which requests are assigned to whom, and which requests have been filled. In addition, it has a link validation utility that checks broken links on a regular basis with an automatic mechanism to inform the service team and the link users. Also, a monthly usage report is generated for the management to track the eThemes services.

**Figure 1: Process flow of the eThemes service**
Results

The eThemes service was formally launched in May 2000. Between May and September 2000, more than 200 resources and 1500 resource links were created. To evaluate the effects of the eThemes service, nine focus group interviews with 27 participating eMINTS teachers were conducted by the Office of Social and Economic Data Analysis at University of Missouri in the summer of 2000.

Value of the eThemes service

The most common benefit stated during the focus group interviews was that the eThemes service was a time saver. One participant described searching for information on China, a search "that would have taken me days or weeks." Instead this teacher used eThemes and saved considerable time. Another participant commented that a teacher could spend hours trying to find graphics. While the evaluation team was present, this participant checked her e-mail to see if the eThemes had answered her request for a moving wagon graphic. It was there and she was delighted with the results.

Virtually all of the participants had positive things to say about the usefulness of the materials that they received. The participants reported receiving multiple sites that could be used in their lessons, and many reported receiving more materials than they expected. In one school teachers were able to construct a school-wide Millennium project using sites collected from an eThemes request. Most of the participants who have not yet used this service acknowledged that they would establish a connection with this service.

Value of the Resource Scouts

Central to the value of the eThemes service are the activities of the resource scouts. The scouts have been perceived as an important resource for teachers, especially as teachers develop new lessons using Internet resources. Many participants have commented on the friendliness and helpfulness of the scouts. Several participants have been impressed by the responsiveness of the scouts and have appreciated their efforts to provide useful and appropriate Internet resources for their students. By and large participants have been satisfied with the turn-around-time for resources. The following comment is typical: "Anytime I've requested anything from them,
Possible Areas for Improvement

First, the participants' opinions about access to the eThemes archive vary widely. Some participants thought that the archive is easy to understand and use. These participants went to the Search module first because chances are that whatever they were looking for had already been collected. Another participant commented that she had to stumble on to the archive to find a resource; and at least one participant said that she didn't know about the archive and had thus never accessed it.

Second, while most participants agreed that the subject matter of the received sites was appropriate for their students, some maintained that the sites need to be thoroughly researched for appropriate content. This includes materials that, while topically appropriate, may not be appropriate for an elementary school audience.

Third, several participants thought that access to lists of sites used by other teachers would be valuable. They have requested that “hot lists” i.e. lists of Internet resources used by individual teachers in their lessons be posted on the eThemes site. The participants had confidence in the sites that their fellow teachers used and recommended. Although eThemes was referred to as an excellent resource, the participants said they still had to figure out the links and decide what was appropriate. But if another teacher used the site, they felt more assured that the site was classroom ready.

Conclusion

As the Internet becomes a more pervasive instructional tool, a resource scouting service such as eThemes is creating a valuable niche for itself. The purpose of this service is to minimize teachers' non-value added efforts on searching resources while maximizing sharing among teachers in order to free them to concentrate on what they do best - instructional design and teaching. The eThemes project is an ongoing effort. While we strive to perfect the technical aspects of eThemes, the experience of this project has affirmed our belief that “any technology design has to reflect its human value.” The real benefits from technology cannot be achieved unless the "human touch" is in place beforehand. The most frequent and serious mistake made is to implement technology for the sake of technology and to neglect human components of the technology. A fair assessment of eThemes is that it is not merely about the quality of the resources relayed to the teachers. The quality of the interaction between the teachers and the scouts is more significant to the teachers. Indeed, eThemes appears to be about building relationships of credibility between the scouts and the teachers. Scouts have been and need to continue to be perceived as helpful and responsive. Thus, scouts may value the confirmation that how they serve is nearly as important as what they serve—in short, being “customer centered.” This is true not only for eThemes but for any technology project.

Abstract: Architects devise the space that shapes our human life. The rise of Information Technology gives birth to the liaison of artistic architecture design and pioneering technology. Making state-of-art visualisation by means of varied environmental configurations, any humble design can attract wider attention from a variety of audiences. This research aims to establish new methods of space creation techniques that can be introduced into architects forming curriculum. The technology, such as virtual reality, remote sensor techniques, and photo/video manipulation skills will be investigated in the research. The research is also seeking the possibility to create a study opportunity for architecture discipline with particular reference in innovating proficient media technology of interests.

Introduction

Through the prevalence of computers and increase of IT (Information Technology) literacy in Taiwan, computer technology has been adopted as part of fundamental knowledge. Nonetheless, the IT education in this level does not intend to cultivate perfect genius of computer scientists in the future, but in a way that more confident and well-accessed to modern form of IT can become part of their future life. However, the concept of integration various media into each school curriculum is moving slow and has not yet growth to the stages of how to teach, what to teach, or why to teach. Enhancing the IT literacy is getting government's attention. However, the stagnant education revision system in this country makes the improvement hardly to take effect. Lack of expertise is another challenge to magnify more strength from teacher forming institutions where the application proficiency of IT is also considerably low. Meanwhile, education practice is conducted by fixed form of teacher-to-student one way instructional scheme which is entirely abrupt to IT's idea of free form of development. Through the increase of the information exchange and good wealth of information presentation formats (Mitchell, 1992), the multimedia is formed and the demand for highly efficient data exchange is intensive. On-line nature of architecture visualisation has indirectly transformed the conventional service-to-client relationship of conventional architectural design project that existed in the past (Morgan & Zampi, 1995). Instead, the realm for potential clients is indefinite and the style of transaction in architecture-related projects are getting out of fence of paper-based drafts and labouring documentations.

Procedures and Findings

In this research, the author first few phases focused on the examining those new technologies and constructing the relationship of the discussed media technologies in architecture related subjects. The goal during this stage was to enhance the students' proficiency in applying new for of media technology in resolving problem that comes in the real-life situation. The later phases will extend the concerns of applying more media technology in architect’s professional and create opportunity for further collaboration between IT and Architecture expertise. The goal of later one was to create Architect’s profession with significant reference to the media technology. The research also expected the creation of media technology was a result of architecture demand-driven technology and the technologies have become essential to architecture study, not a plus to the architecture design capability. For instances, to identify new demands of IT in architects’ career; to devise new demands; to construct of media technology laboratory for architecture design; compose “optional course” for media technology in the strand of current architecture design; open joint degree for it and architecture with particular reference to media technology; a position of projects coordinator who will deal with the acquisition, surveying of tangible, architecture-related projects; course/modules lecturers for instructing and supervising projects for graduate students (Yanik & Hewett, 2000; Fisher, 2000).

To emerging Media Technology for Architecture Design Curriculum can be placed by the following
technologies. **Virtual Reality:** From earliest helmet-assisted viewing generation of virtual and environment-interactive sensation to the growing number of Internet's VR technology of virtual models is a generic term for forming spatial sensation and visualization. VR can both accomplish non-existent environment and distant, rare places with high difficulty of reaching. VR technologies have efficiently evolved into acceptance in ordinary people with less knowledge in programming as that is pretty much required in computer scientists. More and more convenient toolkits not only make flying through space easier but also making space creation a simple job. Internet also allows models to be posted online to gain public attraction and improve the quality of appearance, speed of playing with models and maximal capacities of number of players/viewers.

**Photo/Video Manipulation VR:** While VR is gaining higher and higher acceptance of space modelling, another trend of space/object creation, or space/object re-creation, technique is on the move to attract the conventional VR users along the sinking price of photo/video capturing devices. Photo/Video VR manipulated technology is a visualization application by taking a snapshot of the target space or object or recording a video of desired space through walking around. Subsequent changes made in the process and fit into the devised model or reconstructed models can eventually make it appear more realistic. Broad-band technology in data transmission is a major contributor to make it happen as video clip demands very high data transmission within invisible motion picture frame delay.

**Remote Sensor techniques:** Measuring the dimension of space always complies the problem of reconstruction. GIS(Geographical Information System) and GPS(Global Positioning System) assist to identify distance of interested space. Remote sensor technology can even help to "scan" the dimension of remote objects. Then the acquired digital data can be helped to rebuild the space/object and make changes to them if needed. Architects and archaeologists can even rely on this approach to even reduce the space forming process. With remote sensor skill by devices, any good examples of architectural masterpieces can be reconstructed, resized, re-oriented, re-located, re-layout and re-fabricated by all kind of varieties. VR technology is also supplemented by both Photo/Video manipulation technique and remote Sensor's coordinates mapping techniques to allow for a higher precision of desired conceptual or re-constructed models. New media technology gives rise to higher acceptance of deploying computer at home user end and speed up the springing of computer-generated conceptual environment. As the technology moves in fast speed, people can immerse sooner in the totally computer generated environment easily anywhere by connecting to the desired host place. Architects' then turn their profession in satisfying the cyberspace's architectural environment where the interaction is constructed in a virtual venue. The way of training up architect in this direction is taking shape since more and more tools are available for authoring and the Internet has become the most favoured showing ground for illustrative models and ideas for future style and way of life.

**Suggestions**

The idea of this article is to re-think the IT education under the higher education level by developing curriculum strategies that are closely associated with the students' proficiency in deploying IT as well as data exchange technology.

1. **The Research center of Media Technology with reference in Architecture discipline:**
   The research was to establish a research center to deal with the increasing needs of media technology in architecture related subjects.
2. **Architecture Design Curriculum:**
   - **Near Term Plan:** Compose one media-based project module.
   - **Intermediate Plan:** Compose Joint Degree for IT and Architecture for Graduate levels
   - **Long Term Plan:** Compose Joint Degree for IT and Architecture for Undergraduate level.

Self-regulated learning as a strategy for enhancing the effectiveness of adult online learning

Cheng-Yen Wang
National Kaohsiung Normal University, Taiwan
Email: chengyen@nkucc.nknu.edu.tw

Abstract
Self-based learning is recommended as an effective style for adult distance learning. Adults also conduct online learning mainly distantly and independently. It reveals therefore that self-based learning would be significant and helpful for adult online learning. When the market of online learning is growing rapidly with the facilitation of information and communication technologies, it is becoming significant to explore how adults can learn effectively and successfully via online to achieve the vision of establishing a learning society. Self-regulated learning (SRL) is self-based and has been researched popularly in the field of traditional Educational Psychology but less discussed in adult learning. The author utilizes the literature review linking to his practical experiences to examine issues such as the feasibility of SRL and how to enrich the literacy of SRL for effective adult online learning in this paper. Concrete strategies for conducting SRL are also raised to be recommendations.

SRL for effective adult online learning

Briefly, SRL means the extent of how a learner actively regulates his/her learning in the dimensions of metacognition, cognition, affection and behavior. The key concepts of SRL are focused on how a learner begins, changes and maintains the process of learning and on the learning transferring (Boekaerts, 1999; Dharmadasa and Gorrell, 1996; Gilliam, 1990). When conducting SRL, learner plays the main role in the process actively and independently rather than passively and dependently. Comparatively speaking, self-directed learning (SDL) instead of SRL has received more discussions in adult learning. SDL is defined that adults learn according to their personal conditions such as goal setting, reading speed, and accessible courses. Malcolm S. Knowles and Steven Brookfield are all representative researchers on adult SDL. Accordingly, there is some overlapping between SDL and SRL. As Areeglado, Bradley and Lane (1996) argue, one of the meanings of SRL is learners self-directing to learning. It implies there is a closed relationship between SDL and SRL and both are

2046
Page 1996
self-based and flexible. However, there is potential difference between these two learning styles. Adult learners require more capabilities in regulating and managing their learning in SRL. Their cognition and metacognition and other self-skills are more demanding in SRL. For the subject, SRL has been introduced and utilized for younger school learners but SDL is mostly recommended for adult learners. In online learning environment, since multiple media are used and there are abundant and diverse databases in the Internet, adult learners need more skills to select feasible information by themselves. Therefore, more complex capabilities covering the domains of metacognition, cognition, affection and behavior on which SRL comparatively focuses are required.

Referring to the definition of SRL, we know that a successful self-regulated learner needs to control the process of learning possibly in the domains of his/her cognition, affection or behavior. For adults who are mature in physical and psychological conditions have a greater demand on autonomy for independent learning. Besides, self-based learning is especially suitable to part-time adult learners. It seems that adults would have more advantages to employ SRL in distance online learning. In the context of online learning, which has its own specific and particular characteristics, how adults conduct SRL to achieve a satisfactory learning effectiveness?

**Becoming a successful self-regulated adult online learner**

Adult learners have to learn how to make full use of learning resources carried and set up by electronic media on line. If the entering competences and prerequisites are not ready, adult learners may directly suffer negative effects such as anxiety to computer and lost in the abundant Internet data and information before get positive attainment. This is what Gary (1999) concerns that the Internet may result in alienation for learners. Martinez and Bunderson point out that learning skills such as complex-problem solving and self-managed learning are demanding and challenging to learners and recommend to develop constructs, adequately integrated with conative, affective, social and cognitive factors, to improve the instruction (Martinez and Bunderson, 2000). These ideas are similar to Zimmerman's arguments in SRL (Zimmerman, 1986, 1989, 1999).

Adult learner has to be the master in online learning environment. Oren, Nachmias, Mioduser, and Lahav (2000) also raise similar points. They suggest that personal interests, willingness to participate and motivation to interact with peers, teachers and other knowledge sources are all significant conditions for successful learning in the Web. As mentioned before, these personal factors are also foundation and crucial elements of SRL. It shows that for adult online learners, return to self-based learning would be significant and beneficial. For becoming a self-regulated adult online learner, the following potential strategies are formulated according to conditions for effective online learning and corresponding four domains of SRL ie cognition, affection, behavior and metacognition.
1. **Domain 1: Cognition**

   1.1 Conditions for effective online learning
   
   A. Understanding learning courses
   B. Being able to filter data resources
   C. Realizing his/her own advantages and disadvantages of learning conditions

   1.2 Strategies for successful self-regulated adult online learner
   
   A. Rating entering behaviors and prerequisite knowledge to be the reference framework for selecting online learning courses.
   B. Improving the capabilities of independent judgement to clarify the significance priority of data.
   C. Referring to standardized psychological measures and practical experiences to have more self-understanding

2. **Domain 2: Affection**

   2.1 Conditions for effective adult online learning
   
   A. Cultivating positive emotion to computer and other electronic facilities.
   B. Developing strong motivation to continue online learning
   C. Being independent and active even facing learning barriers such as suddenly losing typed documents

   2.2 Strategies for successful self-regulated adult online learners
   
   A. Recognizing electronic facilities as instruments and intending to learn how to use them successfully
   B. Learning to apply self-motivation as rewards to reinforce self
   C. Making learning peers and groups and having collaborative learning to obtain more social supports

3. **Domain 3: Behavior**

   3.1 Conditions for effective adult online learning
   
   A. Operating electronic facilities familiarly for learning purposes
   B. Applying multiple updated techniques to conduct learning and have continuing learning
   C. Resolving handy mechanic problems to clear out obstacles alone

   3.2 Strategies for successful self-regulated adult online learners
   
   A. Enriching fundamental literacy of information and communication from primary school
   B. Preparing many practical and working know-how manus and continuing to upgrade
   C. Asking other people for help and sharing their operative skills to enrich his/her competency to resolve faced learning barriers

4. **Domain 4: Metacognition**

   4.1 Conditions for effective adult online learning

   2048
A. Being able to evaluate the whole procedure of online learning and have self-correction and critical thinking
B. Being able to revise learning purposes according to the results of self-correction and self-feedback
C. Being able to arrange a helpful online learning environment by modifying advantageous and disadvantageous conditions

4.2 Strategies for successful self-regulated adult online learners
A. Learning skills for self-evaluation and self-correction from the beginning to the end of online learning
B. Examining the gap between learning purposes and resources available continually and making feedback to adjust goal-setting
C. Managing a suitable online learning environment and controlling the potential influential factors to meet personal learning needs

Further researches needed

The new millionaire is a new era of distance learning and online learning would be playing a critical role in distance learning. Adults are the majority population of a society. When information and communication technologies have brought abundant facilities available for creating online learning resources, it is vital to explore how to enhance the effectiveness of adult distance online learning. Effective online learning depends on many conditions encompassing hardware and software factors. Self-based learning is a principal style in distance learning as well as in online learning. A comparatively new concept in the field of adult learning, SRL, is discussed insufficiently. SRL is not a panacea but is beneficial to adult online learning. The application of SRL in adult online learning calls for further researches.

Abstract: This research aims to explore the digital knowledge and human space creation. A large number of papers have examined and investigated how to apply Computer-Assisted Design technique to implement pre-constructional, in-construction and post-construction visualization and simulation. Digital Architecture in this context takes another perspective to re-think how to improve the digital environment in this early stage has a significant impact upon how the expertise of future architecture-related practitioners is formed. This research will in turn investigate how the arrival of Digital Architecture Era affects future ways of living and people's relationship with environment and building construction materials and technology. In addition, how the future architects curriculum react to this trends that new forms of technology applications become essentials to the modern livings will also be examined by means of studying how to best achieve this idea.

Introduction

This research aims to explore the joint strength of modern electronic and IT (Information Technology) applications in devising new forms of prospect architecture and housing prototypes. A wide range of applications can be found in IA (Information Applications) that comprises of computer-like consumer products that people rely on closely for living (Aish, 1992; Mark, 1992). However, they are still treated separately from buildings and not yet brought into the building skeleton itself. The research will investigate how Digital Architecture can make use of modern IA/IT technology in establishing mutually affected relationship of Architecture and IA/IT from building’s designing phase to post-construction catering phase. This new type of future architecture must have a virtually identical capability of sensation processing as much as of human beings (Hendrics & Neuckermans, 1999). In other words, a robot of architecture that can communicate with people, deal with information received and give proper response to it. This architecture will also have a higher ability to self-regulate ventilation, energy circulation and also change its physical conditions upon environmental changes.

Procedures and Findings

This research breaks down the whole course curriculum into components and in each component, a study was to be examined to how best adopt new strand of digital technology in various fields and equip student with essential IT deployment capabilities.

In each group, the research examined the feature of the course and inaugurates digital technology in extending architect's capability in new Information Technology age. Architect in this age has diverse applications and the jobs for architects are not to be confined into constructing houses only. Technology enables architects with thorough IT expertise getting in touch more advance, technology related career, such as film animation for virtual environment, taking part in cross professional projects, etc. In the above strands, architect can also be specialized in specific curriculum.

1. Idea Inspiration: For centuries, the architects also play a role in creating the ideal environment for Human beings, though is not always limited to. Architects in each generation have to break through the restriction of structural/material/technical shortcoming and improve human settlement by creating innovative space that people are looking for. Devising space is an essential job that architect should perform and copying of space is infamous for architects in practice. The goal of Idea Inspiration strand is that student in this profession are always aware of in-depth technology that shape our life and its movement in the future. Computer or media assisted illustration and visualization, Internet-based information exchange and information acquisition are vital in this IT application.

2. Drafting: Most architects have received intensive training on how to best a good drafter that is a common and
an essential life in each generation of architect profession. Modern CAD technology has far penetrated into physical working environment and education ground. The goal that drives the research of this research in this strand is not simply to train student become even an advance drafter but an idea of adopting pattern formulation techniques.

3. Modelling: Elaborate models can always please prospect customers in gaining a higher perception of how architecture is dimensioned and layout. CAD tools for constructing three-dimensional models are getting common and supplying advance environmental setting and materials can give models a virtually realistic view. Modelling also has a significant meaning in reconstructing architecture that of structural or historical significance. Virtual Reality visualization is one of the pioneering technologies in constructing and navigating models in additional to CAD. The research of this Modelling strand will further examine how to add more interesting environmental setting, such as animated models, robotic models for architectures for simulation.

4. Statistics related Subjects: Architects must command a wide spectrum of information that is related to how a specific architect can be constructed and proper function. Internet allows for fast and efficient information gathering and exchanging. Courses in this strand are designed to encourage students to participate on-line Web-based discussion forum and join the various communities of Internet society and in fact a multi-laterals study. Internet and broadband communication infrastructure provide an ideal setting for obtaining and sharing information of interest.

5. Media and Presentation: New forms of Media authoring technology and home-site, customisable application can virtually create film-like presentation in a professional standard. In addition to drafting on desk, architects have to prepare works in an elaborate and customer-pleasing manner. Through advanced software and broadband technology, such as Video on-demand and Video’s teleconference, posting publicly models and ideas can be a much easier job than ever.

6. Site and Environment Cognition: Site survey is essential to understanding of physical construction environment. Modern surveys can work through equipments that can help to obtain environmental data, such as distance, dimensions, climate, botanical data, the nature of land, terrain, demographics, etc. Remote communication in Digital architecture research is to pose a window to construct the virtual environment based on gathered information and student can thus carry out study virtually at every place.

7. Engineering Courses: Complicated structures in physical engineering cases are best examples of teaching innovation in space arrangement and a demonstration of human desire of resolving engineering difficulties. Studying these structural examples or specific teachings materials on theory in Physics and Mechanics can be achieved through illustrative and interactive computer-generated models and animations. This strand can be incorporated with design/navigation/visualisation of models and virtual environment as well as historical studies.

8. Cross disciplines Studies: The future career of architect is not a single career for constructing houses. Cross discipline studies is of urgent priority can single architect professional are unable to resolve cross-functional problems. Future way of life is also highly IT dominated. The function of architecture is gaining complicated and also specialized. This strand of Digital Architecture is to stress the advantages the collaboration with other professionals.

Suggestions

The research explored each division's connectivity to digital application of architectural skeleton and hope to bring a close relation in future training of architect profession. Future architectures are mostly in uncertain forms. Through joint strength with IT, robotics and other professionals that come together, the digital architecture curriculum emphasis the future forms of buildings that possibly have to grow to unanticipated and unimaginable and re-think the current architect education approach that the explicit gap between fast changing technology is getting larger. Deploying IT and robotics human-interaction in architecture in this research was to allow architects immersed at the IT professions, making architect career be part of IT specialists and IT professionals be part of architect career.

Abstract: This study will explore the use of multimedia and hypermedia via telecommunications to improve student performance in a critical area: that of mathematics competency for urban middle school students. The article describes research into the process of preparing sixth graders in urban school districts for the Ohio state math proficiency tests with Web-based lesson plans, as well as using Web-based practice tests to predict their performance on these tests. Results from this prototype will be used initially with other state math proficiency tests, and will ultimately be expanded to the additional proficiency test areas of science, citizenship, reading, and writing.

Introduction and Problem Statement

With rapid increases in the educational use of the Internet, more students are learning collaboratively and K-12 educators are sharing their instructional ideas on the Web globally (see, for example, the PEN-DOR project in Fullerton, Greenberg, McClure, Rasmussen, & Stewart, 1999). The Web can bridge the gaps between urban and rural schools as well as between wealthy and disadvantaged districts by providing common, equally accessible resources to all.

In December of 2000, the state of Ohio released preliminary report card scores for school systems for the 1999-2000 school year based on proficiency test scores, attendance and graduation rates. Urban school districts were particularly notable for their poor performance on these measures, with one of the largest problem areas being performance on the mathematics proficiency tests. This study will explore the use of multimedia and hypermedia via telecommunications to improve student performance in a critical area: that of mathematics competency for urban middle school students.

Research Questions

This study will investigate five questions. (1) Can sixth graders’ math proficiency test scores be accurately predicted by the scores in Web-based practice tests? (2) Can free access to Web-based lesson plans and practice tests help university pre-service teachers to better understand and design math curricula which prepare students well for state proficiency tests? (3) Can free access to Web-based lesson plans and practice tests help current urban school teachers to prepare better math curricula which prepare students well for state proficiency tests? (4) Can free access to Web-based lesson plans and practice tests help parents/guardians to better understand and thus help their children prepare for proficiency tests? (5) Can free access to a common Website and a shared initiative to identify, screen, select, generate and share proficiency-aligned math lesson plans help build beneficial relationships between pre-service and in-service teachers and improve student performance?
The Study

Content is key in Web-based education. Design and development of math lesson plans and practice tests will focus on aligning with state education standards and sixth grade proficiency test mathematics learning outcomes. Approximately 30 sets of lesson plans and practice tests will be categorized into different math topics covered in the 4th and 5th grade levels. Series of math lesson plans and practice tests will be designed, developed, and collected by (1) enrolled College of Education graduate students who are currently working as math teachers; (2) a collaborating lead teacher among the representative educators from the urban school collaboration districts, and (3) other resources developed by other math experts.

Lesson plans will be freely accessible and/or downloadable by pre-service teachers, in-service teachers, students, parents, and interested associates. Access to practice tests will be reserved and will later be made available in accordance with the experiment schedule. All practice tests will be freely accessible by all participants at the end of the experiment. Hypermedia elements such as images, animation, sound, and digital video will be embedded into the lesson plans and practice tests as necessary. A CD-ROM with the collection of lesson plans and practice tests will be burned as requested by users.

All practice tests will be taken online. For practice tests in multiple-choice format, students will receive score reports online immediately after their submissions and the correct answer will be provided for any questions answered incorrectly. For practice tests in open-ended format, recommended sample answers with explanations will be provided to the students for self-evaluation after their submission. All materials and survey data, including information sent and received, will be hosted in a central server (see Wang, 2001).

All content, lesson plans, practice tests, and navigations will be extensively field-tested before Web page delivery. Team members, content creators, pre-service teachers, and urban class students will be invited for beta test and recommendation input. Other interested district educators, administrators, Web masters, and associates are also welcome to join. Based on significant feedback, revision will be conducted.

Sample subjects will be sixth graders in five urban school districts. Subjects will be asked to go over the Web-based lesson plans by following along with teachers in class. Follow-up Web-based practice tests will be administered immediately after each lesson plan is conducted. The proposed experiment schedule is approximately two times a week for fifteen weeks. Thereafter, subjects are welcome to review all lesson plans and/or practice tests at their convenience individually or supervised by teachers or parents/guardians.

Scores in the practice tests following the Web-based lesson plans will be used as the independent variable for research question #1 described above. A set of attitude surveys will be designed as well to measure the other four research questions.

All the experimental material delivery, survey, and data collection will be online. A regression model will be developed to determine the degree to which Web-based math practice tests can predict sixth graders’ state math proficiency test gain scores. Other attitude survey data will be used to analyze research questions 2 to 5 addressed above.

Discussion

A positive regression equation is expected to develop for the final research findings. If so, the quantity and quality of the collection of lesson plans and practice tests will be expanded and enhanced. Further research can be conducted on the impact of aligned lesson plans with other grade levels. If the majority of math proficiency test scores for each grade can be predicted by the regression equation, the materials will be promoted for use in other urban and/or suburban school districts using multimedia collaborative Web-based lesson plans and practice tests in the other core proficiency areas of science, citizenship, reading, and writing.

Communicative Collaboration: Four CSCL Students' Online Group Collaborative Learning Perceptions and Experiences

C.Y. Janey Wang/ Paul E. Resta
Learning Technology Center
University of Texas at Austin
United States
janeywon@mail.utexas.edu/ resta@mail.utexas.edu

Abstract: This paper reports a study exploring four Computer Supported Collaborative Learning (CSCL) 2000 class students' (from diverse ethnic backgrounds) perceptions of and experiences in knowledge construction and group collaboration. Communication and interpersonal relationships emerged as major areas of concern in this Naturalistic inquiry study. Findings indicated that individual and group successes are interconnected in the online collaborative learning environment. Group success lies upon successful negotiation and construction of shared knowledge among members of the group. However, many verbal and nonverbal communication cues are largely missing or limited in the highly technologically-reliant environment. Educators who are interested in designing online courses for students of diverse backgrounds should consider the social and cultural aspects of communication. Future studies should focus on exploring effective cross-cultural communication, challenges, successes, and strategies.

Introduction

Technological advances have allowed global communication. The Internet has created opportunities for widespread electronic delivery of news, information, and curriculum and has altered the way we communicate, share knowledge, deliver education, and conduct business. It provided the possibility to erase geographic and interpersonal boundaries among people of diverse backgrounds.

The Internet population has exploded globally from 3 million users in 1994 to 119 million users in 1998; Internet traffic is said to double every 100 days. (Joo, Jae-Eun, 1999) Driving this rapid growth is the Internet's ability to "bring close what is far away" (Holmes, 1997, p. 28) by enhancing communication, its promise of collaborative opportunities in an array of areas, and our need for connection and interaction. The strengths of communicating on the Internet derive from its accessibility, interconnectivity, immediacy, interactivity, mobility, and flexibility.

However, amidst the hype of new technology, human communication strategies often lag in their adoption of and adaptation to rapid technological advancements, much like any other species caught in a rapid alteration of its ecosystem. In order to understand how learners adapt themselves to the technological environment and what their needs and concerns are, an exploratory study regarding students' perceptions of and experiences in an online CSCL course was conducted.

This paper briefly describes the method, context, participants, and findings of the study. Findings suggest that educators who are interested in designing online courses for students of diverse backgrounds should take into account the social and cultural communication aspects of interaction. Future studies should focus on exploring effective cross-cultural communication, challenges, successes, and strategies.

The Study

Conducted within the constructivist paradigm, this research focused on four students' perceptions and experiences in a computer-supported collaborative learning class where a major aspect of the course design was based on constructivist theory. Naturalistic inquiry was used as the research strategy for this study. As described by Erlandson et al.(1993), naturalistic paradigm assumes that there are "multiple realities;" affirms the "mutual influence that researcher and respondents have on each other;" and assumes that "total generalization is never possible."

The context being studied was a CSCL 2000 course that was designed to assist learners in understanding, creating, and reflecting through engagement in six course modules. A variety of group projects were embedded where learners engaged in collaborative team building, learning, decision-making, problem-solving, knowledge construction, information inquiry, project construction and evaluation, and
critical analysis. To accomplish project objectives, online socialization and communication were essential. Hence, course success, in the classic sense of learning accountability, resided on the students’ success in collaboration.

This study focused on four female graduate students enrolled in a CSCL (Computer Supported Collaborative Learning) graduate course offered in 2000: a 47-year-old Caucasian, a 24-year-old Asian, a 32-year-old Mexican-American, and a 29-year-old Indian. Each individual participated in two interviews and e-mail communications with the researcher from mid-October to mid-December, 2000.

Findings

Study participants reported that misunderstandings often occurred from divergent expectations, worldviews, and values. Interpersonal relationships were perceived as superficial due to distrust in technological tools, concerns about privacy in cyberspace, and uncertainties of the collaborative process.

Participants reported that many communication methods available in face-to-face interactions were either missing or limited in the cyberspace. For example, during the synchronous chat, collaborators were unable to distinguish voice tones and emotions. In online communication, communicators were objectified as names or pictures rather than as humans, and it was difficult to drag a person aside and whisper in the midst of group chats. During video conferencing, limitations of the camera necessitated either long shots that lost details or close-ups that focused solely on the speaker, whereas in face-to-face meetings communicators control and select their focus.

Due to the nature of collaboration and the need to negotiate toward shared meanings, online collaborators reported spending a considerable amount of time attempting to understand, check, confirm, coordinate, negotiate, and discuss with group members. Participants reported that feelings of uncertainty, isolation, frustration, or anomie may occur because of technological failure, limitations in tools, interpersonal interaction, and group relationships.

Participants suggested that in order to make the group decision-making process easier and results more meaningful, individuals should clearly state their expectations, be cognizant of the various cultural and individual notions of time and responsibility, be sensitive to the perspectives and needs of others, and communicate frequently with group members to resolve conflicts.

Conclusions

The study concluded that group success lies upon achieving commonly shared ideas of success and commitment; a clear understanding of problems to be solved; mutual respect and understanding; flexibility; a positive attitude; and openness to new ideas and suggestions. In the online collaborative learning environment, learners were responsible for their own learning as well as achieving group goals. Constant negotiation was required to develop mutually shared meanings. Through communication and collaboration, individuals came to understand their reality as well the reality of others. Through constructive feedback, learners constructed, modified, and reconstructed their knowledge.

Education Support Paradigm as Knowledge Management

Toyohide Watanabe
Department of Information Engineering, Graduate School of Engineering, Nagoya University
Furo-cho, Chikusa-ku, Nagoya 464-8603, Japan
E-mail: watanabe@nuie.nagoya-u.ac.jp

Education can be looked upon as a kind of knowledge management for students. Also, various education styles, which have been traditionally performed in the universities, schools and homes, support individual knowledge-handling phases from different situations independently. For example, we can categorize education styles into 4 classes globally, and observe these styles in our environment easily: 1) Knowledge transfer from text-books or existing materials, 2) Knowledge transfer with other students, 3) Knowledge transfer from teacher with one-way-based lecture, and 4) Knowledge transfer with tutor/adviser with synchronized interactions. Figure 1 illustrates the conceptual framework for these 4 education styles. The arrows show the interaction for student, who acquires knowledge newly, refines the acquired knowledge by itself, integrates the refined knowledge into the already systemized knowledge, and applies the integrated knowledge to various problems. Of course, these knowledge-handling processes can be supported successfully in each domain in Figure 1. In Figure 1, each domain is distinguished clearly by the constructive relationship between teacher (or tutor) and students: (x:y) represents the number of teacher ("0" or "1") for "x" and the number of students ("1" or "n" (n>1)) for "y". For example, (1:n) means that the number of teacher is "1" and the number of students is "n". These education styles have possibly been implemented by means of the corresponding education support systems: (0:1)-style is by CAL (Computer Aided Learning), (0:n)-style is by CSCL (Computer Support Collaborative Learning), (1:n)-style is by CAI (Computer Aided Instruction), and (1:1)-style is by ITS (Intelligent Tutoring System).

The knowledge-handling process in the education can be corresponded analytically to phases in the knowledge management. SECI model which was initially proposed by I. Nonaka, et al [1] makes it possible to explain a knowledge-based activity for human beings or productive organizations effectively and systemizes the intelligent activities from a viewpoint of knowledge management. SECI model is composed of 4 concept domains, as illustrated in Figure 2: Socialization, Externalization, Combination and Internalization. These 4 types of knowledge-handling activities are related in the spiral form. These 4 concept domains are defined through the interactive relationship among individuals, groups and organization, and also are interpretatively explained as a knowledge transformation/reproduction process: the socialization from implied intellect to implied intellect is to acquire the knowledge by self-activity; the externalization from implied intellect to formalized intellect is to refine the knowledge by group activity; the combination from formalized intellect to formalized intellect is to integrate the knowledge by organization activity; and the internalization from formalized intellect to implied intellect is to expand the knowledge by interrelated activity. Figure 3 illustrates the adaptation of education styles in Figure 1 in accordance with the framework of Figure 2. Of course, in our real world these 4 types of educational activities are not always performed practically in the spiral form, but are often organized
independently in the learning environment or learning motivation for/of students. Additionally, the education environment, which can provide sufficiently such a spiral process among related educational activities, has been not yet implemented in our real world.

However, we can organize such a spiral process with mutually related educational activities as a typical architecture of education support system. Figure 4 illustrates various composite modules, derived from elements and their relationships in Figure 3, and also shows 4 types of education support systems, related organically to the composite modules. These composite modules are well-known ones which have been generally investigated in the current education support systems, except for the private learning field. The private learning field is a functional interface for students. The self-learning supports the socialization mechanism, the group learning covers the externalization mechanism, the lecture corresponds to the combination mechanism and the private lesson provides the internalization mechanism. Namely, these 4 types of educational activities are successfully achieved by architectural framework in Figure 4. Especially, the system integrated from ITS for the private lesson and CSCL for the group learning can contain all necessary educational modules, and takes a basic role of managing the learning process successfully. Thus, the unified framework of education support system can be organized on the basis of those of ITS and CSCL. Of course, individual composite modules must be controlled effectively with a view to attaining different learning situations independently.

Evolution of a Student Model Building Program Designed to Assist Understanding of Biological Control Systems

Abstract: Tertiary students in graduate and undergraduate medical and biomedical science courses have increasingly diverse backgrounds in prior academic achievements and culture. This presents problems for teachers assisting students to understand complex biological control systems. Our approach is to have students work in small groups to construct their own simple model of such a control system. This model then provides the basis for a structural framework for them to add further complexity without losing overall perspective, and allows exploration of deeper issues. Our interactive model-building program is suitable for many disciplines and student backgrounds, and provides a visual representation of a difficult concept, aiding in memory retention and providing a basis to ground further knowledge. Audit trail data have been analyzed to identify and resolve areas of student difficulty, and extensive surveys and observations on students' use of the program over three years in several courses have been used to improve and test its effectiveness.

1. Introduction

This article reports on the development of a multimedia module (first described in Weaver et al, 1999) in which students are asked to construct and explore their own model of a complex biological control system and then use that model for further investigations. The long-term continuous formative evaluation and adjustment has now led to the international distribution of this program on CD (Weaver et al, 2000).

Teaching Complex Control Processes in Biological and Medical Sciences

Our new approach is to introduce a qualitative conceptual framework for a model that is suitable for introducing complex control systems to students in biological and physical sciences, economics and engineering. In other words we facilitate the students' building of the 'big picture' of a complex system before going into the details. Such an approach has also been taken to bring teaching into alignment with practices in new curricula that increasingly rely on problem-based learning, problem-solving, student-centred learning, and self-paced learning.

Biological science was previously regarded as a soft learning option, but the growth in biological knowledge has meant that concepts have become increasingly difficult to understand as systems are elaborated through research. It is always a challenge to teach difficult concepts in an engaging manner. This project is a direct response to student and staff difficulties with the teaching of biological feedback control. This approach might equally well apply to fiscal modelling in economics or to a complex engineering principle.

2. Program Design and Evaluation

Pedagogical Issues:

We use the computer program effectively as an expert system that assists students' construction and testing of their model by providing construction tools, simple animations of their model operating, feedback screens indicating success or failure of their model and hints on possible changes they might make. Students may find deficiencies in their model, need to adjust misconceptions, suggest modifications in the expert model for future implementations, or exhibit misunderstandings in common with other students. On completion of the model, students are given tasks with a strong element of reflection in their use of the tutorial as they try 'What if?' scenarios and elaborate on the knowledge into new areas.
Software Design Principles
The essential feature of the program is to present the information in a simple qualitative manner that could be used to give a global view of the control system. This conceptual framework can then be used by students to add specific details of the mechanisms or indeed to better understand a mathematical simulation of the system at a later time, such as would be appropriate for engineers. Teaching programs are always based on either explicit or implicit assumptions about learners and learning and the desired cognitive outcomes. Some issues we have tried to address are described in Weaver et al, 1999.

Model-Building as a Series of Cognitive Steps
Students are required to create and position components of an electrical (neural) circuit to create a control system that will allow a person to maintain the blood supply to the brain when they change posture. Students are then expected to select components consisting of receptors (signal detectors), input (afferent) neurones, processors (interneurones), and output (efferent) neurones.

Our educational approach is to provide feedback at every stage, and this is in the form of a simple animation of the system working (i.e. electrical impulses moving around the connected components of the system), followed by textual feedback. The textual feedback is always in the format of a positive statement (what is correct so far), followed by a statement about what is not yet correct, and a hint about what to consider next.

Evaluation:
The first version of this computer aided learning (CAL) program was tested by electronic audit trails and questionnaires. An example of the information obtained was the requirement to separate the model building exercises from the use of tools and symbols, leading to the introduction of 'practice' screens.

The program was finally evaluated with three groups of 2nd Year students at the University of Melbourne: Medical Students in a curriculum with emphasis on Problem-Based Learning, 2nd Year students in a new Biomedical Science Degree and 2nd Year Science Physiology students. Approaches to evaluation included questionnaires, computer audit trails, pre- and post-CAL tests and analysis of exam results for misconceptions. The program has been distributed nationally and internationally to about 12 Universities who have trialled the program with their students and have provided useful feedback incorporated into the final program.

Overall, the students enjoyed the 'hands-on' nature of the model-building exercise immensely, and gave the program a very positive rating. They judged their own understanding as having increased from 2.23 (Biomedical Science) and 2.35 (Science) to 3.72 and 3.54 respectively, after using the program. Pre- and Post-CAL tests showed a similar significant improvement in understanding (Wilcoxon Matched-Pairs Ranks Test, p<0.005 for whole test score).

3. Discussion
Our approach to help students to learn about control systems by fostering the development of phenomenological understanding has been successful. It has overcome the difficulties our students had previously with a simulation or mathematically oriented approach that we deliberately avoided in our introductory program. The goal was to establish a level of qualitative fundamental understanding that can be overlaid later, where appropriate, with quantitative transfer functions when these are known. Thus our approach is usable in a wide variety of contexts, including those in which mathematical constructs are inaccessible.

This program is also more linear in model construction than others we have developed for modelling epithelial cells and it is difficult to provide specific feedback if students continue to place multiple elements all over the screen without much forethought, since the number of permutations and combinations becomes enormous. Once students start the construction appropriately, their construction problems are largely resolved.

The emphasis is to encourage student hypothesis formulation and visual testing as the continuity between control system input and output components is represented graphically. This approach lends itself to the description of control systems for which real components can be identified (i.e receptors, neurones, blood vessels) rather than systems in which the components are conceptual. The use of task sheets as thought extension exercises provides the opportunity for students to both test and generalize their new-found understanding, and has proved useful in provoking discussion among groups of students. This opportunity was exercised in most classes and students liked to test their ideas extensively with the tutors.

Abstract: The educational administrator is a key player in technology integration in the schools. Yet, many school administrators are not prepared to provide the leadership necessary to provide a vision of, plan for, or implement a technology integration plan. In order to prepare them for the challenges they will face in promoting technology integration, a model for administrator technology training, based on professionally articulated and agreed upon competencies, was developed and delivered to a cohort of 84 doctoral students at Arizona State University. The competencies were those developed by the Arizona Technology in Education Alliance (AzTEA). This paper describes the AzTEA competencies and the model training program designed to address the competencies.

A Model for Administrator Technology Training

School administrators play a critical role in the implementation of technology in pre-12 education. Yet many administrators do not possess the technological competencies required to provide effective leadership in the implementation of technology. In fact, many do not possess the competencies and skills necessary to maximize the use of technology in their own work environment or improve their job performance.

Recognizing the training needs of school administrators with respect to technology, individual school districts, professional organizations, and institutions of higher education have offered a variety of learning opportunities. However, (in most cases) this training has not been based upon any established, agreed-upon technology competencies for school administrators. Such competencies have not yet been established at the national level in the United States as they have for teachers and students. (An initiative to develop national competencies is currently underway under the leadership of The Collaborative for Technology Standards for School Administrators. The Collaborative will involve numerous individuals and professional organizations, including the major administrator organizations and the International Society for Technology in Education (ISTE), in a year-long project to develop a set of “foundation” technology standards for all preK-12 administrators, as well as specific standards for building-level administrators, the superintendent, and other district-level administrators.)

A model for administrator technology training based on professionally articulated and agreed-upon competencies has been developed by faculty of the Division of Educational Leadership and Policy Studies at Arizona State University, the third largest university in the United States. The development of a competency-based program was made possible by the fact that the Arizona Technology in Education Alliance (AzTEA), an ISTE affiliate, had in 1998 developed and adopted a set of “Educational Administrator Technology Competencies.” An abridgement is presented in the following section.

Educational Administrator Technology Competencies
The Educational Leader should be able to:

2061
1. demonstrate functional knowledge of terminology associated with computing, telecommunication and technology
2. identify and use the skills of planning and policy development as the relate to the infusion of technology into the educational environment, including, but not limited to:
   2.1 group process
   2.2 dealing with the rate and character of change
   2.3 community/constituency involvement
   2.4 policy, regulation and procedures as developmental and foundational activities
   2.5 research on effective schools, school improvement and student impact as related to technology
   2.6 authentic assessment as a tool about and using technology
3. identify and use the tools of technology.
4. operate a computer system and utilize software.
5. use a computer network independently. This includes the ability to:
   5.1 implement the policies, procedures, and practices of the district’s Network Agreement
   5.2 navigate confidently throughout the network.
   5.3 Maintain security measures to both passwords and hardware.
   5.4 troubleshoot simple network problems
6. use basic troubleshooting skills and simple maintenance techniques as related to hardware and software.
7. utilize productivity/information tools for problem solving, data collection, information management, communications, and presentations.
8. model appropriate behaviors toward technology that includes equity, ethical (intellectual property/copyright), legal and human issues (including voice mail protocol) of computing and technology use as the relate to society.
9. enhance technology professional development including the ability to:
   9.1 network with peers
   9.2 attend technology conferences (in person and via distance technologies)
   9.3 consult with patrons and parents
   9.4 subscribe to technology print resources (journals, magazines, and newsletters)
   9.5 use on-line manuals and help features
10. demonstrate an understanding of staff support including training and maintenance
11. identify funding sources and costs involved in technology implementations such as:
   11.1 maintenance costs including personnel and supplies
   11.2 infrastructure construction, maintenance and operational fees
   11.3 excess utilities, override bonds, E-rate, etc.

Technology Training

In the Spring of 1999 these competencies served as the core for the development of a course in technology for school administrators which was then taught to three classes of doctoral students (total enrollment 84), all enrolled in a newly designed “DELTA Doctoral Program.” The majority of the students were practicing (both at the district and school level) school administrators. Four held administrative positions in higher education. The course was designed to be the first course in their program of studies. All classes were conducted off-campus: two in school district offices, one in an on-campus location owned by the university. The class included on-line learning experiences where most of the course readings, handouts, and collaborative learning took place on the Internet. Students participated in on-line discussion groups and collaborated on-line to complete a major project devoted to school technology planning. Pre-and post assessments of students’ technology competencies were conducted. The results of the pre-assessment were used by the instructor to design learning experiences for students based on their competency level.
Developing Modular and Adaptable Courseware Using TeachML

Dipl.-Inform. Frank Wehner, Dipl.-Inform. Alexander Lorz

Abstract: In this paper we present the use of an XML grammar for two complementing projects - CHAMELEON and EIT. Areas of application are modular courseware documents and the collaborative authoring process of didactical units. A number of requirements for a suitable document format will be identified. After comparing existing solutions we introduce TeachML, our XML based document format for adaptable courseware documents and reusable didactical units. We describe how courseware documents can be adapted to the learner’s previous knowledge, aims and infrastructure. Then the process of creating different output documents from a TeachML source will be explained. We continue with considerations about the development process of learning material within a professional publishing environment, leading to the necessity of a virtual repository for storing courseware documents and media assets.

Introduction

In an information society ongoing learning and knowledge updating is crucial, especially in the rapidly growing field of new technologies. Access to online-information from everywhere at any time becomes more and more important, for both private and professional users.

However, it is quite difficult for specialists or educationists to create interactive, multimedia courseware documents because in most cases they lack the necessary skills in the fields of design or programming. Regarding this situation we initiated two projects: EIT (Enabling Informal Teamwork) [1] deals with the informal teamwork processes during the development of courseware documents. CHAMELEON (Cooperative Hypermedia Adaptive MultimEdia LEarning Objects) [2], [3] investigates document formats for modular and adaptable courseware documents. These projects aim at the development of media independent courseware documents for autonomous and tutor-supported learning.

For the description of documents consisting of reusable and adaptable didactical units and pre-structured document templates for frequent teaching situations we started to develop the XML grammar “TeachML” in 1998. The use of XML allows the dynamic generation of output documents in different formats and styles (e.g. XHTML - Extensible Hypertext Markup Language - or TeX) adapted to the user’s knowledge, preferences, aims and computing infrastructure.

Both projects imply a scenario focused on the development of didactical units by professionals who fulfil a certain role in this process (e.g. author, editor, expert of a certain subject, software developer, designer, ..). Therefore the main objective of EIT is to understand how the co-operation of these people can be supported by a web-enabled groupware system and which features are essential for a suitable electronic working environment. For that purpose we will design and implement the prototype of a virtual repository for didactical units and multimedia documents using insights and experiences acquired by converting different kinds of conventional learning material - like on- and offline-media, books and comple-men-tary material - to TeachML. The editor, tutor or teacher can select didactical units from the repository which fit his specific target group or learning situation best to create adapted output documents.

In the next chapter we will provide an introduction to the TeachML document format. Chapter three describes how we are approaching the challenges of the-professional authoring process for didactical units in a team-oriented environment.
The TeachML Document Format for Courseware Documents

Analysis of existing courseware material for web-based learning systems reveals that there are primarily two common approaches. The first way is the use of HTML documents, to benefit from the advantages of an open standard (or more precisely a W3C recommendation) to achieve platform independency. Moreover there already exist many authoring tools and export filters for creating HTML documents and it is possible to integrate multimedia elements and interactive behavior using scripting languages, plug-ins, Java applets or SMIL (Synchronized Multimedia Integration Language). However, there are also a number of limitations: Structuring HTML documents whilst preserving adaptability and extensibility is quite difficult. Furthermore HTML is a web-format and not very well suited for creating different output documents — e.g. printed versions or multimedia presentations. Dynamic HTML is very useful for similar looking pages like product presentations, but not for courseware documents.

The second way to create courseware documents is the use of special authoring tools (e.g. Idea [4], Authorware [5]) or universal multimedia authoring tools (e.g. Director [6], Flash [7] or Toolbook [8]). With these tools it becomes easier to develop interactive and media-enriched courseware documents, but the main problem persists: Structuring the documents into reusable didactical units is not supported. Another disadvantage of these tools is the use of proprietary formats which leads to non-interoperable results, making reuse, adaptation and combination of existing courseware modules difficult to impossible.

Requirements for a Courseware Document Format

Considering the problems mentioned above some requirements the document format is to meet in order to structure courseware documents will be specified.

- System- and platform-independency must be guaranteed or the necessary tools and interfaces (APIs) have to be available for most platforms.
- The document format has to be extensible in order to integrate custom structures and future technologies.
- Mechanisms for associating the course-structures with all necessary metadata elements have to be provided.
- The format must not enforce the use of specific output formats or presentation platforms.

To meet these requirements we decided to use XML for the development of a document format for courseware documents. XML covers all of the points above: It is independent from a specific platform and operating system and provides the DOM (Document Object Model) as a platform- and programming language-independent API for the development of the necessary tools. XML grammars can be constructed in a way that they easily can be extended by new or alternate elements. There already exists a metadata scheme for teaching resources — IMS (former Instructional Management Systems, now IMS Global Learning Consortium, Inc.) [9] derived from the IEEE LOM (Learning Object Metadata) [10] metadata scheme. Though the IMS scheme itself is independent from a specific document format there is an XML binding that can be used easily.

In the next section we compare two existing markup languages for courseware documents. Afterwards the TeachML document format itself will be introduced. Finally we describe, how TeachML documents can be used to create modular and adaptable courseware documents.
Existing Markup Languages for Courseware Documents

In the context of the PaKMaS project (Passauer Knowledge Management System) [12] which deals with web-based adaptive hypermedia information systems the document format LMML (Learning Material Markup Language) [11] has been developed. LMML itself is divided into two parts: LMML-structure and LMML-content. The former can be used for structuring courseware content into several units which can be subdivided in basic modules and sections. The latter provides means for representing the real content components. Metadata elements can be integrated into LMML documents using predefined attributes. Thus, there is not much overhead when using metadata. However, integrating a new metadata element requires changes to the LMML DTD. LMML does not allow the definition of different routes through the course and provides no means for modeling dependencies between learner and courseware content.

The TARGETEAM project (TArgeted Reuse and GEneration of TEAching Materials) [13] focuses on supporting the different usage-processes in the lifecycle of courseware material. An XML-based format for courseware documents has been developed recently, called TeachML [14] too. The courseware documents are stored in pools containing modules assembling reusable units. Modules can be structured by nested issue-elements containing text content, tables, links, images and image animations. TARGETEAM-TeachML does not enable the author to create different routes trough or views of the content. Several content elements are defined but there is no way to structure the material in a didactical way. An open question is, why the sub-languages for content elements re-define existing structures for tables (HTML), links (HTML, Xlink) or image animations (SMIL). Java based processors for creating HTML- or TeX-output are used whilst XSLT and CSS should suffice and would be a more open and adaptable approach.

The TeachML Document Format

TeachML has been developed in the context of the CHAMELEON project. Our goals were to give authors the possibility to create reusable didactical units and to enable tutors to select, customize and combine such didactical units to target group specific courseware material.

Each TeachML courseware document is divided into four levels of elements. On the lower level there are media objects like text, images, audio, video, formula, reference, but also interactive Java applets, animations, or 3D-scenes. The mediaObject-element hides media-specific properties, e.g. whether an animation is realized with Shockwave or SMIL.

On the second level there are content units. Content units group media objects which belong together to transmit their message to the learner, e.g. a figure and its title or a proof which can consist of several formulas, texts and references.

The third level are didactical units. They consist of several content units. Didactical units are the primary units of reuse, e.g. example, figure with explanation or different types of exercises.

On the upper level there are so called didactical structures. They are used to create real courseware structures. Possible types of didactical structures are course, chapter, chain of arguments, examinations containing several exercises, a overview path or a detailed path. Didactical structure is the only recursive element because high-level structures like a course can consist of lower-level structures like chapters.

Since all relations between media object, content units, didactical units and didactical structures are references all elements must have a unique ID. This ID is also used for another purpose: Every didactical unit can contain an optional list of references to other didactical units which represent didactical preconditions for its use. With TeachML we do not try to build a semantic network - in our opinion this is too costly and in most cases unnecessary effort. However, in difficult and very detailed courses it can help the learner to find the right entry point.

Information about learners can be represented in a compact learner’s model. It contains administrative information but is also tightly coupled with the courseware itself. In order to adapt the presented TeachML course to a certain learner it is possible to specify information about previous knowledge, aims and actual learning success. The previous knowledge and aims of the learner are represented by references to didactical units. For example an aim could be a reference to a set of exercises the learner wants to (or has to) solve at the end of the course in order to get a certificate. The actual learning progress is represented in two ways. The first is a history list with references to the visited didactical units. If some of these didactical units are exercises, information about their solutions will be stored as well. The second way is by using the variables level of detail and level of difficulty. With this information the appropriate didactical structure (e.g. a path with a matching difficulty) for the learner can be selected.
For assigning metadata to TeachML elements an XML binding for the IMS metadata scheme based on the IEEE LOM scheme is used. IMS defines a core of frequently used metadata elements and a so called standard extension library for other elements. The scheme defines nine categories (e.g. general or educational) and a number of elements inside each category. Every element is optional and can be used in any number and order. However, for an author the great variety of available metadata elements can be quite confusing. Therefore a so called metadata mapping is being defined in TeachML, mapping each TeachML element to the relevant IMS metadata elements along with information about whether the metadata element is mandatory or not. If different types of TeachML courseware documents require different metadata elements it is very convenient to have to update the mapping information only. Some extensions to the IMS scheme became necessary, e.g. for the types of example and argumentation chain. As an equivalent to the existing metadata element difficulty in the educational category the new element detail has been added to this category. All new elements were easily integrated using the extension mechanism of the IMS scheme.

Together with the Cornelsen Verlag [15] we are analyzing how existing courseware material e.g. from schoolbooks can be converted to a TeachML equivalent. This experiment will help us to evaluate the TeachML format in order to find missing types of didactical units and to update or extend existing ones.

**CHAMELEON System Architecture**

In this chapter we show how TeachML documents can be integrated into the context of the CHAMELEON project. Additionally we describe our current work in this project.

To take advantage of the power of the TeachML document format there is a need for some additional tools. In the last chapter we described, how basic information for adapting a course to the learner's previous knowledge and aims can be represented in a learner's model. This model can be updated by using information about the interactions between learner and didactical units. Most information is provided by exercises, because they indicate if the learner understood the contents of the course. Exercises should denote a level of difficulty, so this information can be used to make an assumption about the appropriate difficulty for the next courseware documents to be presented. Exercises are usually interactive components. Thus it is difficult to convert the TeachML based exercise description into an interactive presentation on the learner's side. One possibility is to use HTML forms, but this is applicable to multiple choice and completion tests only. So we decided to develop a set of Java applets for exercises. The TeachML document fragment containing the exercise information (e.g. question, true and false answers, feedback information and help topics) is used to initialize the applet. Then the applet dynamically constructs the visual presentation of the exercise, manages the interactions with the learner and returns the learner's solutions (and the way he found them).

So far we introduced the TeachML format in order to represent courseware documents, but how can these be presented at the learner's computer? Our solution is to use stylesheets to transform the TeachML document into the appropriate output format. This is a quite complex task to perform, because of the large number of different types of content, didactical units and additional information (e.g. from the user model or about the system configuration) which must be taken into account. Currently we are using a combination of XSLT and CSS stylesheets for transforming TeachML documents into an XHTML representation for a web course. In order to provide a printed version of the TeachML document XSL Formatting Objects are used to create PDF documents. In addition an attempt has been made to develop guidelines and stylesheets for adapting TeachML documents to the needs of visually impaired learners based on the W3C recommendation about Web Accessibility Guidelines [16].

The first TeachML based courseware documents were developed using a plain XML editor. Because of the large number of additional information (e.g. IDs, paths and metadata elements) this proved to be a very time-consuming task. Therefore the next step will be the development of a modular authoring tool for TeachML documents and didactical units targeting two main objectives. At first it will simplify the process of structuring the TeachML document as a whole by visualizing dependencies between didactical units and didactical structures. Secondly it will enable the integration of plugin components for creating and adapting didactical units. The main advantage of this approach is that there will be no need for changing the tool framework when the TeachML document format is being extended by new didactical units or existing ones are being changed. That way we will be able to extend the capabilities of the editor by simply adding a reference to the new or changed editor component.

In the next section the authoring process of didactical units themselves will be described in greater detail.
Enabling Informal Teamwork

EIT is a research project in cooperation with Cornelsen-Online and is supported by the German Federal Ministry of Education and Research (bmb+f) as part of the project WEP in the Global Info program [17]. EIT aims at the development of a web-based environment for producing and maintaining courseware documents and learning materials (CD/LM) for various media. The project divides into three parts:

- Unitizing learning material to improve reusability.
- Conceptual design of a virtual repository for web-based multimedia documents and of document management tools.
- Extending these concepts by groupware capabilities with the emphasis on organizing informal collaboration.

Professional Publishing

Publishing companies employ various external and internal specialists for the production of CD/LM. An editor acts as a central role in this process by structuring and coordinating subtasks while authors investigate and create texts, sketches or scripts for multimedia applications. These are transformed into different media by designers, graphic artists, software developers and many others. Coordination of the individual tasks requires additional manual work from the editor who manages the exchange of raw-data and semi-finished materials between the different experts. In this process some disadvantages can be observed:

- The interrelation between tasks, media-assets and meta-information is lost.
- Assets are used in heterogeneous and often incompatible environments. Therefore conversion, systematization and archiving causes additional expenses.
- Reuse and maintenance are impeded by lack of meta-information about the individual assets.
- Coordination of sub-tasks causes additional work.
- Project status and individual workload are hard to estimate. Bottlenecks are discovered very late, flexible reorganisation of subtasks is difficult.

The vision of an electronic working environment supports modular creation of adaptable and reusable CD/LM for books, on-/offline-media and semi-finished materials. A distributed virtual repository stores media-assets and components for CD/LM together with the associated metadata. Thus an efficient management of the stored information in each stage of its lifecycle becomes possible. Access is provided by a distributed middleware ensuring availability and consistency of the stored data, even if a continuous network connection can not be guaranteed. Different role-specific views of the repository will be provided allowing an easy migration from conventional methods of working and supporting group-aware collaboration.

Research Issues

Currently we are examining professional CD/LM provided by the project partner to improve and validate TeachML. By rewriting these documents we try to find out which processes occur and which metadata have to be filed during the production and maintenance of CD/LM. Simultaneously a modular editor for TeachML documents is designed and implemented. This editor features a plug-in architecture, allowing to extend its functionality to handle special XML sub-structures (e.g. formulas, tables, etc.).

The next step will be the transfer of those development tools and procedures into the authoring process of the Cornelsen Verlag to gather further information about workflows and boundary conditions within a professional publishing process.

The knowledge obtained will be used for the design of a virtual distributed repository for storing TeachML-data and media assets along with the necessary metadata.

Summary

In an information based society knowledge needs to be extended or updated in ever shorter time-spans. Therefore the efficiency of storing information and making it available to the human mind becomes crucial to keep up with this development. Creating modular, adaptable, extendable and reusable courseware materials can be one milestone on
the way to meet this challenge. We presented TeachML, an XML based document format for such a class of courseware documents. TeachML enables the courseware author to structure learning material both in respect of content and didactics. Therefore TeachML offers two main concepts: didactical units as units of reuse and combination and didactical structures for creating different views of and routes through the course. A number of didactical units, called atoms, could be identified. Didactical structures and a compact user model enables us to adapt courses to the learner’s previous knowledge, aims and infrastructure. Because TeachML documents are free of presentation aspects it is possible to create different output documents e.g. an XHTML document for a web presentation and a printable version. The EIT project extends this approach by validating TeachML in a professional publishing environment and by designing a virtual repository for multimedia documents, media assets and associated metadata.

Countermeasures against Security Breaches in Web-based Training Environments

Edgar Weippl
Software Competence Center Hagenberg
Hauptstr. 99, A-4232 Hagenberg, Austria
Edgar.Weippl@scch.at

Abstract: Today, as e-commerce is becoming a major issue for companies, security flaws are rapidly gaining public attention. Both corporate and private users consider security to be the decisive factor for Web-based business in future. At the same time the Web is used for distance learning and various platforms for Web-based training (WBT) have emerged. However, none of these platforms focuses on security issues and therefore security is designed and integrated only as an additional feature. In this paper we elaborate on the fundamental security concerns that users of WBT software have and show how existing flaws can be eliminated. Basically we rely on well-established security concepts. However, as these concepts have not been designed for Web-based applications, we have adapted them. Our solution is to use encryption algorithms with keys unknown to the Web server. Therefore our approach is compatible with all available Web servers.

1 Introduction

During the last years the Internet experienced an enormous growth. The Web with its appealing hyperlink navigation has enabled easy access for a variety of users who had not had the chance to use the older Internet services like ftp or telnet. The increasing number of users has given rise to new Web applications and companies are increasingly beginning to think about e-commerce.

The Web with its worldwide access to information is what was needed for efficient computer-based distance learning. There has been distance learning for many years already. It started with correspondence-based learning where the students received studying material and assignments by mail. As technology advanced teaching and learning was enriched by multimedia. Students received video or audiotapes and one- or two-way communication was established via TV and radio. Companies focused on producing teaching aids and could be sure that their investments could not easily be stolen. Despite the fact that videotapes can be copied, the quality decreases as copies of copies are being made. Furthermore it is necessary that the copying process is performed in one place, i.e. the video cannot be transferred to a friend who lives in another continent. The only way to achieve this, is to send the copy by mail - which obviously means additional time and cost for copying.

Digital content, however, can be copied easily. The quality does not decrease with copying and digital content can easily be sent around the world at very low cost. For example, Napster and Gnutella are two programs that are very popular for sharing digital music via the Internet - most of the songs are copied illegally.

Copyright protection alone is not enough as it can be difficult and very expensive to trace copies once they have been made. Although Digital Watermarks can help to clarify who holds the copyright, all current techniques have drawbacks (Yeung 1998). Large companies in the music industry may have the resources to enforce protecting their digital assets but smaller companies or university institutes will never be able to prohibit illegal copying using legal measure only.

We know for a fact that many potential creators of multimedia Web-based training content refrain from their initial plans due to these security problems. Belanger (2000) estimates that developing a premium quality WBT course that is equivalent to a 54 hour in-class course requires approx. 28000 hours. Famous distance learning institutes like the Open University in the UK or the German Fernuniversität Hagen have enough students so that the average cost per student is low enough for such expensive digital content to be created.

Despite the threat of illegal distribution of multimedia course content, very little has been done to integrate security concepts into WBT software. The following section will give an indicative overview over how security threats can be dealt with. Section 3 starts by evaluating existing WBT programs with a focus on the theoretical security flaws
previously identified. We then demonstrate how some flaws can be avoided using a WBT platform called Coimbra and we present an outlook on our current project Alcatraz.

2 Countermeasures

In this section we elaborate on how security issues that are relevant in the context of WBT can be adequately addressed. Throughout this paper we focus on security for general WBT systems and not on security for Web-based information distribution of sensitive information. We assume that the system is safe from attacks if the required effort to break the system exceeds that of creating a multimedia course. The information of university WBT course is not secret as it can be found in textbooks. It is the effort of adapting this publicly available information to a multimedia platform that represents the real value.

2.1 Protection against Theft of Digital Content

The first step to avoid illegal copying is to define a security policy. Digital watermarking techniques obviously cannot solve the problem of illegal distribution. As the recent spread of illegally shared MP3 music files showed, copyright alone is not an adequate protection. For most songs digital watermarks would have little effect as the holder of the copyright is often well known. Personalizing digital watermarks means that digital content is market for the buyer, so that he or she can later be traced as the first who illegally copied a CD. This could be an approach but the organizational overhead seems too large.

Many lecturers are not willing to devote any effort to the development of sophisticated WBT aids and they even refrain from allowing students to download the lecture’s slides. Requiring a username and password for http-access can help to keep non-students, i.e. potential thefts, away from the course material.

One problem, however, still remains. Students and all people who are allowed to access the course can easily copy the whole hypertext structure - even if you only permit them to access the course for a very short time. These illegal copies can then spread through the Web and if the teaching material is of high quality, the probability of illegal ‘reuse’ is very high.

The approach that we propose is to encrypt the content. Unlike encryption standards (e.g. SSL) incorporated in standard Web browsers, we propose a system that stores the content in encrypted form on the server. The Web server does not have the key to decrypt the content because we agree with Wilkinson (1999) who wrote: “If sensitive information is to be included in a shared web, access controls will be required. However, the complex software needed to provide a web service is prone to failure. To provide access control without relying on such software, encryption can be used.” We implemented these concepts in the Coimbra system (Coimbra 2001) using a client-viewer that decrypts the files only for viewing, which implies that they also stay encrypted in the client’s disk cache.

2.2 Guarantees concerning Evaluation

Similar to counting how many students attend each lecture, WBT software can log how many people use the software and for how long. In order to be able to trust the evaluation results, two ‘attacks’ have to be made difficult. First, one has to make sure that the displayed data gives a correct impression. This requires the identification of users who rarely learn with a WBT course, those who use two or more accounts, as well as those who share an account. Second, one must not have the chance to tamper with the auditing records.

Detecting usage patterns that differ from regular usage is a common task in intrusion detection. Pfleeger (1996) briefly discusses some approaches but admits that only simple forms of intrusion can be detected automatically. Automatically detecting usage patterns would be useful to discover if two or more students share the same account.

However, we found that user profiling is especially difficult for students who explore the content of a WBT system. When studying, there is nothing like a routine task and page accesses do not follow any systematic rules. One might be lead to believe that students start reading basic pages first and continue, with detailed information later on, but this is not true. When learning for oral exams a student may focus on overview knowledge but the same
student may need in-depth knowledge one day later for her home assignments. This example illustrates why only simple forms of sharing an account (e.g. two different IP addresses using the same account simultaneously) can be detected automatically.

The best way to guarantee that every single user registers, is to require the registration for the exam. Obviously, students will enter their real names and addresses. Course registration should be free or at least very cheap so that there is no incentive for students to share one account. Encrypting the log files ensures that they cannot be tampered with. By combining a count of page views with measurements of how much time is spent on each page, a rather reliable indicator of usage can be derived.

2.3 Prohibiting Cheating

Computers can be used for in-class tests. This testing situation is the easiest to handle, as it is very similar to traditional exams. The teacher can check student IDs and can ensure that students do not talk to each other or exchange information by other means. For many tests it is necessary to make sure that students cannot use any other application than the testing program. For example in Windows systems it is feasible to prohibit switching to other applications. Teach/Me (Lohninger 1999), WBT software for chemistry students, implements this security feature in its testing modules.

As an option students may not want to take exams at the teacher's university. Test centers can be authorized to provide the exams. The computer-based TOEFL (Test of English as a Foreign Language) is a perfect example for this kind of exam. Compared to the first scenario where the exam takes place in a class organized by the course's teacher, additional security problems occur. First, exams have to be distributed so that no one can 'open and re-close' them before the actual exam starts. Second, the results have to be evaluated either at the test center or centrally. Answers to multiple choice questions can be evaluated automatically but text answers have to be reviewed by humans. These answers should only be accessible for the student and for the examiner. Public key cryptography can be used to achieve the required security.

If WBT is used for distance education it is convenient for students if they do not have to travel to test centers. This third and most demanding option in regards of security means allowing students to take the exam on any computer. The main problem is to authenticate the user and to make sure that no one else enters the answers after authentication and that no one provides illegal help by e.g. hiding in the room and talking to the student. Using teleconferencing software for oral exams can be considered a quite safe way. The conversation takes place synchronously in real time and thus others cannot easily give answers to the student, as the examiner will notice pauses in the conversation. An alternative to oral exams is take-home exams. These exams – being more popular in the US than in Europe – are specially designed so that cheating is difficult by merely using a textbook. Web technology does not offer additional cheating options that could not be exploited for 'traditional' take-home exams.

2.4 Privacy for Users

The easiest and yet most reliable way to avoid that people misuse auditing information is to give them no direct access to the data. Professors, for example, may not access the logs of every individual student but only summary information derived from the logs. As the topic of security in statistical databases is extensively covered by literature, it is beyond this paper's scope to go into details. Castano (1995) gives a comprehensive overview and discusses recent research results.

3 From Coimbra to Alcatraz

Several years ago, we wanted to use the Web to distribute learning aids and to automate testing. We analyzed existing software and found that we missed some features. Therefore, we decided to start developing our own platform called Teach/Me (Lohninger 1999). Having gained experience with Teach/Me, we then fundamentally redesigned the system's architecture. This was the beginning of Coimbra (2001). Today, as the first versions are
available to the public, we continue to move on to Alcatraz, a prototype that incorporates role-based access control. Before we present the Alcatraz architecture, let us have a brief look at some major WBT platforms.

3.1 Related Commercial Systems

We briefly want to point to drawbacks that were common to all WBT and CBT products: (1) no intelligent caching and (2) no encryption. Detailed information about the products can be found on the Web sites (see Table 1).

As most products use standard Web browsers as client software, the client cannot influence caching. In our opinion this is a major drawback. What we wanted is a client program with a browser-like user interface and the option to control the caching. During installation students usually do not mind if large files (like indices, table of contents, etc.) are transferred via a slow connection but they do mind if this happens while learning.

As already mentioned, teachers often refrain from publishing their course material on the Web because they fear theft and usage by others without proper citation of the original source. To avoid copying caching could be prevented but the tradeoff concerning speed is too high. A better solution is to store data in the cache in an encrypted way. The client can then require online authorization every time the program is started. As only a small amount of data has to be transmitted to perform this authorization, the software can easily be used with a modem connection.

Table 1: Major WBT software vendors.

There are, however, other products that focus on providing control over the content using encryption. The advantage is that the content can be safely cached on the local file system. IBM's cryptolope objects are an "envelope" to securely distribute digital content. It is nothing more than a Java Archive file. The self-contained cryptolope package always includes the cryptographic keys that unlock the encrypted content. For security reasons, these keys are themselves encrypted with a key that only a third party can unlock. Therefore this third party, also called a key server, does not have to store all keys of all the cryptolope objects but only the access keys. IBM is not the only company that offers this kind of protection for digital content. Infraworks (www.infraworks.com), QVTech (www.qvtech.com) and Authentica (www.authentica.com) claim to have similar products.

3.2 Coimbra

The Coimbra software system has been developed to create teaching and learning material. Coimbra is an open system based on Internet standards enabling the teacher to provide students with additional material via the web. Coimbra can be used to publish both on CDROM and over the Internet. Unlike with most WBT platforms, distribution via CDROM is very easy with Coimbra. All files that would normally be found on the Web server have to be copied to a CDROM - everything else remains unchanged. When starting the client the user just selects the CD drive instead of typing in a URL and everything works like via the Web only faster. It is one of the key benefits of Coimbra that it offers the possibility to shift a database from one medium to another without effort. Coimbra allows developing any material locally on the disk and then moving the entire database to a Web server and also distributing it via CDROM. Similar to IBM cryptolope, wherever the data is stored, the files are encrypted, making it difficult to steal the textbook or to alter the auditing information in the log files.
It is important to note that the index works even with the encrypted files as the client software - having the keys - updates it when necessary. Standard Web server indexing engines do not work as the Web servers store the encrypted files without having the keys to decrypt them.

3.3 Alcatraz

Coimbra's security system is based on assigning access rights to users or to groups of users, i.e. discretionary access control. There is, however, a more flexible security model that is commonly used in database systems: role-based access control (RBAC). A typical RBAC system assigns privileges to users in two consecutive steps. In the first stage a user is assigned one or more roles. This assignment can be either static or dynamic. Dynamic assignment allows for users changing their roles depending on the tasks they perform. In the second step the roles' authorizations are checked against the operation requested by the user. The obvious advantage of RBAC systems is that the identical roles can quickly be assigned to different people. Moreover, this streamlining eliminates security breaches caused by assigning incorrect access rights. As students take different courses every term, access rights have to be updated frequently. To ensure security throughout a university, it is advantageous to allow teachers and students only access data required to complete their course. RBAC systems should be used to specify for which task (i.e. an application role) one needs access to a specific document. These application roles are then assigned to user roles. Finally, individual users are one or more user roles (see Figure 2).
4 Conclusion

In our work we have explored security issues that users consider relevant for Web-based training. The results of our analysis have lead to theoretical concepts how these issues could be addressed best. Finally, after completing a first version of our Web-based training platform, Teach/Me, we have developed a second platform called Coimbra (www.coimbra.at). Existing weaknesses in managing security policies are addressed by Alcatraz, our current project. It focuses on integrating role-based access mechanisms into WBT software allow flexible assignment of access rights.

Abstract: Coimbra is document database that was specially designed for developing and deploying Web-based Training. Beside usual Meta information teachers can specify browse sequences for different courses, keep track of students accessing pages and cooperatively develop and share content to build various courses (e.g. calculus for computer science, calculus for chemistry, etc.). All information is encrypted using state-of-the-art secret key cryptography to prevent theft of intellectual property. The innovative approach is highlighted by Teach/Me (Lohninger 1999) which is based on Coimbra and has recently been awarded German Award for Educational Software digita 2001.

Managing Web-based Training Content

One of the important issues in creating teaching materials is to organize thousands of basic documents (texts, diagrams, Web pages, scanned images, photos, video, ...) and the corresponding meta information so that (1) all documents can be easily found, (2) teaching materials are fed from a common pool of shared documents, (3) relationships between individual documents are maintained, and (4) new applications can be derived from existing materials by adding new ones or by reorganizing existing ones. In addition to these prerequisites, the document management system should contain a suite of tools specifically tailored to the creation of teaching material.

Coimbra is an authoring system for network based multimedia teaching materials. It is based on common Internet standards, which allow to deploy the materials over the Internet as well over in-house LANs and on CD-ROMs. The content managed by Coimbra is encrypted (Blowfish (Schneier 1994)) to prohibit theft of intellectual property. A freely available viewer supports many additional navigational functions and allows to create easy to install packages which can be passed on to students.

Document Database

On a technical level, Coimbra is a document database system which helps to file documents of different kinds and formats (photographs, videos, sound, written texts etc.) and from different sources (local computer, internet etc.) in one single system thus offering easy access to these documents and enabling the user to combine different types of documents in a single application. Each document is stored unaltered in the database and is accompanied by a list of meta information tags, which provide information about the contents of the particular document. The meta information comprises title, author, references, index keywords, various dates, access rights, links to related documents, and several more technical tags.

The user interface of Coimbra consists of four different channels (see Figure 1): (1) direct access to the database, (2) a preview function, (3) a set of navigational tools, and (4) a document selector which helps to narrow down the number of visible documents in large databases. Besides these basic access channels Coimbra offers a wide variety of tools to manage the documents (i.e. extraction tools for meta information, analysis of indexes, a visual layout editor, search and replace functions, subset editors, basic image processing, etc).

Due to length limitations, we will just give a brief overview of the most important features in Figure 1.
Figure 1: The Administrator's UI supports (1) direct access to the database (top pane), (2) a preview function (lower middle pane), (3) a set of navigational tools (lower left pane), and (4) a document selector (right pane) to narrow down the number of documents visible in the top pane (1).

Initial Design of an Interactive Learning Environment for Statistics

Rob R. Weitz

Abstract: This paper describes the initial analysis and design phase of a research project with the goal of creating an interactive, web-based environment for learning statistics. General design principals were drawn from existing research on constructivist learning. More detailed system requirements were obtained via the use of "empathic design", a participatory system design approach. Empathic design is a methodology for capturing the unarticulated needs of the user via direct observation, and then translating these needs into system/product features. Reported here are preliminary results of an analysis of observations of students solving basic descriptive statistics problems.

Introduction

This paper describes the initial analysis and design phase of a research project with the goal of creating an interactive, web-based environment for learning statistics. The domain of statistics was chosen for a variety of reasons: 1) statistics is a common (and typically required) course across many disciplines and levels, 2) it’s a difficult (and unpleasant) subject for many people, and 3) it requires a variety of skills, both conceptual as well as procedural. Moreover there appears to be a large general interest in the teaching of statistics as evidenced by the multitude of resources on the web, including demonstration applets, case studies, data sets and repositories of relevant newspaper articles (see http://it.stlawu.edu/rlock/ for example).

Analysis and Design

While there are many approaches for building well-designed software, determining user requirements is always a critical first step (Kendall and Kendall, 1999). This research takes two approaches for determining user requirements. The first is a practical notion of constructivism (see for example, Wilson, 1996); Perkins (1992) suggests a framework for a technology-based learning environment.

Though these principles provide general guidance, more detailed design specifications are clearly needed. What in particular do students have difficulties doing/understanding? How are these problems manifested? What might some approaches be for preventing or rectifying mistakes?

Leonard and Rayport (1997) suggest that the best way to fully capture user requirements is to observe users in action. Observing users provides much richer feedback than such approaches as questionnaires, protocol analysis, feedback on existing products, or talking to the users.

The Experiment

Two students were (individually) videotaped “talking out loud” as they worked on some half-dozen basic descriptive statistics problems in a standard textbook (Levine, Berenson and Stephan, 1998). Each session took about 90 minutes. Successful completion of the assigned problems required 1) the ability to recognize and calculate the desired quantities and 2) an understanding of the concepts behind their usage.

Observations
1. When working the problems the students constantly needed to refer back to previous pages for definitions and examples.
2. In doing calculations neither student started by writing down the appropriate expression, then filling in the values, and then proceeding with the calculations. Rather, they just immediately started doing the calculations with the data at hand. This “scratch pad” approach seemed to lead to mathematical mistakes; further, they then had difficulty finding values they had already calculated when they were needed for later problems.
3. One student didn’t order the data in determining the median — from my experience 10-20% of students make this error on exams.
4. Problems understanding fundamental concepts. For example, generally the notion of which measure of central tendency to use when seemed elusive. Neither student could successfully answer questions that required a fundamental understanding of the concept of variance/standard deviation, though one student could do the calculations fairly straightforwardly.

How This Translates To Design

In this section I propose relevant design responses to the user requirements specified above. (The numbers here correspond to the numbered user requirements in the previous section.)
1. Provide a glossary, with definitions and examples, “one click away”.
2. Have the system structure student problem solving at the outset using step-by-step templates: start with the expression, find the known values for the variables in the expression, calculate additional values needed for calculations, substitute the values in the expression, and do calculations.
3. a) Have the system force a step-by-step approach until the user gets the idea.
   b) The system could graphically demonstrate the determination of the median via an animated ordering of the numbers (and then determining the observation at place (n+1)/2).
   c) The system could be designed with “intelligence” so that when the student provides the answer that indicates non-ordered data, the system “knows” how to correct the student.
4. a) Build a coherent set of visual representations (i.e., Java applets) to demonstrate concepts. For example, demonstrate visually the effect on the mean, median, and variance of adding/removing data points.
   b) Provide mechanisms to engender conceptual understanding through knowledge construction via simulations, realistic exercises and collaborative work with other students.
These design criteria mesh directly with Perkins’ (1996) five facets of a learning environment: information banks, symbol pads, construction kits, “phenomenaria” (i.e., simulation environments), and task managers.

Conclusions, Caveats, Further Research

User input is generally understood to be a prerequisite for the creation of well-designed, useful software. The literature on instructional technology seems remarkably bereft of any mention of design issues in this sense. This work has applied an empathic design approach for capturing user needs. Although these are only initial results, a number of interesting observations and related design suggestions have emerged. The ultimate goal is to expand topics to cover the standard MBA one-semester course curriculum.

New Concepts for the Usage of Groupware in Software Engineering Education

Stefan Werner, Axel Hunger, Frank Schwarz
Gerhard-Mercator-Universität Duisburg
Bismarckstr. 81; 47057 Duisburg
Tel: 0203/3792707
e-mail:{hunger|swerner|schwarz}@uni-duisburg.de

Abstract: In this paper we present an innovative Tool for distributed software engineering, which is particularly suitable for the use in software engineering labs in higher education. Tools that are used to support distributed teams run under the term groupware and the respective field of research is summarized in the term Computer Supported Cooperative Work (CSCW). Many publications state the work field software engineering as an example for possible groupware support (see Gibbs 1989). Although many approaches to support software engineering teams exist (Gorton & Motwani 1996, Dewan & Riedl 1993), only few work deal with the development of special groupware for educational purposes in the field of software engineering (one of these approaches is described in Zitterbart et al. 1999).

Software Engineering and Groupware Support

Only in exceptional cases will an individual developer control the entire life cycle of a software system. Modern software engineering in any case signifies team work. The world-wide extension of the data networks and the continuing globalization add another component to software engineering: the development in worldwide distributed teams. Our experiences with software engineering projects showed, that the teams cooperate in different ways in the separate development phases. Different requirements on the computer support result from this. Earlier stages of the development require numerous group meetings with a high proportion of cooperative work. Videoconference systems and group editors can serve these computer supported face-to-face meetings. In addition to that, special software engineering CASE-tools are necessary to support the design phase. Coding during the implementation phase mainly employs individual work and does not require special support because of its strong individual work character. An exception from this can be found in big software companies with development departments all over the world and in different time zones. In this case, the use of special tools can enable a 24-hour software production (see Gorton & Motwani 1996).

Software Engineering Syllabus at GMU

In our degree course, software engineering is an one semester course that consists of two hours lecture and six hours of lab per week (see Hunger 1998). During the lab, the students work in teams on a close-to-reality task that is chosen in such a way that it can not be solved by an individual. Therefore, the students are forced to divide it into subtasks.

Student survey (GMU 2000)

Since 1997 we examined the practical training several times. One of our goals was to find out which phases of the software life cycle are best suited to be supported by a Groupware. Students were asked to fill in a questionnaire every time when they reached one of the following milestones during the lab:

a) requirement specifications,
b) context diagram and data dictionary,
c) transformation diagrams,
d) behavioral models,
e) implementation models,
f) specifications and work programs for implementation,
g) compiled procedures,
h) executable programs and
i) documentations.

For the evaluation we combined the related milestones a), b), c), d) to "Essential Model" and f), g), h) to "Coding". The questionnaire consists of 17 questions and every questionnaire contains the same questions. It was organized in five sections concerning Group work, Work mode, Organization of the group, the role of the tutor and own role within the group. The average number of questionnaires we received at every milestone was 80. Within the questionnaires we introduce three possible work modes as they are originally defined by Borghoff & Schlichter 2000:

- Individual work: each member individually solves the subtask and the group declares the best solution as the group's solution.
- Collaborative work: each member solves parts of the subtask on his own, which contributes to reaching the goals of the group. The personal goals rank higher than the goals of the group. More asynchronous than synchronous sessions are needed.
- Cooperative work: the subtask are solved by the entire group. The goals of the group rank higher than personal goals.

Most students described the most common overall work mode as "Cooperative Work". A closer look has shown that the portion of individual work increases from phase to phase. On the other hand the portion of cooperative work decreases from phase to phase. It also can be seen from figure 1 that during the requirement specification and the modeling phases cooperative work was the most common work mode. Collaborative work was named as the common work mode in all phases by nearly 30% of the students, except coding. This peak can be explained in that way, that most of the students are not very much into programming. Therefore they work together, but the main goal was to complete the own program module.

![Figure 1. Work modes in relation to the phases of the Software Life Cycle](image)

The evaluation shows that the early phases in the Software Life Cycle like requirement specification and also modeling seem to be best suited for a Groupware support. In the later phases like coding and documentation the individual goals dominate the chosen work mode and lead to a high portion of individual work and collaborative work. Therefore they seem not as well suited for a Groupware support as the early phases.

Results and Resulting Predefinitions

Tools to support the early design phases are required for asynchronous and synchronous sessions. Several investigations (Brereton et al. 1998, Sarjoughian et al. 1999) deal with public available tools like Microsoft
Netmeeting or SeeUSeeme but these tools drop out because of the different requirements for use in the educational field. The tools for synchronous work need to have more functions than publicly available tools like

- a better support for discussions,
- the setup of partners images and relationship aspects,
- mechanisms for preventing communication breakdowns and
- support for the students in their cooperative actions.

Looking at commercial systems shows that they drop out according to their high costs (license fees, connection costs in case of ISDN-based systems, asset costs). These results are gained from investigations published in (Sarjoughian et al. 1999). Beyond that, the application of Software Engineering CASE-tools requires additional time of the students that depends on the tool complexity (Boloix & Robillard 1998). In case of Software Engineering CASE-tools it has to be taken into account that modern tools such as e.g. Prosa or Rational Rose perform consistency checks at model transitions from one level to another. But especially this work is supposed to be carried out by. From the design process view, this reduces the needed tool to a simple drawing tool with a special object library. Altogether, these arguments suggest the development of an individual Groupware that should contain:

- a synchronous communication tool,
- a floor control to support discussions and also to handle access to the commonly used resources and
- a Software Engineering CASE-tool for common modeling and document processing.

From a technical point of view a session management to control the network communication and a protocol stack to support the required network services are also needed.

Tool Concept

In the first section we discussed arguments for using groupware to support software development teams in their cooperative actions. These arguments are not as valid for students because of the different experiences, the different group processes and also the disadvantages of the existing technology and tools. The researches undertaken in Duisburg sustained the thesis that these differences and disadvantages can be avoided by making according steps for the tool development. This section describes suitable methods and mechanisms as well as their implementation. The system architecture and the implemented protocol stack will be introduced in the next section, details are given in (Hunger et al. 1999). Afterwards, the prototype of the implemented clients will be presented. The floor control and the user interface will be discussed in detail. Additional tools to support the lectures are described in (Hunger & Werner 1998b).

System Architecture

The above described tools require also mechanisms for multimedia data exchange in order to make efficient working over a computer network possible. Our tool concept sees windows-based systems as its target platform and the global internet as its transport medium. This concept is realised as a client/server architecture and several methods of data transfer have been implemented: unicast connections for client/server-communications and multicast connections for interclient-communications. Client/Server connections require reliable services for the transmission of document data, login data and control data. On the other hand, interclient connections only require unreliable services, but a guaranteed bandwidth and delay for the transmission of video- and audio-data. For the realisation of the above described architecture, a suitable protocol stack has to be developed. In a first step only implementations of standardised protocols which are currently available, or which will become available in the near future are used (IPv6, RSVP, RTP, ICMP..).

Floor Control
The floor control is implemented on the server side and handles the access to the public window and the shared resources. Furthermore it coordinates the course of communication through an administration of different kinds of permissions, e.g. permissions to speak, permissions to alter the documents. Floor control approaches usually are mainly technically or social oriented. Our approach differs from those methods in that way, that it combines the advantages of technical and social floor passing methods. An essential part of our floor-control implementation is the permission list. This list can have three possible entries. The actual spokesperson is followed by the next two clients who requested to speak. Each demand of the permissions and each passing of the permissions results in updating this list. Important is that the list never shows two equal entries. Thus two members cannot exclude the third person from the discussion. Further more a tutor can be called by any user at any time. Therefore the model serves all of the above formulated requirements.

The Client User Interface

Working in a team, dividing up the given task into subtasks, discussing provisional results and integrating first results afterwards, already require discipline of the students without using groupware. The usage of videoconference techniques also requires that students work in a completely new scenario. Thus interface design obtains an outstanding meaning. Our client user interface contains video screens of each member and a CASE-tool in a public window for the common process on the outline documents. Figure2 shows the user interface of the client software. Each member has the same view of the window according to the WYSIWIS-principle, but only one of them can alter the document at a certain time. A telepointer serves to elucidate and to present facts. Each member is also equipped with a private working window for trying out ideas. A chat window was implemented so the conference can be ended simultaneously in case of bad transfer circumstances.

Figure 2. Client User Interface

Other features of the user interface result from the above mentioned demands,

(a) of setting up and promoting partner images and relationship aspects and
(b) of supporting group awareness.

These requirements are taken into account by the following design and implementation steps:

- each member is represented in an individual video screen (a),
- the members are always shown in the same video screen (a),
- the video screens can not be changed in either size or position (a),
- none of the video screens can be covered up by another window (a),
- the video screen of the person who has access to the shared resources is always highlighted (b),
- the entries of the permission list can be fetched and visualized (b) and
- the CASE-tool contains a global and local history of changes (b).
Evaluation

In summer term 2000 the first evaluation of our Tool named the Passenger Case & Video Tool (PCVT) took place. It was a small evaluation that follows the aims:

- get a first feedback on the implemented functions and features,
- gain experience in the usage of the PCVT,
- prepare for a bigger evaluation that will take place in summer semester 2001.

The evaluation uses questionnaires and also log files that have been recorded during the sessions. These log files contain information on the communication behavior of every student.

The environment consists of the PCVT communication component and the Habanero Whiteboard (see http://havefun.ncsa.uiuc.edu/habanero/Docs/index.html) as a CASE-Tool substitute because we haven’t finished our CASE-Tool implementation yet. Therefore the evaluation focussed on the PCVT communication component.

The implemented features to enable group awareness seem to be suitable because 56% of the students have always been aware of the conference situation and 44% most of the time. The implemented floor control to enable a discussion control was not rated as good as expected. Nobody rated it very good but 78 % rated it as good but also 22% rated it as medium. The most named reasons for this are that it is not possible to pull back the ask for permissions after the application for it. A second drawback seems to be, that it is not possible to address questions to a special participant.

During their experiments most of the students worked on modeling tasks (Context diagram, transformation diagrams and behavioral model). Therefore the following evaluation focuses only on the design phases. One question addresses the effectiveness of the PCVT for communication purposes in comparison to natural face to face discussions like in the practical training in Software-Engineering. It can be seen that the students rated this higher from phase to phase, what means at least from week to week. Because the used functions are quite the same and also the course of work, this must be a result of the learning effect.

![Figure 3. Learning effects](image)

Although the number of participants was much too small for a quantitative evaluation, the trends resulting from the above mentioned evaluation seem to be unambiguous. Because this is not true for the other questions, their evaluation will not yet be discussed.

Summary and outlook

This presentation discussed the use of groupware in a practical training for software engineering students. We presented the result of our investigations of a traditional practical training and a tool concept to support the
early software life cycle phases. Three essential differences of our tool compared to publicly available solutions can be specified:

- the floor control to support discussions and to avoid communication breakdowns,
- the described user interface to support the setup of partner images and relationship aspects and
- the measures to enable group awareness.

The function of the tool could so far be verified in an IPv4 based intranet. A first small evaluation took place in the summer term 2000. The final evaluation is scheduled to summer term 2001. Future work will provide the improvement of floor control, so that individual members can be approached specifically. Furthermore, the integration of additional CASE-tools is planned.

Abstract: It is assumed that cooperative learning continuously constructs and extends the shared knowledge of a group of learners with respect to a specific learning domain. Experiences with Computer-Supported Collaborative/Cooperative Learning (CSCL) environments indicate that an explicit representation of the shared knowledge is helpful with regard to two aspects: First, it can preserve (intermediate) results of the cooperative learning process. Second, it can also improve the process itself by providing the context and means for learners’ orientation and navigation in the learning domain, awareness of the learning process, and the construction and negotiation of knowledge. In this paper, we introduce the Learning Net as an interactive representation of shared knowledge and sketch how it can be integrated and used in a CSCL environment.

1. Introduction

Computer-Supported Collaborative/Cooperative Learning (CSCL) is regarded as an emerging paradigm in educational technology (Koschmann 1996). It is based on cooperative learning methods (Slavin 1995) and on constructivist viewpoints of learning as (1) active construction of knowledge, (2) bound to a complex situation, and (3) a social process. CSCL environments respond to these views by providing (1) authoring facilities to create and modify artifacts within the CSCL environment, (2) means to represent complex, authentic, context-rich information using hypermedia technology, and (3) communication and cooperation facilities in various ways such as e-mail, chat, audio/video conferencing, or shared whiteboards.

In the course of a (successful) cooperative learning process, information provided by a teacher, by peer-learners, or from other sources is jointly processed by a group of learners. The result of the cooperative learning process is a jointly structured information base as well as the learners’ shared knowledge of this domain. As material is continuously added, learners need an easy way to access the material, and they have to organize and manage this knowledge and uphold an overview.

Problems known from hypertext, especially the loss of orientation in hyper-documents ("lost-in-hyperspace") and cognitive overload caused by navigation in the document, are amplified in hypermedia-based CSCL environments: Documents may be changed anytime by peer-learners working on the same document, and coordination with peer-learners is needed in order to maintain a common understanding.

In face-to-face situations non-verbal cues provide helpful information to cope with these problems, e.g., a learner can show disagreement with gestures or facial expressions upon a statement and thereby initiate a discussion. Reduced communication channels in distributed CSCL settings render the construction of shared knowledge more difficult. Learners must make non-verbal signals such as gestures or facial expressions explicit in order to communicate to their peer learners. In our research, we aim at supporting learning groups by providing an interactive representation of the shared knowledge, the so-called Learning Net (LN). In the remainder of this paper we present how knowledge is represented in learning nets and how learning nets can be used to support navigation in the shared knowledge, awareness of the shared knowledge, communication and cooperation in the learning group.
2. Knowledge Representation with the Learning Net

A common assumption in cognitive science is that most declarative knowledge can be represented according to the metaphor of a "net", or, more formally, as a directed graph (Churcher 1989; Sowa, 1998). In cognitive psychology, various types of nets are used to represent structural knowledge, i.e., the pattern of connections among concepts in memory, and nets are often used in educational settings to convey knowledge (Jonassen et al. 1993). Also, in the CSCL field net-like representations are used to visualize relations between concepts, statements, data, or hypotheses, e.g., in the Belvedere software environment (Suthers, 1999). Here, we aim at representing the essential structure of socially shared knowledge as it is dynamically constructed during the cooperative learning process in a more active way by linking documents and persons with the net.

A LN scheme is defined by the types of nodes, the type of relations between nodes, and the type of links to documents and persons. With respect to the types of nodes and relations between nodes empirical studies lead to the hypothesis that variation in these types can significantly affect the learning process and outcomes (Suthers, 1999). Therefore in our approach, the LN scheme can be user-defined, e.g., by the teacher, according to the kind of learning situation. An appropriate LN scheme then can be selected for each instance of the LN by the teacher or the learners. Specific LN schemes have been developed and implemented for the domain of problem-based learning (Miao et al., 2000). In the remainder we use a simple general-purpose LN scheme consisting of goals, topics, definitions etc. and focus on the connection of the LN to documents and persons.

![Figure 1: An example of concepts and relations in a Learning Net](image)

Using the general-purpose scheme the LN is structured in the following way: A learning goal is the central node of the LN. To achieve the goal, several topics need to be tackled; a topic can be any concept, principle, or problem. To understand a topic, special cases can be presented as examples or analogies; e.g., a case-study on phobia treatment can serve as an example for the concept of behavior therapy; similarly, a topic can be introduced just by definition.

3. Usage of the Learning Net
3.1 The Outcome Perspective

From the outcome perspective, the LN should provide a common frame of reference and represent the current state of shared knowledge in a CSCL environment.

In cooperative learning it is (mostly) unclear a priori what the exact boundaries of the learning domain are. This
problem becomes more severe when the learning process evolves over time. Here, the LN provides a frame of reference, i.e., a structure that denotes what is part of the domain of concern and what is not. It is a kind of index all participants agreed upon. It is not fixed, since it dynamically changes during learning; changes, however, are not arbitrary, since they presuppose some kind of consensus among the participants. A LN supports various situations, e.g., informing a new person joining the group about what the learning process is about, or let a group continue where it left the learning process previously. The problems associated with the concept of shared knowledge (e.g., Nickerson 1993), especially how to measure it in a CSCL environment, are discussed in Pfister et al. (1999).

3.2 The Process Perspective

Besides the static viewpoint of the LN presented above, there is also an important dynamic aspect: The construction of a LN is a cooperative process during which knowledge is negotiated, different perspectives are integrated, and conflicts are made explicit. The degree of agreement (Pfister et al., 1999) on each element of the LN is reflected on the user interface, e.g. by different colors of nodes or links. This visualization provides an easy overview with respect to the “hot spots” of the group, e.g., conflicting concepts of group members. These hot spots can help to decide on the next steps in the learning process.

The construction of a LN can proceed optimistically or pessimistically. In the optimistic case, whenever a participant creates a new element, it is assumed that consensus is above a certain threshold. Anybody who thinks this element should not be part of the LN must actively object; a participant who does not object is assumed to agree. Hence, as long as nobody objects, the construction can proceed very smoothly by participants synchronously or asynchronously adding or deleting elements. To enforce active learning, a possibility is to proceed pessimistically, i.e., each element introduced in the LN by some person has to be explicitly accepted by everyone else, or by a majority defined by the consensus threshold. We assume the latter to be more time consuming but that it leads to more elaborated and deeper knowledge, both on the individual as well as on the group level. Anyway, the mode of the LN construction has to fit to the collaboration mode of the group. The mode should be determined in consideration of the group size, productivity, synchronicity etc. For example, in an asynchronous collaboration of a large and productive group, the pessimistical construction hampers the progression of the LN: Each learner has to wait till the other learners agree before his or her contribution is included in the LN.

4. Realization

We distinguish the "document level" and the "conceptual level" in CSCL environments. The (hypermedia) document level comprises all basic documents created and imported, i.e., texts, graphics, etc. These documents are all related to concepts, i.e., the basic issues and topics the learning process is about. On the conceptual level, all concepts can be linked by semantic relations, e.g., "is example of", "is definition of". By defining the relation types users can model a wide range of domains and learning strategies. The LN is a representation of the conceptual level. It contains the concepts and relations between these concepts. Figure 2 shows a screenshot of the current implementation of a LN for problem-based learning (Miao et al., 2000).

4.1 Supporting Navigation: Connecting LN and Documents

In addition to the relations within the LN, there are links between the LN and the document space, i.e., each node refers to one or more specific documents, which provide detailed information relating to that node (e.g., a text, a diagram, etc.). Thus, by looking at the LN representation, learners are able to orient themselves and gain an overall and common understanding of the domain, but may then "dive" into the document space by following a link from a node of the LN to an associated document.
4.2 Supporting Awareness: Visualizing the Group State and Progress
The LN provides a color bar for each node and relation on the user interface (a line at the bottom of each node and relation in figure 2). Using a context-sensitive mouse menu (see figure 2) a learner can express her or his opinion with respect to a number of scales, e.g. whether he or she agrees or disagrees with a certain node or relation, whether he or she has knowledge about the topic of a certain node. The color bar visualizes the percentage of learners which agrees/disagrees, which has knowledge about this topic. Thus, the LN can be used to get a quick overview of the state of the learning group as a whole, e.g. with respect to the consensus in the group or the progress of a group with acquiring a certain knowledge domain.

4.3 Promoting Cooperation (1): Connecting LN and Persons
More generally, persons, who are also a knowledge resource - especially, in the context of cooperative learning, are represented in the same way as documents. Thus, persons can also be linked to concepts, for example, an expert in spreadsheets can be linked to the concept "Table creation" with a link labeled "is expert of".

4.4 Promoting Cooperation (2): The Construction of the LN
Access to the LN is available from everywhere in the CSCL environment. When a user opens the LN, a collaborative LN editor starts for the user and all other users in the same group. There are two ways to construct the LN. Nodes, relations, and anchors can be generated directly, or they can be the output of a system-controlled cooperative learning method, a so-called learning protocol (Wessner et al., 1999). In addition, some modifications could be initiated automatically according to the system's knowledge about the learning process, e.g., enforcing specific nodes according to the learning strategy.

For direct construction and modification the collaborative LN editor contains separate functions to construct and modify the LN, especially to create, edit, and delete nodes, relations, and anchors to documents or persons. Node types and relation types are fixed, so the direct construction is more or less the same as working with a graphical editor. However, the LN must not be independent of documents and participants, i.e. in general, each node should reference at least one information resource. Thus, there are smooth transitions between the LN, the
documents, and the participants in the CSCL environment: From each node in the LN, one can navigate to the associated resources.

Learning protocols systematically support a special kind of communication or cooperation activity in a group of learners. For example, the explanation protocol controls a dyadic explanation process by systematically switching roles (explainer and explainee), providing a specialized interface to enter explanations and questions. If both agree, the dialogue can be stored for future use or further discussions, and the information (x is an explanation dialogue concerning topic y) can be incorporated appropriately into the LN. While in this example the modification of the LN is a side-effect of the learning protocol, there are other learning protocols specially designed to modify the LN.

5. Summary and Open Questions

We have proposed the Learning Net (LN) as an interactive representation of shared knowledge for cooperative learning. The learning net is a socially constructed, dynamic meta-level above the hypermedia learning artifacts, (1) providing orientation and navigation in the learning domain and (2) supporting cooperation between learners. The LN is part of a learning environment called CROCODILE, developed in the internal research project CLear at GMD-IPSI (Pfister et al., 1998; Miao et al. 2000). For further information on the CLear project and downloads see http://www.darmstadt.gmd.de/concert/projects/clear.

Preliminary evaluation results at GMD-IPSI indicate that the learning net can be used in various ways, e.g.,

- **Tool for scaffolding:** A teacher builds a LN as a skeleton for the intended learning process. The students take this LN as a starting point for their learning, “fill” it step-by-step with related documents, extend and modify the LN as the learning proceeds.
- **Tool for summarizing and reflecting:** The group starts with an empty LN. After each learning phase the group summarizes what they have collected and discussed by creating and extending the LN. They use the LN to reflect on the last learning phase.
- **Inductive vs. deductive learning:** The learners can start with examples or cases and proceed towards more general concepts and rules and vice versa.

Some problems we encountered and which we plan to investigate in the future are:

- **Participation of absent learners:** How can and must absent learners be involved in the maintenance of the LN? Should absent learners block changes in the LN?
- **Reducing the cognitive load:** Can we reduce the additional cognitive load for maintaining the LN by prompting learner(s) to update the LN under certain conditions, e.g., at the end of a session or after creating a certain number of new documents?
- **Scalability:** Preliminary evaluation results indicate that the usability decreases rapidly in groups with more than three or four members. How can we improve the usability in larger groups?

Developing and Deploying Online Courses with JCourse

Willie Wheeler, David Danks, Joseph Ramsey, Richard Scheines, Joel Smith, Andrew Thompson
Carnegie Mellon University
5000 Forbes Avenue
Pittsburgh, PA, U.S.A.
wwheelerP,andrew.cmu.edu

Abstract: JCourse, created at Carnegie Mellon University, is a Java- and XML-based system for developing and deploying web-based courses. On the development side, JCourse allows content providers to work more independently of web designers than has been previously possible. On the deployment side, JCourse provides basic (albeit incomplete) support for the IMS Question and Test Interoperability v1.0 specification (www.imsproject.org), which allows questions and tests from one compliant system to be reused in other compliant systems. Because Java and XML are platform-independent, JCourse runs on Windows and Unix (including Linux). JCourse was used to create a web-based course on Causal and Statistical Reasoning (www.phil.cmu.edu/projects/csr) that has been successfully used by about 150 students at the University of California, San Diego, the University of Pittsburgh, and Carnegie Mellon University.

JCourse supports the development and deployment of web-based courses. Development support includes instructional and assessment pages. Deployment support includes an assessment engine, a user interface for student and instructor access to student performance data, and security-related access control.

Without JCourse, instructional content for online courses is typically created as HTML web pages by the content author. The instructor uses his or her favorite text or HTML editor to create the HTML file, and then FTPs it to a web server so the students can access it.

This approach works well when instructional materials do not require professional design from a visual design perspective, but otherwise it falters. (Consider, for example, an online course intended to be packaged and distributed as a commercial product.) Because content authors are subject experts, not visual designers, the course development effort requires a separate visual designer role.

HTML presents several major problems in such a situation. First, since HTML encodes both content and presentation, content authors and visual designers cannot work independently, which reduces the number of design iterations. Second, content authors produce non-HTML versions of the content (e.g., Microsoft Word), which leads to synchronization issues. Third, HTML does not provide a mechanism for keeping multiple pages consistent in appearance. Finally, the course developers may want to give the course a completely new look from time to time. For large courses this is difficult with HTML, as each page must be individually updated.

JCourse solves the above by separating content and presentation into different files. The content files use a simple XML (eXtensible Markup Language) format appropriate for the content author. The presentation files, or stylesheets, are based on XSL (eXtensible Stylesheet Language), a sophisticated language that visual designers can use to define page appearance. The XSL stylesheets are applied to the XML content files to obtain web-ready HTML files, which can then be viewed using any web browser without special plug-ins. The transformation process is called XSLT (XSL Transformations). XML, XSL, and XSLT are all W3C technologies (www.w3c.org). Using JCourse, authors and designers can work more independently, allowing rapid design-test-revise iterations. Since the content format is simple, there is no need for the multiple copies that become out of sync. Having a stylesheet enforces a consistent look across pages. Finally, changing the look of the entire site is simply a matter of changing the stylesheet (or small number of stylesheets) responsible for that look.

For assessment development, JCourse provides basic support for the IMS QTI specification, which defines a portable XML-based format for the creation of questions and tests. As the format is complex, JCourse includes an assessment authoring application, implemented using Java Swing. The interface allows the author to create IMS-compliant questions and tests, including single- or multiple-response choice questions, and fill-in-the-blank.
questions. JCourse also provides extension functionality not directly supported by the IMS QTI specification, including support for tables and Shockwave movies. Questions and tests created in JCourse can be used in any IMS-compliant system, as long as they use only nonextension functionality. Similarly, questions and tests created in IMS-compliant systems can be used in JCourse.

JCourse can also be used for course deployment. JCourse includes facilities, in various stages of completion, for course management (e.g., maintaining class rosters), student account management (e.g., viewing one's assessment scores), delivering instructional pages and assessments, tracking student performance, and security-related access control. JCourse runs as a Java web application on any web server that supports the Java 2.2 Servlet web application specification. (This includes most major web servers; see www.java.sun.com.) A single JCourse instance can host multiple courses and multiple instances per course.

The JCourse assessment engine performs three major functions: assessment delivery, response processing, and results storage. The user requests an assessment by clicking on a hyperlink on the web page. The hyperlink points at the URL where the assessment engine resides, and the query string includes an assessment ID so the engine knows which assessment to deliver. The assessment engine then loads the assessment, and generates HTML dynamically for that assessment, using JavaServer Pages (JSP). It sends the HTML back to the client browser, which displays it. At this point the student answers the question, presses the submit button, and sends the results back to the assessment engine. The assessment engine evaluates the results according to the assessment specification as created by the authoring tool. It then writes the performance data to the student performance database, and finally returns feedback to the student.

The JCourse gradebook gives course instructors simple web access to the student performance data. The instructor can view the score for any given student/assessment pair, as well as summary statistics for given students or for given assessments.

Deployment options are flexible. Course instances can be configured to have their own question and test repositories, or they can share them. Sharing saves disk space and simplifies management by avoiding the need to synchronize updates, while having individual repositories allows customization. Similarly, course instances may share student performance repositories, or have their own. In the case of performance repositories, a JDBC-based abstraction layer sits between the repository and the application proper, and allows any JDBC-compliant database (e.g., Access, SQLServer, Oracle, Sybase, mSQL, and MySQL) to be used to persist student data.

JCourse was used to create a web-based course on Causal and Statistical Reasoning (www.phil.cmu.edu/projects/csr) that has been successfully used by about 150 students at the University of California, San Diego, the University of Pittsburgh, and Carnegie Mellon University. Approximately four people, all working part-time on the project, produced the bulk of the course in under a year. The material includes dozens of Shockwave simulations, almost 500 questions tracked and recorded in the JCourse database, and a large virtual laboratory in Java, all delivered in approximately 18 content modules.

Classes at UCSD and at Pitt are delivering the same material to students with traditional lecture/recitation format, and with JCourse. On the first midterm, students using JCourse scored 6 percentage points higher at UCSD, and 3 points higher at Pitt. Although these groups were self-selected, a similar experiment in the spring of 2000 found the selection effect to vary between 2 and 4 percentage points. Students using JCourse to learn the fundamentals of experimental design and causal inference are faring as well as their peers in lecture.

Future directions for JCourse include the following:

- More complete support for the IMS QTI specification, including support for additional question types and support for question selection and sequencing when it is specified.
- Performance-based (as opposed to security-related) access control. For example, students cannot progress to later course sections until they have demonstrated mastery of earlier sections.
- External API to the student performance database so performance data can be collected for exercises implemented as applets, Shockwave movies, etc. We already have several such applets (Causality Lab, Carnegie Proof Tutor, D-Separation Tutor, Set Builder), but currently they provide their own persistence capabilities. We want JCourse to provide at least general support, such as saving scores and timestamps.
- We will investigate the possibility of open sourcing the project.
A Multimedia Tool for the Classroom:  
A Cross-Curricular 
Multimedia Knowledge Construction Environment

Elizabeth McAlpin & Robert Whelan,  
New York University, Educational Communication & Technology Program, USA  
emcalpin@earthlink.net, rrw216@nyu.edu

Abstract: This paper describes how six constructivist instructional theories were combined and incorporated into the design of a prototype multimedia learning tool. The tool, a multimedia learning environment for high school students, is intended to meet the demand for a cross-curricular knowledge construction system that supports anchored, situated and generative learning, cognitive flexibility, metacognition and rich-interaction that fosters open dialogue and critical thinking. A prototype interface is described.

Background

Our aim with this project was to explore the possibility of combining six key features of constructivist instructional theories into a generic design formula to help develop a prototype instructional tool that is purpose-built for laptop computers and that exploits the attributes of multimedia and the World Wide Web. The instructional needs were to design a knowledge construction environment that (1) integrates curriculum subjects so that students can better inter-relate them with respect to context and meaning; (2) Enables unique, engaging, meaningful, memorable, collaborative experiences for the students; (3) Facilitate intellectual growth beyond the present level of learned skills; (4) Incorporates an intuitive interface with little or slight learning curve for both teachers and students; (5) Demonstrates how an effective learning tool can bring learners and teachers together. In this prototype, materials are organized into case studies that engage learners in knowledge construction. Teachers can customize the cases or use cases already embedded in the multimedia tool. Thus, knowledge acquisition and construction are central features of the tool.

A Constructivist Design Model

The theoretical models we combined for the design of the prototype draw from the work of constructivists such as Cunningham, Duffy & Knuth (1993), Jonassen & Tessmer (1996/7), as well as Spiro et al. (1988), Wilson, Teslow and Osman-Jouchoux (1995). These models, each highly regarded, were chosen for their individual merits but also because they are widely recognized in the field of instructional design for the elements they include and because they each represent key aspects of constructivist approaches to learning. The integrated constructivist theoretical framework gave us a foundation for the design of the multimedia tool in prototype.

Six theoretical features guided this phase and helped to form the main interface design. The first feature for students using the prototype tool is that they can engage in meaningful knowledge construction. Learners, especially in well-structured domains, are often faced with prepackaged materials that minimize generative problem solving or preclude opportunities for learners to create their own complex interpretations. The implication for our design is that a deep resource of 'knowledge objects' can be represented in multiple forms (from 3-d object models, films, texts, illustrations, or VRML spaces, for example) that learners can explore and collect into an integrated notebook or digital scrapbook. Students engaged in knowledge construction exercises would use integrated programs such as a personal scrapbook, multimedia viewer or communication tools to accomplish teacher-defined tasks.

A second feature is to provide for cognitive flexibility with multiple perspectives on, and multiple representations of the learning materials (Spiro, 1988). A key implication for learners is that they can access, view and navigate a given environment while creating, selecting from and/or editing various biases. A third feature is to
situate learning in relevant contexts. Students utilizing the multimedia tool ought to be able to search, view and gather information from multimedia elements that relate meaningfully to the ‘real-world’ problems designed by the teacher. The environment accommodates the creation, editing and navigation of teachers’ assignment ‘templates’. This helps to foster a fourth feature of the prototype: generative learning with ownership of the learning process. Students are able to customize their own portfolios, websites, templates and the workspace interface itself as befits the problem-solution context. The fifth feature of the prototype is to support social experience in learning as much as possible. The communication tools in the system support socially negotiated tasks where alternative viewpoints can be explored and shared by students. Thus, Email, Websites that support messaging and Chat, as well as Collaborative Notebooks and shared project spaces.

The final feature of the prototype learning tool is that it can engage the learner at the metacognitive level. This requires functionality that emphasizes feedback, rich interactivity, customizability, control over self-assessment, as well as access to the structured assessment of others. This involves tools such as task-adaptive creative workspaces with modular palettes of controls and communication tools where the locus of control rests with the learner. The aim is for the student to arrive at a state of self-awareness through the use of ‘cognitive tools’ that support the creation and editing of their work. Learners using the multimedia tool can conduct research, analyze reading material, view, create, edit video, illustrations, compose an expository essay, compose multimedia projects, post efforts on a class web page, engage in cooperative learning and peer evaluation, and contribute to the building of a library of resources. The goal of providing the learner with tools to engage in active knowledge construction, explore multiple perspectives, practice generative problem-solving in anchored, relevant contexts, with rich social learning experience and metacognitive interaction support, led to the navigation device described here:

Navigation ColorWheel©

Figure 1. The color wheel is the curriculum navigation device used by students and teachers for navigating across and within curriculum subjects. The wheel’s multi-layered ocular navigation metaphor provides access to knowledge construction, perspective-seeking, contextualization, problem-generation and orientation. Control functionality is accessed via tool palettes integrated with media resources.

Conclusion

The modular, customizable interface of the prototype incorporates the integrated logic of the constructivist learning environment features in terms of learning resource navigation, communication and control, and supports students’ and teachers’ knowledge construction needs in an intuitive manner, exploiting the affordances of the Case Study paradigm. Students can access, arrange, create, edit and control their projects and creative material in a customizable portfolio. The challenge in the creation of a tool like this is not only the development of a real platform, but also the design of a library of quality-controlled learning resources and references.

Abstract: This paper proposes the application of a structured content base to Web-Based Training settings and introduces a workflow using an XML-based file format for educational data. Content is authored in a SGML/XML editor employing a modified DocBook DTD that caters for semantics needed in educational scenarios. Using a Java servlet, this content is formatted according to learners' preferences on-the-fly from XML files deployed on a web server. Additionally, all user requests are logged with their parameters into a database, supporting statistical usage evaluation.

Introduction

Interactive Computer-Based Training (CBT) has experienced a tremendous growth over the last few years. However, the rapidly growing demand for interactive CBT revealed that the traditional content creation workflow has serious shortcomings that make its large-scale application difficult: Reuse and exchange of content modules are hard to implement, because most learning environments use proprietary authoring tools and data formats. It soon turned out that also HTML, the common standard on the Internet, lacks much of functionality to fulfill many of the needs of online educators, e.g. no dedicated semantics for online exercises, no support for complex equation rendering, difficult reuse of HTML content in new contexts. This paper presents a workflow that tries to solve some of these problems using an non-proprietary content structure and a web server extension that enables HTML browsers to access the features made possible by XML content.

Why structuring educational content?

Structured educational material decouples style from content. Storing course content in elements that reflect its semantics (e.g. introduction, example, quiz, ...) allows the reuse of data in different situations and formats - adapted to learner preferences, target media or purposes. All groups concerned with the online learning process benefit from the use of structured documents:

Authors
- Authors can concentrate on content not (necessarily) on style and formatting
- Structural integrity can be checked/enforced by an authoring application (e.g. link checking)
- Indexes, summaries, glossaries etc. can be generated automatically
- Content modules can be reused in other contexts (e.g. related courses, in different skill.levels)
Publishers / Internet Service Providers

- Content is well machine-processable (i.e. easily stored in databases to facilitate content administration and improvement of retrieval performance)
- Crossmedia publishing is possible from one, single source (e.g. online/offline versions, printed material). The concept of viewgroups presented in (Müller & Deponte 1999) addresses this idea.
- Versioning is facilitated.

Learners

- Mandatory structure facilitates navigating the course content.
- Advanced search and retrieval of content components.
- New features like multi-representation content become feasible (e.g. the same content in both visual and textual representation. (Ram et al. 1999) suggests a Presentation Markup Language.)

Researchers / Quality Assurance

- Enhanced possibilities for learner tracking and usage evaluation allow the collection and sharing of comparable data on applicability and effectiveness of the content and help to improve its quality.
- Flexible rendering allows experiments with screen designs, navigation concepts etc.

Current activities employing structured content in the educational field

XML (Bray et al. 1998) is, like its predecessor SGML (ISO 1986), a scheme to define new languages. It does not specify what kind of application data is stored in a file by itself but rather provides a framework to define purpose-depended languages that follow one common syntax. This is done in a document type definition (DTD) that describes the overall structure and the components of generic data file. There have been already different suggestions to apply SGML, XML or at least structured documents to educational purposes:
- The Tutorial Markup Language (Brickley 1998) provides a language to describe several classes of online exercises like multiple-choice tests, drag & drop puzzles etc. IMS is currently defining a specification for standardized questions and test data formats (IMS 2001). Other structured file formats (Krauße 1999, Arneil et al. 1999) pursue the same goal but currently don’t use neither SGML nor XML.
- The IEEE Learning Technology Standards Committee proposes a learning object meta-data standard (LOM) (IEEE 2000) to facilitate the retrieval, reuse and exchange of educational content. Learning objects range from small components like a single sentence, a figure or a Java applet up to complete on-line courses. LOM contains information on technical, didactical and legal issues of educational content and provides support for versioning. LOM does not standardize the actual internal data structure of learning content.
- The recently released specification for content packaging by the IMS (IMS 2000) has also bindings to an XML file format. There are already commercial applications like Microsoft’s LRN project that are strongly influenced by these specifications (Microsoft 2001).

Our implementation

We offer several online courses on computer science topics to our students at our department. This material consists typically of some 200 linked HTML pages per course, enriched with additional interactive elements like Shockwave animations, Flash movies, and Java applets. The courses were created from legacy content in Adobe FrameMaker format as a starting point. Dealing with mathematical and statistical subjects the courses contain over 500 equations.
A typical page is shown in (Fig. 1).

Although Adobe FrameMaker ships with HTML/XML export functionality, files generated by the HTML export function needed manual clean-up which took one person about 1-2 days to complete for each new release of a course. Additionally, an evaluation among student users turned out that the poor display quality of equations was a major annoyance to learners. From our previous experience we also could identify two main usage scenarios for our online content: the tutorial mode, in which learners tend to navigate through the course linearly and slowly paced and the script mode, in which users want to look up small amounts of information like definitions, proofs or concepts.
quickly. Because both modes are related representations of the same content, we wanted to keep maintaining course content simple and generate both versions from one single data source. Because interface design for WBT is still a young discipline we also realized that there might be a need for additional modes in the future. Ideally, a learning environment would therefore apply formatting and user preferences to the desired content not until the moment of an incoming learner’s request.

![Figure 1: Left: Typical page from online course “Evolutionary Algorithms”. Note the high number of equations and symbols in the main content area. Small symbols, especially indices, are hard to read on-screen and do not print very well. Right: Using our improved system, learners can click on any equation to open a high resolution version in a separate windows. An additional print view offers also a high quality hardcopy option.](image)

Our new publishing workflow consists of six steps:
1. Choosing/creating an appropriate document type definition (DTD).
2. Structuring a complete course according to the DTD in an authoring environment.
3. Converting the SGML content into XML and preparing it to be served on the WWW.
4. Creation of HTML page templates and navigational controls.
5. Developing a servlet that converts XML to HTML on-the-fly.
6. Tracking content usage into a relational database.

**Document Type Definition (DTD)**

We decided to enrich an XML-compliant, light-weight variant of the DocBook DTD (OASIS 1998) used in technical publishing with additional elements and attributes that cater for educational needs, different media types and hyperlink capabilities. We classified the elements inherited from DocBook into the given aggregation levels according to the LOM specification (IEEE 200). All level 0 objects were assigned a 32-digit hexadecimal identifier attribute - unique in time and space.

**Authoring environment**

FrameMaker+SGML was chosen as an XML editor because it combines the ease of use of a modern word processor (especially equation handling) with the structural functionality of an XML editor. To track down learning objects during the following processing steps, each level 0 object was assigned a globally unique identifier. Once the identifiers are assigned, they will be present in FrameMaker+SGML files as well as in exported SGML documents. It
is important to note that even though the content is kept in the FrameMaker+SGML file format, this format represents nothing more than a wrapper around a DTD compliant structure.

**Converting and preparing XML content**

The next step is to export the FrameMaker content into an SGML file using built-in export functionality. Image representations of embedded equations are also generated in this step.

A common problem creating scientific content for the WWW is to display mathematical equations. While some browsers already feature limited MathML rendering capabilities it is common practice to embed equations as bitmap images, e.g. GIF or PNG files. This one-way conversion complicates later on modifications for the author and results in poor image quality of the content (especially when hardcopied). We decided to keep equations in this format within FrameMaker but to convert them in GIFs during SGML export. By exporting the course content twice with different resolution (72 dpi, 300 dpi), we get two versions of the same equation. This allows features like zooming into equations that are hard to read (Fig. 1) or high quality hardcopy options.

In a final step the *course description*, a hierarchical table-of-contents structure is extracted from the SGML document to serve as website structure. Course description, course content (stored in a set of XML files) and equation images are now copied onto the web server file system, ready to be served.

The complete conversion procedure is depicted in (Fig. 2). Export and equation rendering of a 200 page course on an Athlon 900 MHz Windows PC takes roughly 6 minutes for the 72 dpi version (30 minutes for 300 dpi) and does not require any human interaction.

![Authoring Workflow](image)

**Figure 2**: Authoring workflow. Content creation takes place inside the SGML editor (like FrameMaker+SGML). In two passes, SGML versions and two variants of equation graphics are exported. Finally these file get converted to XML and prepared for being served by our servlet-based system.

**Page templates and navigational controls**

Page templates were designed in an HTML editor, containing placeholders for dynamic content. These placeholders get replaced by applying several XSLT transformations using the open source XSLT formatter Xalan to the requested course content file. XSL style sheets exist for several target media (on-line, print) and usage modes (tutorial and script mode).

The globally unique learning object identifiers are preserved during conversion, allowing web browsers to make use of this information. We have implemented a smart, fine-grained annotation system that works at the subcomponent level within HTML pages and allows learners to tag individual page elements with personal comments. These comments can also be classified by the learner (question, answer, general remark, bug report) and given a restricted visibility to other users.
**Serving the content**

Because most browsers currently provide only limited XML support, the course content is server-side converted from XML to HTML. Additionally, this allows adaptation of the content to a specific user’s learning context (e.g. formatting preferences, target media, usage mode) at this point.

To bridge the gap between web server and XML content, we developed a Servlet Interface for Online User-adapted XML (SIoux). Java Servlets are plug-in extensions written in Java that add functionality to a HTTP daemon. To serve a request, SIOUX reads in the requested XML file, applies an XSL transformation to the target medium and mode, inserts the content into a page template, resolves server-side includes and other placeholders, returns the HTML page to the learner’s client and logs user id, URL and learning context into a relational database.

Our setup builds on an Apache HTTP daemon and the MySQL RDBMS running on an RS/6000 workstation. Servlet support is provided by the JServ servlet engine, connecting to the SIOUX servlet on a Windows PC (Windows 2000, Athlon 900 MHz, 256 MB, Sun Java Runtime Environment 1.3). The response times vary between 0.2-0.6 seconds per page request depending on complexity of the XSLT style sheets. This is acceptable compared to the 1-5 minutes it takes a learner to work through the page content. (Fig. 4) shows how a request is handled by Apache/SIOUX and which resources are used.

![Diagram of SIOUX architecture](image)

**Figure 3:** Resources used within the SIOUX architecture. The SIOUX servlet generates dynamic content from XML structure, content, style and template files. Static content is handled by the Apache server without SIOUX intervention.

**Tracking content usage**

The system contains a learner database that allows restricting access to course content, personalized tracking of content usage and persistent storage of user preferences. After a request has been served, the user’s ID, the requested URL and all session parameters (e.g. current mode, target media, individual interface settings, date and time of access, referring URL, agent, ...) are logged into a relational database.

**Conclusion**

2099
The paper illustrated how structured content supports the online learning process in creating, deploying and using course material. An example has been given, how an existing DTD can be modified to include the dedicated semantics needed in didactical processes while avoiding getting trapped in a proprietary format. Using one single, consistent source which is varied on-thy-fly also avoids complicated and error prone maintenance of several parallel versions. Rendering is acceptable fast for online learning purposes. Several modes (tutorial, script) match the main usage scenarios closer than a single all-purpose version. Preserving learning object identifiers in the resulting HTML pages makes way for applications like fine-grained annotation mechanisms on sub-page detail level. The flexibility in displaying content in different flavors provides also a test bed for evaluation of different user interfaces or navigation concepts. Equally important is the ability to measure the usage of these experimental variations. While it is obvious that web interface design plays an important role in online education process, it is arguable which is the best way. Due to extended tracking possibilities we can offer an approach that helps to collect hard facts. In the likely case we'll learn that there is no single ideal interface for all learners, the presented workflow is already powerful enough to serve highly personalized educational content.

The Impact of Epistemological Beliefs on Middle School Students’ Knowledge Acquisition and Problem Solving While Working in a Hypermedia-Supported Problem-based Learning Environment (HALE)

Doug Williams, Univ. of Louisiana at Lafayette, USA

Hypermedia-supported authentic learning environments (HALE) leverage the characteristics of hypermedia to immerse students in an authentic context while engaging in authentic tasks. Research indicates that students’ epistemological beliefs affect performance in traditional learning environments. Yet few studies explore the relationship between epistemological beliefs and performance in hypermedia-supported authentic learning environments. Analyses show a trend of being able to predict performance, though the results were not statistically significant. Though none of the results were statistically significant, the findings may suggest that students with naive epistemological beliefs might be low performers on measures of achievement when learning in hypermedia-supported authentic learning environments.
Analysis of Navigation in a Problem-based Learning Environment

Abstract: Research has shown the potential of a problem-based approach to enhance students' learning. The interactive nature of hypermedia technology and its ability to deliver information in different media formats can provide unique capabilities for implementing problem-based learning (PBL) environments. Yet, we know little about the types of tools that are effective in supporting learning in hypermedia supported PBL environments. The purpose of this exploratory study is to investigate both the use of tools and design features in a piece of PBL software and their effectiveness on middle school students' learning. Since data gathering has just been completed, there has not been sufficient time to complete the data analysis. Data analysis will be completed and research results and conclusions presented in the conference presentation.

1. Research Framework
1.1 Problem-based Learning

There has been a growing body of research on authentic and situated learning environments utilizing the problem-based approach to learning [Cognition and Technology Group at Vanderbilt, 1992; Pedersen, Williams, 1999]. Problem-based learning (PBL) emphasizes solving authentic problems in authentic contexts. It is an approach where students are given a problem, replete with all the complexities typically found in real world situations, and work collaboratively to develop a solution. Problem-based learning provides students an opportunity to develop skills in problem definition and problem solving, to reflect on their own learning, and develop a deep understanding of the content domain learning [Cognition and Technology Group at Vanderbilt 1994; Jacobson & Spiro, 1995; Lajoie 1993]. This approach was developed in the sixties for medical education, and has since been used in various subject areas, such as business, law, education, architecture, and engineering.

Literature has shown that problem-based learning can facilitate the improvement of student attitude toward the content area learning [Cognition and Technology Group at Vanderbilt, 1992; Williams, 1999]. Explanations offered for this are that students perceive the relevance of the work [Barrows 1986] or compare the task of finding information and developing a solution to solving a mystery [Cognition and Technology Group at Vanderbilt 1992]. Medical students using a PBL curriculum have been shown to be able to pursue learning independently better than their peers receiving a traditional curriculum [Aspy, Aspy, & Quinby 1993], a finding which supports the claim that PBL prepares students to become independent, lifelong learners. High school students in a semester long class which used PBL exclusively showed a significant increase in their spontaneous use of one problem-solving step: problem finding, the ability to identify and formulate problem statements [Gallagher, Stepien, & Rosenthal 1992]. Similarly, students in a PBL curriculum have shown a greater ability than students in traditional classes to break complex problems into their component parts and identify sub-problems which must be solved in order to solve the main problem [Cognition and Technology Group at Vanderbilt 1992; Gallagher & Stepien 1996].

In recent years, there has been a growing interest among educators to use PBL in the K-12 setting. However, the experiences of college level programs and early efforts in K-12 schools have shown PBL to be a particularly demanding instructional approach for both students and teachers [Barrows & Tamblyn, 1980; Cognition and Technology Group at Vanderbilt, 1992]. Students must perform a wide variety of tasks with which they may have had limited prior experience. These include problem finding, hypothesis generation, identification of learning needs, location of resources to meet these learning needs, data collection and
organization, and development of a solution plan supported by evidence and reasoning. Teachers, in their role as facilitators, are responsible to provide support for this wide variety of activities to students who may vary greatly in their needs. Because the variability of the classroom teacher's ability to function in this role has a profound effect on the success of PBL [Walton & Matthews 1989], instructional materials that provide some of this support seem warranted.

1.2 Hypermedia and Problem-based Learning

The interactive nature of computers and the ability to deliver information in different media formats provides unique capabilities for the implementation of PBL environments. In particular, the capabilities of hypermedia have much to offer designers of advanced learning environments. Hypermedia is a rich environment containing information in many different forms, including text, graphics, audio, video, and animation. The student is not forced to access the resources in any predetermined order, but can navigate within the environment in a nonlinear fashion [Burton, Moore, & Holmes 1995]. The support of multiple media types and the possibility of nonlinear navigation are particularly useful in the creation of computer-based PBL environments.

The nonlinear nature of hypermedia is consistent with the characteristics of PBL. As students are engaged in PBL, they need to collect data and access resources. This suggests a high degree of control on the part of the learner. Hypermedia can support this by allowing students to access needed resources at the time it is most appropriate. Hypermedia allows students to have more control over their learning. They become actively engaged in decision-making while traversing the environment. Research on learner control versus program control in hypermedia environments suggests that subjects under learner control score higher than those under program control on achievement posttest and have a more positive attitude toward learning [Hannafin & Sullivan 1995].

Though PBL can be implemented with traditional media, hypermedia provides unique capabilities for its implementation. The nonlinear nature of hypermedia allows students to explore the PBL environment accessing resources as the need arises. Hypermedia can also facilitate the development of authenticity in the learning environment. Williams [Williams 1992] suggests that law and medical school curricula could be improved by the use of hypermedia environments to engage students in authentic activities within an authentic context.

1.3 Hypermedia and Cognitive Tools

When working in everyday situations, individuals use tools and resources such as computers, calculators, concepts, and formulas in order to solve problems. Therefore, tools must be considered when creating authentic environments for student learning. A tool does not necessarily have to be a tangible object. For example, an engineer may use a mathematical formula to calculate the area of a cylinder. Different disciplines and professions may use ideas and tools in very different ways.

Many researchers argue that cognitive tools can support and enhance student learning [Lajoie, 1993]. These tools come in many forms and can support students in a variety of tasks they must perform as they engage in problem solving. Hypermedia has the potential to make these tools readily available to students.

As discussed earlier, PBL occurs within a context where knowledge is naturally situated. Tools can be employed to create an authentic context in which students can work. The Adventures of Jasper Woodbury series utilizes video-based scenarios in order to create a context for learning [Cognition and Technology Group at Vanderbilt, 1992]. The video segment provides a focus for the learning activity and may also help students who are poor readers. Hypermedia can also present a scenario, but has the advantage of allowing students to explore the environment in which the scenario is set.

Hypermedia can augment memory and support students in reflecting on their problem-solving process. Sherlock I, software that creates an environment in which Air Force technicians practice avionics troubleshooting, includes tools to support cognitive processing [Lajoie, 1993]. Avionics troubleshooting is a complex task requiring the technician to entertain many variables and remember a series of completed tests. Sherlock I allows the student to view the steps he or she has taken in troubleshooting a problem. The ability to view the solution path supports students in reflection on the problem solving process without the need for them to rely on their recollection of every step. The software-generated problem solving step also make explicit student thinking, an essential component in stimulating metacognitive awareness. Likewise, reflective questions can also be effective in promoting metacognitive thinking.
Hypermedia environments can offer a comprehensive set of resources to enable students to meet their learning needs. In order for students to engage in problem solving, they must have access to information. Information can be provided to students in a number of tools. The Lab Design Project (LDP), which allows students to actively take part in sociological research concerning a fictitious biotechnology building, permits students to gather information from such diverse formats as interviews with employees, building plans, letters, and sketches [Honebein 1996].

Hypermedia can provide electronic notebooks, which, in addition to providing space for student note taking, can include advanced features to help support the student in constructing meaning. The notebook in Bio-world contains a section that displays the students' previous actions such as database searches and diagnoses for patients [Lajoie 1993]. These features help support the student's memory and metacognitive thinking. Other projects have augmented the traditional notebook with the ability to support multimedia, collaboration among students, and the ability to create links between concepts [Edelson, Pea, Gomez 1996].

Though literature supports the efficacy of problem-based learning, little research exists which investigates the types of tools or features that are effective in supporting students working in PBL environments. PBL software is beginning to find its way into schools. However, the relative effectiveness of the various tools incorporated in these programs has yet to be studied. In order to design an effective computer-supported PBL learning environment, it is important to understand the tools and design features included in the software, and their impact on learning. It is, therefore, the purpose of this study to examine and understand how middle school students use and interact with a piece of recently available computer-supported PBL software.

2 Research Questions
This study investigates the use of tools and design features as employed in a piece of problem-based learning software and their effectiveness on middle school students' learning of science concepts. Specifically, the following research questions formed the focus of the study:

1. Do any navigational profiles emerge among the student teams, and if so, how do they compare in usage of the tools embedded in the PBL environment?
2. If navigational profiles exist how do they compare in terms of the external criteria: science aptitude, recall and transfer measures, and attitude toward the environment?
3. If navigational profiles do not exist, what is the relationship between tool use and student achievement and attitude?

3. Design of Study
3.1 Sample
The participants of the study (N = 100) were students enrolled in sixth grade science at a middle school located in a medium-sized city in the southwestern United States. The age of the students ranged from 12 - 14 years. There were approximately an equal number of male and female students. Students worked in teams of heterogeneous groups determined by the classroom teacher.

3.2 Treatment
For this research, a hypermedia-supported problem-based learning environment was developed in the content area of astronomy. The learning goals of the HALE were for students to be able to:

- Plan and implement procedures for solving complex problems
- Identify relevant information needed in solving a complex problem
- Identify the characteristics of objects in our solar system
- Describe components that comprise probes used for astronomical research
- Rationalize the design of a probe in regards to its intended mission
- Analyze data and draw conclusions from astronomical data

The environment supports students with the following tools: notebook, bookmarks, presentation tool, probe builder, solar system database, mission database, alien database, and expert tool.
3.3 Dependent Measures

Of primary interest in this study is how students of varying characteristics working in teams utilize the tools and support present in the PBL environment and how those tools affect student learning. Therefore, all student actions in the environment were logged to a data file for analysis. Additionally, measures of knowledge recall and transfer were administered, and interviews were conducted with the participants and the classroom teacher. The triangulation of the quantitative and qualitative data sources will help to answer the research questions with richer and more detailed information.

3.3.1 Audit Trail of Tool Access

The learning environment kept a log of all student actions in the environment, notebook contents, probes built, and time spent using the program. The log consists of time and date stamped entries.

3.3.2 Recall Measure

The recall measure evaluated the amount of declarative knowledge students have concerning the astronomy concepts being taught in the study. The measure consists of multiple choice and fill-in-the-blank items. A panel of reviewers were asked to verify the validity of the measure. Items were revised until agreement was reached. The recall instrument was administered as a pretest, posttest, and retention measure. Due to the factual and objective nature of the measure, it was scored by the principal investigators. The recall measure was used to gauge the degree to which students acquire an understanding of astronomy.

3.3.3 Attitude Toward Science in School Assessment

Attitude toward science was measured with Germann’s (1988) Attitude Toward Science in School Assessment (ATSSA). Germann developed ATSSA in response to the ambiguity that exists in science attitude as a construct. Germann points out that there are many dimensions that make up attitude toward science and that attitude measures must be clear as to what they measure. Attitude toward science can include such things as scientific careers, methods of teaching science, scientific interests, assessing ideas and information, and science as a subject. The purpose of ATSSA is to measure a single dimension of attitude toward science, that is, how students feel about science as a subject (Germann). The instrument consists of 15 Likert scale items and has a Cronbach alpha of 0.95.

3.3.4 Attitude Toward the Environment

The Attitude Response Log gathered information on students’ attitudes toward the difficulty of the learning environment, level of interest in the activity, attitude toward learning science with computer, and attitude toward the tools. The questionnaire used in this study consisted of 20 likert-scale items. The 20 items are partitioned into statements concerning the following areas: how students perceived the difficulty of the activity (difficulty scale), what students’ level of interest was in the activity (interest scale), whether students prefer learning science on computer or in class with other students (computer preferences scale), and how students liked the tools (tool scale).

3.3.5 Transfer Measures

As noted in the literature review section, students are often unable to apply what they have learned in problem solving situations. The review of literature put forth that this is due to the decontextualization of learning. Therefore, in order to evaluate student learning it is not sufficient to only measure acquisition of concepts. But one must also measure the ability to apply that knowledge in context. Hence, near and far transfer measures have been included in the design of this research.

3.3.5.1 Description of Near Transfer Measure

In order to evaluate to what degree students are able to apply their knowledge in solving problems similar to the one received in the treatment, participants were given a scenario in textual form describing a problem similar to the one received during the study. The near transfer measure was given as a posttest and used to provide information on the effects of the expert stories on student learning. After reading the
problem scenario, participants were asked to provide the following information: hypothesis, rationale, list of information needed to solve the problem, and a description of the tools needed to solve the problem.

3.3.5.2 Description of Far Transfer Measure
In order to evaluate to what degree students are able to apply their knowledge in solving problems that they have not encountered before, students were asked to solve a problem unlike those encountered during the treatment. The far transfer measure was given as a posttest and used to gauge the degree to which students are able to apply what they have learned to a novel situation. After reading the problem scenario, participants were asked to provide the following information: hypothesis, rationale, list of information needed to solve the problem, and a description of the tools needed to solve the problem.

3.3.5.3 Scoring of Near and Far Transfer Measures
Since scoring the near and far transfer measures is subjective in nature, responses from the near and far transfer measures were evaluated by three trained graders who will be blind to the subjects’ treatment conditions. Due to the large number of responses to evaluate, the responses will be randomly divided between the three graders. In order to ensure inter-rater reliability, each grader was given an additional 20% of the essays from each of the other two graders. These additional essays were randomly selected, scored, and compared with the scores from all graders. Each essay was scored in the following manner:
1. A score from 0 to 15 was given for the essay on the following criteria: (a) Quality/plausibility of the hypothesis and supporting rationale, (b) Level of incorporation of details and facts in the essay, (c) Thoroughness of analysis of needed information to support answer, (d) Number of tools cited and the appropriate use of them, (e) overall originality of ideas, (f) overall quality of the essay.
2. Scores from each of the criteria were collapsed into one overall score for the response.

3.4 Procedures
Data was collected from ten intact classes resulting in data from 60 student groups. Students were presented with information about the nature of the learning environment. They were informed that at the end of the activity they would be asked for input concerning the aspects of the environment they found useful and those they did not.

Prior to treatment, students were asked to complete the recall measure and attitude toward learning science instrument. After all groups had completed the activity, participants were asked to complete the recall measure, near transfer measure, and far transfer measure and attitude toward environment instrument. Three weeks after the completion of the study, the recall measure was administered once again to all of the participants to collect retention data.

3.5 Analyses
Since data gathering has just been completed, there has not been sufficient time to complete the data analysis. Data analysis will be completed and research results and conclusions presented in the conference presentation. In several studies of hypermedia, researchers analyzed navigational data and found that different profiles of users tended to emerge. In this study, the users were students working in heterogeneous teams of two to three students determined by the classroom teacher. Each team used the HALE as a group, and hence we will analyze the group navigational data. Individual navigational performance is difficult to record, given that the students used the learning environment as a group. To determine whether different group profiles emerge, we will analyze the group navigational data, using cluster analysis. If clusters do emerge, we can study how each cluster tends to use the different navigational tools and design features, giving us a profile for each cluster. As other authors have done in similar studies, the external variables will be compared to the profile groupings using analysis of variance procedures. If differences do exist, this will not only lend support to the existence of such profiles but also give insight into whether learning as expressed by the recall and transfer measures is different among the profiles.

If no clusters emerge, we will look for relationships between the group measures of navigational variables and the individual student measures of the external criteria. Pearson correlation coefficients and analysis of
variance procedures will be used to find these relationships. Here the heterogeneity of the group may hinder
the analysis. For example, if one group was composed of students of varying levels of ability, the
 navigational scores would be the same for all group members whereas their recall and transfer measures may
range from high to low. The resulting correlation coefficients may be insignificant. In this scenario, future
studies of learning environment may need to take into account an individual’s navigation through the
program.

4. Conclusions
As problem-based learning becomes more popular, instructional designers must find new ways to
utilize technology in order to support problem-based learning. For this research an innovative problem-based
learning environment was created which provided the context for learning and authentic activities for students
to engage. Once the analysis is completed, it should provide insight into the tools and features that can
support students of varying characteristics when working in hypermedia-supported problem-based learning
environments.

Streaming Video Cases for the Support of Pre-Service Teacher Education

Douglas C. Williams, University of Louisiana at Lafayette, Department of Curriculum & Instruction, USA, dwilliams@louisiana.edu
Susan Lyman, University of Louisiana at Lafayette, Department of Kinesiology, USA, halo@louisiana.edu

Abstract: Universities struggle with ways to help better prepare pre-service teachers for the realities of teaching in today’s schools. Professional organizations call on teacher preparation programs to increase the opportunities for teacher candidates to observe good teaching and reflect on professional practice. Case-based learning provides an opportunity to immerse students in various teaching contexts where they are given opportunities for reflection. Video cases embedded in hypermedia learning environments hold great promise for providing the much needed context individuals need to learn. This project is a web-based learning environment where teacher candidates are provided a series of streaming video cases that illustrate teaching methodology. The cases are enhanced with textual descriptions, teacher reflections, and expert analyses. Since the learning environment is currently under development, there has not been sufficient time to complete a summative evaluation of the system.

1. Theoretical Framework
Reformers have urged educators to make schooling relevant to students through emphasis on learning through experience and making connections to the world outside of the school walls (Dewey, 1938). Popularization of current learning theories, such as constructivism and situated cognition, further emphasize the value of providing opportunities for students to engage in authentic activities (i.e. reflection, problem solving) in authentic contexts (i.e. real world situations). Emerging technologies such as hypermedia and streaming video provide unique capabilities for the creation of authentic contexts. These environments can provide rich experiences not economically feasible prior to the availability of technology.

This paper describes a case-based hypermedia system for pre-service teachers. Streaming video cases help provide a context for the examination of classroom teaching methodology. Expert analyses of the cases help students reflect on the essential components of the lesson.

1.1 Situated Cognition
An issue concerning school-based learning is the difficulty many students experience in applying what they have learned in school to everyday situations. Many schools are concerned with the transfer of abstract, decontextualized concepts (Brown, Collins, & Duguid 1989). Increasing amounts of research indicate that the inability of students to apply concepts learned in formal contexts is due to the abstraction and decontextualization of learning (Cognition and Technology Group at Vanderbilt 1992). Situated cognition argues that the context in which students learn and the activities in which they engage are essential to the learning process. Situated cognition helps provide a rationale for the use of video-based scenarios in this project since the cases illustrate teaching methodology in specific contexts and engage students in authentic activities such as reflection on professional practice.

1.2 Case-based Learning
Case-based learning has been used for many years in other professional fields such as business and law. A case is a descriptive narrative based on a real-world situation. The case attempts to represent the different perspectives and context of a given situation. The essential elements of a case include realism, grounding in a rigorous examination of research and practice, and possibility for student development of multiple perspectives (Merseth, 1994). Many researchers believe that individuals problem solve by engaging in case-
based reasoning. In case-based reasoning, an individual draws upon situations that are similar to the one under consideration in order to reason or make decisions (Schank & Edelson, 1990). By providing pre-service teachers cases in streaming video format, they will have opportunities to examine teaching methodologies from many different perspectives. The video-based case provides a rich medium for providing a descriptive narrative of the situation under consideration.

2. Description of the System
The National Council for the Accreditation of Teacher Education (NCATE) has called on universities to increase opportunities for pre-service teachers to observe good teaching and reflect on professional practice (NCATE, 2000). Yet increasing pre-service teacher field experience hours is difficult and expensive. The media capabilities of hypermedia can help create rich environments that are consistent with real-world contexts. Hypermedia allows for the creation of authentic situations in which students can be immersed without the costs associated with real-world contexts.

Based on the theory and research cited, a case-based learning environment is currently under development. The environment is web-based providing pre-service teachers access to rich video-based cases that illustrate teaching methods in context. The core features of the system are listed below.

- **Streaming Video**: Streaming video provides a rich medium for the delivery of the case descriptions and allow efficient anytime anywhere access. Additionally, streaming video allows quick access to different segments of the scenario.
- **Rich Case Descriptions**: The case descriptions are enhanced with resources such as lesson plans, online readings, teacher reflections, and expert analyses.
- **Reflection**: Pre-service teacher reflections on the cases are enhanced through online discussions with their peers and university faculty members.

3. Conclusions
As case-based and problem-based learning becomes more popular, instructional designers must find new ways to utilize technology in order to support situated learning. The use of hypermedia and streaming video provides unique opportunities for the enhancement of pre-service teacher preparation. Case-based learning is well suited to teacher preparation since the method exposes the learner to concepts illuminated in context. Video enhances the cases by providing rich context and engaging students in authentic activities such as reflection on professional practice. Hypermedia enhances the learning environment by providing students control over the access to the case-based materials and enhancing the case descriptions with various media types.

Distance Education Creating an Environment for All: Content Accessibility - Tools, Techniques, and Methods

David M. Williamson

Assistant Professor of Computer Technology
Indiana University Purdue University Indianapolis
davwill@iupui.edu

ABSTRACT

This paper covers various tools, techniques, and methods that educators, who are involved with Web-based distance education, may utilize to create a total environment for virtual participants. When dealing with distant participants an educator cannot know the diversity of the total group. Participants may be second language speakers, blind, deaf, or they may be color-blind, to name a few. Currently, there are techniques and methods available that can be used to create materials that will serve a more diverse population. For example, content can be translated back to the natural language of a participant. Content can be tested against browser screen readers. Materials, which contain audio/video segments, can be prepared with static captioning. Materials can be tested on monochrome monitors to test color contrast. This paper will stress tools, techniques, and methods which are available to content designers that will assist them in opening the world of distance education to a diverse population.

INTRODUCTION

The following statement by Tim Berners-Lee [1], W3C Director and inventor of the World Wide Web, sums up what should be an essential concern of all Web-based educational content developers:

"The power of the Web is in its universality. Access by everyone regardless of disability is an essential aspect."

W3C and WAI

The World Wide Web Consortium (W3C) is committed to developing the Web to its full potential. A subset of this commitment includes promoting a high degree of usability. Yet, where do individuals go when they wish to create educational content that is accessible to a diverse population? A good starting point for developers is to survey information set forth by the Web Accessibility Initiative (WAI). WAI in conjunction with organizations around the globe pursues accessibility of the Web through the areas of: technology, guidelines, tools, education and outreach, and research and development. WAI has developed a set of Web Content Accessibility Guidelines, which when followed, help content developers create Web pages that are accessible to a more diverse population.

CAST and BOBBY

An organization that has utilized the accessibility guidelines from WAI to develop evaluation software is the Center for Applied Special Technologies (CAST). The mission of CAST is to expand educational opportunities for all people through the development and innovative uses of technology. One of its products is Bobby ResearchWare a tool for Web page authors. It helps Web content developers identify needed changes to pages so users with disabilities can more easily use their Web pages. Bobby provides authors with suggested corrections, which will help ensure content accessibility to a diverse population. Bobby recommends additions based on priority levels established by the Web Content Accessibility Guidelines.

Priority levels are three tiered. Web content developers must satisfy priority 1 checkpoints. In priority 1-accessibility issues, Bobby lists problems that seriously affect the page's usability. Satisfying priority 1 is a basic requirement for some individuals to be able to use Web documents. It places content at an approved status equivalent to Conformance Level A for the Web Content Guidelines. Priority 2-accessibility is access problems that an author should try to fix. Although not as essential as priority 1-access, these items are considered important for access. Satisfying this level removes significant barriers to accessing Web documents. It places content at an approved status...
equivalent to Conformance Level AA. Satisfying priority levels 1 and 2 is considered to be the minimum standard that Web authors should strive toward in their Web-based materials. Developers may address priority level 3. If they do not, one or more groups will find it somewhat difficult to access information in their pages. Satisfying level-3 improves access to Web documents. It places content at an approved status equivalent to Conformance Level AAA. CAST offers Bobby as a free public service. CAST also offers a downloadable application that meets the needs of content developers who want to test sites before publishing their content to the Web. Using the content principles and guidelines set forth by WAI and testing sites using Bobby ResearchWare places developers in line with the statement by Lynch [2]: “…developers are creating the street grid and social contract of a virtual society that will have concrete long-term effects on the way your organization thinks and works, and the way the world thinks of you and your mission.” Educational content developers might phrase this statement in the following manner: “Access for All equals Knowledge for All.” Especially in light of the fact that between 10 and 20 percent of the world’s population has some type of disability.

BROWSER SCREEN READERS

For some individuals print-based text can be completely inaccessible. In recent years developers have produced electronic browser screen readers that have an ability to produce sound that resembles human speech. Although they can’t match the full spectrum of human cadences and intonations, speech synthesis systems can read text files and output them in a very intelligible voice. Following the WAI Web Content Guidelines and passing priority levels 1 and 2, in most cases assures that Web content pages will be accessible to most browser screen readers. Educational content developers would do well to test their content against one or more browser screen readers to assure a less stressful journey through their education content by individuals with learning, visual, and reading disabilities.

CASCADING STYLE SHEETS

Another means of assisting individuals is to utilize cascading style sheets (CSS). Style sheets allow an author to separate the formatting from the content of the Web page. This allows authors the ability to concentrate on content separate from style. Various CSS features assist in making the Web more accessible to individuals. Authors can use the properties to control font appearance. An author can create several style sheets with different font sizes and then place a change style button on Web documents which when pressed simply cycles through the various style sheets and thus change preferences for viewers. Individuals with visual impairments are able to change the size of print by simply making a selection using the change style button instead of using browser options. Utilizing style sheets, authors can control various media types. Pages can now be tailored to specific devices and media types. Style sheets also give authors more control over voice and audio output, and other multi-media output.

SMIL

Synchronized Multimedia Integration Language (SMIL) is another tool that developers can use to make Web content more accessible to individuals. SMIL is a W3C sponsored language. When streaming multiple clips, SMIL lets the designer layout the presentation and integrate multimedia components into a unified presentation. Using SMIL authors have the ability to add static captioning to audio/video clips. Static captioning opens the audio/video information to hearing impaired individuals. It is becoming the glue that holds multimedia elements together.

FINAL STATEMENTS

Utilizing the above tools, techniques, and methods, authors can be assured that educational content is accessible to a wide variety of individuals. I have found them effective in the distance educational environment. A major gauge, but not the only measure, of their effectiveness is the improved retention rate in distance education courses in which I have been involved. I have been able to maintain a retention rate between 97 and 100 percent versus a normal retention rate of 83 percent.

Six WWW Based Learner Supports you can Build

Koos Winnips  
University of Twente  
Netherlands  
winnips@edte.utwente.nl

Catherine McLoughlin  
University of New England  
Armidale, Australia  
mcloughlin@metz.une.edu.au

Abstract: Effective teaching is systematic and well planned and student learning depends not only on student-based factors such as ability and prior knowledge, but also on the teaching context and on good management. Often, students need to be supported in gaining mastery in skills and new concepts. In this article we outline two forms of support that can be offered online which we call initial and ongoing support. Initial support is provided from the start of a course, and faded so that students can learn to self-regulate. Ongoing support is provided during a course, and is based on student input. The examples mentioned in this paper are not intended as an extensive framework for WWW-based learner support, but more as examples of good practice.

Introduction

One of the challenges for instructors when designing a course for online delivery is to provide a task that is demanding enough for the learner, but not too challenging, as the learner should be able to accomplish the task. When learning in a classroom where face-to-face contact is possible, an instructor may easily spot the difficulties students have while learning, and provide extra support, so that the learners are able to accomplish the task. When learning via Web-based environments, possibilities for face-to-face contact are reduced, making it more difficult for instructors to respond to student requests, and to provide adequate support. This paper provides some examples and opportunities for WWW-based learner support as forms of effective pedagogy. In an ongoing effort to find ways for supporting students, the settings wherein these supports are provided are varied, but have some common factors. First of all the learners are assumed to be active, which means in practice that students will be working on designing a product. Hereby the product is a proof of learning, and monitoring of progress takes place by delivering and providing feedback on a number of prototypes for this product. In some cases the result of student work is used as content for the course itself (see Collis, Winnips, & Moonen, 2000). For the teaching-learning context, a course support environment is used, and it is assumed that the supports presented in this paper can be applied in any course support environment.

Learning theory underpinning learner support

The key concept underlying learner support is scaffolding. Traditionally, scaffolding has been a principle aimed at promoting self-reliance in students. The principle of scaffolding was originally described in the context of language learning (Bruner, 1978; Wood, Bruner, & Ross, 1976), where it was used as a metaphor to describe effective interactions between a teacher and a student. The term can be traced to Vygotsky’s concept of “the zone of proximal development” which is the actual developmental level of the learner compared with the level of potential development that can occur with guidance or collaboration with a more competent person. Scaffolding should enable learners to perform activities they were unable to perform without this support (McLoughlin, 1999). Scaffolding as a form of learner support is related to cognitive-apprenticeship theory (Collins, Brown, & Newman, 1989) in that cognitive-apprenticeship theory provides one of the frameworks in which scaffolding can be conceptualised.

When we think of scaffolding we often think of the temporary structures thrown up around buildings to support workers as they build. When the building is completed, the structures are removed, as the support is no longer needed. Similarly, in a learning context, when students can cope with a task independently, the support is faded.
Scaffolded learning should eventually result in self-regulated learning, and thus more self-reliant students. Recent developments in pedagogy and educational science also picture this more active, self-reliant role for students, self-regulating their own learning processes (Boeckaerts, 1995, 1999; Pressley, 1995; Shin, 1995; Winne, 1995); and actively creating new knowledge (Perkins, 1991). For self-directed learning, metacognition is needed (Boekaerts, 1995), which is also helpful for lifelong learning (Dunlap, 1999). As students are being supported to work self-reliantly they can learn how to learn, which is critical for their professional futures where they will be required to keep themselves up-to-date in their own professions. Designers of WWW-based learning environments can benefit from this research in order to help students learn to self-regulate their learning.

In this paper we distinguish between two types of support, initial and ongoing. Initial support is provided from the start of a course, and faded so that student can learn to self-regulate. Ongoing support is provided during a course, and is based on student input. Examples are given of initial and ongoing supports, with advantages and disadvantages, supported by attitude data from students. These examples are not meant as an extensive framework for WWW based learner support, but as examples of good practice.

**Initial supports**

Many forms of initial supports can be discerned. For example, learners can be given access to a database of student projects of the year before, hints can be given about common problems and planning can be provided to structure course activities. During a course, as fading is going on, students should have less need for initial supports as they learn to self-regulate. The following examples of initial support are described: giving away parts of the solution, providing WWW links, and providing video comments.

**Giving away parts of the solution**

When the learner has to complete a specific task, that requires a variety of cognitive skills, some form of initial support can be used to free learners from potentially boring, repetitive tasks. This enables students to engage with the more complex and cognitively demanding aspects of the task. By giving away a part of the solution the learner can devote more time to the more challenging cognitive elements of the task. Acovelli & Gamble (1997) used this form of support when learners had repeatedly demonstrated mastery of a modeling task. If a learner has proven to be able to complete a task, a computer coach will complete all of the tasks smaller components for the learner.

A similar approach was chosen in a course about learning to design educational media-products in the faculty of educational science and technology. The task was to build a WWW site with some explanation about a specific design guideline for the design of media-products. The layout for the explanation page was provided for the students, as they had already demonstrated their ability to design and build a WWW site, and the content of their explanation was more important than the layout of the page. A screendump of the template for doing this assignment can be found in Figure 1.
**Design Guidelines, extra explanation**

**Bad example**

---

**Figure 1.** A WWW template for providing extra explanation about a design guideline.

By providing this WWW template, students did not spend time on doing layout for their pages, and could free more time to focus on the content, which was more cognitively demanding.

**Providing WWW links**

Another way to provide initial support is by providing WWW links. In a course about the theory of media use in education, called ISM-2, students were asked to design a WWW page with information about the theory of designing media products. In the course environment of ISM-2 links were provided as starting points for the search for information about the topics students chose. When asked in the beginning of the course student scored neutral on the question whether they would like to receive more support via built in explanations on the WWW (such as text descriptions, video, examples, hyperlinks) (mean 2.97, sd 0.83, on a five point scale ranging from negative to a positive attitude), indicating at least no dislike of being supported in this way.

**Video comments**

In the same ISM-2 course of the last example video comments were included to give the first introduction to the topics of the course. These were 2 to 3 minutes long video clips in Realvideo format that were synchronized with the accompanying PowerPoint slides with software called 'Sync-O-Matic 2000' (available from http://www.syncomat.com/). Figure 2 shows a screen dump of one of these video comments.
Figure 2. Video comments synchronized with PowerPoint slides as initial course support.

The text of the clips was also made available by clicking the 'View text' button. Students could browse through these comments in order to choose a topic they would like to explore further and provide more information on. Providing extra information on one of the course topics was the product students were asked to design for the course. Some, not all, students were very positive about having these video comments to study. Not so positive students experienced problems with the length of the video clips (too long), and bandwidth problems (the clips were designed for 56K modems).

**Ongoing supports**

There are many ways to include ongoing supports in a course. Ongoing support should be based on monitoring the progress of students. So, ongoing support is personalised support, and therefore will generally cost more time-investment from the instructor or peer-students providing this support. Further, in ongoing support scaffolding can easier take place, as support can be faded when it is no longer needed. Ways of providing ongoing support can be building a list of frequently asked questions during a course or providing hints based on student work. Three other examples are explained below.

**Providing open feedback comments**

The ISM-2 course was planned for students to submit several subproducts of the WWW site before submitting the final version. By way of these subproducts learner progress could be monitored and feedback could be given. First learners had to submit what articles they had chosen as an addition to the course, with a statement of the reason why they had chosen this particular article. After that learners produced a summary of the article to contribute to the course materials. When the learners improved their summaries with the help of instructor feedback they were added to the course materials. The instructor feedback typically consisted of one page, with comments about the chosen articles, personal notes about the authors, and the adequacy of fitting this article into the course.

Students were positive about receiving these kinds of extensive instructor feedback. Table 1 indicates that students were more satisfied in this course with receiving feedback from instructors than with receiving feedback from peers.

<table>
<thead>
<tr>
<th>Student level of satisfaction</th>
<th>Mean (n = 29)</th>
<th>SD (n = 29)</th>
</tr>
</thead>
<tbody>
<tr>
<td>The support from staff members is sufficient (in group sessions, by personal e-mails, conversations, etc.)</td>
<td>3.41</td>
<td>1.10</td>
</tr>
<tr>
<td>I think the support given from staff members (by personal e-mails, conversations etc) fits my actual level of knowledge.</td>
<td>3.62</td>
<td>0.88</td>
</tr>
<tr>
<td>I would like to receive more support via peer-feedback</td>
<td>2.71</td>
<td>1.05</td>
</tr>
</tbody>
</table>

*Table 1. Student levels of satisfaction with teacher feedback compared with peer feedback*

*All scores are based on responses to a five-point scale, with 1 = strongly disagree and 5 = strongly agree.*
A problem with providing extensive feedback comments was instructor time-investment (see Collis, Winnips, & Moonen, 2000). In order to write the feedback, the course instructors needed to read all the proposed articles in order to form their own opinion about them, and needed to take care in recording the comments, as they were included in the course support environment. However, when we compared a group of students who received this feedback with a group that did not receive this feedback but did a similar assignment, no significant differences were found on achievement scores for the final examination of the course.

Using a peer-feedback form
Peer-feedback can be used as a way to deal with time-investment problems of instructors when they are providing open feedback comments. In a peer-feedback form groups of learners can comment on each other’s work, using the criteria as stated in the course requirements as a framework for providing comments. Apart from reducing some of the workload of instructors, and providing support for students, giving peer-feedback could help students to focus on the course criteria in relation to their own work. By using the criteria for others, learners become more active and may be challenged to reflect on the criteria in relation to their own work. Form fields can be used on a WWW page to structure the feedback. When the form is posted to the course support environment learners can directly see what feedback was received and they can respond to it. Not all course support environments nowadays have the possibilities to include self-made forms. This problem was solved in one of our own courses by programming in Active Server Pages (ASP) which made it possible to include the filled-in form directly on a WWW page. Though awkward in terms of usability, this problem could also be solved by including the questions in a text file, asking the learners to add to this file, and repost it into the course environment.

Linking to good examples of student work
A further way of providing ongoing support in ISM-2 was to link to good examples of student work. The assignment of adding to the ISM-2 course materials was repeated two times in the course. After points were given for the first assignment good examples of student work were linked to the 'Newsflash' section of the course support environment. The comments in the Newsflash message related back to the criteria for the products that were provided beforehand. In Figure 3 the message with the links to good examples in Newsflash can be found.

Figure 3. Message in 'Newsflash' with links to good examples of student work.
This way of providing learner support can help to give learners more clarity of what was aimed for with the criteria for products as stated by the instructor. A disadvantage of this way of learner support however is that it is a 'public display' of work, and resulting from that only positive examples should be included.

Conclusion
In this paper six examples of providing WWW based learner supports are provided. Three of them are initial supports, 3 of them are ongoing supports. Implementation of these depends on course structure and requirements, the course support-environment that is used, and the desired time investment of instructors. The supports mentioned require no advanced technologies so they can be implemented in most course support environments to help learners self-reliantly perform their tasks.

Collaborative Technology Exploration: Bridges Between University and K-12 Education

Carol Wolfe, PhD, Saginaw Valley State Univ., USA; Jeffrey Ashley, PhD, Saginaw Valley State Univ., USA; Nancy Elliott, Master Teacher, Ubly Public Schools, USA; Ericka Taylor, Master Teacher, Saginaw Public Schools, USA; Janice Wolff, PhD, Saginaw Valley State Univ., USA

This paper describes and analyzes the process of five educators learning about technology as a pedagogical tool in university and public school classrooms. Information is drawn from a collaborative project between content and teacher education faculty at Saginaw Valley State University and master elementary and secondary teachers from urban and rural schools surrounding the university. Participants grapple with the effectiveness and pitfalls of technology while redesigning curricula for implementation at their various sites.
Capturing the Past: 
How Technology Helped Middle School Students Learn History

Center for Technology in Teaching and Learning  
Rice University  
Houston, Texas, USA  
wolfrum@rice.edu, lmm@rice.edu and odlsmith@rice.edu

Abstract: This paper describes how technology was central to the process and the outcomes of a middle school history project. The role of technology in the following areas is discussed: teacher instruction; student research; and presentation of student work. Observations suggest that students’ overall learning experience is enhanced through the incorporation of technology into history teaching.

Introduction

In 1998, the Center for Technology in Teaching and Learning (CTTL) at Rice University and Hogg Middle School in the Houston Independent School District began a three-year project to make history more relevant to students’ lives and to incorporate technology into humanities instruction. In the spring of 2000, seventh grade history classes began exploring World War II by collecting the oral histories of community members who lived through the wartime period. Technology was incorporated into this history project as a vehicle for facilitating student research and for presenting student work. The purpose of this paper is to discuss the implementation of technology in, and its impact on, this project.

Implementation of Technology

The goal of the World War II project was not just to teach students the history of World War II, but also to capture and to preserve the history through a series of interviews with community members who lived through the wartime period. Before the students could begin assembling oral histories, they had to learn the basic facts of World War II and the methods used to collect oral history. To teach the students about World War II, the teachers relied upon a combination of traditional methods and tools such as lectures, independent student research, and textbooks and new technology—specifically Internet sites such as “What Did You Do During the War, Grandma?” and the BBC’s “Modern World History.” While conducting independent research about World War II events that were specific to their interviewees’ experiences, the students discovered a plethora of additional Internet sites which expanded their understanding of the war.

To teach students about oral history methods, the teachers relied on the advice of a professional oral historian and on technology. Before the interviews began, the oral historian spoke to approximately thirty students at the school and presented the methods they needed to gather oral history. These students and their teachers then had the responsibility of returning to their classes and teaching oral history methods to the remaining students. To facilitate this task, the CTTL staff captured the presentation with a digital video recorder. The video was converted to Quicktime and Real Media formats, and then made accessible via an Internet site. Thus, when the teachers and selected students began teaching oral history methods to other students, they had an abridged version of the presentation for use in their instruction.

To present the students’ work, technology was used to create an Internet site and an accompanying print booklet. Each World War II veteran’s oral history interview was recorded with a digital video camera.
Carefully selected portions of the interviews were converted to Real Media format and made a part of a new Internet site entitled “The Heights Remembers World War II.” Additionally, narratives describing the highlights of each interview were written and compiled with brief biographies and photographs of the interviewees, comments from the student interviewers, wartime memorabilia, and other special anecdotes that arose during the interviews to create a print booklet. These booklets, bearing the same title as the Internet site, were distributed to all the project’s participants, community supporters, and any interested individuals. Finally, the contents of the booklet were combined with the Real Media clips of the interviews to complete the “The Heights Remembers World War II” Internet site.

Impact of Technology

The technology which was used to implement the “The Heights Remembers World War II” project contributed positively to student learning in three ways. First, technology similar to that used on the “What Did You Do During the War Grandma?” Internet site and the digital video of the oral history methods presentation provided concrete examples on which students’ could model their own work. For example, one student recounted in great detail the methods that were articulated by the professional oral historian. Also, several students relished playing the role of interviewer and conducting themselves as professionals. Technology not only made the presentation of skills more interesting, but also made the students’ recollections of these skills more powerful and lasting.

Second, the incorporation of technology in this project provided students with the enthusiasm and the means to learn more. The students used the Internet to research specific aspects of World War II prior to their interviews. A preliminary questionnaire was returned from each interviewee so that students could be as specific as possible in their research. Many students returned to the Internet outside of the classroom and after the interviews to further explore topics such as the Bataan Death March or women in the military. The students’ independent research also yielded several informative and useful Internet sites which the teachers will use in future lessons.

Last, technology allowed the CTTL and Hogg Middle School to create a final product which served (and continues to serve) students, educators, historians, and the community at large. “The Heights Remembers World War II” Internet site not only offers a multimedia display of students’ work, but is also a model project for other history teachers and students, an archive of primary sources for historians, and a lasting tribute to the community’s veterans.
Faculty Development Webbing:
A Model of Just-in-Time Mentoring and Beyond

Donna G. Wood, Ed.D.
Northeastern State University
United States of America
wooddg@nsuok.edu

Melissa Roberts Becker, Ed.D.
Northeastern State University
United States of America
beckermr@nsuok.edu

O. Susan Frusher, Ph.D.
Northeastern State University
United States of America
frusher@nsuok.edu

Abstract: This research-based example of good practice presents a fresh approach to faculty-development needs for technology training. The purpose of the Just-in-Time Mentoring research addresses the training needs of faculty members across career stages. Use of the faculty development model will assist faculty in staying current with technological change while reducing computer anxiety. The results of a significant difference in computer anxiety reduction through hands-on training reflected the effectiveness of this program. A case study documents “just-in-time” mentoring.

Narrative

Teaching in the digital civilization presents opportunities and rewards for making use of technology in teaching, learning, assessment and communication. However, as digital tools change and increase, public school teachers and University faculty are faced with a “need to know" challenge: meeting their training needs required to keep pace with technological change at just the right time (Papert, 1998).

This faculty-development strategy is implemented through Northeastern State University’s College of Education. Students admitted to the teacher education program meet weekly with a technology instructor. The students then mentor public school teachers or university faculty members in technology integration techniques once per week.

Within the spring 2001 semester, the mentoring program was expanded to incorporate faculty/peer mentors in each academic unit at the university. The University has a ubiquitous computing environment that provided faculty development from non-academics. The need was stated through dialogue across campus for faculty development to be conducted by faculty. Colleges were asked to select a representative who would be interested in assuming a role of instructional technology mentor to their faculty (MacArthur & Pilato, 1995).

Procedure

This research-based example of good practice presents a fresh approach to faculty-development needs for technology training. As education students meet the International Society for Technology in Education’s national educational technology standards, they in turn mentor public school teachers and university faculty in the identical concepts (International Society for Technology in Education Accreditation and Standards Committee, 1996).

During the Spring 2001 semester, a study was conducted to investigate computer anxiety among undergraduate students enrolled in EDUC4823, Technology in Education. These students were asked to voluntarily participate in this study to evaluate computer anxiety reduction. Students were randomly selected for participation. Initially, students completed a participation consent form approved by the NSU Human Experimentation Advisory Committee. Students
completed the Computer Anxiety Index (CAIN) published by the Iowa State University Research Foundation, Inc. (Simonson, Montag, Maurer, Oviatt, & Whitaker, 1992) at the beginning and end of the semester to identify changes produced in levels of computer anxiety.

Random number codes were assigned and individual student scores entered and compared. All individual identifying information was eliminated, insuring complete anonymity. Each student’s CAIN pretest score was paired with his posttest score and sorted. Pretest scores were subtracted from posttest scores, reflecting a gain or difference in computer anxiety levels at the end of the course.

**Results**

The results of the data analysis of the CAIN test for EDUC4823 students were based on an independent t test. The value was calculated and the data showed a significant difference in computer anxiety reduction of participating students. Statistical significance was determined at the .05 level.

The results of a significant difference in computer anxiety reduction through hands-on training reflect the effectiveness of this program. Data are currently being gathered to determine the correlation between a faculty mentoring program and a student-to-faculty mentoring program. The anecdotal data indicate a positive result of the reduction of computer anxiety via faculty mentoring.

**Case Study**

During the fall 2000 semester, an educational psychology faculty member was given a unique opportunity to research “Life at Sea” on a US Naval destroyer for a portion of their deployment to the western Pacific. In the process, the professor experienced teaching in the digital civilization in an unfamiliar culture in a most unexpected situation. The circumstances precipitating the opportune leave and the professor’s novice skill level of the use of technology integrated in the classroom was such that she quickly solicited the aid and expertise of colleagues, which resulted in collegial mentoring and a classic case of “just-in-time” learning.

The informal mentoring situation, which took place before the professor left campus, inspired the need for online instruction and the continued dialogue with colleagues and students created the need for modification in the areas of the logistics of integration of technology in the classroom environment and the instructional procedures and awareness of personal responsibility in a hybrid class.

**Conclusion**

There exists a myriad of implications for this study. The faculty development model incorporated at Northeastern State University begins in the classroom with pre-service teachers partnering with public school teachers and university faculty. The mentoring aspect networks into the colleges and the university faculty in the specific colleges who serve as models for instruction to pre-service teachers. This webbing effect incorporates teaching strategies to enhance learning that carries into the professional careers of students after having participated in this open community of learners.

Authoring Tools for Construction of Personally Meaningful Artefacts

Rob Wright, Barry Harper and John Hedberg
Educational Media Laboratory (emlab)
Faculty of Education
University of Wollongong
NSW, Australia, 2522

Abstract:

Multimedia authoring tools have long been used by teachers, to support learners in representation of their ideas when adequate technology has been available in classrooms. Through the 1980's and early 1990's, tools such as HyperCard were used extensively in schools with the emphasis on children as designers. However, many of these tools used old design metaphors and tended to constrain learners to specific ways to construct their representations of their ideas (e.g. HyperStudio). Additionally, there has been some concern expressed at the unfocused nature of the construction process within such tools. New tools are being developed to attempt to reduce the imposition of technology and to limit the recognised constraints. Designers of these tools are seeking to offer modern interface conventions and to simplify design including use of pre-constructed objects as well as task or problem templates that set goals for learners. One such tool, MediaPlant, is being used to construct tasks for learners, situated in unconstrained environments. These types of task templates, with scaffolding tools, are being investigated within classrooms.

Interactive Learning Environments

Interactive learning environments, if well designed, can support learner construction of knowledge through problem solving experiences or through more creative expression. Such frameworks are based upon arguments that learners should be placed in authentic environments that incorporate sophisticated representations of context through such constructs as "virtual worlds". The assumption is that within these environments the learner is supported by visual metaphors constructed to represent the information structure supplied and how the "world" operates. Within these learning environments, students are often given a rich set of resources to construct artefacts, which reflect their solutions to problems. Designers construct these environments assuming the resource base included has the argumentation elements and data needed to resolve the problem posed. However the transfer of skills and learning from the 'virtual world' to the real world is not always well supported.

Researchers such as Seymour Papert (Papert, 1993 p.142, 1980) have long called for more open environments based on his theoretical view of learning termed constructionism. Constructionism is based on two different senses of 'construction'. It is grounded in the idea that people learn by actively constructing new knowledge as well as asserting that people learn with particular effectiveness when they are engaged in 'constructing' personally meaningful artefacts in the context of resource rich 'virtual worlds' containing embedded tasks, designed for, or as a result of, open-ended construction by learners.

Authoring Tools Supporting a Constructionism View

Multimedia authoring tools have long been used by teachers, to address this second aspect of constructionism, when adequate technology has been available in classrooms. Through the 1980's and early 1990's, tools such as HyperCard were used extensively in schools with the emphasis on children as designers. However, many of these tools used old design metaphors and tended to constrain learners to specific ways to construct their representations of their ideas (e.g HyperStudio). Additionally, there has been concern expressed at the unfocused nature of the construction process within such tools. New tools are being developed to attempt to reduce the imposition of technology and to limit the recognised constraints. Designers of these tools are seeking to offer...
modern interface conventions and to simplify design including use of pre-constructed objects as well as task or problem templates that set goals for learners.

MediaPlant (Wright et al, 1999) is an example of such a tool, making use of a simple design interface and drag and drop design conventions to offer children a powerful tool to represent their ideas using not only the full range of media types, but also cognitive tools to support their investigations (Harper et al, 2000). This new authoring tool for students and teachers has been designed to support student centred exploration of ideas and is based on a constructivist view of learning. Through our investigations with MediaPlant, we are identifying the pertinent characteristics of an authoring tool that best embody contemporary views of learning. Within this authoring environment, learners can rapidly construct multimedia representations of their ideas and share resources and projects with their friends across the room or around the world. Learners can reuse all of their media resources from project to project and publish their projects on the World Wide Web as interactives. A level of transportability between projects means that each new object constructed, such as active buttons or animations, can be shared and taken from project to project. Part of our research plan includes the fostering of a web-based community of users where the opportunity to share 'objects' with other MediaPlant users becomes heightened. In this way learners have a much more open and resource rich environment in which to construct representations of their ideas.

Task Driven Construction of Artefacts

Learner construction of a representation of their knowledge in open-ended environments, such as an authoring tool, may be facilitated by support tools and task templates, which represent the kernel of a project. This approach could offer learners an unconstrained environment to develop a representation of their knowledge, and at the same time scaffold the learner with pre-constructed cognitive tools to support their thinking and design approaches. Unlike constrained systems, users would be free to make use of whatever resources best suited their needs.

In order to investigate use of such environments by learners, a number of learner task templates and sophisticated mpObjects are being constructed within the MediaPlant authoring environment. Some initial generic cognitive tools have been developed and a further series of tools are under construction. This paper will report on the ways in which learners will make use of such tools to resolve a task and their understanding of the representation they have developed. An assessment of how the MediaPlant authoring environment supports contemporary views of learning will also be provided.

Abstract: The Central Police University (CPU) is the only institute that is responsible for police higher education in Taiwan. The two-year recurrent education program is the unique channel through which more than seventy thousands of police can earn a bachelor degree and an instant promotion. However, the current problems for the recurrent education are limited learning opportunities, incompetent curriculum and low cost-effectiveness. Therefore, there is a critically urgent need for technology-based learning solution to the in-service training of police in Taiwan. A learning technology infrastructure forms the focus of this paper. As the infrastructure building up, it could foster high capacity of police and promote the police learning organizations in the near future.

Background

While the situation of public security becomes rigorous daily, the threats to the police service are real. It is necessary for police departments to find solutions for manpower cultivation. Ideal solutions should focus on the intelligence of police, not on their quantity or physical strength. However, police administrators recognize that the complex demands of the job dictate that police receive as much training and education as possible. The first thing is how to improve the capacity and performance of police effectively. As Dixon (1997) stated that “police departments can be changed, have changed and will continue to change.” It is no doubt that learning is the best strategy of adopting changes and that the key to change puts the components of learning into police departments. The Central Police University (CPU) is the only institute that is responsible for police higher education in Taiwan. The two-year recurrent education program is the unique ‘narrow’ channel through which more than seventy thousands of police can earn a bachelor degree and an instant promotion. Of course, learning does not end at the police academy. To push over seventy thousand police earning bachelor degrees is a major task for police administrators in Taiwan.

Challenges of Police Recurrent Education
Limited Learning Opportunity

The recurrent education has the great influence on police career development. According to the statistics of pass rate in entrance examination in the 1997~2000 academic year (1997: 3.5%, 1998: 3.3%, 1999: 4.3%, 2000: 4.4%), we could understand that the serious lack of the recurrent education opportunities. Because the CPU dose not supply enough educational resources in terms of facilities as well as faculties. Meanwhile, the opportunity for recurrent education is far away from the request of police nationwide.
Incompetent Curriculum

The CPU doesn't re-design a specific academic curriculum for the two-year in-recurrent education program. A number of condensed programs adopted from pre-service programs of each CPU department, and same faculty groups without practicing experience form the incompetent curricula, which cannot meet the needs of in-service training. Meanwhile, CPU has no special consider if students have enough basic knowledge. The curriculum can't meet their actual needs. So, the learning outcomes become questionable.

Low Cost-effectiveness

According to the statistics of police recurrent education budget, it costs approximate US$30,000 per person per year. At the same time, they do not need to work during two-year school days. Every year there are only 200 in-service police get the benefits. During their studying period, the loss of the police service value perhaps is far ahead six million US dollars every year. It is not only inefficient, but also low cost-effectiveness.

Technology-based Learning Infrastructure

To be effective, technology-based learning needs to be a 'police-driven' process. The whole technology-based learning infrastructure (Fig.1) needs to be directed towards providing an environment conducive to integrating technologies into education and training effectively. One distance learning experience for police and allied criminal justice personnel demonstrates that (1) techniques proven in past applications of distance learning continue to be valid for this medium, (2) instructional design and production know-how are vital components of successful application of the medium, and (3) available production tools do permit dedicated workers to generate effective distance learning materials with minimal technical support (Walker et al 1998).

There are four aspects that we should focus on, named Visionware (police learning organization), Hardware (broadband learning environment), Software (professional curriculum) and Peopleware (degree and program certification). A critical factor when considering the implementation of technology-based learning infrastructure is to establish a vision (Riley & Gallo 2000). To police, the vision is based on police learning organizations. Consequently, a vital role of technology-based learning could be to focus on making this type of learning available to police, especially consider police job characters and organizational culture.

Conclusion

Nowadays police need to be able to think, analyze, perform, and make decisions based on life-long learning. This solution could enhance the life-long learning opportunity for police. To technology-based learning succeed, nationwide police must be highly motivated and disciplined.

Communication Styles of Mentoring in an Electronic Forum

Cheng-Chih Wu, Chin-Yuan Lai, Greg, C. Lee
Department of Information and Computer Education
National Taiwan Normal University
162, Hoping East Road, Sec. 1, Taipei, Taiwan
[chihwu, yuan, leeg]@ice.ntnu.edu.tw

Abstract: This study investigated the communication styles of five mentors in telementoring a class of 33 preservice teachers. Electronic forum was the instrument of communications between the mentors and the students. Data collected in an 8-week period resulted in 52 mentors initiated discussion threads and 43 follow-up posts. Analysis of these posts revealed four discussion threads initiating styles and six follow-up posting styles.

Introduction

With the advent of computers and telecommunication technology, Computer-Mediated Communication (CMC) has shown its impacts on teacher education in the recent years. Usage of CMC can extend the traditional preservice teacher education teaching and learning environment. CMC enhanced environment can facilitate interactions among student teachers and help building new partnerships between preservice teachers, inservice teachers, and their prospective pupils (Van Gorp, 1998). Well-designed CMC activities can result in valuable learner-centered experience. Electronic forum, one of the widely used form of CMC, by being able to support reflective dialogues and collaborative processes, can facilitate the construction of teaching knowledge of preservice teachers (Loiselle, St-Louis, & Dupuy-Walker, 1998). Successful implementation of electronic forum in preservice education programs is abundant in the literatures (e.g., Casey, 1997; Wu & Lee, 1999).

Mentoring refers to a relationship where experienced teachers work with preservice teachers to help strengthen their professional skills. Traditional mentoring relationship is usually limited by school context factors, and the characteristics of experienced teachers and preservice teachers (Wildman, Magliaro, Niles, & Niles, 1992). By using CMC as a median in mentoring, telementoring gives the mentors the flexibility to collaborate with preservice teachers at anytime and any place. It provides a mechanism for dialoguing and sharing pedagogical practices; it helps preservice teachers construct teaching knowledge through real world experiences (Dobson, 1997). Studies in telementoring have shown plausible gains of the preservice teachers (e.g., Sanchez & Harris, 1996; Wu, Lee, Chiou, & Ho, 1999). However, they also raised many issues, among others are selection of electronic mentors and timing of replying to raised questions.

Spitzer, Wedding, & DiMauro (1995) attributed the success of LabNet electronic forum for high school science teachers to that of the moderators. They noted that skilled moderators are able to use variety of modes of communication to nurture collegial connections and reflective conversations. McMann (1997) also attest to the requirement of having specific skilled moderators for fostering learning in a CMC environment. When telementoring via an electronic forum, mentors usually double as forum moderators so that they can employ their professional expertise to stimulate reflective dialogues among preservice teachers. Although there is no clear-cut qualification for being a good moderator, but being able to prompting questions and following on responses skillfully are two fundamental aspects of moderating. For example, prompted questions that only require a yes or no answer often result in no discussion. On the other hand, responses that bring about related questions have better chance of maintaining the discussion.

The purpose of this study was to investigate the communication styles of mentors in initiating and following-up discussing threads in a preservice teacher's electronic forum.
Method

In this study, we used a web-based CMC system, namely Student Teacher Network (STNet) (Chiou, Ho, Wu, & Lee, 1998), to facilitate the instruction in the Teaching Practicum course. The Teaching Practicum course concentrates on micro-teaching in the first semester and field-teaching in the second semester. Thirty-three preservice computer teachers who enrolled in the course were asked to access the course materials and to attend the discussion forum in STNet. The students were randomly assigned to five groups. Each group consisted of six to seven students and had its independent forum. Five experienced teachers, all from different schools, were invited to serve as the mentors of the groups. Each of the experienced teachers was to initiate topics for discussions and to lead the discussions in the forum of their respective group.

Data analyzed in this study were the articles posted by the mentors during a five-week micro-teaching period and a three-week field-teaching period. Two raters examined the articles. The examination focused only on the communication styles of the discussion initiating articles and the follow-up articles of the mentors. Two worksheets had been designed and used by both raters, one for the analysis of discussion initiating article and the other for analysis of follow-up articles. The worksheets specified possible communication styles and their operational definitions. A preliminary analysis was conducted before the two raters actually went on rating all articles separately. As it turned out, the percentages of agreement on analysis of initiating styles and follow-up styles were 87% and 80%, respectively. The disputed points were singled out for discussion so that the two raters could adjust their bases of judgment in later analysis of all articles. The worksheets were revised after the preliminary analysis.

Results and Discussion

Participation of the forum

Table 1 is a breakdown on the post counts of data collected in an eight-week period. On the average, there are over 100 posts per week, indicating a moderate discussion activities going on the forum. Aside from Group A, the other 4 groups had comparable count. Note that the mentor of Group E is very active in the discussion forum, almost doubling the posting counts of the all the other mentors and accounts for almost a third of the posts in the group.

Table 2 gives an account on the mentor initiated discussion threads, the students’ responses, and the follow-ups by the mentors. The last column indicated the average length each discussion thread. From which, the average thread length in Group E is the longest, by an average of 2 more posts than the other groups. This can be attributed to the active involvement of the mentor of the group.

Initiating Styles

By analyzing the 52 posts among the 5 mentors (see Table 2), we are able to categorize the styles of the thread initiating articles into 4 categories:

(1) Direct questioning - asking questions in a straightforward way. This mentor-questioning/student-answering style usually results in no discussion; thus causing short threads.

(2) Context explaining - providing background information to make a question more explicit and influencing the directions of the discussion. For example, one mentor initiated the thread *Which programming language will you choose to teach in high school?*:

*In the high school computer science curriculum, computer programming accounts for 14 to 16 hours of lectures. . . . If you were a high school computer science teacher, which programming language will you teach? Why?*

Although the mentor could simply asked the question, by pointing out that there are only 14 to 16 hours of lectures allocated to teaching programming language, the discussion are therefore more focused and in depth.

(3) Experience sharing - sharing personal experience before prompting the question. For example, in initiating the thread *Have you met a ferocious teacher?*:

*When I was in Junior high, I had a ferocious math teacher; most of my classmates disliked her, but not me (perhaps because I was good in math). . . . What kind of teachers would you like to be? What kind of professional relationship would you like to uphold with your students? ...*

Sharing personal experiences helps bridging the gaps between the students and the mentors. Furthermore, students are better able to immerse into the circumstance so described and therefore inducing more discussions.

(4) Greeting - starting by polite "how are you" like remarks or social conversations before prompting the question. This type of posting gives the impression of politeness; thus the discussion tends to be polite in nature. However, as indicated in Table 3, mentors are more reluctant in using this style in originating discussion thread.

As Table 3 indicated, direct questioning and context explaining styles are the favorites among the mentors.

Follow-Up Styles

The 5 mentors had a total of 43 follow-up posts (see Table 2). Six communication styles can be categorized from those posts.

(1) Direct answering - answering questions raised by students directly. Though quick to the point, this style provides few opportunities for further interactions with the students.

(2) Suggesting - offering several possible alternative solutions rather than giving one "right" answer.

(3) Agreeing - recognizing and agreeing with the viewpoints of the students. This gives students great self-esteem; thus more willing to participate in future discussions.

(4) Summarizing - summarizing students' discussion and refocusing.

(5) Relating - explore an issue in depth or bring up related questions. For example, when discussing about what to teach on operating systems (O.S.), one student wrote:

At first, I thought teaching Win95/98 is not necessary ....a senior teacher suggested that using Win95/98 as an example when lecturing on O.S. I now think that the students can probably better receive the lectures with the aid of a real working O.S. ...

The mentor's reply was:

Sure it was a good starting point. But don't forget to give some examples when talking about the Win95/98 architecture. BTW, what are some of the most important characteristics of Win95/98 in terms of the O.S. architecture? ...

(6) Questioning - asking for clarifications, mainly to solicit ideas and responses. For example, on the issue of Who is to blame, the teacher or the student?, one student wrote:

... Well, if the teacher comes to class well prepared, then it must be the students' fault (not learning the material taught) ...

And the mentor's reply was:

Really? Sometimes I thought I was really well prepared for the lecture and the students were all very earnest too. But they still cannot comprehend everything that I talked about. I feel so discouraged when that happened. So what went wrong? ...

As indicated in Table 4, the agreeing and relating styles are used most often, followed by the direct answering style.

Conclusions

In this study, electronic forum was used as an instrument to enhance a class of 33 preservice teachers' teaching preparation course work. They were divided into 5 groups, each group was lead by an experienced teacher acting as mentor and forum moderator. The mentors were asked to initiate group discussion topics that could entice students to participate in the discussion and to follow-up on the responses by the preservice teachers. It was found that active participation by the mentor in the discussion can prolong the discussion thread. Timely follow-up posts by the mentor was perceived by the preservice teachers that the mentor is interested in their comments.

Further analysis of the 5 mentors' 52 initial thread generating posts, four styles can be abstracted: the direct questioning, the context explaining, the experience sharing and the greeting styles. It was found that the 5 mentors most often post a question in straightforward fashion (direct questioning). Context explaining style was used quite often too.

On the follow-up posts, it was found that six categorical styles exist among the 43 posts: the direct answering, the suggesting, the agreeing, the summarizing, the relating and the questioning styles. Here the agreeing, the relating, and the direct answering styles were used most often. It seems that the follow-up posts in those 3 styles are easier to generate.

The generalization of the communication styles of the mentors is a first step toward formulation of the necessary skills of the mentors in a telementoring environment. Further investigation into the effect on students' will and posting tendencies in response to the different styles of mentoring is necessary to obtain insights into the best telementoring communication styles.

Collaborative Adaptive Instructional Planning: Problems, Issues and Concerns

Albert K W Wu
Chinese University of Hong Kong
Shatin, HONG KONG
albertwu@cuhk.edu.hk

Abstract: There are significant requirements imposed on the planning of adaptive instruction. Usually multiple experts are called to come into play and work in a collaborative manner. This paper discusses, via a proposed framework, on these problems, issues and concerns for collaborative adaptive instructional planning. It is suggested that in order to be successful, a versatile scheme for the representation and manipulation of the various related knowledges and their interactions and relations has to be in placed. Together with WWW adequately empowered with Java applets and servlets, the problems associated with “collaborativeness” are surmountable.

Introduction

Planning for adaptive instruction is a formidable task involving the consideration of many and sometimes competing factors and constraints such as the organization of subject domain knowledge for efficient information structuring on one hand and for adaptive and responsive on the other. Very often, multiple experts would participate in the process. (McCalla, 1992; Peterson, 1988)

A Framework

Here we propose a framework (see Fig.1) to facilitate the discussion on the problems, issues and concerns for adaptive instructional planning.

Fig 1: Framework of Dimensions for Adaptive Instructional Planning

Referring to Fig 1, there are four fundamental major dimensions related to adaptive instructional planning. They are domain knowledge modeling, ii) pedagogy, iii) adaptiveness to learners and iv) collaborative computing. Due to space reasons, the various problems, issues and concerns for adaptive instructional planning are summarized as in the following table.
<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Issues &amp; Concerns</th>
<th>Problems</th>
</tr>
</thead>
</table>
| Domain Knowledge Modeling | - how curriculum knowledge is organized for efficient storage and versatile retrieval for instruction and learning  
- how curriculum knowledge is structured for easy accessing for queries  
- how knowledge is organized to allow for update under a many-access distributed situation | - what knowledge representation scheme can be used and manipulated for the purpose of versatile knowledge storage and retrieval, queries and update  
- how curriculum knowledge is presented for distributed concurrent editing and update |
| Pedagogy            | - what learning and teaching strategies are adopted  
- how various styles of teaching and learning actually function based on the chosen model of domain knowledge, more particularly the selecting, sequencing and, elaborating of subject knowledge  
- what type and particulars of interaction are anticipated for the teaching and/or learning | - how different learning and teaching strategies can be described and prescribed  
- how different interaction models can be described and described  
- how the different models mentioned above are presented for distributed and concurrent editing and update |
| Adaptiveness to Learners | - what type of adaptiveness will be anticipated, e.g. reactive key-press feedback, proactive adaptiveness on learner’s states  
- what type and amount of learner’s information will be saved and used  
- how the learner’s information will be used for i) interaction; ii) learning status monitoring, iii) performance assessment and what learner models will be adopted | - how different types of adaptiveness are modeled  
- how different learner’s information be collected and captured and modeled in the computer  
- how the different learner models are presented for distributed and concurrent editing and update |
| Collaborative Computing | - how different experts interact for results in view of the design concerns listed above | - how the different fundamental issues related to distributed control, session management, communication and concurrency control are addressed |

As shown above, the central issue and concern for adaptive instructional planning is modeling which turn out to be the problem of representation and presentation. In addition, “collaborativeness” introduces an additional dimension of collaborative computing addressing the problems of session management, communication and concurrency control. While these problems are usually tackled by shared objects/tokens, a number of criteria must be met first. They are: availability, transparency, consistency, and responsiveness (Koch, 1995). Given if the implementation is with Java applets on the web, its limitation on execution scope has also to be dealt with. As either the centralized or replicated architectures for shared object management have their own pros and cons, careful consideration should be cast on balancing simplicity, consistency maintenance, responsiveness, system robustness and latency.

Conclusions
Collaborative adaptive instructional planning has been a very difficult task for years. With a framework and tabulated discussion presented, we hope the problems and concerns could be duly exposed and expounded. It is suggested that with a properly reasoned KR scheme and notation and adequate tackling of the “collaborativeness” with the right tool, say adequate empowering of the World Wide Web (or just the Web) with Java applets and/or servlets the problem is not that insurmountable.

A Web-based Tool for Collaborative Adaptive Instructional Planning

Albert K W Wu, Chinese University of Hong Kong, HONG KONG, China

Adaptive instructional planning places heavy demand on the representation and manipulation of various knowledges of domain, curriculum, student, pedagogy and communication related to instruction and is usually involving multiple experts. In order to enable the situation, apart from the availability of a versatile scheme for the representation, the support for collaboration amongst experts is also needed. Here we describe such a tool for the purpose. Namely it is a system for collaborative adaptive instructional planning adopting Abstract Connected Model (ACM) where ACM is a scheme for representing and manipulating curriculum knowledge for adaptive instructional planning. Besides the provision of support to multiple and concurrent graph editing, the system also features session control, real-time chat and local saving of instructional plan.
An ICT Based Project for The Facilitation of Equality, Understanding and Tolerance Among Israeli Jewish and Bedouin High School Students

Yaacov B Yablon and Yaacov J Katz
School of Education
Bar-Ilan University
Israel
katzya@mail.biu.ac.il

Abstract: One of the major conflicts in Israeli society focuses on the Jewish-Arab axis. Israeli Jews and Arabs are wary of each other and latent hostility permeates the atmosphere between the two societal groups. This study describes how Jewish and Bedouin high school students participated in workshops designed to promote inter-group mediation and bridge-building, attended a number of face-to-face meetings, and most especially interacted intensively through Internet-based chat-room and email correspondence sessions. These complementary strategies were designed to promote the societal values of understanding, equality, tolerance, and peace between Israeli Jewish and Bedouin Arab high school students. The results of the project indicate that Internet-based communication contributes to the reduction of inter-group estrangement and positively promotes the adoption of favorable inter ethnic group attitudes.

Introduction

The Internet network in its present form is the product of an exceptionally dramatic development of a communication network that evolved in the 1960s and 1970s in order to serve the needs of the United States Armed Forces in time of war. During peacetime academic institutions utilized the communication network and as time passed it became a dynamic, worldwide communication medium that turned the world into a global village (Merkle and Richardson, 2000).

There is now no doubt that the Internet serves as a social meeting place and as such it provides new opportunities for the development of interpersonal relationships (Parks and Floyd, 1996). It may be said that in modern society the Internet has greater social influence than any other medium known. This is because nowadays the Internet is used to widen ones social network, to form online virtual communities, to find a marriage partner, to become involved in successful business relationships and even to fulfill sexual fantasies (Wysocki, 1998). Thus for Internet users the face-to-face relationship has been complemented by a social technology that creates a new genre of interpersonal relationships. Today an individual "...requires little more than a computer, a modem and an ability to make conversation to find a companion of ones dreams online" (Wysocki, 1996).

Regarding the influence of the Internet on social relations it appears that early studies that dealt with Computer Mediated Relationships (CMR) led to the conclusion that the network does not create a social climate that leads to the development of interpersonal relationships because the electronic meeting is anonymous and lacks the features (such as outward appearance and non-verbal cues) of a face-to-face meeting (Sproull and Kiesler, 1991). Therefore in comparison with face-to-face meetings the relationships established via online communication are more hostile, divisive and uninhibited (Kiesler and Sproull, 1992). However recent work has raised serious theoretical and empirical challenges to this pessimistic view of Internet-based social relations and indicate that such online relations are intensive and include a large measure of self disclosure (Parks and Roberts, 1998).

Walther (1996) pointed out that the change in the perception of the Internet as a platform for the establishment of social relationships began with the observation that many of the differences between computer mediated and face-to-face interaction diminish over the course of time. When the limitations of time are removed, online social groups as well as face-to-face groups report similar levels of affiliation. It appears that the possibility of frequently using the network for long-term communication, the opportunity to reflect and plan self presentation and the possibility to carefully choose the message to be sent provide Internet-based communication with far-reaching advantages that outweigh negative aspects of related to this medium when compared to what is achieved in face-to-face interpersonal relationships. Walther, Anderson and Park (1994) added that Internet-based relationships are characteristically more intimate and intensive than those maintained in a face-to-face setting.
A study conducted by Wysocki (1996) also indicates that Internet users form more intimate relations with their peers in less time than that taken to create traditional face-to-face connections. This finding may be explained by the seeming disadvantage of the online relationship, namely the use of anonymity which allows for self-disclosure without taking any risks. This serves as a springboard for the forming of intensive, pleasurable, deep and rich interpersonal connections. An added advantage of the online relationship is the ability of the participant to "disconnect" easily from a distasteful or unsuitable connection as well as the opportunity provided by the medium to enter into simultaneous relationships with a number of people (Schnarch, 1997). Thus it appears that online relationships do not only not differ in terms of the breadth and depth achieved in offline relationships, but may also lead to greater self-disclosure and feelings of intimacy.

The Mosaic of Israeli Society

In Israel there are significant historical, cultural, religious, and social differences between the ethnic groups that make up the mosaic of Israeli society. Among the different groupings are the Jewish and Negev Bedouin sectors. Between the two there is a lack of cohesion, suspicion, anxiety and even hostility (Glaubman and Katz, 1998). This tension is very much rooted in the differential level of governmental, municipal and public services available to both population groups. This leads to the widening of educational, cultural and other gaps between the Jewish and Bedouin ethnic groups in Israeli society and to resulting tensions and frustrations between the two sectors.

Characteristics of the Bedouin Population in Israel

Since the establishment of the State of Israel in 1948 the Bedouin population in Israel has undergone radical change and has been transformed from a traditionally nomadic population to one which is now largely urbanized (Ben-David, 1993). The Bedouin population has been loathe to accept the process of urbanization and as time passes the Bedouins are increasingly more active in their attempts to reject government attempts to settle them in cities, towns, and villages (Glaubman and Katz, 1998). As time passes, the urbanization policies of the successive Israeli governments are perceived by the Bedouin population to be discriminatory and designed to move them from their tribal lands without consideration of their traditional, cultural, social, and economic needs (Abu-Rabia, 1986). In addition to the problem of urbanization the Bedouin population has other acute problems such as a lower standard of living than the national average and unemployment is higher than the national average. All these problems contribute to a feeling of alienation and desperation on the part of the Bedouins as well as a feeling of hostility towards the Jewish authorities and population at large.

Bedouin Education in Israel

Katz (1998) indicated that the Bedouin educational system is characterized by a number of serious limitations which mitigate against educational achievements and success. Bedouin schools are typified by a significant lack of physical facilities, such as classrooms, libraries, laboratories; a significant lack of qualified teachers; a significantly high student drop-out rate; a remarkably low rate of success in the Israeli matriculation examinations which serve as a major criterion for entry into education at the tertiary level; an almost total lack of extra-curricular activities offered to students by school authorities; and an almost total lack of parental interest in their children’s educational future.

Characteristics of the Jewish Population in Israel

The State of Israel gained its independence in 1948 after the United Nations resolution (passed on 29th November 1947) called for the establishment of two states (one Jewish and one Arab) in the territory of Palestine which was ruled from the end of World War I by the British government according to a League of Nations mandate. Israel was established as a Jewish and democratic state with equal rights granted to the different minority groups residing in Israel (Talmi and Talmi, 1977). The Jewish population of Israel in 1948 was 600,000 and since then, as a result of mass immigration throughout the state’s existence, the Jewish sector of the Israeli population has grown to
5,000,000. Israel has become a modern western oriented country with a well established economic, social and educational infrastructure. The per capita Jewish income in Israel approaches $19,000 per annum and the standard of living of Israeli Jews is similar to the standard of living in an average Western European country.

**Jewish Education in Israel**

The Jewish educational system in Israel is highly developed and enjoys a large budget which allows for dynamic development of facilities, school-based technology, advanced teaching and learning methodologies, and varied extra-curricular programs for students at all levels in the school system (Gaziel, 1999). The level of teachers is good with almost all teachers in the educational system in possession of a college degree and a teaching diploma. School facilities, such as classrooms, libraries, laboratories, computer rooms, and sports facilities are well developed; achievement of Jewish students in matriculation examinations is on a par with achievement in the average Western country; the drop-out rate of students is fairly low and, in general, Jewish parents are involved in their children’s education. In marked contrast to the Bedouin population, the Jewish population in Israel can be described as generally satisfied with the educational outputs of the schools which caters for Jewish students. Jewish parents cooperate with their children’s schools and provide assistance and support when necessary, and are at ease with the generally successful Jewish educational system (Gaziel, 1999).

The aim of this research was to add another perspective concerning social relationships conducted through the medium of the Internet. In this study the development of a group relationship was investigated in which Israeli Jewish and Bedouin high school students established and maintained online connections in a project designed to promote a greater feeling of equality and understanding between the students as well as to facilitate greater understanding, tolerance and peace between the two population groups.

**Method**

**Sample**

The research sample comprised four 11th grade high school classes, two attending the Jewish high school and two from the Bedouin high school. In each class there were approximately 25 students with a total of 93 students, evenly spread between the two genders, participating in the project.

**Instruments**

An 80-item research questionnaire was specially designed to examine Bedouin and Jewish 11th grade high school students’ perceptions of the other ethnic group (Jewish students respond about Bedouins and Bedouins students respond about Jews) as well their perceptions about their own ethnic identity. The questionnaire was administered twice to the project participants in a year long “before-and-after” research paradigm.

**Procedure**

In the first phase of the project 6 teachers (3 from each high school) participated in an intensive two-day workshop designed to train them as moderators of student workshops in both the Jewish and Bedouin high schools. The topics discussed by the teachers during the workshop were as follows: dealing with ethnic stereotypes, perception of inter-ethnic inequality, inter-ethnic democracy and equality, inter-ethnic understanding, interethnic tolerance, and the importance of inter-ethnic peace. In the second phase of the project the Jewish and Bedouin students met in a day-long face to face gathering, during which they participated in three activities: a) all students responded to the research questionnaire which examined their perceptions of the other ethnic group as well their perceptions about their own ethnic identity; b) all students attended two lectures given by experts on inter-ethnic mediation in order to prepare them for their participation in the year-long project; and c) students participated in informal face-to-face inter-ethnic small-group meetings in which they were encouraged to get know each other and to form acquaintances that would be the basis of intensive interactions in an internet-based chat-room as well as through the medium of email. In the third phase of the project students from both Jewish and Bedouin high schools participated in fortnightly, teacher-moderated workshops on the following topics; understanding of inter-ethnic
stereotypes; perceptions of inter-ethnic inequality; understanding of inter-ethnic democracy and equality; importance of and inter-ethnic tolerance. In the core project activity students from both schools participated in ongoing intensive internet-based chat-rooms in which they discussed their perceptions of each other and problems related to inter-ethnic understanding, equality, tolerance and peace. The chat-rooms were moderated by the teachers responsible for the workshops. The students also corresponded through the medium of email on topics that arose from the weekly workshops and chat-room discussions.

In a second face-to-face day-long meeting which summed up the year-long project and was similar in its structure to the first face-to-face meeting in which they participated, the Bedouin and Jewish once again responded to the research questionnaire which examined their perceptions of the other ethnic group as well their perceptions about their own ethnic identity. The students attended a lecture by a well-known Arab Israeli TV sportscaster and met in small groups for inter-group activities and discussions about their impressions of the project and how they could plan for further inter-group social contact in the future.

Results

Jewish and Bedouin students were compared in a "before-after" experimental design on the factors deriving from the research questionnaire. Two significant factors, labeled "social feelings" and "psychological attitudes", each of which had an eigenvalue greater than unity and explained 10% of the variance, were computed from the data in a primary components factor analysis with varimax rotation. The first factor, social feelings, included 11 significant items which demonstrated social affinity (such as understanding, closeness, warmth etc.) in the inter-ethnic situation. This Cronbach Alpha reliability of this factor was 0.79. The second factor, psychological attitudes, included 8 significant items which indicated psychological feelings (such as anxiety, anger, fear, tension, etc.) towards members of the other ethnic group. This factor has a Cronbach Alpha reliability coefficient of 0.71. The mean scores and standard deviations on the two factors in the "before-after" paradigm are presented in Table 1.

Table 1: Means and Standard Deviations on Social Feelings and Psychological Attitudes for Jewish and Bedouin Students in "Before-After" Experimental Configuration.

In order to establish possible inter-group differences as well as to evaluate the contribution of each factor to the differences between the two groups after their participation in the project, Discriminant Function Analyses were computed on the data obtained in the "before-after" experimental paradigm. The results of the Discriminant Function Analysis, conducted to examine differences between the Jewish and Bedouin students at the beginning of the project as well as the contribution of each factor to these differences (Table 2.), indicated statistically significance differences between the two groups and correctly assigned 92.3% of the respective subjects to their particular groups. This analysis also indicated that the social feelings factor contributed more intensively to the inter-groups differences than the social feelings factor.

Table 2: Standardized Discriminant Function Coefficients for Jewish and Bedouin High School Students in Pre- and Post-Project Analyses.
A similar Discriminant Function Analysis was conducted to examine differences between the Jewish and Bedouin samples after their participation in the project (Table 2). The results of this analysis also indicated statistically significant differences between the two groups of students, and correctly assigned 78.25% of the subjects to their respective ethnic groups. In the post-project analysis the psychological attitudes factor discriminated similarly to the differences between the two groups whereas the social feelings factor discriminated more intensely than in the pre-project analysis.

Discussion

The aim of the project was to promote a feeling of equality, understanding, tolerance and peace between Jewish and Bedouin 11th grade high school students. It is apparent, that despite the deep social gap that exists between the Jewish and Bedouin population groups in Israeli society, a rationally constructed intervention project has the ability to contribute to bring about a greater affinity and closeness between the two participating groups.

The inter-group communication, especially utilizing the medium of an ongoing internet-based chat-room and email correspondence through which both Jewish and Bedouin high school students were able to air their views, ask questions, pose dilemmas and receive answers from their peers apparently leads to a closing of the gap between the two ethnic groups in the domains of social feelings as well as psychological attitudes. At the onset of the project there were definite differences between the Jewish and Bedouin subjects and they were easily identified according to their inter-group patterns of social feelings and psychological attitudes (92.3% of Jewish and Bedouin subjects were correctly assigned to their respective ethnic groups). However at the end of the year-long project the sharp inter-group differences were reduced indicating that there was a definite movement of each group in the direction the other with the originally polarized social feelings and psychological attitudes partially depolarized (78.25% of Jewish and Bedouin subjects were correctly assigned to their respective ethnic groups). This reduction in the precision of the prediction of correct group membership indicates that a certain amount of positive mediation and bridge-building between the two groups took place during the communication project.

The positive results of this project indicate that the use of technology, such as internet-based chat-rooms and email correspondence, indicate that technological methodologies are similarly suitable for the promotion of intensive interpersonal contacts and attitudinal change as are face-to-face meetings and contacts. It is apparent that the technology used in the project provided the participants with additional motivation and incentive and added significantly to the inter-group contact. In summary the present study can serve as a model for the further development of the use of technology in social research based on interpersonal and inter-group contact.

Factors Contributing to Ideal Instructional Interactivity

Michael Yacci
Paul Hyman
Information Technology
Rochester Institute of Technology
Rochester, NY USA 14623
mav@it.rit.edu

Abstract: What are the factors that contribute to "ideal" instructional interactivity? In this study, subjects observed different interactive situations between a student and teacher, displayed in video format on a computer and were asked to subjectively rate the quality of interactivity for each situation. Analysis of pilot test data using multiple regression analysis showed a small but significant effect for factors of information redundancy and paralanguage.

Introduction

The purpose of this project was to determine factors that contribute to an "ideal" interaction. In particular, we examined the effects of three independent variables: redundancy of information, instructor paralanguage, and overt affective cues on one dependent variable: quality of the interactivity. These variables were selected from several possible variables of interest as they related to a structural model of interactivity (Yacci, 2000).

The structural model of interactivity posits that instructional interactivity is a loop between two entities, originating at the student and concluding again with the student. (see Figure 1.)

![Figure 1. A completed message loop between two entities](image)

The structural model suggests that there are factors within the loop that will make the interactivity between student and teacher more effective. Some of these factors are: the redundancy of information, the paralanguage used, overt affective cues, lag time of response, and the cohesiveness of the exchange. This study was interested in isolating and testing the effect of redundancy, paralanguage and overt affective cues and the impact observers perception of the interaction.
The quality of this interactive loop is determined by a variety of influencing variables. For instance, consider a question in which a simple response of "yes" adequately completes an interactive loop. If this "yes" response occurs 30 seconds after a question, it will probably be perceived as more immediate and useful feedback than a "yes" response occurring 30 minutes, 30 hours, or 30 days later. Lag time of response, (as used in this example) is one of the many structural variables that has an impact on the quality of the interaction. Some examples of other variables include message duration (the length of the message and its response), overt affective cues (statements included in the message that signify "liking" or "disliking"), paralanguage (smiles, head nods) and redundancy (the predictability of the response). Message duration refers simply to the time span of a particular message from its beginning to its ending. Overt affective cues describe statements that are included within a message that signify friendship or other "approach/avoid" indication. Paralanguage is a term used in communication theory to describe a message's nonverbal constituents such as voice tone, rate, and velocity and other non-verbal communication behaviors (Yacci, 2000). Information redundancy is sometimes referred to as entropy. Entropy, a term used in many other disciplines, was used by Shannon (1948) to describe the amount of uncertainty in messages. An example of low entropy occurs when an individual can predict an incoming message with a high degree of accuracy. In this case, the information is also considered to have high redundancy. Pierce (1961) eloquently articulates entropy by asserting, "The more we know about what message the source will produce, the less uncertainty, the less the entropy, and the less the information."

It is believed that these factors will impact the quality of interactivity. That is, these factors can be optimized to produce interactivity that is more "ideal." Although we do not know the exact values of these variables, the structural model suggests these to be important factors for further study.

The Experiment

The following three variables were investigated in this study.
1. Paralanguage, operationally defined by whether or not the teacher smiled and used an upbeat tone of voice.
2. Overt affective cues, operationally defined by whether or not the teacher used a polite phase ("Thanks for that insight, Jerry.") when talking to the student.
3. Redundancy in the information, operationally defined by whether or not the student responded by saying "Thanks, but I already knew that." That is, the information was not new to the student.

A repeated measures experimental design was used in which each of these variables was combined with all others, creating a total of eight treatments showing all possible combinations of these three variables. In turn, each subject was exposed to every treatment condition.

The treatments were in the form of a several short, 20 second dialogues between student and teacher. In each of the treatment conditions, the dialogue itself was kept constant, while different video clips of teacher and student were inserted, producing the eight different treatment conditions.

The program was created using Macromedia's Director, and presented the eight video treatments in a random order. The Director program also collected all of the research data. After subjects observed one of the eight treatments, they were asked to rate the level of interactivity on a scale of 1 to 10, with 1 being the "least ideal" interaction and 10 being the "most ideal" interaction. This pattern was repeated for each of the eight treatments until each subject had seen all treatments. Also, as an option, subjects were asked to type comments in a message box to describe their ratings for each situation. All of the information entered by each subject was exported and stored categorically as text files.
Subjects

The study used 32 subjects as a pilot test of the study. This convenience sample was primarily friends and family of the experimenters with ages ranging from late 20's to 60's.

The Treatments

The following notations represented the eight treatments that subjects viewed. A brief description of each treatment follows.

</tr>
</tbody>
</table>

Results

The purpose of the project was to pilot test the treatments. These results are preliminary and based on a small convenience sample (N= 32) and should not be generalized at this time. A replication of the study, with a larger N and under more controlled conditions is being conducted at this time.

Average Ratings of "Ideal"

Averages of the ratings from our subjects for the eight different treatments are shown in table 1, below. The highest rated treatments had the same mean score—and differed only in their presentation of the overt affective cue (in this study, the inclusion of a polite phrase by the teacher). Also interested, the lower rated treatments also differed only in their inclusion of the overt affective cue variable.

</tbody>
</table>

Key: N= Not (Variable is off)  P=Polite Phase  SV=Smiling with pleasant tone of voice  R= Redundancy

Table 1. Average Ratings of Ideal for each of eight treatments.
The highest rated two treatments both showed a teacher smiling with a pleasant tone of voice and a student stating that he is receiving new, non-redundant information. However, in one treatment, an overt affective cue is used; i.e., the teacher says a polite phase while in the other treatment she does not. According to this data, it appears that the inclusion or non-inclusion of overt affective cues has no effect on either of these treatments. Furthermore, two treatments tied for fourth place with all variables being equal except for whether or not the overt affective cue was included. Here again, the inclusion of the overt affective cue by the teacher does not appear to affect our subjects' ratings. The overt affective cues, apparently have little effect on the rating of "ideal."

Non-redundancy associated with the student receiving new information and paralanguage such as the teacher smiling and using an upbeat tone of voice were the only significant variables according to our multiple regression analysis.

A stepwise multiple regression analysis was used to create a model of the variables. Stepwise regression automatically includes variables that are significant, and includes them in the model in the order of the most variance accounted for. In this situation, both non-redundancy and paralanguage variables were similar individually in the amount of variance accounted for. Non-redundancy (individually) has an $r = .2249$, while Paralanguage has $r = .2213$.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Individual correlation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-redundancy</td>
<td>$r = .2249$</td>
</tr>
<tr>
<td>Paralanguage</td>
<td>$r = .2213$</td>
</tr>
</tbody>
</table>

However, there is not an additive effect in a multiple regression model, because there is overlap in the variance accounted for between the two variables. Therefore, the Multiple $r = .31553$ for the two-variable model is not a simple additive result of the two individual correlations. Multiple regression models are sensitive to the order in which the variables are entered into the equation. Stepwise regression automatically selected non-redundancy as the first variable in the equation based upon the amount of variance accounted for. Both variables, however, were significant at $p < .0003$. This means that there is a real effect of these variables, although the effect is relatively small. Because these numbers are small, we are led to believe that there could be other factors, which we have not measured that are contributing to "ideal" interactions.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Multiple $r$</th>
<th>significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-redundancy</td>
<td>$r = .2249$</td>
<td>$p &lt; .00001$</td>
</tr>
<tr>
<td>Paralanguage</td>
<td>$r = .31553$</td>
<td>$p &lt; .0003$</td>
</tr>
</tbody>
</table>

Overt affective cues were not a significant variable, and that variable was automatically eliminated from the regression equation. This confirms what our simple comparison of the means suggests--overt affective cues are not significantly important to creating an ideal interaction.

**Conclusion**

This study suggests that non-redundancy of information and paralanguage are important factors in designing and improving instructional interactions. At the same time, overt affective cues do not seem to create an impact on perception of "ideal" interactivity. What does this suggest for online interactivity, for example? Based on this data, we might suggest that broader bandwidth communication, such as video, which can transmit paralanguage would be more ideal than smaller bandwidth communications. It would also appear that students might see information that is not redundant, but rather new and novel as more ideal than information and content that restates what they already know. Apparently, the inclusion of overt affective cues was not detectable by students, and consequently had little impact when used in a situation in which paralanguage could dominate.

yoavya@oumail.openu.ac.il

Rachel Mintz  
Science and Technology Education Center  
Tel-Aviv University, Tel-Aviv, Israel

Abstract: The use of powerful visualization technologies in astronomy and planetary science education offers a new and exciting learning experience for students. Simulations and VR make use of updated scientific data. This makes the presentation of complex phenomena easier. Experience with teachers and students shows that without mentoring and guidance, the effectiveness of high-tech astronomy programs is reduced significantly.

Astronomy Teaching in the age of IT

There are many new tools that information technology (IT) offers to astronomy education. CD-ROMs packed with databases on planets and stars, publicly shared images from telescopes and spacecraft on the Web, and astronomical software that produce accurate star maps are the obvious examples. The introduction of powerful computers with very high graphic capabilities have paved the way for scientific visualization, which provides a way of observing natural phenomena that, perhaps due to their size, duration, or location, are difficult or impossible to observe directly. In astronomy, data sent back by the Hubble Space Telescope and by other spacecraft and satellites are transformed into images that are enhanced, edited, and analyzed to reveal important new details about the earth, planets and other celestial objects. Astronomers often create video animations with elaborate computer graphics to model cosmological theories and to study stellar evolution. These scientific visualization tools and techniques can be easily harnessed to science education, allowing teachers new methods to deal with the inherent difficulties of teaching complex subjects such as astronomy.

Students’ Initial Conceptions of Astronomical Phenomena

Students have initial conceptions of astronomical objects and phenomena, which are often reminiscent of ancient philosophical ideas, notably the Aristotelian geocentric view of cosmos. Already Piaget noted many such conceptions in his early studies of child development, and showed that children evoke their own cosmological explanations even at very young ages. As they grow up, their early ideas are probably influenced by erroneous information presented in everyday culture and mass media (Lanciano, 1999) such as science fiction films and TV series. The private cosmological ideas become deeply rooted beliefs, which are often inconsistent with the accepted scientific view. Some of these alternative frameworks continue well into adult age, and are even found in university students. DeLaughter et al. (1998) present a variety of misconceptions found among students in an introductory Earth Science course and cites the famous Shapiro et al. (1988) video that showed Harvard graduates failing in explaining the cause of seasons. Comins (1993) identified common misconceptions students have in astronomy and derived a set of origins that account for them. This set includes, among others: factual misinformation, mythical concepts, and language imprecision, misinterpreting sensory information and incomplete understanding of the scientific process and of scientists. With the plethora of visualization tools at our disposal, it is remarkable that such misconceptions persist.

Scientific Visualization and Virtual Worlds

In its modern, digital version, scientific visualization links science, technology, computer science, and applied visual arts in the designing of systems that can translate huge amounts of quantitative data into digital graphic images. However, even a rather simple and unique form of
scientific visualization in planetary sciences, such as the one introduced by Miller and Hartman (1993), can be a powerful tool for teaching. They provided vivid and spectacular renderings of the clouds of Jupiter and the rings of Saturn, the volcanoes of Io and the craters of Miranda. These images enabled one to tour and study the surfaces and atmospheres of different planetary objects in the solar system, with no other means but a still picture.

Modern ultra-fast computers enable scientists to use ever-gentler variations in color and shading to represent numerical data, that describes different aspects of natural phenomena and processes. Such representations can portray complex phenomena in their entirety and can also consist of a series of images depicting changes over time. In relation to astronomy teaching, scientific visualization can easily become a powerful strategy to overcome the described hurdles. Images from satellites and spacecraft, as well as from the Hubble Space Telescope, become a source to updated scientific information. Classroom materials, lesson plans and complete courses were already developed by NASA (see for example: http://www.thursdaysclassroom.com/) and are widely popular.

The introduction of virtual reality (VR) technologies to desktop computers have greatly increased the ability to simulate and present complex three-dimensional objects and phenomena to the average PC user (Mohler, 2000). Lately, Yair et al. (2000) described the application of scientific visualization technologies to astronomy teaching. They developed a 3-dimensional model of the solar system, which includes the sun, planets, moons, asteroids and comets. The user can navigate in space, fly above and below the ecliptic plane, approach any object and view it from many angles. The continual motion of the planets around the sun generates basic astronomical phenomena such as day and night, seasons, eclipses and phases, which can be easily explored and studied.

A new, powerful visualization feature is the fly-over capability that permits extreme close-up views of the surfaces of Earth, Mars and the Moon. This visualization was generated from high-resolution aerial photos (Earth) and from close-by spacecraft images. Fly over enables a student to literally fly above the terrain in a desired speed and altitude, and thus to identify the main landforms and some famous locations (for example the landing sites of the Apollo missions, etc.). A student can tour the streets of London and to speed through Valles Marineris on Mars, and then to keep flying as they wish between the craters and basalt flows on the Moon. This extremely realistic portrayal of planetary landscapes further enhances the learning experience, making it enjoyable and engaging.

The Teacher’s Role

This and other learning environments offer an exciting learning experience and help facilitate the construction of a proper scientific picture of the solar system (heliocentric vs. geocentric). It may seem that students can learn it all by themselves just by interacting with sophisticated programs, by mastering the various aspects of technology. Our experience with science teachers shows that users require guidance and assistance in their interaction with the VR program, and that they have difficulty in constructing their knowledge without mentoring and mediation by an instructor or teacher. The teacher’s role is to guide students as they freely travel in space, pointing them to special points or phenomena that need exploring. A skilful use of visualization technology requires intensive teacher’s involvement, otherwise the VR and CDs remain with limited educational benefits.

Abstract: The FutureBoard system has been developed to support collaborative design activities. Two kinds of board systems have been created: one is a Personal Board for supporting a personal reflective thinking process developed on a wireless note PC, and the other is a Collaboration Board for supporting collaborative learning and the creative process developed on a 50 inch monitor with pen input support.

Design Activities in Japanese Primary and Secondary Schools

In Japan, the national curriculum standards will be changed in the year 2002, and project-based learning known as "The period of integrated study" will be introduced into elementary and secondary schools throughout the country. During the process of project-based learning, design activities such as making presentations and posters are of utmost importance because they give students the chance to reflect on their ideas, as well as enter into negotiation and discussion with others. Computers have been used for design activities in project-based learning prior to this. However, they are limited to a student's individual expression when using graphic software.

At the same time, in subject such as “Art and Design” in Junior High Schools, computer-based activities to favor painting and drawing software will be officially introduced to the curriculum. In these kinds of activities, teachers employ ordinary graphic software used by professionals. However, the software is mainly optimized for professional people, and is not meant for students.

We believe the system for educational design activities must meet the following conditions. Criterion: 1) Natural Interface 2) Supporting Collaborative Design Process 3) Supporting Expression Process.

In reference to the third Point, KARIYADO and his colleague at Daito Bunka University have developed the Paint software called “No-no-Kagami” (These words mean Reflector of the Brain). It has a unique function where a user can go back and change previous work. This enables students to reflect on the process of drawing.

Let us turn our attention now to point 2 (Supporting the Collaborative Design Process). No system has been designed for this topic. We believe that this point is especially important when it comes to designing activities in Project-based Learning.

The Design Process of Professional Designers

To this end, we analyzed the design process of professional interface designers (a university professor and two professional designers in a private corporation) in order to clarify the best way to support the collaborative design process. Let us now share some of our findings with you.
1. Using Tracing Paper
It is interesting to note that all used tracing paper in the collaborative design process. One designer drew an idea on paper, while the other put tracing paper on it, revised and added new ideas to previous ideas.

2. Fast and Interactive Process
The process was fast-paced and interactive. They sketched ideas in a few seconds and talked to themselves as follows: like a “This is better,” pointing the revised idea.

3. Using Personal Spaces
Sometimes, personal spaces were used such as a small memo or a corner of the tracing paper to dot down ideas.

Outline of the FutureBoard System

Following this analysis, we made design policies for the new system that supports the collaborative design process. We named it "FutureBoard".

1. Tracing Paper Function
FutureBoard contains 8 layers of tracing paper wherein the levels of transparency can be modified. The lowest layer is called the “Master Layer”, a special layer for guiding design activities such as Maps, Axes, Tables, and so on.

2. Pen Input and Drawing Tool
A user can employ the pen input (or his/her finger) similar to drawing on ordinary paper resulting in the interaction being much quicker. Moreover, the software becomes not merely a paint tool but rather a drawing tool, so that each object drawn can be moved or deleted.

3. Personal Board and Collaboration Board
Two kinds of board systems have been developed: one is a Personal Board for supporting the personal reflective thinking process use of a wireless note PC, while the other is a Collaboration Board which supports both collaborative learning and the creative process use of a 50 inch monitor with pen input support.

Personal Board and Collaboration Board

The hardware of the Collaboration Board system (CB) consists of a PC, a 50 inch projection monitor with pen input support and a wireless LAN station.

The software of CB is a simple drawing programme with 7 semi transparent layers. The user can control the visible/invisible aspects of the specific layers and at the same time, control the 5 levels of transparency. All operations are assigned to icons, thereby eliminating the need for a menu bar.

The hardware of the Personal Board (PB) system consists of a pen-based PC and a wireless LAN card.

The software of the PB is a subset of the Collaboration Board that has two layers and is optimized for SVGA screen. (The CB is of XGA size)

Initially, students will use the PB, and then send the work to the CB’s layer. With the CB, they can lay ideas out on the other half of the transparent layers. And CB’s data can be downloaded to a PB using the wireless LAN system.

FIGURE 1: Students using Personal Board and Collaboration Board
Case Studies

The FutureBoard system was evaluated from November to December of 1999 at Utase Junior High School in Chiba Prefecture, JAPAN. The system was used in project-based learning activity involving "Makuhari Bay Town" where the students live. To meet the goals of the curriculum, small groups were formed. The students explored and researched many different aspects of their town, such as the traffic system and road safety, the soundscape of the town and so on. They reported the result of their research on the Personal Board and transferred the data to the Collaboration Board. Using Collaboration board, they discovered new ideas from the overlapped information and made final presentations to an audience composed of classmates, teachers, municipal officials and parents.

We have evaluated how these tools supported the collaborative process via protocol analysis and interviewing. In this paper, we will select three cases in order to consider the role of these systems in the educational activities. ("I" in the protocol data is an Interviewer)

Case 1 - Finding relationships

When students overlapped their work on the Collaboration Board, some students discovered new ideas about the relationship or analogy between the information.

![Finding relationships using the Collaboration Board](image)

<td>O</td>
<td>M, K</td>
<td>Well, I think they might be careless there, if traffic accidents usually happen in places where people feel safe.</td>
</tr>
</tbody>
</table>

Table 1: Protocol data of case 1

In this case, students researched traffic accidents in their town. Student M interviewed many people about areas people think are safe and areas people think are dangerous. During this time, Student K researched places where traffic accidents happened. The members of the group selected these two layers and overlapped them intentionally. They discussed their findings some traffic accidents happened in places that people think are relatively safe. This finding contradicts the common sense idea that traffic accidents only happen in dangerous places. They discussed the finding and they created a new idea that people might get careless in places they think are safe, and that in turn may cause the traffic accidents.

They changed the transparency level and exchanged layers while discussing. We infer that the characteristics of the Collaboration Board helped students' collaborative discussion process.

Case 2 - Coordination of communication style.

Many students changed their ways of expressing ideas in order to overlap their information more effectively. Some students changed their ways of expressing ideas so that they could compare the information, and some coordinated colors and shapes in order to express the relationship more clearly.
I am the only one who uses the pie chart.

O changed his work to the map based idea.

<tr>
<td></td>
<td>F</td>
<td>It’s like a gradation.</td>
</tr>
</tbody>
</table>

FIGURE 3: Coordinating communication style with others.

In this case, Student O made a pie chart when he worked by himself with the Personal Board. But in the process of overlaying his work with another other student’s map-based work, he noticed that he could not compare his work unless he changed the style of idea to that of others. He tried to accommodate his work to the other student’s work, by changing the transparency level and exchanging layers. This kind of working together is difficult to achieve without aid of the Collaboration Board.

Case 3 – Creating new styles of exchanging ideas

Some students created new styles of expression using the special transparency functions. They are interested in Art and belong to the art club at school.

FIGURE 4: Creating new styles of exchanging ideas.

In this case, Student F and H discovered the change that was linked to transparency. Moreover and they created a new ‘expression’ way to express their styles with subtle colors using the transparency function. These are important even crucial activities for students in Arts and Design.

Implications

1) Natural Interface encourages student’s activities through trial and error.
   Because the FutureBoard system is pen input based drawing tool, students can add, delete, and change information easily. As a result, they made many such trial and errors while creating their products. We found that many students moved and changed the objects other students had made in order to improve their work.

2) The real size interface activates the student’s communication process.
   The Collaboration Board is big enough for three to four children to access at the same time. In every group, students had lively discussions about how to express their ideas. In these processes, they often pointed to the work...
on the Collaboration Board and used the word “This” or “That”. This semi mediated communication style decreases the cognitive task need for the information sharing and activates greater social exchange of ideas.

Acknowledgements

This research is generously supported by an IPA (IT Promotion Agency, JAPAN) Grant. We deeply appreciate the cooperation of the students and teachers at Utase Junior High School, Makuhari, JAPAN in furthering our research.
Digital technology has provided a chance for non-professionals like ordinary educators to be able to create and produce their own audio/video and be professional. Texas State Board for Educator Certification has published new technology application standards for educators who want to be certified, including teachers of technology. The standards require that educators should know how to create digital audio and video products for a variety of purposes and audiences and use them in multimedia applications. This paper discusses the difference between traditional audio/video and today’s digital audio/video in multimedia, examines the latest technology in digital audio, video, and streaming video, and provides a real course example of how video/audio is taught in a classroom to promote the implementation of the standards.
Abstract: School for All in the EduCities is an innovative project funded by both the Ministry of Education (MOE) and the National Science Council (NSC) of Taiwan. This project aims to challenge the rationale of traditional education—only teachers educate and students learn. We want to explore via a Web Course-offering contest in the EduCities in order to know if anyone who is willing to dedicate to the Web education can teach regardless of the age and professions, if he/she wants to with the assistance of the Information Technology. In this first contest, 290 courses were registered for competition and evaluation at several phases. Consequently 15 outstanding online teachers were selected for award. The purpose of this paper is to document the process of the study and to report the results. Characteristics of the outstanding online teachers, such as age, professions and pedagogical strategies were also identified.

Introduction

The Ministry of Education (MOE) and National Science Council (NSC) of Taiwan had jointly called for innovative Internet-based research proposals in 1998 under the umbrella term of “Four-year Program for Promoting Academic Excellence of Universities.” Consequently, 17 outstanding projects among the hundred candidates were selected for funding. Only one out of the 17 significant nationwide projects is related to applying information technology in education; it is entitled “Learning Technology: Active Social Learning and Its Applications, from Taiwan to the World.” This research project for excellence aims to investigate and develop networked learning models that will profoundly affect education in the information era. The target user population is people from 8 to 80. This excellence project basically consists of four major sub-projects: 1) Future Classroom Learning; 2) Structural Knowledge Learning; 3) Task-based Learning; and 4) Community-based Learning.

This paper focuses on the preliminary evaluation the 4th sub-project implemented over the past year. The Community-based learning model will be supported by a newly established web site called “EduCities.” It is challenging to create a significant and rich learning environment on the Web (Palloff & Pratt, 1999). Teaching on the Internet is different from traditional classroom teaching. Many of the skills of good teaching transfer to a distance learning environment, but some additional teaching skills are required.

The Study: School for All—the First Web Course-offering Contest in the EduCities
Educities intends to provide a web-based educational environment where we can cultivate a cyber learning community with members across different sectors of society, including students, teachers, parents, volunteers and any web browsers of various professions who are willing to make a contribution. It takes city and citizen as the operating metaphor, providing a variety of opportunities for students to take roles such as peer tutors, police, and student journal editors to serve others. Through role-playing in this cyber city, students' efforts and contribution will be recognized and respected.

Nowadays students have much more intellectual freedom on the Internet (Nolan, 2000). Moreover, it has long been predicted from the advent of the Internet that if access and communication turn out to be free and natural, then the emergence of informal, subject oriented groups of learner/teachers can be expected. Those who educate will not be so exclusively teachers, but fellow browsers in cyberspace (Pickering, 1995). The Web Course-offering contest of the School for All aims to experiment with the above prediction and challenge the traditional concept of education, i.e. only teachers educate and students learn.

Purpose of the Study and Research Questions

The purpose of this paper is to provide a new perspective on Web-based instruction and learning which incorporates peer tutoring and peer assessment. Due to the limitations of this paper, the focus of this preliminary report is on the characteristics of the outstanding online teachers; more about the learners will be reported in a separate paper. A set of questions have been raised as follows:

1. Is there a possibility that we can provide courses that are accessible and free to all people in Taiwan?
2. In addition to the accredited teachers in the real world, who will be willing to and able to become the online teachers in the Internet-based learning environment?

The first online Web Course-offering contest was in 2 phases: a pre-contest/promotional phase (January through March, 2000) and a contest phase (March through June 2000). The paradigm adopted has elements of both qualitative and quantitative research methods, with the researcher collaborating with two co-researchers and five other research assistants in data collection. Major data were collected during the Web Course-offering contest during March through June 2000. In chronological order, the following methods have been employed.

On-line questionnaires. The first questionnaire requested personal and background details (demographical data, such as sex, age, profession, behaviors of using the Internet) of the online teachers and students. The follow-up questions at the end of the project solicited thoughts and feelings about their own role and specific skills experienced in teaching in or learning from the School for All.

Individual email questions. At the half-way point of the course offering, the 285 online teachers still remaining were sent an email containing a few questions about the organization, management and communication within their classes. In addition, data from each online class were analyzed to identify teachers, and students' use of the course offering system for their class management and pedagogical strategies.
Data Analysis and Preliminary Results

During the first Web Course-offering contest from March to June 2000, a total of over 17,000 participants enrolled as online learners in the School for All. In the real world, we could hardly find a school this size formed in such a short period of time. Their age distribution ranges well from 10 to 60. There were more than 968 courses offered, and in the School for All approximately 290 out of the 968 courses were registered for the contest.

In this contest, 15 students comprised an online class size minimum. Any class that failed to maintain 15 students would be cancelled. Throughout the course-offering contest, about 8% (22 out of 290) of the courses were terminated for various reasons, such as not enough students, poor course contents or inability to fulfill course requirements. The Online teachers’ ages ranged from 10 to 55. The primary group of the online teachers fell in the age range of 23-30 (Figure 1). According to the data analysis, people who offered courses came from various occupations, such as psychologist, lawyer, government official, teacher, student, administrator, teaching assistant. Consequently, among the final 15 selected outstanding online teachers, 8 out of 15 were students, 5 teachers, 1 interpreter, and 1 teaching assistant.

Data collected from the focus group interview, web classes and observations indicate that the 15 successful teachers in the web-based environment have certain characteristics in common. They

1. Are comfortable with the use of a computer network or Internet;
2. Enjoy the sharing of ideas and thoughts with anonymous people, and feel self-fulfilled in on-line teaching;
3. Are students in the real world (here, we mean 8 out of the 15 online teachers);
4. Are active and highly self-motivated; are very self-disciplined, and have higher expectations of themselves;
5. Are good at on-line classroom management and organizing students into groups;
6. Spend huge amounts of time (day and night) in web discussion and communication (including emailing) with students;
7. Adapt their teaching methods to accommodate the web-based learning environment by integrating creative ideas and including other means, such as group contest awards, unlimited online tests, etc., in the instructional process;
8. Tend to possess a more serious attitude and responsibility toward their course offerings;
9. Tend to establish good relationships and connections with distributed students;
10. Use their nicknames or registered codes, instead of their real names, to interact with distributed students.

According to the data collected from the focus group interview, their motivations to offer courses in the EduCities can be categorized into 3 types: 1. Self-fulfillment: to seek new information, to improve homepage skills and to enjoy teaching as a highly respected job; 2. Job-related and Job-extended: to support their primary teaching work or to associate with their research work; and 3. Group-sharing: to look for a group of people with whom the online teacher can share his/her expertise through intensive interactivity and mutual understanding; to teach and to learn.

From the data analyzed from their class homepages, the pedagogical characteristics of these outstanding online teachers included: 1. Rich web course design: Multimedia presentation to attract students; 2. Self-expression: Teacher intensively posting messages via e-newsletters and requiring students responses 3.
Dialogue: Teacher responding immediately to student’s enquiries; 4. Extension of real-world teaching: Teacher using this website to enhance students’ learning; and 5. Learning Community of similar interests: Students and teachers sharing and learning closely together and having additional face-to-face meetings.

Conclusion and Future Work

The results of this study show that people who teach excellently on the Internet are not necessarily accredited teachers. This fact indicates that the active web browsers who took advantage of web literacy could become outstanding network teachers if they dedicated themselves to web-based teaching. The result of this contest confirms Pickering’s point (1995) that those who educate on the Internet will not be so exclusively teachers, but fellow browsers in cyberspace. Teaching on the Internet is different from the traditional way of teaching. It is noteworthy that without information/web literacy, accredited teachers could not become online teachers.

So far there has been only one round of the Course-offering contest. The preliminary results pave the way for our future work. In the following four years, more data will be collected through a series of different campaigns as stated earlier. The generous support from the Ministry of Education (MOE) and National Science Council (NSC) for this project enables us to conduct this research project. This study provides evidence that free courses on the Internet are possible, but not without placing substantial demands on system maintenance and teachers. The results also confirm the possibility, as mentioned in Pickering’s paper, that those who educate on the Internet will return education to more convivial and less authoritarian practices.

We hope that more people will participate in many significant experimental activities held in the EduCities and that meanwhile, business and industry will continue to support this innovative web site. Those on-line teachers are the representatives of the online generation who have taught us much about the 21st century and they can envision future education with their creativity, commitment and enthusiasm. Teaching online is a totally new experience. In order to be able to understand how to teach well online, we will continue to explore the possibility and potentiality of the use of the Internet via the EduCities in the years to come, while meanwhile challenging the traditional concept of formal education.

Confident Men - Successful Women: Gender Differences in Online Learning

Abstract: This paper describes gender differences in a cohort of undergraduate computing students studying a course that is taught flexibly. We report three years of research using pre- and post-course questionnaires, assessment results and online behaviour of the different demographic groups of students. We consider differences such as online material usage rates, formative and summative assessment completion rates, communication skills, confidence levels, student motivation and learning strategies.

The Internet and Web Development course is available as either classroom sessions or as a completely remote online course and students are free to choose how to study and which sessions to attend. The option of online learning has proven to be very popular with the students, particularly those with work and family commitments.

We found that our online course favours women and older students, who seem to be more motivated, better at communicating online and at scheduling their learning. In contrast, the male students and younger participants need the discipline that classroom sessions provide perhaps these students approach the course and its assessments with over-confidence. The ongoing challenge continues to be encouraging young loner males to succeed with self-paced online study.

Introduction
It is generally noted that computing is gendered, with women opting out of IT. Will the impact of online learning change this? Some researchers claim that women are disadvantaged in online courses (e.g. Blum, 1999) and that we need "women friendly cyber-classrooms". Yet our experience is that the women achieve better results than the men; it is loner males that are disadvantaged by distance learning. We argue that online courses need to be people friendly so that no learners are disadvantaged; and that motivational strategies need to be built into the course.

The Course
Internet and Web Development is a popular first year introductory course in the Bachelor of Computing Systems degree, that is studied by students with a diverse range of ages, ethnic backgrounds and life and work experiences.

Since 1999, IWD has been taught flexibly (Young et al., 1999; Dewstow et al., 2000; McSporran et al., 2000). As well as classroom sessions, we offered our students the choice of working remotely on a course website hosted using WebCT. Students could access the self-assessment quizzes, course notes and exercises in the classroom sessions or offsite at any time of day or night. The option of online learning proved to be very popular with the students, particularly those with work and family commitments.

In two summer school semesters the course has only been available completely remotely, with no face-to-face sessions. The students found this a more challenging way of studying, when there was no option of attending class to seek specific help (Dewstow et al., 2000).
Study Methodology
This study is part of an ongoing program of research that uses pre- and post-course questionnaires and focus groups, and includes the assessment results and online behaviour of the different demographic groups of students.

There have been few changes to either the method of assessment or the nature of the questionnaires over the last three years. We can thus directly compare the gender differences between the following groups of students:
- studied in class, with supporting resources online
- studied online, but had the option of attending class to seek specific help
- studied online, truly remotely, only electronic tutor-student contact

Results
Among our results are the following:
- The IWD course is more popular with women than the degree as a whole
- The women are more likely to choose to work remotely than men
- The women access many more course website pages and many more discussion forum posts than men - from 1.5 to 2 times as many pages/posts
- The women attempt more self-assessment quizzes than the men, and are much less likely to never attempt any self-assessment quizzes

We found that women and older students succeed on our course; they seem to be more motivated, better at communicating online and at scheduling their learning. In contrast, male students and younger participants need the discipline that classroom sessions provide. Our young males appear to be over-confident of their abilities, and lack the basic skills of time-management and self-regulation necessary for successful online study. The challenge now perhaps is to motivate young “loner” males to succeed online. Some of the motivational strategies that we use include:

- Weekly emails to the entire class that remind the students what they should have accomplished and what they need to plan for, along with more general motivational content.
- Reminder emails to those students who have not accessed the online course or not attempted any self-assessment quizzes.
- Answering bulletin board and email inquiries promptly.

Innovative use of Bulletin Boards in undergraduate and masters level online courses

Stuart Young
School of Information Systems & Computing,
UNITEC Institute of Technology,
Auckland, New Zealand
syoung@unitec.ac.nz

Abstract: This paper describes the use of web-based discussion forums (bulletin boards) in undergraduate and masters level Internet and Web Development courses within the School of Information Systems and Computing at UNITEC Institute of Technology.

At both undergraduate and masters level, bulletin boards were used for general class discussions, soliciting help and advice from tutors and classmates, and inter-group communication during group research assignments. Levels of bulletin board participation across five semesters of the undergraduate course gradually increased as we tried more ways to encourage student use.

Additionally at the masters level the bulletin board was used in a variety of highly structured ways as part of the formal assessment, including both individual and group critiques and debates. This case study reports on the different assessments that were tried, and shares my experiences of what worked and what went wrong.

Both the WebCT and Blackboard Courselnfo course building shells were used, and some differences between the discussion forum facilities of each are also noted.

Introduction

Online conferences, either synchronous or asynchronous, are generally recognised as a powerful tool for active learning. As Klemm (1998) points out, they require students to “comprehend what is being discussed by others, to create ideas in the context of the topic at hand, to organize thinking coherently, and to express that thinking with carefully constructed language (hopefully, clearly and concisely)” However it is also generally recognised that students are reticent about posting in shared class spaces – perhaps because they lack the confidence to assert themselves in public, or they are afraid of embarrassing themselves in front of their peers.

In 1999 when we first used the WebCT course building shell for our Internet and Web Development course website (Young et al., 1999), we enabled the bulletin board facility and encouraged the students to use it for general class discussion and to ask questions. There was a very low level of usage, even on completely online courses where the students were denied normal classroom interaction with their peers (Dewstow et al., 2000).

In 2000 we began to use the private forum facility, so that the students could communicate with the other members of their team during their group research assignment. We also assessed their discussion, with a component of their research report mark awarded for discussions that were effective, timely, and showing evidence of discussion of content. Levels of usage of the bulletin board increased somewhat although the average number of postings made by each student was still only 3.

Also in 2000 the Masters of Computing degree started at UNITEC. This degree programme is taught part-time one weekend a month, with a large part of the course work taking the form of online discussions between the monthly class sessions. To avoid minimal student participation, many of these discussions became part of the formal assessments. Following the advice of Klemm (1998) and the ideas of my colleagues I designed several different highly structured assessments using the bulletin board of Blackboard Courselnfo.
Innovative Assessments

Website critique exercise
This assessment type was an individual component of a group research project. The students formed three member syndicates and chose a topic, and then each student submitted a critique of a single website within that general topic area. A week later the students were required to reply to the critiques of their fellow syndicate members. After a further week the writer of the critique submitted a response that integrated all the posts. Thus in a three person group, each student wrote two replies, and each student received two replies. This exercise worked well although there were a few minor problems in student usage and a high marking workload.

Debate exercise
This assessment type was a syndicate assessment and followed a typical debate format, again on a weekly basis, with the groups required to make opening and closing statements and to respond to the points made by the opposing syndicate. Some very high quality discussions resulted, although I found the exercise hard to mark.

URL Synopsis
This assessment was individual, designed to encourage the students to continue their reading around the subject and develop their communication skills. I required them to write one sentence reviews of a useful web resource. These were marked on quality and applicability of the resource and accuracy of the review. I also required the students to use simple HTML formatting – for many this was their first experience of HTML and was intended as an introduction to

Software Evaluation
Another assessment type was software evaluations. I wanted each student to evaluate one piece of software and to share that evaluation with the rest of the class to build up a deep and wide knowledge base. The first time I tried this many students had problems with HTML formatting as they tried to incorporate tables into their evaluations. As a result, the next time I tried this exercise the students used spreadsheet software and attached their evaluations to a discussion forum message.

Levels of Student Participation
Masters students would be expected to be more motivated to take part in class discussions than undergraduate students. However levels of participation in non-structured, non-assessed discussions were equally poor. Levels of participation in structured non-assessed exercises were disappointing. Only when the exercises were assessed was there near 100% participation.

Differences between WebCT and Blackboard bulletin boards
Both course-building shells offer private group and whole class forums. Both have support for HTML and attachments in posts, and discussions are threaded by topic. The major differences include:
- The Blackboard interface is slightly easier to use and has a more pleasant visual design.
- Crucially, for use in assignments, Blackboard allows students to edit their posts.
- WebCT offers a more powerful tracking mechanism, giving information about how many posts were made and how many were read by each student. Blackboard only offers summary information.

AN INTERACTIVE MULTIMEDIA VISITING AND STUDYING PROGRAM FOR VÄRTHAN TRIGENERATION POWER PLANT IN STOCKHOLM

Hal Yu1, Per Almqvist2, Johan Alsparr3
Royal Institute of Technology (KTH)4
Division of Heat and Power Technology
S-100 44 Stockholm, Sweden

ABSTRACT
The Division of Heat and Power Technology at the Royal Institute of Technology Sweden, in cooperation with Birka Energi AB, has developed a "Virtual Visit of the Vårtan Trigeneration Power Plant" program. The program is intended to serve as a concise yet comprehensive educational and visiting tool in the related field.

The Vårtan power plant is well known for its high-tech production of electricity, heat and cooling. It supplies a large proportion of Stockholm city's district heating and district cooling demands. The program has been successfully served for the visitors to the Vårtan power plant. The program has also been used in the lectures at the Division of Heat and Power Technology, Royal Institute of Technology, Sweden. Both teachers and students profoundly believe that, if combined with traditional education, this multimedia tool will enhance not only the knowledge of the students but also their interest in the Power and Energy field.

INTRODUCTION
The twenty-first century will be the multimedia communications century. The development of a global view of multimedia computers and its applications provide one a direct interactive environment for learning and career enhancement.

The Division of Heat and Power Technology at the Royal Institute of Technology, Stockholm, Sweden, has developed a "Virtual Visit to the Vårtan Trigeneration Power Plant" program using multimedia technology. The major objective of this "Multimedia Visiting the learning process for the university students or people who are interested in the Power and Energy field. The Multimedia Visitation is also a good tool for the visitors to the Vårtan power plant.

Thus, this paper mainly presents the pedagogical advantages of multimedia and how this multimedia visiting tool enhance both the teaching and learning efficiencies in the field of Power and Energy Technology.

BACKGROUND AND OBJECTIVES
The Vårtan power plant is Stockholm's main combined heat, cooling and power plant. Since commissioned in 1903, it has expanded and developed into one of the biggest in Europe.

The plant covers more than 65% of Stockholm city's current heating demand in the central grid. About 50% of the heating requirement is covered by heat pumps in what is in fact the biggest heat pump plant in Europe. Just over 25% is covered by coal, and slightly less than 25% by oil and electrical boilers, when needed. The Vårtan plant produces annually about 2700 GWh district heating.

District cooling is extracted from cold sea water or from the cold side of the heat pumps and is distributed through a grid similar to the district heating system, with annual production capacity about 100 GWh.

Electrical output from the Oil-fired and Coal-fired Combined Heat and Power plant (Pressurised Fluidised Bed Combined-Cycle) is 220 MW and 140 MW respectively, with an annual total production of 600 GWh.

The goal of the "Virtual Visit to the Vårtan Power Plant" is not to develop a multimedia show. Instead the main aim is to develop an educational tool that illustrates how a modern power plant is designed and operated in order to cope with the delicate adaptation to the economic and environmental conditions, and efficiently enhance both the students' knowledge and motivation in the Power and Energy field by using a multimedia learning environment.

ADVANTAGES OF USING MULTIMEDIA LEARNING TOOL
Multimedia complements traditional material such as books. It enriches the learning process by mixing different media, such as text, still pictures, sound, moving pictures, and animation. Good multimedia educational software simultaneously stimulates different senses, resulting in better assimilation and memory. Each student reacts differently in these two processes; for instance, some appreciate visual memory, others oral memory.

During the past years, a significant amount of multimedia-based learning program have been developed aiming to perform an effective and efficient study. Ideal educational software could be compared to a supra-intelligent teacher, able to identify the needs of each of the students. Such a tool is very hard to establish as it can be compared to an Artificial Intelligence tool. Nevertheless,
there is one aspect that enables the user to judge a large part of the multimedia software's quality: "interactivity". Interactivity can be defined as an intelligent agent within the computer able to communicate with the user depending on user's requirements. For instance:
- Make suggestions to the users;
- Give answers to the interrogations;
- Evaluate the user's assimilation of the knowledge;

Apart from providing benefits to the students, the multimedia educational software can also bring support to the teachers in terms of availability during the lecture. Lecture notes can be updated and integrated in the multimedia educational software as well.

Moreover, the multimedia-based on-line technology has been a great potential for the distance education in the future. The use of World Wide Web has been introduced into the program, where the users can browse some useful web-site or journals related to the subject covered.

Convinced by the tremendous advantages which could result from the application of multimedia education to the field of Power and Energy field, the Division of Heat and Power Technology, in cooperation with Birka Energy in Sweden, has initiated this effort and developed the "Virtual Visit of the Värtan Power Plant" program.

The "Virtual Visit" program can be also integrated in the "Multimedia Educational Package" developed at the Division of Heat and Power Technology, serving for the practical part of this electronic learning tool.

GENERAL LAYOUT OF THE PROGRAM
The program has been developed by using authoring software: Macromedia Director. Several aspects of the Värtan Power Plant have been developed in the "Multimedia Visit". The ones shown here are History, Guided-Tour, Tour of Your Own, Environment, Frequently Asked Questions and Quiz. The whole program is developed in a way to be user-friendly and attractive to the students. The user can start with the program by entering a "Guided-

Guided-Tour
The Guided-Tour gives the users an overview of the Värtan plant, the main production units and the main sites of the plant, providing the visitors a feeling how a real power plant is sited and operated.

The guided-tour is a 10 minutes' general tour from the plant site to the harbour site, with both speakers and texts available. During the Guided-Tour the visitors can also get access to different production units and components to get detailed information by using the bottom tool bar, or they can go back to the previous scene or jump to the next scene if they want. A small arrow-guided map is always available in each scene to show where the visitors are in case they get lost (Fig. 2).

History
History provides the users an overview of the development and the technical milestones of the Värtan power plant over nearly 100 years since commissioned in 1903. Many historical photos and information are available in this part (Fig. 3).

Frequently asked questions
A brochure of "Frequently Asked Questions" is developed for this part, where the users can find many common questions they might come up with during the visit (Fig. 9). These questions are ranging from very general ones to the technical ones, the answer to each question is always available under the form of hypertext or link to certain part of the program.

Tour of your own
"Tour of your own" consists of three sections: The Trigeneration System, The Plant Site and The Harbour Site (Fig. 4).

The "Trigeneration " concept and the practical operation of the power plant are introduced and shown to the users (Fig. 5).

By laying out all the production units at the plant site (Fig. 6) and the harbour site (Fig. 7), the users can easily enter their interested site to get detailed information. For example, if the user visit the "Oil-fired Combined Heat and Power Plant", he will have the possibility to get the general information of the plant, the process flow chart, the heat balance of the process, the steam turbine, the boiler, and the control room. Also the users can go inside to see the components and equipment within the plant. Moreover, for each production unit, there are quiz questions specifically designed for the students to evaluate and enhance the quality of the Study-Visit.

Environment
"Environment" (Fig. 8) highlights the environmental concern and efforts that the Värtan power plant has made to maintain one of the Europe's not only biggest but also cleanest combined heat and power plants.

Electricity is an environmentally friendly source of energy and is indispensable for a cozy environment with light and heating. District heating has contributed a great deal to the improved environment by reducing local firing. The district cooling system has greatly reduced individual use of harmful refrigerants. Cleaner fuels, new production and emission technology, are being successively introduced.

In the program, it has shown that the emissions of dust, nitrogen oxides and sulphur oxides have all been reduced. For sulphur and nitrogen oxides, the total reduction is several thousand tons.

Fig. 1: The user can start with a "Guided-Tour", nevertheless, it is up to the user to choose the content by using bottom bar.
Fig. 2: One site in the "Gulded-Tour".

Fig. 3: Interface of "History".

Fig. 4: The interface of "Tour of Your Own".

Fig. 5: The Trigeneration system at the Värtan power plant.

Fig. 6: The layout of the plant site.

Fig. 7: The layout of the harbour site.
USING MULTIMEDIA FOR TEACHING AND TRAINING

Using multimedia for teaching and training must fulfill two main objectives: it must improve the pedagogical quality of teaching when used by the teachers and it must increase learning speed and quality when used by the students or trainees.

Presently, the “Virtual Visit to the Vårtan Power Plant” is developed as a complement to the Heat and Power course at the Chair of Heat and Power Technology. The program can be also used as a training tool for the trainees in the industry.

As a student, why should I use this program

For the students studying Heat and Power Technology, an important aspect enhancing their knowledge is getting practical experience by visiting the real power plant. This “Multimedia Visit” gives the students a unique opportunity to visit the world’s first Trigeneration power plant right from their desktop. The “Multimedia Visit” is designed in a way that the students will learn more, better and faster when complementing it with the conventional education.

The first advantage of using this program is that the student will get a feeling how the knowledge learnt from the lectures and books are applied in the reality. For example, when studying combined cycle theory, the students can use this program to find out how the CHP plant is designed at the Vårtan plant, similarly, when studying gas turbine, the students can go to the PFBC plant to see how the gas turbine is designed and operated there. In this way, the students will get a better understanding and an enhanced knowledge of what they are supposed to learn during the lecture.

Secondly, using multimedia-based products for study is time-independent, the students can use it at school, at home at any time they want. It is faster and time-efficient compared with a real visiting of the power plant. However, this “Multimedia Visit” is not intended to replace the real study visit, it is simply a complement to the lectures and the visit of the real power plant in order to enhance the quality of learning in the related area.

Moreover, letting the students to visit the plant with questions is also an important pedagogical objective of this “Multimedia Visit”. There are many questions related to the corresponding production units in the Study-Visit. Since some of the questions will be also related to the further exam, the students will have to think about it when they use this “Multimedia Visit” or go to the real power plant. This will, in turn, enhance the knowledge they assimilate in the lecture and the quality of the real study visit.

What can I learn from this program

The program explains how a modern power plant is designed and operated in a multimedia environment. The Vårtan plant is the world’s first Trigeneration power plant for a high-tech production of electricity, heat and cooling. For the future engineers, visiting the Vårtan plant is a great opportunity to learn how the Trigeneration system, district heating system and each single production units are operated in a modern power plant.

This “Multimedia Visit” provides the students an efficient tour of the system and production units, they will be able to learn some important points such as:

- How the Trigeneration system is designed and operated in a modern power plant?
- How does the district heating production work in a modern power plant?
- How the heat and electricity are produced at the Combined Heat and Power Plant?
- How the heat and electricity are produced using PFBC (Pressurised fluidised Bed Combustor) technology?
- How is district heating and cooling is produced using heat pumps?

Furthermore, the program includes many other technical subjects related to the visit, such as the technical layout the CHP plant, the basic principle of the heat pump and so on. The purpose is to make this “Multimedia Visit” easy, time-efficient and user-friendly.

I can browse the program beforehand and afterwards to ensure a high quality of the real visit

Of course, this is also one of the purpose of the program. The program, which is stored in the CD-ROM currently, can be used at home, at work, even travelling. By playing the CD-ROM, the user can have an overall feeling of how the Vårtan plant is sited and operated, and can also have a detailed repetition of the visit afterwards.

The role of this program in the classroom and training process

Again, this program is not intended to replace traditional book and teacher. It is used as a good complement in the classical teaching
environment to enhance the quality of teaching and learning process.

**USING MULTIMEDIA FOR THE VISITORS AND COMMERCIAL PRESENTATION**

Every year many visitors visit the Vårtan power plant to see how urban "Trigeneration" really works. The visitors represent a wide cross section of both the domestic society and from abroad. The "Multimedia Visit" can serve as a good tool for the visitors, providing them information on the plant from both general and technical perspective in an efficient way.

The "Multimedia Visit", which will be put on the Internet later on, is also an effective way to present this world's first "Trigeneration" plant. It can be also used by the business persons for commercial presentation.

**CONCLUSIONS**

In cooperation with Birka Energi AB, the Division of Heat and Power Technology at the Royal Institute of Technology, Sweden, has developed a "Multimedia Visit of the Vårtan Power Plant". The Virtual Visit contains detailed information on the "Trigeneration" system and main production blocks at the Vårtan plant, providing the users a feeling how a modern power plant is designed and operated in an urban environment.

The "Multimedia Visit" is used both by the teacher during lectures and by the students at school or home. By performing this "Multimedia Visit", the students will have a chance to see how the theory is applied in the real power plant during the lecture. The "Multimedia Visit" also allow the students to use it as a pre-visit of the plant in order to enhance the quality of the real study visit.

Multimedia learning tool conveys the information to the students by means of several senses. Teachers and students at the Division of Heat and Power Technology are deeply convinced that education is further enhanced when complementing this multimedia tool in the traditional education environment. Undoubtedly, the computer and associated multimedia tool will play an ever-increasing part in the education and many other fields in the future.

**FUTURE WORK**

More feedback and evaluation are needed. In order to serve for the visitors and students worldwide, the "Multimedia Visit" will be also available on the Internet later.

**ACKNOWLEDGEMENT**

The financial support from the Birka Energi AB is gratefully acknowledged. Special thanks to the great work done by Dr. Ian Cotgreave, who revised the texts and acted as the speaker for the "Guide-Tour", MSc. Vincent Demargne, who designed the CD-ROM cover, and photographer Eddie Granlund who provided outdoor pictures for the Vårtan Visit. Further thanks to Prof. Torsten H. Fransson, MSc. Eloi Klein, and MSc. François-Xavier Hillion, for their critical assessments and significant supports.
Evaluation of Asynchronous Web-assisted Instruction: A Case Study of NTU WAI Project

Abstract: This paper first introduce the theoretical background of this study as well as the implementation of the asynchronous web-assisted instructional project at National Taiwan University (NTU); then describes the research questions and methods used in this study. It also reports the results of data analyses and provides implications and recommendations in relation to web-assisted instruction and educational technology.

Rationale

With the impact of emerging computer technology and network techniques, the rapid change of current informational society, as well as the shift of learning style and instructional paradigm, web-assisted instruction has overcome the limitation of traditional instructional methods in many ways. It brings a new way for the use of instructional media, and inevitably become the major trend in the field of education of the 21 century. Along with this change, educational technology is now an area in which educators look into for better plan, design, development, and evaluation their instruction. With systematic instructional design, teachers can assess students' learning needs, analyze instructional objectives and tasks, sequence instructional content and information, select an appropriate media to deliver their instruction, and implement formative and summative evaluation to assure their instruction achieve the goal.

The web-based learning environment is more flexible and has more functions than traditional instructional media as well as many computer-assisted instructions. Although there have been significant efforts put into the application of web and network technique in education, the quality and function, however, are never the same among them. Due to the lack of systemic research available regarding a well-constructed model for web course design, development and evaluation, the purpose of this study is first to investigate students' and teachers' attitude toward the web pages created for assisting instruction of courses in the asynchronous web-assisted instruction project at National Taiwan University which includes 50 courses offered by different departments of 9 colleges. Also, using both quantitative and qualitative research methods, this study further assesses the effectiveness of the web courses on teachers' teaching and students' learning. It is expected that the result of this study will contribute to the
improvement of web instruction at all level of schools in Taiwan, and to provide important information to the field of educational technology and curriculum design in general as well as to web-assisted instruction in particular.

Research Questions

The purpose of this study are: (1) to investigate the effectiveness of the web-assisted instruction approach in supporting teachers' teaching and students' learning, (2) to examine how students' attitude toward web-assisted instruction and some background variables can affect their learning process as well as outcomes, (3) to examine how the appropriateness of subject matters can affect the students' learning and teachers' teaching via web-assisted instruction.

Research Methods

This study attempts to empirically investigate the effectiveness of construction of course web pages in supporting classroom teaching and learning. The web-assisted instructional pages are used as a learning tool in terms of providing alternative channels for students to learn outside the classroom. The learning context (courses) includes 50 courses offered by different departments in 9 colleges at National Taiwan University. All of these courses provide web-assisted instructional pages in addition to classroom meetings.

The target population for this study is students registering in these 50 courses in Spring, 1998. Students are required to fill out a questionnaire designed to collect their attitude toward the use of web-assisted instructional pages in facilitating their learning. Also, teachers in these courses are required to fill out a similar questionnaire to collect their perceptions toward this practice in terms of facilitating their teaching and students' learning. Some qualitative data will be collected by individual interview with teachers and students. The data collected on the different types of assessment will be analyzed by means of Descriptive Statistics and Chi-Square Analysis.

Results

For the attitude survey, both teachers and students shown highly positive attitude toward the application of the web-assisted instructional approach. Although most students do not know in advance that their instructors were going to apply web system in assisting class instruction, however it doesn’t affect their motivation of taking these courses. Most functions applied in different web-assisted courses include course information supplement and discussion board application. Most students browse the course homepage one to three times per week, and they think the course homepages are convenience for their self-learning. Moreover, they are willing to take web-assisted course in the future.

On the other hand, result of this study also demonstrate that there are different degrees of correlation among the function, design, content organization of the web pages, the achievement of students' learning, the effectiveness of teachers' teaching, the implementation of the web-assisted instructional approach, the on-line assessment, as well as the integration of curriculum planning. It is also found that the more students browse the webcourse pages, the more the encounter system functional problems in the process. However, for students who use the webcourse pages more often, they tend to think that webcourse applications are more effective than other courses without webpages.

Conclusions and Implications

Based on the results of this study, conclusions and implications are discussed as follows. First of all, evidence from teachers and students' attitude survey and feedback comments shows that web-course pages can assist teaching
and learning in many ways such as course material delivery, course content review, information retrieval, relevant resources connection, as well as student-teacher interaction.

Secondly, most teachers and students of different courses in different areas all agree that the practice of applying asynchronous web-assisted instruction is generally better than conventional classroom teaching. Also they agree that students taking asynchronous web-assisted instructional courses do perform better on learning than they do in conventional courses.

Thirdly, most teachers and students claim that the experience from asynchronous web-assisted instructional practice can help them in other classroom teaching and learning. Moreover, they feel that they do have learned a lot from this experience.

Fourthly, almost all teachers state that they would like to continue this effort in the near future. A variety of reasons include that (1) this kind of practice can help improve teacher-student interaction; (2) it can facilitate classroom instruction; (3) it can help instructional design process; (4) it shows better instruction and learning outcomes; and (5) it is one of the most important trends of education in the near future.

Fifthly, although it shows a great deal of positive responses in results in applying asynchronous web-assisted instructional practice, however, there are some disadvantages as well. First of all, this kind of practice demands more time and efforts in designing and developing instructions, which add a lot more load to teachers. Secondly, students need to have certain levels of computer literacy to learn better in web-assisted instructional classroom. And thirdly, course contents and materials need to be well organized which demands more efforts from teachers and instructional designers.

Sixthly, while most teachers are not familiar with web technology application and also lacking of instructional design background, training programs are needed to improve the quality of web-course pages and the effectiveness of implementing web-assisted instructional practice in a large-scale project.

Finally, to design a better web-assisted instruction, teachers need to plan in advance with instructional design perspectives. They need to first define the main purposes and functions of the course pages and then cautiously plan for the content. In addition to the design of the web pages that include extent, organization and presentation of information, teachers also have to consider the interactivity and innovation of the course pages design, as well as the potential impact on teachers' teaching and students' learning in the classroom.

Abstract: We have developed a prototype application called the Fluid Reading Primer to help emergent readers with the process of decoding written words into their spoken forms. When a reader requests help for a particular word, the Fluid Primer uses interactive animation to break the word apart to visually indicate its constituent sounds. The Fluid Primer can also play back audio versions of each segmented constituent sound, as well as the blended complete word. We envision that our method could be incorporated into future e-books to provide scaffolding on demand for readers of arbitrary texts. Moreover, we believe that the animations shown by our tool provide a valuable visualization of the decoding steps that will help readers learn to perform the same steps more quickly and confidently on their own.

Introduction

Although reading remains a crucial skill in the Information Age, learning to read is a difficult task. A carefully controlled study of adults in the United States by the National Center for Educational Statistics found that 22% could not answer simple questions about short newspaper articles (McGuinness 97, page 9).

Computers have been applied to a variety of aspects of teaching reading. Computer programs and games can help children develop reading readiness skills, such as replacing initial consonants to form new words (e.g., Reader Rabbit (The Learning Company 94)), read aloud to them while highlighting the words or phrases being spoken (e.g., Living Books (Bruder bund 92)), and provide pronunciations of unknown words on demand (also Living Books). Some programs reformat text to enhance readability (e.g., Proportional Reading, which displays one word at a time for a length of time that is proportional to the length of the word, with optional synchronized speech (Adams 98)). Other programs reformat text for comprehension (e.g., Live Ink, which analyzes sentence structure and displays semantic phrases (Walker 00)). Computers have been used to lengthen and enhance constituent sounds within words to help disfluent readers improve their audio processing for reading (Merzenich 96). Researchers have also applied speech recognition to listen to children read and to highlight incorrectly spoken words (Mostow 94). Eyetrackers have recently been used to judge from children’s eye movements when to provide spoken assistance with a printed word (Sibert 00). A good overview of other electronic support for literacy can be found in (Topping 97).

However, most previous efforts have ignored a crucial and difficult piece of the reading process—namely, the actual steps involved in decoding a written word into its spoken form. Mastering the decoding process enables a reader to read any word, even unfamiliar or nonsense words.

We have developed a prototype application called the Fluid Reading Primer to help readers with the process of decoding written words into their spoken forms. When a reader requests help for a particular word, the Fluid Primer uses interactive animation to break the word apart to visually indicate its constituent sounds. The Fluid Primer can play back audio versions of each segmented constituent sound, as well as the blended complete word.

Because the Fluid Reading Primer can be used with arbitrary text, it should motivate early readers by allowing them to select material of interest to them. Furthermore, we believe that the animations involved in our tool provide a valuable visualization of the decoding steps that will help readers learn to perform the same steps more quickly and confidently on their own. Finally, since the Fluid Primer focuses on the decoding part of the reading task, it can be combined with other computer-based techniques for supporting readers.

Wise et al provided some decoding support in their computer-assisted remedial reading program (Wise 00). However, their support was given at a higher level (subset + rimes, such as /stiv/ , /stir/ , rather than single sounds), and they used a much simpler visual presentation (white text on alternating green and blue backgrounds, with no animation). They found no benefits of their segmented form over whole-word support. We believe that our method’s sound-level segmentation and careful animation will yield benefits, but verification awaits future empirical study.

The Fluid Reading Primer is part of a larger research project called Fluid Documents, which is exploring the use of interactive animation of typography to show additional information in computer-based documents. A user study indicated that animations do not prevent readers from attending to the reading task (Zellweger 00). However, some subjects preferred static text to animated text. These results suggest the need for careful animation design. The Fluid Reading Primer extends this prior work by focusing on an educational task and incorporating audio into the interactive animation.

Reading

Diane, Carmen, and Geoffrey McGuinness have recently developed a systematic and relatively simple way to conceptualize and teach the decoding process using conventional paper-based books and exercises (McGuinness 97, McGuinness 98). They argue convincingly that it is important to teach these steps explicitly because other current methods, such as phonics and whole language, fail many students. They have experienced broad success with their method with both reading remediation and new readers. This section summarizes the issues and their method.

The Fluid Reading Primer:
Animated Decoding Support for Emergent Readers

Polle T. Zellweger and Jock D. Mackinlay
Xerox Palo Alto Research Center, California and University of Aarhus, Denmark

Abstract: We have developed a prototype application called the Fluid Reading Primer to help emergent readers with the process of decoding written words into their spoken forms. When a reader requests help for a particular word, the Fluid Primer uses interactive animation to break the word apart to visually indicate its constituent sounds. The Fluid Primer can also play back audio versions of each segmented constituent sound, as well as the blended complete word. We envision that our method could be incorporated into future e-books to provide scaffolding on demand for readers of arbitrary texts. Moreover, we believe that the animations shown by our tool provide a valuable visualization of the decoding steps that will help readers learn to perform the same steps more quickly and confidently on their own.
Reading English

We learn to hear and speak on our own, but we must be taught to read and write. Writing uses symbols to show sounds. We reverse this process to read—that is, readers decode symbols into sounds.

The English language, in particular, poses a challenging set of problems for readers. [Note: We focus primarily on children learning to read English as their first language. However, the basic concepts behind our tool are also applicable to learning to read other languages, to older individuals, or to learning to read English as a second language.]

- Unfortunately, although English has 43 sounds, it has only 26 letters, so some sounds are represented by groups of letters.
  Ex: The letters “ch” show a sound /ch/ (as in “chair”) unrelated to the sounds shown by “c” or “h”
- To make matters worse, some letters and letter groups can represent more than one sound.
  Ex: The letter “o” shows the sound /u/ in “ox” and the sound /o-e/ in “old”
  Ex: The letters “ow” show the sound /o-e/ in “own” and the sound /o-w/ in “town”
- Moreover, there can be multiple ways to show a single sound.
  Ex: The sound /a-e/ can be shown using 9 different combinations of letters: “a_e”, “ai”, “ay”, “ea”, “ey”, “eigh”, “a”, “ei”, and “aigh” (the letter groups are shown in the order of their frequency of use in English words)

Recent research in reading suggests that a better way to teach reading is to start with the sounds, which students know already, and teach the corresponding letters or letter groups. This reverses the traditional phonics approach of letters to sounds.

The decoding process

An emergent reader must learn three steps to decode words into sounds: visual segmentation, sound assignment, and sound blending.

Step 1. Visual segmentation. The reader must divide a word into groups of letters such that each group shows a single sound. A difficult word like “though” may have several possibilities that must be considered, including:

  though
  th ou g h
  th ough

Step 2. Sound assignment. The reader must assign a legal sound (again, typically choosing among several possibilities) to each letter group.

Step 3. Sound blending. The reader must remember each sound and sequence them in the correct left-to-right order to form the spoken word. No letter group’s sound may be omitted or reordered during this step, nor may any other sounds be inserted.

For a difficult word, the entire process may require several applications of these steps to try alternative segmentations and assignments. The process ends successfully when the resulting spoken form matches a known word that makes sense in the given context.

Teaching the decoding process

The McGuinnesses teach the decoding process by starting with a Basic Code, in which each of the 43 sounds in English is associated with a specific letter or a pair of letters. After the emergent reader has learned the three decoding steps described above, the Advanced Code is taught as “spelling alternatives” for those sounds with more than one spelling, and “code overlaps” for those letter groups that show more than one sound. The code developed by the McGuinnesses uses every letter in the word in a left-to-right fashion to show the final spoken form, which simplifies the logic of the decoding process for the emergent reader. For example, the letter “k” in the word “know” is not thought of as silent. Rather, the letter group “kn” is another way to show the sound /n/. The so-called “silent e” requires only a bit more explanation: a few letter groups can be written in two separate parts. For example, the letter “a” and the letter “e” in the word “ate” work together as a single letter group “a_e” to show the sound /a-e/.

Once the Advanced Code is mastered, the McGuinnesses teach two additional steps for decoding multi-syllable words: chunking and emphasis assignment. In the chunking step, which takes place before the steps described above, the reader must segment the word into chunks, or auditory syllables. Chunks are related to conventional syllables, but they obey auditory rules rather than visual ones—for example, they do not break between two doubled letters; the doubled letters go to one side or the other of the break. In the emphasis assignment step, which takes place afterwards, the reader must choose which chunks should have strong or weak emphasis applied to them.

The McGuinnesses have also developed a home schooling curriculum that includes a few stories in which each word is printed using special typography to represent the results of the visual segmentation step, as shown below. Emergent readers who are trying to master the Advanced Code find these prepared stories much easier to read than the unmodified versions. This printed form, which they call the Phono-Graphix code, uses a minimal representation to avoid confusing early readers with new and unfamiliar symbols. Studies have shown that introducing special symbols can create a greater barrier to reading conventional text later (McGuinness 97, page 179).

Ex: McGuinness Phono-Graphix code: t ea ch

Fluid Reading Primer and Animated Decoding Support
The Fluid Reading Primer provides animated online support for the steps in the decoding process. Our contribution is to use the computer a) to provide a powerful new dimension to the method described above and b) to broaden its applicability from a few specially prepared texts to potentially arbitrary texts.

The Fluid Reading Primer initially shows simple static text formatted in the usual way, which encourages readers to decode words on their own. When students need help decoding a word, they click on it with the mouse. The first click triggers an animation that demonstrates the visual segmentation step: the characters of the word move slightly together or apart to form the correct letter groups (Figure 1). The animation proceeds in a left-to-right order so as to emphasize the correct processing of groups into sounds, since sounds are inherently one-dimensional (time) and must be ordered properly, while text is inherently two-dimensional (x-y). This segmented form encourages the students to proceed with the sound assignment and sound blending steps on their own. If they need more help, they can click on the word again to fire a second multimedia animation that demonstrates the sound assignment step: again proceeding from left to right, letter groups are individually highlighted as the corresponding sound is played (Figure 2). Finally, a third click demonstrates the sound blending step: all of the letter groups are highlighted simultaneously while playing back an audio version of the complete word (Figure 3). Discontiguous letter groups use a special linked highlight (Figure 4).

The Fluid Primer will ultimately have adjustable settings corresponding to a reader’s current ability. An early reader may need slower animations than a more experienced one. A reader who is just beginning to read multi-syllable words would see a more complete animation, beginning with chunking, and proceeding through visual segmentation, sound assignment and sound blending for each chunk, followed by emphasis assignment and the spoken version of the entire word. A more experienced reader may generally require only the chunking and emphasis assignment steps, although full decoding assistance should remain available. The final minimal level of assistance would simply play back an entire spoken word on demand.

Issues in effective animated user interface design

The user interface of the Fluid Reading Primer has been designed carefully to promote learning the decoding process. Although the basic concepts involved in animating the steps of the decoding process are relatively simple, subtle issues are involved in developing an effective animated design. This section discusses some of these issues.

The Fluid Reading Primer necessarily accentuates the decoding process in order to demonstrate and teach it. However, we use a careful and parsimonious design for displaying the text and the animations to promote easy transfer to printed books. Although it would be possible to create elaborate graphics or animations to entertain children, we have deliberately resisted this temptation. Recall that some experimental studies suggest that introducing special typographical symbols can either confuse readers or make them dependent on these representations (McGuinness 97 p 179). Elaborate graphics or animations are likely to distract readers in a similar way.
Step 1: Visual segmentation. We use a single distinguished color for the selected word throughout the three decoding steps (red is the default, but the color can be changed if desired). Because this color differs from the background color of the remaining text, the word remains a visual unit: its letter groups neither visually join adjacent words nor become separate "words" on their own. However, color does not distinguish between separate letter groups.

We use only whitespace to separate letter groups in the visual segmentation step. This choice differs from the McGuinness Phono-Graphix code, which also emboldens and underlines various characters, for two reasons. First, since the Fluid Primer uses a distinguished color and it only shows the segmented form of one word at a time, the spaces are more distinctive. Second, the animation in the visual segmentation and sound assignment steps further accentuate the distinction between letter groups.

Following our design principle of parsimony, the closer we can remain to the printed form without compromising clarity, the better.

The discontiguous "vowel+e" letter groups pose special problems. They must indicate their two-part but related nature in the visual segmentation step. We use a light shaded background to join the two parts of these letter groups even in the visual segmentation step, where other letter groups have no background shading. This shaded background darkens in the sound assignment step (Figure 4).

The animation of the visual segmentation step provides a smooth transition between the conventional form of a word and its segmented form. The smoothness of the animation, which shows several intermediate positions of each letter, demonstrates that no letters appear or disappear in the transition to the segmented form; the letters simply move together or apart. Thus a reader is shown that every letter in a word becomes part of some letter group that shows a single sound in the following sound assignment step. This removes the concept of "silent" letters, which can lead to inaccurate reading strategies.

This animation is also intended to encourage readers to notice each letter group and hence to realize that it represents an actual sound that is part of this word, because studies show that disfluent readers may fail to notice letter groups (McGuinness 97). Each letter group changes color as a unit and then all of its letters move left at once. The distinguished color and the motion call attention to it.

Finally, the visual segmentation animation is designed to demonstrate the left-to-right ordering of the decoding process, because disfluent readers may also perceive letters out of order. After experimenting with a variety of movement strategies, we determined that a good way to emphasize the left-to-right ordering is to move each letter group exactly once, to the left, into its final position. We can see the importance of this as follows: if an earlier letter group moves during the positioning of later letter groups, it tends to distract attention from the desired focus on the later letter group. Similarly, if earlier letter groups move after the positioning of later letter groups, it breaks the left-to-right flow of the process. Thus the letters in the first letter group turn red and move smoothly into their final position, followed by the letters in the second letter group, and so on.

Ideally, the segmented word should still be centered between the surrounding words. This can be a bit tricky to accomplish while maintaining the emphasis on left-to-right ordering. We combine the following two strategies to avoid reader confusion: First, the initial layout algorithm places the words on the screen to allow room for each word to expand into its visually segmented form. Second, we borrow a trick from cartoon animation, which anticipates movement in one direction by a pre-movement in the opposite direction. Here we move the entire word a bit to the right and compress it slightly as feedback for the reader's first click (requesting the visual segmentation), to allow more space for moving left during the remainder of the visual segmentation step (Figure 1b).

Step 2: Sound Assignment. In the sound assignment step, we use filled rectangles behind the letters to create the impression that a separate visual layer is showing the sound assignments. These filled rectangles must neither be too dark (interferes with readability) nor too light (interferes with the perception of synchronized sound and letter group).

The animation of the sound assignment step again emphasizes left-to-right processing. Starting from the left, each corresponding sound is played back independently. The sound playback is synchronized with the appearance of a filled rectangle behind the corresponding letter group, thus demonstrating that this sound is a possible alternative for this letter group. Slight pauses between playing the sounds keep them audibly separate.

Step 3: Sound Blending. All rectangles are shown while the word is spoken aloud. A smooth animation is used to remove the filled rectangles and close the letter groups after it has been read.

Fluid Primer Infrastructure

Several underlying dictionaries, tables, and files support the operation of the Fluid Primer:

- A dictionary of words. Each entry includes:
  a. its segmentation into letter groups. Care must be taken here with the discontiguous e, which must appear in its own segment, but participate in a single sound in the sound assignment step
  b. its assignment of which sound corresponds to each letter group
  c. its segmentation into chunks
  d. emphasis assignment for chunks
  e. a pointer to an audio pronunciation of the entire word

Sample dictionary entries:

<table>
<thead>
<tr>
<th>Word</th>
<th>Visual segmentation</th>
<th>Sound assignment</th>
<th>Chunking</th>
<th>Emphasis assignment</th>
<th>Audio file</th>
</tr>
</thead>
<tbody>
<tr>
<td>snow</td>
<td>s n ow</td>
<td>s/ n/ o- e/</td>
<td></td>
<td></td>
<td>snow.au</td>
</tr>
</tbody>
</table>
This dictionary contains information that cannot be derived easily from standard dictionaries, so it must be created anew. Note that in general, it must also explicitly contain inflected forms of all words: top, tops, topped, etc. However, once created, a single dictionary can be consulted to help readers with arbitrary texts. If desired, regional pronunciations can be provided for selected words in a separate user dictionary. This feature is particularly useful for names.

Note that some words have different pronunciations for different word senses, such as “read” or “lead”. Simple versions of this situation, in which the different word senses form different parts of speech, could be distinguished by automatically parsing the containing sentence. If the different word senses form the same part of speech, such as “primer” (introductory book) and “primer” (undercoat of paint), the Fluid Primer could offer a choice to the teacher or reader.

- **Audio files pronouncing all 43 English sounds.** This small set of short audio files requires careful speech, preferably by a trained speaker, to isolate the sounds of individual English phonemes. High-quality recording and audio processing are likewise required to make the sounds as clear and distinct as possible. For example, aspirated sounds such as /p/ and /b/ may need to be accentuated, while their plosive portion may need to be softened.

- **A table mapping each sound to the letter groups that can show it.** (for interactive exercises; see below)

- **A table mapping each letter groups to the sounds that it can show.** (for interactive exercises; see below)

**Status and Future Work**

Our prototype Fluid Reading Primer is implemented in Java JDK 1.1, which provides minimal support for animation and audio playback. Our animations are implemented in custom code using Java’s thread facilities. They are carefully tuned to synchronize with the playback speed of our audio files on a 200MHZ Pentium II. We plan to reimplement the prototype in JDK 1.2, which has better audio support. We expect to need better synchronization technology as we extend the prototype to support a larger range of texts on arbitrary computers.

We have not yet conducted an empirical evaluation of the Fluid Primer. However, we have shown it to several dozen parents and elementary school teachers in California and Denmark, and their reaction has been very favorable. We also got an encouraging reaction from two emergent readers who were being taught the McGuinnesses’s home schooling curriculum. They quickly grasped that they should click on words to get help, and they did not find the animations confusing. We are currently exploring opportunities to evaluate the Fluid Primer with more early readers.

The Fluid Primer can be extended to allow emergent readers to perform the decoding steps on their own via interactive exercises. For example, in the visual segmentation step, readers could drag the mouse across several letters to collect them into a single letter group. Alternatively, they could choose from lists of legal English letter groups. In the sound assignment step, they might choose among visual representations of the legal sound alternatives for a letter group. Audio feedback for each sound alternative would be given on request.

**Discussion**

The World-Wide Web is making it possible to access the entire literature of the world quickly and easily. However, the promise of this technology will be reduced if the retrieved literature cannot be read. Decoding words into their sounds is a key skill that will empower a child to use computer-based documents. In this paper, we have described how a computer-based document can also be used to teach an emergent reader this decoding process. Smooth animations demonstrate the three decoding steps: visual segmentation, sound assignment, and sound blending. The animations are carefully designed to illustrate the decoding process with a minimum of graphics and animation. Each step encourages the students to complete the decoding process on their own. Although a systematic evaluation of this technology awaits the development of a more robust prototype, we expect from our previous evaluation of Fluid Documents that these carefully designed animations are not likely to be disruptive to the emergent reader (Zellweger 00). The preliminary observations of our two sample emergent readers support this conjecture.

Abstract: Many projects and researches on online distance learning have emphasized the application of multimedia elements that are more necessarily helpful in children education than in life-long/adult education. The researches did not pay much focus on two crucial elements: personalization and intelligent tutoring. SPACE (the School of Professional And Continuing Education, The University of Hong Kong) has developed an online course-learning program which emphasizes on the personalization and intelligent tutoring aspects. This paper is to identify and illustrate the importance of personalization and intelligent tutoring issues especially in Adult Distance Learning and present Smart Tutor as a solution. It will also introduce and explain how they can be practically applied onto the design and implementation processes using some Artificial Intelligent methods.

Introduction

The School of Professional and Continuing Education (SPACE) at The University of Hong Kong performs a role to encourage the Hong Kong population to develop themselves into a better shape for future growth. In SPACE, we provide life-long learning for the public, and create an opportunity for them to pursuit a bright prospect in their own career developments and training. In year 1999, the number of people registered with SPACE programs is around 65,000. The SOUL (SPACE Online Universal Learning) project from SPACE is a project aiming to provide online support for educational purpose and develop SPACE online support courses in both Hong Kong and the Mainland China.

In Adult Continuing Education, Working adults come from a wide range of backgrounds. Most of them have their own full time employment and they are facing the dilemma of preparing for examination and working away. So the way they grasp their limited spare time for further development is respectful and they need more detailed and effective instructions during their learning process. Consequently, there is room for universities and IT companies to develop e-Education to better suit the needs of these adult learners in the domain of learning and examination. However, most exiting platform put much more efforts on technology that facilitates interaction between learner and instructor and among the learners, such as multimedia, computer conference and something like this, neglecting personalization in the learning environment. So an intelligent tutoring system for online education is necessary. Our Smart Tutor system project intends to build an intelligent multimedia learning environment with particular stress on individual tutoring. In the education area to achieve a more automated and personalized learning environment. Private tutoring has proven to be as much as four times educationally effective as a normal classroom setting and 98 percent of the students perform better with private tutors (Bom. B. S. 1984). Intelligent tutoring
systems (ITS), modeled after the idea of a private tutor, provide individualized instruction. In summary, we want to achieve an online intelligent learning environment that helps students to learn more effectively with few human working.

The Architecture of Smart Tutor

The main architecture of Smart Tutor consists of six parts: Course Manager, Content Structure, Student Model, Question Bank, Expert Module and User Interface.

The Course Manager is the control center of Smart Tutor. It has the following responsibilities:
- Invokes the Expert Module to create a tailored course content from Domain Knowledge for each student and to give individualized suggestions during each student's learning process
- Maintains student's personal information, learning histories, testing results in the Student Model
- Deliver the course via the User Interface
- Creates adaptive test or examination via the Question Bank

Content structure of Smart Tutor provides content orientation. Giving a preview and then going onto the detail directly by a description of the material to students is a normal way to achieve orientation. This resulting clear, flexible and non-linear structure would be used to categorize the course content. The whole content structure can be exhibited as a diagram. Smart Tutor can author and modify the content diagram to represent the resulting content map satisfying each individual's requirements and fitting for his or her prior knowledge. Individuals then will follow their finished content structure diagram as the executing structure for a course.

The key element of Student Model is Personal Learning Record which tracks the progress of each student and reflects individual learning performance. It can be a serial of testing results attached to each node. Smart Tutor records the student's learning performance following their personalized content structure and gives some personalized instructions, specific trainings for everyone.

Question Bank is a warehouse of questions that supports the generation of tests. It is also an essential part of an online course system. Smart Tutor controls and evaluates each student's learning steps by using the test generation and results, which are on basis of Question Bank.

Expert Module consists of the Advisor and Planner, which are main functions of Smart Tutor. We make it possible based on the combination of Content Structure, Question Bank and Student Model. We use rule-base, fuzzy model and other methods in Artificial Intelligence to achieve them. There is a rule-base consists of expert rules that allow the Planner to determine the selection and ordering of materials that should be presented to the student and allow the Advisor to generate the appropriate instructions and tests that should be presented to the student. Test generation is both a supporting function of Smart Tutor as well as a basis of Planner and Advisor. More details of Smart Tutor can be found in (Jie et al. 2001).

Conclusion

In the current stage, the SOUL intelligent tutoring system is being implemented. The paper has reported the high-level design of the system and the principles behind. It has provided E-education research with a new horizon because no such an Artificial Intelligence application, which focuses on supporting distance learning and life-long learning, has present yet. Most importantly, the system design also caters for different learning paradigms of education theory which the teachers want to use through application of sophisticated mechanisms of the content structure, student learning record, question bank and smart planner & advisor.
