This proceedings contains papers from the 2002 Society for Information Technology & Teacher Education (SITE) conference. Papers are organized in the following sections: (1) Invited Papers and Invited Panels; (2) Concepts & Procedures; (3) Corporate & Distance Education; (4) Educational Computing Course; (5) Educational Leadership; (6) Electronic Portfolios; (7) Faculty Development; (8) Fine Arts; (9) Graduate and Inservice Education; (10) Instructional Design; (11) International; (12) Mathematics; (13) New Media; (14) Partnerships across Organizations; (15) Preservice Teacher Education; (16) PT3 (Preparing Tomorrow's Teachers To Use Technology) Papers; (17) Reading, Language Arts, and Literacy; (18) Research; (19) Science; (20) Simulations; (21) Social Studies; (22) Special Needs; (23) Technology Diffusion; (24) Telecommunications: Graduate and Inservice & Faculty Use; (25) Telecommunications: Preservice, Graduate, and Faculty; (26) Telecommunications: Systems and Services; (27) Theory; (28) Video Cases; and (29) Young Child. In addition to long and short papers, many brief summaries of conference presentations are also included. (MES)
Information Technology & Teacher Education Annual

SITE: From Our Society’s Foundation Towards Shared Leadership for an Intercultural Future.

Niki Davis
President of the Society for Information Technology and Teacher Education (SITE) 2001-2004
Co-Director of Iowa State University Center for Technology in Learning and Teaching, ISU, USA
Professor of Educational Technology in London University Institute of Education (part time), UK
nedavis@iastate.edu

Abstract: The current context for teacher education in many countries worldwide has brought new technology and teacher education to the forefront of policies, with major initiatives to renew education through technology. Our Society for Information Technology and Teacher Education (SITE) is moving to a new stage of maturity with over a decade of scholarship and the participation of over one thousand teacher educators. We have a significant role in promoting reflective, participative leadership for the deployment of new technology in education, particularly teacher education. SITE’s first decade is described to provide a view of our shared heritage. The society is further developing its scholarly publications on paper and on the web. The new governance ratified during our 2001 annual conference is accompanied by changes in our conference and the emergence of innovative virtual environments to enhance our community. This builds upon the innovative social and technical engineering already underway and aims to develop shared leadership and to encourage cross-generation, interdisciplinary, and intercultural participation. In recognition of the loosely coupled nature of educational organizations my vision for SITE, as president, aims to be a model of good practice for an inclusive knowledge society.

The first decade of the Society of Information Technology in Teacher Education has seen the formation of a wonderful loosely coupled system, which we enjoy. Part of that enjoyment is our common socialization we think and act like teacher educators with enthusiasm and expertise with new technology. We enjoy sharing that enthusiasm and developing the scholarship and practice in our field and service to our societies worldwide. Even though we often do not communicate much with each other, we can still coordinate our actions because we can anticipate what other SITE participants are thinking and doing and we enjoy hearing about it at our conference. We also share the administrative support of SITE, through the strong arms of the Association for the Advancement of Computing in Education (AACE).

Educational organizations are loosely coupled systems and as such require more leadership than tightly coupled bureaucratic systems (Weick, 1982 and 2001). Our society is even more loosely coupled than a university or school organization and, within it, leadership comes from many angles. Leaders include editors, committee chairs, and leading researchers, as well as administrators such as the President and Executive Director. They all participate in the leadership of our society. We aim to increase this participation. Therefore, it is important for me to share the developments underway by as many forms of communication as possible, including within the archive that these proceedings provide.

For these reasons I have decided to provide a preface to the SITE proceedings for 2002 that documents the roots of our society and then to share with you the developments underway, as well as the leadership’s emerging vision for the future. Figure 1 provides a time line for our society as it moves into its teenage years.
SITE's First Decade

SITE 2002 is the thirteenth annual conference of the Society for Information Technology and Teacher Education. Jerry Willis, DeeAnna Willis, and Glen Bull, among others, founded SITE in 1990 to provide a scholarly home for teacher educators who had come from many directions to find their place in preparing teachers to become comfortable with the use of information technology in education and to play their part in renewal of educational systems worldwide. In the preface to the 1992 SITE Annual, Jerry Willis and DeeAnna Willis, as co-directors of the third SITE conference, made this prediction, which has now come true:

During this decade, the last of this century, technology-using teacher educators will bring information technology out of isolation in the educational computing course and integrate it into the entire range of teacher education. Many of the innovative, cutting-edge projects described in this publication will be routine, expected activities by the turn of the century. (Willis & Willis, 1992, p. x)

It may be difficult to realize how different things were in the early 1990's. Just a decade ago, few papers suggested that there was any problem with technology in teacher education. I met the SITE founders in a conference in Belgium, where I was audacious enough to suggest a need for curriculum development in information technology (IT) in initial teacher training (Davis, 1990). We joyfully recognized each other as pioneers with a mission in a special field, the importance of which had yet to be recognized. At the time I was chairperson of the UK Association of Information Technology in Teacher Education (ITTE), a small collegial body founded by Roger Keeling and others less than a decade before to promote development of IT in teacher education in the UK, especially preservice teacher education. My own professional development and enjoyment were significantly enhanced by participation in ITTE. My participation progressed from elected committee member to chairperson to newsletter editor, and then to taking over as editor of ITTE's international scholarly journal, the Journal of Information
Technology for Teacher Education (http://www.triangle.co.uk/jit). The little word “for” in its title is the most important because it states that through our scholarly field, we aim to serve the needs of teacher education with new technology rather than to simply educate teachers about information technology in education. This sympathy for a new scholarly community, many of whom had yet to recognize the importance of their work, was the reason for my joy in meeting up with SITE and its founders.

As a result of this meeting in Brussels, I was invited to give the first international keynote at the 1991 SITE conference, which was organized and managed by its energetic founders in Greenville, North Carolina. Jerry Willis, DeeAnna Willis, and Glen Bull have all continued to contribute their unique energy and support for the field. Although AACE “became the supportive organizational home” of SITE in 1992, the editing of the SITE Annual (and now the leadership and coordination of the SITE proceedings) has been undertaken by DeeAnna Willis and Jerry Willis. SITE and its Annual have provided a very supportive and fertile ground for the establishment of our new scholarly field for many teacher educators across the world. In the preface to the 1992 Annual, the co-directors noted the arduous labor undertaken. They described the editing process undertaken to ensure high quality of content. SITE was one of the first conferences to use the technology and energy of its editors so that the Annual was ready at the start of each conference, because they believed that it was important for technology-using teacher educators to use the technology well. Only recently was a move made to proceedings with digitally ready papers to reduce the editing effort. This was a hard decision for the committee to make, but was forced by the volume of contributions. The first Annual had 42 papers, the second 84, and the growth continued to be exponential. The 1992 Annual preface recognized the labor, the underlying motivation, and our debt to the editors (and now section leaders):

All these people are volunteers who do the work because they think it is important to the field. Although the Society thanks them for their work, they are themselves, in reality, the heart of the society. When you have the opportunity please convey your appreciation to all the editors and let them know you recognize and appreciate their work. (p. xi)

In 1997 SITE created an award for lifetime achievement in our field and named it after Jerry Willis, as the first recipient. In 2000, we presented the Willis award to Glen Bull and in 2001 we also gave special recognition to DeeAnna Willis as a founder of SITE. All of them have continued to make outstanding contributions to our Society each year for more than a decade because they thought it was important for our field.

I would like to help readers recognize the supportive scholarly community that grew through this collaboration. For this purpose, I will describe events around my keynote speech at SITE’s second annual conference that led to ongoing collaboration. In that speech, I described the first decade of the development of Information Technology in UK teacher education (Davis, 1992). The UK was probably the first country in the world to promote strategic development of technology in teacher education, including pre-service teacher training. With encouragement from SITE’s founders, my speech later became the first paper in ITTE’s new scholarly Journal of Information Technology for Teacher Education (JITTE). SITE’s own journal, the Journal of Technology and Teacher Education (JTATE), was founded a few years later in 1993 and the two journals have continued to support each other’s development.

The 1991 SITE conference was dazzling, providing between three and five parallel sessions, all of which I wanted to attend. In a pre-conference workshop I attended, David Morasund, a founder of the International Society of IT in Education (ISTE) inspired me in the application of problem-based learning. It is notable that SITE will present the Willis award to David during our 2002 conference in recognition of his lifetime work in the wider field of information technology in education, including that for K-12 schools. Before that second SITE conference in Greenville, North Carolina, I decided to gain a feel for the context of technology in education in the USA. With an impromptu introduction from Jerry Willis, I visited the University of Virginia Curry School of Education and established what became a long-term collaboration with Glen Bull. We both had been experimenting with the use of communications technologies to support education, including the professional development of teachers. My national network was called ResCue and Glen’s statewide network was the Virginia Public Education Network. We therefore had much in common. Glen and his colleagues in Virginia were kind enough to let us establish their software in England and, using this common on-line environment, we were able to promote collaborative activities for student teachers across boundaries of culture and time. We still collaborate across the Atlantic today.
The UK Association, ITTE, became a sister with SITE. Older and smaller, it had a view that complemented the expertise that resided in the USA. Colleagues in ITTE continued to raise awareness of international issues and cultures and to share our evolving knowledge of the political context of technology in teacher education. Following that first keynote, I became a regular attendee of SITE, often representing our sister organization ITTE along with the late Brent Robinson, who was the founding editor of the UK journal, JITTE. We also welcomed SITE's founders as representatives of SITE to the annual ITTE conference and our Journal Editorial Board. Both organizations formalized this relationship with an Accord agreement, crafted by Brent Robinson and ratified by ITTE at the Annual General Meeting. Brent and I supported the establishment of SITE's own Journal of Technology and Teacher Education and became members of the Editorial Board. Over the years, the Association for ITTE struggled with the notion that it should support an international membership. There are less than one hundred institutions of initial teacher training in the UK, less that a tenth of the number that are in the USA. So ITTE has been more than happy to promote the international role and responsibility for SITE.

Because of my experiences with telecommunications in teacher education, I was also eager to promote the use of communications technologies, including the on-line Academical Village envisioned for SITE by Glen Bull and implemented through Barnard Robin's thesis scholarship (Robin, Bull, Bull, & Willis, 1995). This web site design was modeled on Thomas Jefferson's Academical Village design for the University of Virginia. At the University of Virginia, you can visit the rotunda, faculty houses, and student accommodations built around the green. SITE's first attempt at building an electronically supported academic community adapted this concept, and faculty leaders became curators for the themed sections that aimed to build resources and opportunities. However, the technology and collaboration available at that time did not prove to be robust enough for an enduring approach. ITTE has also found extensive web site development challenging for busy teacher educators. I will return to related web developments later in this preface.

SITE has also proved to be a fertile ground for strategic change of teacher education. SITE's American founders found that ITTE had an unusual approach. ITTE was formed as a scholarly community to improve practice and to lobby for strategic change in information technology in teacher education. By 1990 ITTE had undertaken a national survey, and Janet Trotter had produced the seminal Trotter report on the state of IT in initial teacher education. SITE also decided to step into the policy arena in the USA and invited Kathleen Fulton of the federal Office of Technology Assessment (OTA) to provide a keynote at its conference. Later a project was negotiated to survey technology in teacher education across the USA using a range of approaches, including case studies and quantitative information. I provided a small complementary study on the UK that showed that the position there was better but far from perfect (Davis, Willis, Fulton, & Austin, 1995). The OTA published its report (see http://www.pt3.org) (OTA, 1995). We were disappointed that the OTA was disbanded shortly afterwards. However, the PT3 program (Preparing Tomorrow's Teachers to use Technology) eventually developed and has exceeded our wildest dreams (Carroll, 2000). Kathleen Fulton, now a consultant in our field, is an invited speaker for the SITE 2002 conference. The current leader of the PT3 program, Lavona Grow is also invited to share her perspectives on this important initiative in the USA and its value for teacher education worldwide.

**Maturity for SITE**

SITE has provided over a decade of scholarship, and the annual conference has grown from a few hundred to over a thousand participants. Today SITE is well established, with significant ongoing participation from across the USA and from more than 40 countries worldwide. Most activities are currently supported and managed through AACE, under Gary Mark's able leadership as SITE's current Executive Director. In scholarly terms we are more than a village, yet the founders and past and current presidents wish to retain the informal scholarly community and support that was the early hallmark of SITE. Given today's challenging environment for education, especially teacher education, we need all the networking and support that we can give each other. We are fulfilling our aim to have a significant role in promoting reflective, participative leadership in the deployment of new technology in education, particularly in teacher education.
The expertise of the Society’s membership is recognized. The good news is that we are wanted; the bad news is that there is too much to do! However, over the years the work of the committees reduced. This was probably due to conflicting needs. The informal open membership for all committees appears to have resulted in less participation. This included the Governance Committee that had been deliberating for many years. Challenged to retain open governance, the society also needed to constrain it within a framework. Glen Bull and I took on the challenge during 2000 and vowed that we would get it done! The result is the Governance Document that follows this preface, which was debated and ratified during the SITE 2001 conference. The Governance envisages the work of SITE to be firmly rooted in its committees, which undertake their collaboration in an online environment and at its conferences and meetings. Our governance lays out our society’s mission, which is ‘to encourage appropriate uses of information technologies in teacher education worldwide.’ We aim to keep our membership ‘open to all those with an interest in information technology in teacher education’ and we welcome all participants in our conferences to share our mission.

SITE Developments Underway

The governance also lists our main ongoing activities. This section will describe current developments to facilitate them. There has been significant development of on-line environments with the collaboration of SITE participants and AACE, its organizational home. SITE has developed to a sophisticated presence on the web, from the early Internet sites already described. The structure of the organization is also undergoing a rapid maturation that will be described in this section. The activities are:

- Annual conference and its proceedings
- Scholarly journals (traditional: JTATE and on-line: CITE)
- Web site(s)
- Ongoing Working Committees
- Liaison with organizations promoting information technology in teacher education worldwide, including the negotiation of complementary activities to support scholarly development of information technology in teacher education within and across countries and cultures around the world.

SITE Conference and its Proceedings: Each year the SITE conference web site provides key information for prospective delegates and then provides the portal through which they submit their proposals and register for the conference. AACE, under the leadership of Gary Marks, our Executive Director has developed an effective SITE conference web site with integral proceedings collection and publication. DeeAnna Willis has led the reviewing of around 1500 submissions, resulting in acceptance of over 1000 presentations and the coordination of more than 25 sections within the proceedings. Gary Marks and Jerry Price’s careful web designs ensure that those papers can be reviewed on-line, that the abstracts could be moved to the database that provides the conference program of abstracts, and that access for the papers to be loaded by delegates and created the source file for the proceedings on CD ROM. The SITE president contributes the preface, with keynote and invited speakers adding their pieces. Coordinated by DeeAnna, the individuals and teams who write the section introductions step into action during Christmas vacation, reading abstracts to provide an introduction to each section. In this way the SITE proceedings retain their objective of becoming an important resource for technology and teacher education across the world. You may also notice the web site being transformed as the executive committee leads the firming up and finalizing of the conference program. The previous conference committees’ suggestions are implemented during this process where practical.

The editing of the SITE Proceedings will move through a new stage to update its structure and process during 2002. The aim is to capitalize on the expertise within our society and to better spread the activity across the year, including better links with working committees and leaders within the field. The first stage will be to review and revise the section categories. As a temporary measure we have introduced two new categories (electronic portfolios and video cases). However, it is clear from the uneven number of papers in the sections and contributors’ comments that a substantial revision is required. This process will also be informed by the ASTUTE (A Survey of Technology Using Teacher Educators) survey of conference participants’ needs and contributions, which was undertaken during SITE 2001 (Davis, Mumma, Sprague, Riddle & Carter, 2002). This will be discussed by the conference committee during the conference in Tennessee and on-line. That committee will advise the editorial...
team. In addition, both the general editors and section leaders will also be reselected. The editorial team will seek applications and nominations for section leaders, who will be required to provide a resume of their scholarship, including research, teaching and service. The role of the section leader will be expanded to actively promote their section and contributions to it. Their introductions to sections within the proceedings will aim to provide an update of the topics and some links to the contributions within their section.

The society does much of its work at its conference, but it is also hoped to improve the work throughout the year through the meeting all committees and working groups online in the SITE Forums that have been established during 2001. The formal structure of SITE's committees is laid out in the governance. However, it is the informal structure and the feeling of community and collaboration that are more important to our society. The ASTUTE survey also indicated that side participants wish to have more opportunities to contribute to SITE. During 2002 the major focus for SITE participants must be the establishment of these communities, facilitated by meetings (face-to-face and online). The digital scholarship portal, described below, also aims to promote the development of our scholarly community. Therefore Glen Bull and myself have convened a task force to promote this change. We are particularly pleased by the contributions of Judy Harris of the University of Texas at Austin and Roger Carlsen of Wright University, and we look forward to an increased community spirit in all SITE participants.

**Awards:** The awards that SITE has established during this conference have proved their value:

- Best paper awards have permitted the society to highlight interesting and important work from around the world. However, the number of paper awards has caused some 'constipation' for our society's journal, because award papers are invited to make a submission to the journal. For this very practical reason the number of best papers awards will shrink to five in 2002. The section leaders will continue to be the first line of those who nominate papers for consideration of an award.

- SITE will retain four awards for best poster/demo, which were established in 2000. It is important to note that SITE sees these awards of equivalent value to papers in our field, due to the rich scholarly discussion that take place around poster display. The demonstration of software, student work and web environments is much valued by our society.

- The Willis Award for lifetime achievement acknowledges those who have become lifetime fellows in our society through their sustained commitment to information technology in teacher education has already been described. The names of these distinguished fellows of our society are provided in the timeline in Figure 1.

- The new Digital Equity award to be inaugurated during the 2003 conference has a specific purpose. Nominations will be sought accompanied by a brief description of the ways in which an individual or group have worked to increase digital equity in teacher education. It will also include the ways in which the issue of digital equity is integrated into courses, service learning, or ways in which teacher education has been expanded to include under represented populations. Nominations for the award may come from activities within the conference or beyond. The short descriptions provided with nominations that will be posted at the conference and on the SITE web site will serve to expand our knowledge and engagement with digital equity in teacher education. The Committee on digital equity with support from the committee on special education and assistive technology will judge the nominations and make a recommendation to the President.

**SITE Scholarship:** It has been a busy year for SITE journals, a time of change and strong growth. JTATE is benefiting from AACE's web developments. These are permitting our scholarly journal on paper to complement our second site web-based journal, Current Issues in Technology and Teacher education (CITEjournal), and our new discussion forums providing the foundation for a Digital Scholarship Portal for technology and teacher education (Bull, Sprague, & Bell, 2001).

- **The SITE Journal of Technology And Teacher Education (JTATE)** founded in 1993 by Jerry Willis and DeeAnna Willis changed editor to Debra Sprague of George Mason University during 2001. Debra Sprague, in collaboration with Glenn and Gina Bull, has added a series of editorials to acknowledge the contribution of the two founding editor's and to plot the new direction of the journal. We are delighted to see a new generation of leaders emerging in SITE. Debra's scholarship will impact the whole of our field.

- **Current Issues in Technology and Teacher Education (CITEjournal)** is SITE's second journal. Glen
Bull and Jerry Willis became co-editors of this innovative and exemplary online journal in this field, with support from a PT3 catalyst grant ‘National Technology Leadership Initiative’ led by Glen Bull. The innovative approach of the Current Issues in Technology and Teacher Education (CITE) journal is to place, from the start, its content sections within the quality control, direct input, and participation of the teacher education associations for core content areas of mathematics, science, social sciences, and English, while retaining the technology and teacher education sections under the control of SITE (Willis & Bull, 2000). In addition, care is being taken to model exemplary practice for others, including research and development support from Digital Libraries projects in the University of Virginia, to ensure that the potentially transient contributions with integral multimedia will remain accessible for generations to come. During 2001, Glen Bull became the sole general editor.

The Journal of Information Technology for Teacher Education (JITTE), JTATE’s sister journal, has also changed editor during 2001 from myself to Avril Loveless of the University of Brighton in the UK. JITTE went online some years ago, at http://www.triangle.co.uk/jit. The editorial board has decided to change the title to reflect changing times, so from volume 11 JITTE will be renamed: Technology, Pedagogy And Education: The Journal for IT in Teacher Education. Avril gave an acclaimed international keynote for the 1998 conference helping us to rethink pedagogy (Loveless, 1998). In 2001 the following chairperson of the UK association, Tim Denning of University of Keele in the UK, will also consider the critical issue of the influence of ICT on pedagogy.

Inter-cultural collaboration: Possibly the most exciting development during 2001 has been in the creation of the digital scholarship portal for technology and teacher education led by Glen Bull. Through this portal our field may be seen in its entirety. In his first stage the view is a national one from the perspective of the USA. There is commitment to extending this perspective to intercultural and worldwide view by adding relevant websites and scholarly archives such as that of the UK (utilizing JITTE) and the AACE Asia Pacific chapter.

The challenges of collaborating across organizations and cultures are immense. Those of us proficient in English may not appreciate the challenge posed by the Internet and English as an academic lingua franca. On the other hand, we who are only proficient in English miss out on many other cultural riches through our lack of access to other languages. SITE, as a society with a large proportion of its membership in the USA and the UK, will have to take special care not to let the common language of English block legitimate participation. Indeed, SITE will also have to take special steps to encourage development of educational systems that are rich in tradition while also cosmopolitan and culturally diverse. Language will only be a part of this multicultural effort.

In 2001 we welcomed our first invited speaker from the Asia Pacific region. Shelley Chiwa Young chaired the AACE Asia Pacific chapter conference, ICCE’00, and her scholarship takes particular care to widen participation for teachers in that region including Chinese language and culture on the web. In 2002 Enriquez Hinestrosa, our 2002 international keynote speaker, brings us a view from South America. Chile is a country that has used technology and teacher education to revitalize the educational system. This included the educational renewal for indigenous people who did not have a written language. Success with information technology in education in a context that faces up to the enormous challenges with few resources has much to offer teacher educators in other cultures and educational systems, particularly for those who are concerned about the increasing digital divide within and between countries.

Inter-organizational collaboration: The challenges faced by SITE are also shared by other scholarly and professional societies. The Association for Teacher Education has convened a task force led by Paul Resta, of the University of Texas at Austin, to guide that association in its use of technology. As a member of that task force I will be using my experience with SITE and ITTE to guide that community and hope that we can also build collegial links between the two societies to the benefit of both. Such collaborative procedures have already been established under the leadership of our former SITE president, Glen Bull and his dean, James Cooper. The National Technology Leadership Initiative, funded by a PT3 catalyst grant, has been promoting the collaborative leadership of technology in teacher education through a National Technology Leadership Retreat to reflect upon technology and teacher education and to share educational philosophies. This has brought together, in an unprecedented way, leaders from all core content areas, plus those for technology. This included leaders from the professional organizations for teachers of science, social science, mathematics, English, and their teacher education associations. The
National Technology Leadership Retreats have consolidated and disseminate this important strategic collaboration. Future action aims to encourage the spread of this approach to other content areas and other countries. This reflective "retreat" of people is complemented with the CITEjournal described above. The conceptualization of this synergistic multifaceted publications and change agency is a major piece of artful engineering (information, social, and technological) for an emerging knowledge society.

The ongoing collaboration between SITE and the UK ITTE association has been described above. There has been discussion regarding a collaborative conference sponsored by SITE, ITTE and the UK University Council for the Education of Teachers. It is hoped to follow this through and to organize a collaborative conference in Europe on a topic of mutual interest. It may also be possible to develop further collaborative links in the Asia Pacific region through the AACE Asia Pacific chapter.

On a more personal level, I am delighted to note that we have been successful in gaining the first EC-US (European-USA) collaborative project that focuses specifically on the preparation of future technology using teacher educators, which will develop an intercultural certificate (Davis, Brown et al, 2002). Students from the six collaborating universities in Europe and the USA will undertake studies together online and study abroad as well as service learning that addresses issues raised by the lack of digital equity nationally and internationally. I also see myself personally representing SITE in the UNESCO task force that is creating an ICT curriculum for teacher education in UNESCO supported countries (Resta, Semenov et al, in preparation).

These collaborative developments represent relatively few of creative scholarship and service associated with SITE participants, especially in the USA where the PT3 program is currently providing significant resources and impetus. SITE's proceedings provide accounts of many actions, evaluations and action research.

Concluding Remarks

Our Society for Information Technology and Teacher Education stands at a threshold of an exciting opportunity and increased challenge. The importance of both teacher education and of new technologies is widely recognized. In order to fulfill our responsibilities to future teachers and their students, we must refocus our resources of expertise and knowledge to establish new models of good practice for society. Clearly, communications technologies can and are being deployed to support learning and collaboration in ways that would have been impossible. However, mobilizing new ways of working together will require engagement by a significant proportion of SITE's participants in ways that serve their pressing needs and concerns. The Society will need to creatively ensure wide participation in its meetings and in on-line environments, while avoiding duplication and competition with other organizations that have overlapping remits. The CITEjournal shows us that, with artful leadership, such shared leadership is possible. We now need to go further and encourage a similar synergistic collaborative ethic within SITE's reformed committee structure, and expand our collaboration across into complementary organizations' committees where relevant. Similarly, new approaches to team teaching and scholarly research are becoming viable with stronger on-line tools and techniques. The opportunities for innovation have never been more exciting, just the sort of work technology-using teacher educators enjoy!

SITE's interlaced knowledge community will require both technical and social engineering to match our needs and challenges. The social engineering that I lead will be transparent, showing our dilemmas and reasoning for the choices that we make. I believe that ensuring that processes are transparent to all participants, as we develop our knowledge community, is an important aspect of a knowledge society. It is a means of ensuring ease of transition between roles and receiving support from one another, hopefully without increasing administration (Collins, 2001). This is also a means to educate the next generation of leaders. I hope that it will be accompanied by artful delegation and support, so that our community grows by spreading our knowledge and recognition as far and wide as possible. Our challenge is to synergize the expertise within our membership in a way that opens our SITE community up to legitimate peripheral participation and strong growth of our scholarship across many cultural contexts, as well as to respond to the many challenges faced by the educational systems of the world.

ISU’s innovative project “Shared Leadership for Institutional Change” (SLIC) for university development has contributed enormously to my professional development over the past year, and several of the sources for my Keynote and this associated Preface. My thanks go to its leaders and my mentors and fellow participants.

I would like to thank ISU CTLT’s JoAnn Brown for her assistance in polishing the keynote for 2001 and for helping my family and I ‘relocate’ in the USA. I would like to thank my graduate assistant Rema Nilakanta for her reciprocal mentoring, including suggestions on this preface and Figure 1.

Last, but not least, I acknowledge the collaboration and friendship that I hope shines through this preface.
Reflections and Dedication from an Editor

Spring 2002 – the phrase holds hope of new beginnings. After a long dark autumn and a winter of worry the birth of this New Year holds special promise for better days. As the Annual 2002 nears completion, I reflect on the year past and what it may mean to all of us as technology-using teacher educators.

Welcome
First, if you are new to this profession or at least to this particular coterie, “Welcome.” As you read through these papers you will find colleagues here who will become your friends. Some will be “old friends who’ve just met” and others will be new friends who have found their academic ‘home’ amongst those of us who use technology in our teaching of teachers, who can’t imagine going back to a classroom, on either side of the desk, without IT.

Second, if you are returning to SITE, “Welcome back.” Thank you for your contributions. It is always particularly exciting to receive proposals from authors who met here last year and are now collaborating. Seeing the professional growth that takes place when new ideas are exchanged is extraordinary. While the World Wide Web gets all the press, the SITE world wide web of colleagues is equally great and has the potential to become even greater. It is made up of people – people who teach, people who care, people who learn, and people who share. What could be greater?

Reflections
When I was a child, adults meeting asked each other, “Where were you on December 7, 1941 when Pearl Harbor was attacked?” My children asked, “Where were you on November 22, 1963 when John Kennedy was assassinated?” Today we all ask, “Where were you on “September 11, 2001?” While these are US-centric questions, albeit with world wide implications, consider the impact technology has had on the delivery of such information. News of the first was delivered on the radio; news of the second was delivered by television as well, but not quite as it happened; news of the third was delivered as it occurred, burned into our retina, etched on our souls, by means of radio, TV, satellite, and the Internet.

Last fall, when a student entered my classroom with news of the first attack, my initial response was polite disbelief, but then the news was confirmed and spread through our building, which includes a middle school [11, 12, 13 year olds] as well as university classrooms. I released my class and we moved into the auditorium to view a large screen television. While others might have seen that as a ‘teachable moment,’ I was too stunned for so cogent a thought. We watched, horrified, as the second plane detonated a second building and as the ashes covered New York.

In the following days, glued to the television coverage, alternately crying and filled with anger, I assumed a ‘mental fetal position.’ I could not help thinking how much we
Americans have offended the rest of the world, how much they hate us, all the sorts of non-productive, self-pitying thoughts one could have at times like this.

But almost instantly, wonderful things began to occur. I started getting e-mail from friends and acquaintances around the world with messages of sympathy and encouragement and hope. I was sent a PowerPoint file that showed people, ordinary people, around the world bringing flowers to our embassies. I learned that the terrorists didn’t attack the US they attacked the World. It truly was a World Trade Center and people from around the globe worked and lost their lives there. An act designed to shatter the US instead brought us closer, not just Americans, but peace loving peoples all over the World. Just writing that I have a sense of euphoria, of the touching of friends from around the globe, some I know, many I do not, but friends nonetheless.

This feeling, this knowledge, could not have occurred in the same way in 1941 nor in 1963. The almost instantaneous outreach was not possible. Information technology delivered the wounding news, but it also delivered the healing messages.

After September 11, the planners of this conference feared that attendance would be drastically reduced. Travel was more complicated, more expensive. Would the international community avoid the US? Would Americans stay home? As the proposals began to first trickle and then flood in over the Internet they gave answer to those questions. No, they would come. They would participate.

**Dedication**

Therefore I am honored to dedicate this annual to each of you, you who were not intimidated by terrorists, not put off by the difficulties of travel, nor dissuaded by the additional costs. Each of you faced these hurdles to come together in our common goal of educating tomorrow's teachers to lead our youth into the technologically rich new millennium. I salute each and every one of you.

The pedagogical scenario as a tool of professional development in the in-service teachers and pre-service teachers. ........................................................................ 1443
Dilmeire Sant’Anna Ramos Vosgerau, PHD candidate Universite of Montreal - Canada - Professeur-PUC-PR/ Brazil, CA

Developing Appropriate ICT Competencies in Trainee Teachers: An Australian Example ...................... 1445
John Schiller, The University of Newcastle, AU

Creating a Technology Competency Agreement between Partnership Colleges ......................................................... 1447
Kathleen Sindt, Montana State University - Billings, US

Meeting the Educational Technology Standards for Teachers: Measuring One College of Education and Human Services ........................................................................ 1448
Kathleen Sindt, Montana State University - Billings, US

Multi Media Meets Multiple Intelligences: Training Teachers for the New Century .......................................... 1450
Gail Slye, Drury University, US; Ed Williamson, Drury University, US

Preparing Teacher Educators to Use Technology: Issues and Perceptions in Elementary Education Methods Courses .................................................................................................................. 1452
T. Colette Smith, Arizona State University, US; Thomas Brush, Arizona State University, US
Creating a Constructivist Classroom Using Technology: Preparing Preservice Teachers .......... 1454
  Denise Staudt, University of the Incarnate Word, US

Learning and the Use of Technology in Preservice Teacher Education: The Primacy of
Interaction ......................................................................................................................... 1456
  Jean Steitz, The University of Memphis, US; Susan Magun-Jackson, The University of Memphis, US

Using Web-Based Modules to Support an Introductory Computing Course for Preservice
Teachers ......................................................................................................................... 1458
  Jennifer Summarin, The University of Tennessee, Knoxville, US; Aileen Nonis, The University of Tennessee,
  US; Thilla Sivakumar, The University of Tennessee, Knoxville, US

Technology Standards in Teacher Preparation - ISTE NETS Distinguished Achievement Award
Program ......................................................................................................................... 1460
  Harriet Taylor, Louisiana State University, US

ISTE NETS on the Digital Edge: Accomplished Teaching With Technology ....................... 1461
  Lajeane Thomas, Louisiana Tech University, US; Don Knezek, ISTE, US; Dianne Porter, Louisiana Tech
  University, US

An Award Winning Technology in Teacher Education Program: Description of a
Comprehensive Approach ............................................................................................... 1463
  Ann Thompson, Iowa State University, US; Denise Schmidt, Iowa State University, US

The impact of an intensive technology integration internship program on pre-service
Teaching practices ........................................................................................................... 1468
  Lee Vartanian, ACTT Now PT3 Program, US

Simulations, educational technology, and teacher preparation: Working towards authentic
Student experiences in a required technology course .................................................... 1470
  Rick Voithofer, Ohio State University, US

Practical applications of technology in the General Methods course ............................. 1474
  Roxanne Walker Bridges, College of St. Catherine, US

Assessing Mentoring Teacher's Technology Proficiency: What Do They Have to Say? .......... 1476
  Stephen White, George Mason University, US; Debra Sprague, George Mason University, US

Supporting Teacher Training Programs with an Electronic Reserve System (ERes) ............ 1478
  Ed Williamson, Drury University, US; Gail Slye, Drury University, US

Supporting Teacher Training Programs with an Electronic Reserve System (ERes) ............ 1481
  Edward Williamson, Drury University, US; Gail Slye, Drury University, US

Pre-service and In-service Teachers' Knowledge, Experience, and Perspectives on Portfolio
Assessment: A study in Taiwan ...................................................................................... 1484
  Hsu-Ping Yueh, National Taiwan University, TW; Chih-Yin Hsiao, National Taiwan University, TW; Shan-
  Hsin Chiang, National Taiwan University, TW

PT3 ................................................................................................................................. 1486
  Mary Thompson, University of Houston, US; Jerry Price, University of Houston, US

Sharing Expertise: The Technology in Urban Education Summit ................................... 1487
  Ronald Abate, Cleveland State University, US; Judy Stahlman, Cleveland State University, US; Kathleen
  Bonghtat, Cleveland State University, US

Providing for Student Professional Development as part of the Teaching, Learning and
Technology Project ......................................................................................................... 1489
  Valeria Amburgey, Northern Kentucky University, US

A Framework for Integrating Technology into Teacher Preparation Programs ................. 1491
  Staples Amy, UW-Milwaukee, US; Marleen Pugach, UW-Milwaukee, US; Dj Himes, UW-Milwaukee, US

Meeting NCATE Standards for Technology Integration: Survey Results of Technology
Integration in an Elementary Education MAT Program ................................................ 1492
  Cindy Anderson, National-Louis University, US; Arlene Borthwick, National-Louis University, US

Faculty Use of WebCT: Impact of PT3 Faculty Development Initiatives .......................... 1494
  Hua Bai, Purdue University, US; Suttichai Chuvessiriporn, Purdue University, US; James Lehman, Purdue
  University, US

Results after two years of a Preparing Teachers for the Digital Age (PT3) Grant on a State
University Teacher Preparation Program ....................................................................... 1496
  William Barker, Indiana University of Pennsylvania, US; Kurt Dudi, Indiana University of Pennsylvania,
  US
Assessing of the ISTE NETS for Teachers .......................................................... 1498
Helen Barrett, UAA/ISTE, US

Preservice and Inservice Teachers Collaborating with Technology in K-8 Multicultural Classrooms: Year 2 ....................................................... 1501

Using immersive 360 degree images to enhance active involvement and comprehension in the learning process ........................................... 1508
Peggy Benton, San Francisco State University, PT3, US; Yen-Ling Shen, San Francisco State University, PT3, US; Mercedes del Rosario, San Francisco State University, PT3, US

Preparing Teachers to use Modeling and Visualization in Science and Mathematics ................................................................. 1510
Lisa Biever, NCSA, University of Illinois, US; Sharon Derry, University of Wisconsin - Madison, US; Marcia Linn, University of California - Berkeley, US; Mary Ellen Verona, Maryland Virtual High School, US

Consortium Building: The NAU Teaching and Learning With Technology PT3 Project .............................................................. 1512
Michael Blocher, Arizona K-12 Center, US; Patty Horn, AZ K-12 Center, US; Sherry Markel, Northern Arizona University, US; Ann Batchelder, Northern Arizona University, US; Greg Sherman, Northern Arizona University, US

Evaluation: Challenges in Measuring a Moving Target ....................................................... 1514
Marcie Bober, San Diego State University, US

Implementation Strategies for PT3 Grant .................................................................. 1517
Robert Bowe, National-Louis University, US; Daniel Ryan, National-Louis University, US

UNT technology integration fellows: Results of several case studies .................................................. 1519
Kaye Bray, University of North Texas, US; Linda McDonald, University of North Texas, US; Mary Charlotte Mooneyham, University of North Texas, US

Carrots, Velvet Whips, and Propeller Beanies: Providing Incentives That Facilitate Institutional Change ...................................................................... 1521

Sustainability: How Can a Temporary Grant Have a Long-Term Impact? ................................................................. 1524
Dolores Brazycki, Indiana University of Pennsylvania, US

Collaborating for Change—Michigan’s Consortium for Outstanding Achievement in Teaching with Technology .................................................................. 1529

Professors’ Reflections on Changes Implemented After Technology Professional Development Sessions .......................................................................................... 1532
Rebecca Callaway, Louisiana Tech University, US; Kathy Matthew, LATEch University, US; Catherine Letendre, Louisiana Tech University, US

Designing Web-Based Modules to Assist Teachers with Teaching Mathematics to Minority Students ............................................................................................................ 1537
Carlous Caple, North Carolina A&T State University, US

Student Teaching Technology Sites: Creating Opportunities for Developing Technology-Using Educators ................................................................ 1539
Nancy Casey, St. Bonaventure University, US; Patrick Casey, St. Bonaventure University, US

Letting Technology Support Learning: Preservice Teachers Design Technology-Enhanced Learning Experiences .................................................. 1544
Patrick Casey, St. Bonaventure University, US; Nancy Casey, St. Bonaventure University, US

“ You purchased the software, now what?” Plan, Implement, Evaluate and Reflect on Software Usage in the Classroom .................................................................. 1549
Val Christensen, Valley City State University, US; Patricia Gegelman, Valley City State University, US; Linda Holcomb, Valley City State University, US

Exploring Digital Equity Using Digital Video Case Methodology ........................................................................................................................ 1551
Nancy Clemens, Arizona State University, US; Debra Stirling, Arizona State University, US; Paul Skiera, Arizona State University, US

Information and Communications Technology in Education:  
A Personal Perspective

David Moursund  
University of Oregon, USA

Abstract
Throughout my professional career I have worked, played, studied, taught, experienced, and learned about Information and Communications Technology (ICT) in Education. I have been an active participant in this field as it has slowly moved from infancy into early childhood. In this presentation, I will share some of the things that I have learned and that I think are particularly important. I will illustrate some of these things with personal stories and reflections. My goal is to help move the field of ICT in Education out of its current early childhood phase.

Introduction
My first experience in the field of Information and Communications Technology (ICT) was in the summer of 1963, shortly after I received my doctorate in mathematics. My area of specialization was numerical analysis, and this involved developing computational methods for solving various types of math problems. In the summer of 1963 (nearly 40 years ago), I helped to teach Talented and Gifted high school students who were learning about computers and computer mathematics. This remains one of my interest areas (Special and Gifted Education).

In the summer of 1965 I taught a course for secondary school teachers in a National Science foundation (NSF) summer institute, and by the summer of 1966 I was running my own NSF summer institute for teachers. All of the summer institutes and other NSF programs that I have run have focused on uses of ICT in precollege education.

My professional career has been one of learning and of sharing my learning. I have been fortunate in having job situations that supported this approach. I have held faculty appointments in Mathematics at the University of Wisconsin, in Engineering and Mathematics at Michigan State University, and in Mathematics, Computer Science, and Education at the University of Oregon. In addition, I started the professional society that eventually became the International Society for Technology in Education, and I headed that organization for 19 years (ISTE).

This document is divided into somewhat isolated pieces, but readers may find that some of the pieces tie together as they work to create meaning from the document. The organization of the document, as well as the messages I am attempting to convey, are fuzzy.

Throughout my professional career I have had an increasingly broad range of interests. These can be thought of in terms of discipline areas such as mathematics, computer science, and education. Significant chunks of my professional career have been spent in each of these three fields.

Or, my interests can be thought of in terms of more general ideas such as teaching, learning, problem solving, and research. The academic positions that I have held have all allowed me considerable time to pursue these general ideas.

In the next few sections of this document I will explore some topics that I would like to share with you. Some of the topics will be illustrated through personal stories. Over the years, I have gradually come to understand that storytelling is an important aspect of teaching.

Research
You have all heard the expression, don't reinvent the wheel. This is a profound idea. There are many problems that people want to solve. Some have the characteristic that once one person solves the problem, others need only imitate what the first person did. This is sometimes called the Einstein effect. For example, perhaps it was an "Einstein," living many thousands of years ago, who invented the wheel. (See Figure 1.) Others saw how useful the wheel was, learned to make wheels, and taught still others to make and use wheels.

Figure 1. Invention of the wheel.

I view research as solving problems in a manner so that others can build upon the results—so that others do not have to reinvent the wheel. My initial research was in mathematics. As a mathematician I posed and solved some problems, wrote and published some papers, and achieved both promotion and tenure at the Associate Professor level. While at Michigan State University, early in my teaching career, I also did research on the various methods used to teach freshman mathematics at that University.
One of the key ideas in mathematical research is that a problem gets posed and solved. If the statement of the problem and the solution are carefully done, then that problem is solved once and for all. People have been able to depend on the correctness of the Pythagorean Theorem for more than 2,000 years.

Imagine my surprise later in my career when I eventually began to read the research literature in education and ran into the idea of a meta study. In essence, a number of studies are carried out on various versions of an education problem. A meta study analyzes the results, attempting to discern results that others can build upon. However, what one typically finds is that the problem being studied is so complex and involves so many variables that no clear-cut solution emerges. We pose such problems as “What is the best way to teach a child to read?” At the same time that we know that a combination of nature and nurture makes every learner different. Thus, education problems are not solved once and for all. Moreover, changes in technology lead to changes in possible solutions to educational problems.

Thus, my career as a researcher in mathematics and in education feels somewhat schizophrenic. My father was a research mathematician. One of his favorite statements was, “Either it is or it isn’t.” Fuzzy logic had not yet been invented back in those days. Fuzzy logic is now important in mathematics, engineering, and other fields. It helps to describe our research findings in education.

My career as a researcher is thoroughly intertwined with those of a large number of master’s and doctorate students. In 1970, I created this country’s second master’s degree program in the field of computers in education. In 1971 a student asked me if the University of Oregon offered a doctorate in that field. After a brief discussion with Keith Acheson, a math education colleague in the College of Education, we decided the answer was “yes.” I think it was more than ten years before the Dan of the College of Education realized that such a new program had been created and was graduating a large number of students. I have been the major professor or co-major professor of about 75 doctoral students in this field (along with five in mathematics). By and large I have been able to work with whatever area of interest the students have had. Thus, I have had the opportunity to work in a huge number of different aspects of the field of computers in education.

**Computer Science**

I was one of three people who worked together to create the University of Oregon’s Computer and Information Science Department in 1969, and I served as chair of the department for its first six years. In those days I believed strongly in the importance of computer and information science and such topics as computer programming, artificial intelligence, computer graphics, and information retrieval. Although I didn’t have any undergraduate or graduate coursework in these areas, I eventually learned enough to teach a variety of such courses.

During those years, a colleague of mine suggested that the single most important ideas that were coming out of computer science in the 20th Century were effective procedure and procedural thinking. A computer program can be thought of as being an effective procedure, even if it contains bugs and fails to solve the problem it was intended to solve. Procedural thinking is the type of thinking that one uses when developing computer programs and in making use of computer programs to solve problems.

The early master’s degree and doctorate computer in education programs at the University of Oregon required a substantial amount of computer and information science coursework. There was a considerable emphasis on the ideas of effective procedure and procedural thinking. I considered that to be one of the strengths of the programs. A number of my doctoral students went on to hold positions in Computer and Information Science Department.

To a large extent, this emphasis on computer science has disappeared from both the University of Oregon programs and from computer in education programs throughout the country. We are producing ICT master’s and doctorate students who tend to have very little knowledge in the field of computer and information science. This saddens me.

**Science of Teaching and Learning (SoTL)**

In recent years I have become quite interested in the Science of Teaching and Learning (SoTL). Branford et al. (1999) and Bruer (1993) provide excellent summaries of this field. Bruer’s 1993 book contains an example that resonates with me and helps to illustrate what SoTL means.

One of my earliest memories is of my parents doing some gardening in our backyard, and my father asking me a question somewhat like “What is 9 plus 14?” I had no idea what the answer might be, or how to solve such a problem. A few minutes later, however, I happened to walk past our picket fence, and it occurred to me that I could answer the question by counting pickets. I “discovered” counting on as a way to solve such a problem. I was so excited that I ran to find my father to tell him my answer.

Bruer’s book contains an example of research suggesting that perhaps one-third of first graders have not discovered or been taught counting on prior to entering the first grade. This is a significant barrier to learning the arithmetic in the typical first grade curriculum. The SoTL intervention was to develop a short unit about the number line and counting on that could be taught to first grade students. Less that an hour of instructional time was required to make a significant difference in the math education of many students who had not previously discovered or been taught these ideas.
This research result and educational intervention illustrates a very important idea. Think for a moment about whether each first grade teacher is able to determine which, if any, of his/her students would benefit by such an intervention and has the knowledge and skills to implement the intervention. We immediately see a major problem in our efforts to improve education. How can we “bring to scale” our educational research findings? How can we translate good research results into widespread practice?

For the most part, we are not successful in doing so. The difficulty is that teacher knowledge and skill cannot be mass produced and mass distributed. Over the years I have done lots of staff development, written books and articles on staff development, and taught both courses and workshops on staff development. It is clear to me that staff development is a critical component of improving our education system.

However, we need better ways to turn educational research into practice. ICT is a powerful aid to doing so. In addition, computers and computerized equipment are contributing significantly to progress in Brain Science. This helps explain my current interests in Brain Science, SoTL, and ICT in math education (Moursund, 2002).

Intelligence

Howard Gardner’s 1983 book on Multiple Intelligences had a significant impact on my thinking about teaching and learning. Both my father and mother taught in the Mathematics Department at the University of Oregon, and my father served as head of the department for about 30 years. It is clear that my father raised me to be a mathematician. My report card from early in the first grade indicated: “Now that we have hit numeration, David really shines.” It turned out that the combination of nature and nurture facilitated my getting a doctorate in mathematics and achieving some level of success as a research mathematician.

I have a reasonably high level of logical/mathematical intelligence from Howard Gardner’s Multiple Intelligences point of view. However, my spatial intelligence is below average. Spatial intelligence is considered to be very important for success in mathematics. But, my other talents, supported by our formal and informal educational systems along with intrinsic and extrinsic motivation, allowed me to achieve success as a mathematician. I find this particularly interesting as our educational system continues to label children and pigeonhole them. The tests that I State of Oregon vocational tests that I took during my senior year of high school indicated that I should not seek a career in mathematics.

Of course, I heard about the idea of IQ long before I graduated from high school. But it was only when I ran into Howard Gardner’s first book on Multiple Intelligences that I began to take a serious interest in this topic. The following definition appears in Moursund (1996, 2001) and is synthesized from the work of Howard Gardner, David Perkins, and Robert Sternberg.

Intelligence is a combination of the ability to:
1. learn. This includes all kinds of informal and formal learning via any combination of experience, education, and training.
2. pose problems. This includes recognizing problem situations and transforming them into more clearly defined problems.
3. solve problems. This includes solving problems, accomplishing tasks, and fashioning products. It involves creativity and higher-order thinking skills.

I find that this definition works well both in being a teacher and in being a computer-using educator. For example, ICT is a powerful aid to solving problems. Thus, part 3 of the definition allows me to argue that computers make us more intelligent. In addition, ICT contributes SoTL.

Problem Solving

In this document, I use the term problem solving in a very broad sense. Thus, it includes activities such as accomplishing a task, making a decision, answering questions, and solving a problem.

Problem solving has been a unifying theme of my professional work (Moursund, 1970). In my teaching and writing I make frequent use of the diagram of Figure 2.

![Figure 2. Aids to problem solving.](image)

The central focus in Figure 2 is a 1-person or a multi-person team that wants to solve a problem. This team is assisted by Mind Tools, Body Tools, and the formal and informal education of the team members. This education includes learning to make effective use of the Mind and Body Tools as well as the (human) members of the team. Thus, we have a clear representation of three areas for focus in improving the capabilities of a Problem Solving Team.
ICT provides us with improved Mind Tools, Body Tools, and Education. Moreover, ICT is an aid to integrating these three aspects of problem solving. For example, a Mind Tool or a Body Tool can contain Intelligent Computer-Assisted Learning (ICAL) that "just in time" can help members of the Problem Solving Team learn to use the tools. If the ICAL is sufficiently intelligent, the instruction can take into consideration the specific problem to be solved. We see this in contextual help being built into software applications.

One of the key ideas in problem solving is building on the previous work of others and the previous work of oneself. Throughout my professional career I have studied, written, and taught about problem solving. One of the points that I stress is that ICT provides a new way to build upon previous work. Some types of previous work can be stored in a "The ICT system can do it for you." form. ICT has allowed us to accumulate a huge number of computerized procedures and automated machines that can automatically solve certain types of problems.

Our educational system is severely challenged by the pace of progress in these aspects of ICT. Much of our formal education still focuses on having people learn to do things that ICT systems can do much better than people. Some of this teaching and learning effort should be moved into domains in which people far outperform computers. I often use Figure 3 in discussing this idea in my teaching and writing.

Areas in which ordinary people can readily outperform ordinary ITC systems.

Areas in which ordinary ITC systems can readily outperform ordinary people.

Areas in which people versus ITC systems is a major issue and/or where the two together readily outperform either alone.

![Figure 3. ICT versus people in solving problems.](image)

I am particularly interested in identifying teaching/learning situations in which an ITC system can readily outperform a teacher. A simple example is the contextual help that is built into a computer application. A teacher with a classroom of students—each using different components of a computer application and/or different applications—cannot compete with this steadily improving computer capability.

I will close this section with a story from my graduate school days. I was taking a course in Complex Variable, and we were using a text written by the course instructor. However, the professor kept giving us really hard homework problems that were not in his book. Finally, a student got up the courage to ask where these problems were coming from. The answer was that these were research problems from papers published about 30 years earlier.

A little thinking about this helped me decide to do my dissertation work in Numerical Analysis. The recent advent of computers made it possible to pose and address new problems. At the same time, it made it possible to solve old problems in new ways. In some sense, I could skip over much of what had been done in the past, moving directly to the frontiers.

This idea, of course, applies to all areas of human intellectual endeavor in which an ICT system is a powerful aid to representing and solving problems. It helps explain why many young people—often without advanced college degrees—have been so successful in the ICT field. They used their brainpower and the new tools to solve new problems, rather than spending so much time and effort learning to solve problems that had already been solved. Readers of this document may want to do some introspection about their own lines of scholarly activity!

Cost/Benefit Analysis

Figure 4 portrays the balance between some of the obvious costs and benefits of making use of ICT in one's professional and non-professional activities.
At a conscious or subconscious level people make decisions all of the time about how to use their personal resources such as money and time. This simple diagram helps explain why many teachers are not making significant use of ICT in their classrooms and in their other professional work. They face a severe shortage of time. Their perceptions of potential benefits to themselves and their students are not sufficient to tip the scale to the right.

I can think of numerous personal examples in which I have made conscious or subconscious decisions that might be analyzed from a cost/benefit point of view. For example, I know that I am relatively inept in dealing with computer hardware and software problems. The time and effort to gain the needed knowledge and skills is not forthcoming. Fortunately for me, my wife is highly skilled in this aspect of ICT.

Thinking along these lines led me to write about Compelling Applications (Moursund, October 2000) of ICT in education. These are applications that are so intrinsically motivating and intrinsically valuable to a teacher (or to someone else faced by the cost/benefit decision) that the scale is heavily tipped to the right. Most teachers are not finding many Compelling Applications.

Learning and Learning Theories

I have no recollection of ever having heard about transfer of learning or about any learning theory other than behaviorism during my K-20 education and early years as a university faculty member. In retrospect, this makes a strong statement about our education system. What do we know about learning and learning to learn? Why don’t we place more emphasis on this topic in each course that students take? I would think that a math teacher would know quite a bit about how to learn mathematics and would share this knowledge with his/her students. But, I don’t recall ever receiving any explicit instruction in this area.

I recall being rather impressed when I first learned about Near Transfer and Far Transfer. But, this “theory” doesn’t seem to be very useful in teaching and learning. I was far more impressed when one of my doctoral students worked on Low Road and High Road transfer. This theory seems relevant to teaching and learning. It helps explain why rote memory approaches to education don’t work very well, and why teaching a computer application such as a word processor at a keystroke level is not a good approach to facilitating learning that transfers.

In more recent years, one of my doctoral students did his dissertation on cognitive learning theories. I have learned that Constructivism and Situated Learning are all quite important in the field of ICT in education, and that there are many other learning theories (Cognitive Science: Online).

Figure 5 is a model of how a typical person learns to use a Mind Tool or a Body Tool. It is a “learn by doing” model. This model is supported by Constructivism and by Situated Learning. Our formal educational system does only a modest job of following this model. People learning ICT on their own or on the job typically follow this model.

The teaching/learning model in Figure 5 is highly dependent on the individual learner obtaining feedback on when more learning may be needed. This feedback may come from self, peers, teachers, the tools being used, and so on. As more instructional intelligence is built into ICT systems, more feedback—as well as more contextual, just in time instruction—will occur. In ICT, aids to learning include peers, teachers, oneself, ICT systems, books, reference manuals, and so on. Learning from one’s colleagues and fellow students is quite common.

Intelligent Computer-Assisted Learning

When I first encountered the Computer-Assisted Learning (CAL) work being done by Pat Suppes in the 1960s, I couldn’t help but laugh. Very expensive computer systems were being used to teach students to do paper and pencil arithmetic. The computer system “knew” how to solve the problems that it was helping students learn to solve. Moreover, even in those days the computer was thousands as times as fast as students, as well as more accurate, at doing arithmetic. Handheld calculators were beginning to be reasonably priced.
However, over the years my attitudes about and approach to CAL have changed. Here are a few reasons for my changing attitude:

- Research on individual tutoring, small class size, and individual education plan (IEP) points to potential changes that could greatly improve the effectiveness of our educational system.
- Studies, meta-studies, and a meta-meta study on CAL suggest that in a wide variety of settings, even CAI of modest quality can produce better learning gains than typical whole class instruction.
- Microworlds, computer simulations, and virtual realities have moved CAI well beyond the behaviorist drill and practice approach to learning.
- Significant progress is occurring in Intelligent CAL (ICAL). This entails increased machine understanding both of the materials to be learned and of the learner. We are beginning to see a significant number of examples of ICAI systems that can out perform a classroom teacher working in a whole class setting. Indeed, some can out perform an individual tutor. See, for example, Fast ForWord’s use with sever speech delayed children and with people receiving cochlear implants (Scientific Learning Corporation).
- The cost effectiveness of CAL and ICAI continues to improve both because of research and because of continued rapid decreases in the cost of computation and telecommunication.

During all of the years since first encountering the work of Pat Suppes, I have held onto my amusement about using a computer to teach a person to compete with a computer. In many cases it makes far more sense for a person to learn to use the ICT tools, and then for the person and ICT tools to work together (see Figure 3).

Here is an example of what I mean. Handheld ICT systems (including cell phones, calculators, palmtop computers, etc.) are now small enough, cheap enough, rugged enough, and useful enough so that many people find them and their applications to be compelling. Such devices have had a significant impact on the world. And, of course, the ICT systems need not be handheld. Wearable ICT systems and implanted systems are alternatives. But, they have had minimal impact on education (Center for Highly Interactive Computing).

Distance Education

Over the past two years I have served on the Oregon Department of Education’s K-12 and K-20 Distance Education Committees. In addition, I currently have a student doing her dissertation on Distance Education. My experience in this field goes back about 50 years. My parents ran the math education correspondence courses for the University of Oregon. I began grading correspondence course lessons about the time I finished the ninth grade. In more recent years I created some Distance Education courses for the International society for Technology in Education and made use of them in the UO master’s and doctorate programs.

Last year it occurred to me that all education is distance education and all learning takes part in a person’s head. From a teaching point of view, the issue is how distant the education is, and how interactive it is. A hardcopy library may be both distant and not very interactive. A large lecture course is rather distant and not very interactive. A small seminar is better than a large lecture both because of the smallness and because it allows a high level of interactivity. A contextual help feature in a computer application is not very distant and may be highly interactive. (Note that much of the interaction may be trial and error on the part of the learner, with feedback coming from the machine and the learner.) We all agree that one of the goals of education is to help students to gain expertise in being an independent, self sufficient, intrinsically motivated, lifelong learner. This was true well before ICT came on the scene. But, ICT adds Some new dimensions. I see this in my own life. For all practical purposes, I cannot read email without also being on the Web. Many of the messages I receive lead me to looking up stuff on the Web so that I will have a better understanding of the messages received and of the responses I want to send.

Moreover, I find the build in dictionary and thesaurus in my word processor to be excellent examples of Distance Education. They provide me with just in time instruction.

The point I am trying to make is that that most people nowadays think of Distance Education in terms of entire course being delivered over the Internet, over a two-way video network, over TV, or via video tapes and disks. But, the size of the desired unit of instruction is often much smaller than a course—it might well be instruction on the definition or spelling of a word. ICT can help move our educational system toward Distance Education being an integral, every minute component of teaching and learning. As we move our education system in this direction, we can place significantly increased emphasis on the learner becoming increasingly responsible for their own learning.

Computational Science, Social Science, Etc.

I first encountered Computer Algebra Systems while I was still in graduate school. In the 1960s and 1970s quite a bit of work occurred on developing artificially intelligent computer systems that could solve a huge range of math problems. In essence, discipline-specific knowledge and skills is built into the ICT system.

In the 1980s and continuing to the present such work has blossomed. For example, the 1998 Nobel Prize in Chemistry went to a pair of Computational Chemists for work they had done during the previous 15 years or so.
The change in the sciences is clear-cut. We now have Computational Biology, Computational Chemistry, Computational Mathematics, Computational Physics, and so on. Scientists now tend to be classified as experimental, theoretical, and computational. In all fields of science, Computational Scientists are helping to push the frontiers.

But, this pheromone is not limited to research in the sciences. We have seen major changes in the Mechanical Drawing and Graphic Arts curriculum due to ICT. We have also seen major changes in certain parts of the business curriculum. We have seen scientific and graphing calculators become commonplace in math and science courses. Indeed, students are now allowed to use calculators on some state and national tests.

Still, we have a very long way to go. Take a look at Figure 6. I use this figure in discussing educating in a variety of disciplines. For example, our current K-12 math curriculum appears to place about 75% of its time and effort on students learning to do Step 2. This is, of course, the step that ICT systems do best. If we merely cut this component of math education to 50% of the curriculum, that would allow a doubling of the time spent on problem posing, problem representation, mathematical modeling, meaning making, interpreting the results, and other higher-order processes in math education.

Figure 6. Using Computer Model/Simulation to solve a problem.

I like to think about "profound" issues such as allowing students to use a full range of ICT facilities when learning, doing seatwork and homework, and taking tests. Of course, this topic has been addressed in a variety of science fiction stories that I have read. Indeed, I have found that science fiction has provided me with many interesting ideas. Recently I read Kingsbury (2001), a novel that extends ideas from Isaac Asimov's "Foundations" books, and includes a major focus on people having external computers wired into their brains. I have begun to think of some of my Websites as being parts of my auxiliary brain.

Closely related to this is my contention that each researcher should be developing a Website in which they share their steadily growing expertise with the world. I think of this as an expanded or extended Professional Vita designed to help oneself and others.

Project-Based Learning and Other Books

Earlier I have indicated that "Don't reinvent the wheel." Is one of the most important ideas in problem solving. At the same time I have suggested that in certain cases one might skip over or touch upon quite lightly what is already known in a field. These two ideas seem somewhat contradictory. But, they shed some light on one of the major activities of my professional career.

I write books. This began with my initial teaching at Michigan State University when I repeatedly taught an introductory numerical analysis course for juniors in Engineering. I did not find a book that reflected my newly-learned ideas in this field—ideas that assumed that students would have good access to powerful computers and would learn how to write programs in FORTRAN. So, I enlisted the help of two of my colleagues and we wrote an introductory numerical analysis book (Moursund and Duris, 1967).

Since then I have written a lot of books, some individually and some with coauthors. In most cases what I did was to write a book for a course I was teaching. I would find that the existing books did not adequately reflect my thinking about and approach to the course. I would prepare extensive handout materials during the course, polish them into a draft book, use it the next time I taught the course, and eventually end up with a publishable book.

Perhaps the key to all of this was my feeling that I was "ahead of the curve." That is, I felt that my ICT knowledge and skills in education were at the frontiers. Thus, I believed that whatever I taught should be put into book form, published, and shared with others.

An Example: ICT-Assisted Project-Based Learning

Project-Based Learning (PBL) has a long history, going back to Dewey and earlier. Research supports this as an effective mode of instruction. I can still recall some of the projects that I did in high school.

But, ICT brings some new dimensions to PBL. Thus, it seems "a natural" that in recent years I have written a book in this area, developed courses and workshops in this area, and had supervised a doctoral dissertation in this area.

One of my key thrusts in ICT-Assisted PBL came from a professor in Architecture who was an outside member for a student of mine who did a dissertation on problem solving. At the dissertation defense the Architecture professor asked if I understood the principle of AND. I hemmed and hawed, trying to think about what A. N. D. might stand for.
that was related to problem solving. Finally the professor explained that Architects solve many problems simultaneously, and often added new problems as they proceeded in solving a problem. For example, designing a fountain for the City of Springfield included addressing the idea that the name of the town came from the fact that there were springs in a nearby field. AND, this region was a center of logging, so the fountain should capture this idea. AND, this was one of the early towns in Oregon, so the fountain should capture a pioneering spirit. And...

Now, apply the idea of AND to anything that you teach. As you become more skilled in a course area, you find more and more ideas that you can weave into the course. This helps you move up the expertise scale (see Figure 7). I use such an expertise scale in discussing roles of ICT in teaching and learning. ICT is a powerful aid to helping a person move up the expertise scale in areas of personal interest.

![Figure 7. A general-purpose expertise scale.](image)

Now, think about PBL and ICT. It is possible to use PBL in essentially any course. AND, at the same time, students can be learning and using ICT. AND, at the same time students can be gaining skill in cooperative learning, self assessment, peer assessment, problem posing, and so on. AND, a teacher employing ICT-Assisted PBL can be learning ICT, authentic assessment, a wide variety of subject areas, and so on.

A year ago I was asked to do a workshop on ICT-Assisted PBL. This was to be done in a hands on environment, making use of a wireless network. Wow! An opportunity to develop a new type of workshop, and hence a new book. This time, however, I decide that the book should be interactive and made available on the Web. This was my first endeavor in writing a "never ending" book. When the muse hits me, I add to and revise the book. Whenever I do a workshop on the topic, I tend to make significant additions to the book (Moursund, 2001).

**Current Project: Math, Brain, and ICT**

This past summer I did a workshop with two of my long time colleagues. The workshop was for inservice provides who provide workshops and courses for the Math Learning Center, a non-profit organization located in Portland, Oregon (MLC). I have served on the Board of this organization since its inception in 1976, and I have been Chair of the Board from time to time. The 1.5 day workshop was done by:

- Dr. Gene Maier, who focused on his lifetime learning in math education, with special emphasis on Visual Math.
- Dr. Bob Sylwester, who focused on recent finding in Brain Science and their education implications.
- Dr. Dave Moursund, who focused on roles of ICT in math education.

After the workshop was completed, I reflected about what it had covered and its overall success. It soon dawned on me that the workshop provided a good starting point for my next project. Thus, I am now working in the area of Math, Brain, and ICT (Moursund, 2002). I applied to do workshops on this topic at three different conferences, and I began work on a Website to support my studies and workshops. The workshop, as well as the overall combination of topics, provides a great environment to practice AND.

**Final Remarks**

Some of you may have heard the foul rumor that I am moving toward retirement. The University of Oregon allows a faculty member to work one-third time for five years as a phase in to full retirement. My current intent is to begin this five year plan starting this next fall.

Meanwhile, I am trying to develop hobbies and other activities that will help to keep me active and involved over the next decade or so. I hope to continue to come to conferences such as this, doing presentations and workshops. I hope to continue to do consulting, lending my advice even when it is not asked for.

AND, I have made a major commitment to a new non-profit organization, the Oregon Technology in Education Council (OTEC, 2002). Currently I am serving in the volunteer positions of being Chair of the Board and the Web Master. This environment requires me to read widely and communicate with a lot of people. It also allows me to write almost anything that I want to write, and to have an immediate audience. I believe that you and some of your students will find this Website to be quite helpful to your work and learning.

Beth Schneider, Museum of Fine Arts, Houston, Education Department bschneid@mfah.org
Sara McNeil, University of Houston, Instructional Technology Program smcneil@uh.edu
Donna Odle Smith, University of Houston, Instructional Technology Program odlsmith@uh.edu

Abstract: The Museum of Fine Arts, Houston (MFAH) and the University of Houston (UH) have collaborated on the design and development of multi-faceted web sites related to both permanent and traveling exhibitions at the museum. Stakeholders from the museum and the university describe the web sites and their various educational resources, including multimedia games and activities for K-12 students. The authors discuss the collaborative efforts from their individual perspectives, including the UH Instructional Technology program, the UH Art Education program and the MFAH education department. The paper also includes an examination of the development of online educational resources for K-12 teachers and students and describes how students and instructors in two graduate IT courses participated in this partnership. The paper includes an overview of the role of technology in art education in general and in art museums specifically to suggest the importance of context in the development of art educational materials.

The University Perspective—Part I: Creating a New Kind of Instructional Technology Course

In the fall of 1997, faculty from the University of Houston (UH) met with representatives of the Museum of Fine Arts, Houston (MFAH) to discuss how the museum could take a small amount of grant funding and develop innovative uses of new technologies that would enhance public access to the arts. Since Instructional Technology (IT) faculty members at the university were searching for authentic and meaningful projects that students could work on as part of their course of study, it was decided that the museum would provide the content that students would use in a web design course. Project-Based Web Design and Development is the name of a graduate IT course which is offered twice a year in the UH College of Education. In this course, students work in small collaborative teams to design and develop online educational resources that the museum wants to make available to a larger audience. Students are challenged to explore authentic investigation techniques and, working with museum staff members, they attempt different creative approaches to presenting museum content online.

The first museum/university collaborative project in which students used content from the museum was the development of a web site for Bayou Bend, the American decorative arts wing of the MFAH. In this project, student designers created the overall appearance and layout of the site. Students worked with museum content experts to develop site navigation, page design, and educational resources to showcase Bayou Bend and its collection. Student teams created searchable databases, produced virtual room tours, and integrated streaming media content into the site. In addition, several students conducted research to evaluate the effectiveness of these technological components as educational resources. The Bayou Bend project is described in greater detail in the paper, A Museum-University Partnership to Develop Web-Based Educational Resources (Robin, Jenkins, Howze, & O'Connor, 2001).

Over the last three years, the structure of the course has undergone significant changes and revisions as the partnership between UH and the MFAH has evolved. First, because the web projects that students create are complex and multi-faceted, they cannot be completed in a single semester. Consequently, the course is now offered in both fall and spring semesters to enable work to continue throughout the school year. This poses a considerable challenge as each new semester brings a fresh group of students into the course that must first investigate the work done in the previous classes and then devise strategies for building upon that
work. We have dealt with this transition from one semester to the next by employing course facilitators who work with each new group of students. The facilitators come from a variety of sources, including graduate students who previously took the course and want to continue working on the project, other faculty members who are interested in the content, and museum staff members. Facilitators are in charge of different components of the web project and they provide guidance and continuity to the new student teams that continue the work that previous students began. One of the interesting effects of working with the museum is that students participate in a cross-disciplinary exploration of such topics as history, geography, religion, economics, politics, and other cultural influences associated with works of art and artifacts, not the typical type of exploration normally found in a web design course.

Another modification to the course is that students from outside the IT program are encouraged to enroll and participate in these museum-based projects. So far, students from both the College of Education's Art Education program and the university's Art Department have enrolled in the course. These students have been extremely helpful to the success of the project and the course. Even though they often do not possess the same level of technical skill as the IT students, their knowledge of art and art education nicely complements the technology expertise of the other students. In future semesters, it is hoped that students from additional programs, such as history and social studies education, will also enroll in the course.

The Museum Perspective

The MFAH has moved slowly into cyberspace. Developed as a pilot project funded by a small grant from the National Endowment for the Arts, the Bayou Bend web site was the first effort of the partnership between the MFAH and the UH Instructional Technology program. Brochures on Bayou Bend's collection, founder, and gardens, and the newly published catalogue American Decorative Arts and Paintings in the Bayou Bend Collection provided important information and images. Also, with access to the Bayou Bend director and curator, UH students and faculty had a wealth of information about Bayou Bend and produced an innovative web site that featured a rich assortment of information and educational resources.

The success of the Bayou Bend project led to discussions between the IT faculty and the MFAH education director about future projects. In all aspects of its programming, the MFAH education department forms collaborations with a wide range of community organizations including libraries, schools, the city parks department and housing authority, colleges and universities, hospitals, and community centers. The education staff recognized the need for a greater web presence and was eager to collaborate with the team of professors and students at the University of Houston.

The next project the collaborators undertook was to develop a comprehensive web site for an exhibition, The Grandeur of Viceregal Mexico: Treasures from the Museo Franz Mayer (http://www.fm.coe.uh.edu). This exhibition from the Museo Franz Mayer in Mexico City consists of approximately 130 works that will travel to the MFAH and two other American venues and present the rich artistic heritage of colonial Mexico during the Viceregal period (1521-1821). The museum education team and faculty from the university mapped out the following components as the focus students would work on over four semesters:

1. A thematic exhibition introduction;
2. Resources for teachers;
3. Interactive multimedia games;
4. A comparison of colonial art from Mexico and the U.S., including a comparison of Bayou Bend and the Museo Franz Mayer and their collections;
5. An historical and cultural timeline;
6. Documentation of a cultural exchange between art students in Houston and in Mexico City;
7. Web-casts of exhibition lectures and symposia.

This latest project presented a major challenge—a lack of readily accessible information about the Franz Mayer collections and few images of the works of art in the exhibition. Museum staff members know that images and texts relating to exhibitions often are not available far in advance. However, the students, who began working on this project in the fall of 2000, and newer classes of students who continued this work,
needed images and content in order to design and develop the basic structure of the web site as well as the content pages and educational resources. At the beginning of the project, the exhibition curator gave presentations to all classes and discussed a small number of works of art for which the museum had slides. The education director was responsible for providing as much information as was available and researching additional background information. Late in the spring semester of 2001, students had access to catalogue essays and entries and a complete set of exhibition images which greatly facilitated the project.

For the museum, this collaboration has built stronger ties between the university and the museum; introduced students to the museum as a resource for learning; provided web site design services; and supported the museum’s commitment to education. The potential of the web site to provide information about the exhibition to a very large audience is of great importance to the museum. The collaboration with the university has further enabled the education department to put its teacher resource center catalogue online, to work with middle school students on a pilot museum web site for kids, and to be a partner in a major grant-funded project developed by UH focusing on teaching American history.

The strength of the partnership, its educational focus, was also its major drawback. Students who worked on the project, with a new class arriving each semester, were a very diverse group with little or no background in art or art history. Progress was often slow and frustrating from the museum’s point of view, although necessary for the students’ learning. In the educational setting of a graduate course, students need to learn to assess their own work and try several approaches before reaching a solution. The museum is both client and teacher, which sometimes becomes a conflicting role. But overall, the project has been a success, as measured by the quality of the web site and the eagerness of students to enroll in the course. In the future, it will probably make sense to focus the partnership on the museum’s own collection for which images, publications, and research materials are readily available and deadlines are not as critical.

**The University Perspective—Part II: Creating Multimedia Educational Resources**

In the second series of IT courses, Collaborative Design & Development of Multimedia, students also worked in collaborative teams, but these students designed and developed multimedia resources using Macromedia Authorware™. Students enrolled in two courses sequentially (fall and spring) that focused on instructional design principles, the application of technology to multimedia design and the use of teams to develop effective instructional initiatives. The challenge for the student teams was to develop a learning module that could be incorporated into the museum web site and presented on a kiosk at the museum.

At the start of the course, students completed an initial assessment of computer skills, multimedia skills and team strategies. In addition, this survey also asked students to rate their multimedia project experience in such areas as designing navigational structures. Students were presented with brief descriptions of projects by the clients and were asked to rank their first, second, and third choices. The second week of class, students were assigned to different teams based on a combination of factors: the skill assessments, the instructor’s knowledge of each individual’s background, and student preference. Teams were given the job of visualizing, designing, and developing a module to meet the requirements of their client. The team that worked on the MFAH project consisted of five members, each with a variety of backgrounds and experiences ranging from K-12 teaching to corporate training.

The fall semester focused on team building and developing competencies in the authoring software that would allow students to complete the project. The team developed ideas and prototypes for the project and presented these to a representative of the MFAH. It took the team several weeks of meetings to develop a plan and direction for their project, and students soon realized that working in a team and trying to develop a piece of software is an intensive process that requires a multitude of skills. By the end of fall semester, the team had decided to integrate all information in short game-like activities. Based on the previous findings of museum visitor attention spans, and of visitor preference for self-directed learning, the activities were designed to be short in duration, with a menu of individual activities so they could be accessible by choice, and in any order.
During the spring semester, six activities were developed along with a finished menu interface with links to all activities. In the Paper Dolls game, for example, users may select any combination of dress and hair taken from portraits from the Franz Mayer and Bayou Bend collections, and drag those components onto a face on the computer screen. When finished, the program displays the visitors' combination, along with an image of the face in its original portrait for comparison. The Concentration game differs from the original in that the matched pairs are not identical but are conceptual. For example, the cocoa cup from the Franz Mayer collection is a match for a teapot from the Bayou Bend collection, because both beverages were extremely important in social gatherings in their respective countries.

At the end of spring semester, seventh graders in a local school district evaluated the six activities using a survey that included questions that might indicate student engagement as well as the efficacy of these activities for conveying museum content. Student endorsement of the interactive multimedia activities was high and indicated that these users preferred this type of activity to merely reading for content. The highest rated activities, Make a Vase and Paper Dolls, were coincidentally the two activities that allowed the participants the highest measure of individual choice and control. Although the formative evaluation testing was carried out in a classroom setting as opposed to a genuine museum setting, the student responses to the interactive multimedia activities seems to align with the literature about visitor studies regarding interactive experiences in museums. The students expected to learn, but they were also interested in playing computer games to reveal the content and enjoyed the delivery method. This experience appears to parallel the literature indicating that museum visitors come to the museum expecting both to learn and to have an enjoyable experience while there.

These prototypes were developed by the team in anticipation of an increasing presence of interactive multimedia incorporated into museum exhibits. The MFAH is still developing new concepts toward inclusion of projects like these in museum education. The team hopes that these activities will lay a foundation toward on-site testing and evaluation and that we will see a continued development toward capitalizing on the growing strength of technology inside museum exhibits.

The Art Education Perspective: How these Projects Fit into Art Education Pedagogy

The Art Education program at the University of Houston has only recently become a formal component of the fruitful collaboration between the MFAH and the IT program at UH. While a few students from the Art Education program have enrolled in the project-based web design course and have been involved in constructing the exhibition web site, the possibilities for further contributions from the field of art education generally and from considerations of technology in art education specifically are yet to be realized. In light of this, this section will:

- detail some of the early involvement of Art Education program students and faculty in the collaborative project;
- discuss briefly recent pedagogical trends in art education and how the museum collaboration reflects these ideas;
- position the technological development of art-related educational resources within recent thoughts on technology use in art education; and
- propose the strength of broadening the university part of the collaborative structure to include content areas.

An art educator was involved in the museum/university collaboration from the beginning in that an Art Education Professor Emeritus became involved in the collaboration by serving as a team facilitator in the early days of the project. Art Education graduate students then participated in the IT course and served as team members under the direction of the Art Education Professor Emeritus. Additionally, the Art Education program at UH, like the IT program, has made a commitment to focus on real-world projects within its course structures, and students in the program have suggested that their learning is increased because of the authentic nature of the intellectual endeavors. Knowing that the research the students conduct and the
lessons they develop will be utilized by area arts organizations and teachers creates a level of motivation that is unmatched by class group projects or other assignments.

In keeping with its commitment to real-world projects, the Art Education program at UH also has a commitment to working with real works of art which further enhances the outcomes for all stakeholders in the museum/university partnership. Because the UH Art Education program subscribes to Discipline-Based Art Education (DBAE) as its theoretical base for learning in the visual arts, working directly with and through works of art in the museum’s exhibition coincides with students’ pedagogical expectations of sound art education. DBAE is an art teaching methodology that considers a holistic approach to the study of art including its four disciplines: art history, art production, art criticism, and aesthetics (Wilson, 1997). Works of art figure prominently in this methodology asking students and teachers to engage with a work of art in a variety of ways prompted by the strands of DBAE. For example, students expect to consider the art historical provenance of an 18th century portrait and also ask aesthetic questions about the difference between oil paintings and photographs. Art Education students well-versed in these kinds of pedagogical ideas bring depth of content and multiple layers of experience to the courses and the collaboration.

One of the best ways to address the always expanding depth of content and the forever bifurcating layers of experience within the visual arts is through the appropriate use of technology. Art education has embraced technology as both an important art medium and an important forum for considering art virtually. Digital imagery in the art classroom is a 21st century venue for seeing and discussing art. New communication technologies and digital media are changing the practices of making, understanding, and responding to art (Bruce, 2000). The computer age has created a shift from the textual to the visual. Pedagogy of visual pragmatism acknowledges the informal curricula of the World Wide Web and values individualized learning recognizing that the education audience is larger than K-12 teachers and students (Stafford, 1998). The Electronic Media Interest Group of the National Art Education Association has as its expressed goal to promote informed and responsible applications of media and technology in art education, and over 50 sessions at this year’s national convention of art educators have a technological focus ranging from using basic technology in the elementary art classroom to considering the museum as a hypertextual narrative.

Conclusion

In extending the museum/university partnership beyond the IT component to include Art Education faculty and students, the collaboration grows in depth through the various layers that the different content areas and viewpoints add to the partnership. Expansion of new projects and the addition of even more content area experts and students will also increase the number of beneficiaries of this endeavor. The partnership has not been without its share of problems and frustrations, it seems almost inevitable that differences of opinion will result with this many creative stakeholders involved. But this model for creating a museum/university partnership has been worthwhile for the museum educators who are learning to harness the power of the web, for the students who are learning to create real-world technology projects while working with actual clients, and for the faculty who are learning to transform their courses into exciting new learning environments that are more challenging and more educationally meaningful than ever before.

Abstract: This paper reviews the first stage of a technology initiative to assist K-12 teachers in developing Web projects that integrate K-12 curriculum content and the collections of the National Gallery of Art. A select number of these projects will be made available on the Gallery's Web site (www.nga.gov). While the Gallery has offered education resources through the Web site since its inception in 1997, this program marks the first significant effort to provide online teaching resources designed by K-12 educators. The program's goals, design, and evaluation objectives are summarized by the two staff members primarily responsible for its conception and planning.

Program Goals

As an art museum with a national mandate, the Gallery has produced distance learning materials since opening its doors to the public in 1941. Films, slide programs, teaching packets, CD-ROMS, and videodiscs have long been available to teachers and other adult audiences on a free-loan basis. The establishment of the Gallery's Web site in 1997 brought more immediate, versatile, and dynamic means through which to foster awareness of the visual arts and make the Gallery's collections widely accessible. Exhibition literature, teaching packets, lessons and activities, and interactive virtual tours are among the many educational resources available through the Gallery's site (www.nga.gov).

This two-year technology initiative (2001-2002) was conceived as creative way of extending our distance learning resources and thus continuing to serve those educators without firsthand access to the Gallery's collections. It was also conceived as meeting teachers needs in the following ways:

- pertinent resources: by having the teachers develop these online projects, they would better match K-12 curriculum content and the more practical considerations of classroom instruction or independent research
- learner-driven models: with their potential for interactivity, online projects would be viable in a school setting favoring learner-driven or constructivist education models
- enhancement of skills: charged with conceptualizing and building their own Web-based curriculum projects, teachers would enhance their skills and encourage the use of online technologies

Instructional Design and Resources

Twelve three-member teams were selected from approximately seventy applications, based on the strength of proposed curriculum projects. (Successful team applicants were those with creative topics that could be taught using works of art in the Gallery’s collections). Six teams came to the Gallery for a week-long seminar in July 2001; the other six received the same instruction in August 2001. During the program, teams worked with education and computer technology specialists to begin developing the content and storyboards for their Web resources. Instructors were Gallery staff and outside experts in art, education, and instructional...
technologies. The course of instruction was sequenced to help teachers explore the potential richness of online resources, analyze and critique select sites focused on art and education, and establish criteria for high-quality Web-site content and design before beginning to build their own projects. Toward this end, teams were asked to prepare for their week in Washington by studying and critiquing a preselected list of Web sites and by reading two books pertaining to online curriculum design. One book (Harris, 1998) was chosen to provide a general introduction to the different types of online projects that might be designed, depending on content objectives and desired outcomes. The other publication (Williams and Tollett, 2000) addressed design issues. This preparatory work allowed participants to arrive at the Gallery with shared knowledge and a framework for group discussion.

During the seminar, teachers were offered training in HTML and Dreamweaver, and were given packages of software with which to develop their projects (Adobe Photoshop 6.0; Macromedia Dreamweaver 4 with Fireworks 4 Studio; and Inspiration 6). Teams also learned more about the Gallery's permanent collections and which objects might best support the content of their online curriculum project—be it related to math, music, Renaissance history, or autobiographical writing—to name just a few of the subject areas chosen. At the end of the week, teams gave brief presentations on the direction of their projects. Each team had a clearer focus for their work, with a better selection of possible works of art and resources to support their theme.

Upon leaving Washington, teams were charged with continuing their collaboration through the completion of their Web projects in April 2002. To support their work in the interim, each team was assigned two mentors with whom to consult about either the content or the technological development of their projects. A listserv was established to facilitate communication with, and among, the groups. In addition, teachers had access to a password-protected Web site that offered easy reference to project guidelines and deadlines, links to educational resources, mentors' and colleagues' names and email addresses, and separate work folders for submitting the individual stages of their projects (Fig. 1).

![Figure 1: Home page of the password-protected Web site designed to support teachers during the design and construction of their online curriculum projects.](best_copy_available)
Team Commitment and Application Process

Educators were asked to apply in teams of three and to submit a joint statement outlining their collective qualifications and the Web project they would develop if selected to participate. They were not required to be from the same school, but had to agree to collaborate with their teammates for the eight months needed to conceptualize, build, field-test, and finalize the project. It was recommended that team members possess different areas of expertise, each of which contributed to their particular curriculum topic. Individuals selected to participate received a stipend of $1,000 with an additional $500 payable on completion of their team's online project.

The successful teams were those demonstrating sophisticated computer and Internet skills, experience with curriculum development, and commitment to teaching through online technologies. Priority was given to creative topics that made meaningful use of the Gallery's collections and targeted a specific grade (or age group), subject area(s), and national standards for K-12 curricula. (Information and an application for the 2002 program can be found at www.nga.gov/education/cyberworkshop.htm.)

Evaluation

Evaluation of the 2001 and 2002 programs will seek to measure achievement of two objectives: 1) providing useful Web resources for K-12 educators, and 2) increasing Institute participants' skills and comfort levels using online technologies. Useful Web resources are defined as those published and used on the Gallery's Web site, and those remaining unpublished but actively used in the classroom by their creators. Evaluation will assess both content quality and usability of sites. Methods employed will include direct observation of site use (by either teachers or students, depending on the intended audience), and interview sampling techniques designed to gauge user reaction to content and navigability.

Questionnaires will also be used to solicit participants' affective, or attitudinal, responses to the program and the process of building the Web projects. The first of these, available online at the password-protected Web site, asked participants to evaluate the instructional design of the week-long summer seminar and how well it prepared them for the task of conceptualizing and building their curriculum projects. Participant response to this initial survey was 40 percent.

National Technology Leadership Initiative Fellows Panel

Lynn Bell, UVa, US

NTLI Fellows

As part of a larger initiative to facilitate interactions among teacher education faculty from different content areas and disciplines, SITE and the teacher educator associations from the core content areas have established the National Technology Leadership Initiative (NTLI) fellowships. The Association of Mathematics Teacher Educators, Association for the Education of Teachers of Science, the Conference of English Educators and the National Council for the Social Studies College and University Faculty Assembly have joined SITE in sponsorship of a technology leader from each content area. The NTLI presentations at this year’s SITE conference will feature an exemplary paper in each content area – science education, mathematics education, English education and social studies education.

CITE Journal Editors Panel

Editors from each of the sections of the online journal, Contemporary Issues in Technology and Teacher Education, will discuss the goals of the journal and recommendations for publication of articles. Journal sections represented include mathematics education, science education, social studies education, English education, and educational technology. Editors will consult with prospective authors.
As we began to put together this year's *Concepts and Procedures* section, we were struck with two observations: first, the number of selections has increased dramatically, and second that the topical coverage in the section is more varied than ever.

Several themes emerged in this year's selections. One cluster of papers deals with concept mapping, visualization, and knowledge representation. A paper by Robert Jones, Caroline Crawford, Ruth Gannon-Cook, and Jan Willis all from the University of Houston-Clear Lake analyzes concept patterns found in textbooks. A selection by Marino Alvarez, Michael Busby, Geoffrey Burks and Goli Sotoohi from Tennessee State University, entitled "Exploring Minds Electronic Network, describes the use of the "interactive V diagram" to encourage monitoring, reflection, and critical thinking. A Tennessee State colleague, Charles Dickens, has a paper entitled "Metaconceptualizing Knowledge: The Challenge for Teacher Education. In a somewhat different vein, Victor Kasyanov from the Ershov Institute of Informatics Systems in Novosibirsk describes the use of graphs for visual presentation of "complex and intricate" information.

Issues of equity and ethics form a second cluster. In "Technology overload: Are we meeting the needs of the individual student," Steve Jenkins, Cathy Lott, Walter Buboltz, Jr., and Lamar Wilkinson from Louisiana Tech note the challenge that emanates from the increasing demands of technology proficiency on the part of employers and educators in the typical college setting where only half of each freshman class owns a computer. In a provocative essay, Robert Bruen from Babson College discusses the paradox that increased attention to issues of computer security in our courses may have the unintended impact of increasing computer incursions.

Distance Learning was another topic that generated multiple submissions. No fewer than six papers deal with serving the needs of off-campus students. One submission by Robbie Melton of the Tennessee Board of Regents describes their on-line degree programs. Ken Stevens and David Dibon from Memorial University of Newfoundland discuss the need to train teachers to work effectively with geographically separated students. Assessment in on-line learning works its way into several papers and is the central topic for a paper by an international team of C.Y. Janey Wang from the University of Texas at Austin, Rafael Cota and Guillermo Espinoza from the ITESM Institute in Mexico. In their paper Wang, Cota, and Espinoza present rubrics as a framework for evaluation. Two selections study outcomes in traditional and on-line instruction. Yuejin Xu from the University of Alabama examined transcripts of on-line discussions and contrasted them with face-to-face class discussions that were videotaped. The study examined levels of student contribution as well as an analysis of style, grammar, and sentence structure in both modalities. The same author collaborated with Asghar Iran-Nejad to examine whether one modality is more likely to change student learning perceptions than the other. Finally, Joanne Pelletier, Margaret Brown, and Gregory McKinnon from Acadia University expand upon their earlier work on cognates, a macro-based coding system for interactive discussion.

Several papers focus on web site design, web site and multimedia design tools, and evaluation of web sites. Included in this section is a paper by Jean-Marc Laubin from the University of Valenciennes in France on teaching multimedia design using what he terms a "tri-component model." Terence Cavanaugh of the University of North Florida discusses web site design features to insure that disabled persons are appropriately accommodated.

Another noteworthy thread consists of two papers by Lamar Wilkinson, *et al.* from Louisiana Tech on technophobia and technostress. In both papers the authors repeat the often-cited observation
that the pace of life is increasing, and with it comes a host of medical and social problems for individuals who find it difficult to adapt. In their paper “Computers, Technostress and Breathing” the authors offer suggestions for breathing techniques designed to overcome the physiological effects of stress.

Finally, in what may be a harbinger of what to expect next year, we saw the first paper on the use of personal digital assistants, in this instance as a data acquisition device. We can only speculate with regard to the educational applications for these devices that are likely to emerge in the next few years, particularly when PDAs are used as access points for wireless networks.

Abstract: Exploring Minds is an active electronic venue for professors, teachers, researchers, and students to reflect, negotiate, and evaluate the teaching/learning process that enables systemic changes to occur under meaningful and thoughtful circumstances. Ideas are revealed in narrative and visual formats through electronic journals, conceptual arrangement of ideas, and V diagrams so that metacognitive tasks such as self-monitoring, reflective and imaginative thinking, and critical analyses is a crucial part of the learning process. The basic premise that underpins Exploring Minds is that the mind deals with meaning and meaning is the basis for conceptual understanding of facts and ideas.

# Exploring Minds Network

Exploring Minds is an educational interdisciplinary project under the auspices of the Center of Excellence in Information Systems, Tennessee State University (http://exploringminds.tsuniv.edu). Exploring Minds is an interactive electronic network that is password protected and contains provisions for teachers, professors, researchers, coordinators, director, and parents/guardians, and students to communicate about their class work and/or research agendas (Alvarez, 2001). The network contains several interactive tools for posting journal entries, constructing hierarchical concept maps and vee diagrams, and storing information (print and nonprint) in a backpack (portfolio). Exploring Minds is a self-contained system that encapsulates transactions between teachers and learning stakeholders over the Internet interactively.

# Management System

The management portion of Exploring Minds site is divided into five consoles: Director, Coordinator, Teacher, Researcher, and Students. Researchers at TSU's Center of Excellence in Information Systems and those at affiliated
colleges and universities along with teachers and their students manage their own respective students. The Teacher Console enables either the teacher or researcher to assign passwords and usernames, control incoming and outgoing communications between students, and have access to student concept maps, V diagrams, electronic notebook entries, and backpack. Students, once given a password and username by their researcher or teacher are able to construct concept maps, V diagrams, enter notations and thoughts into their electronic journal, notebook, and enter video clips, photographs, journal articles, drawings, simulations, and any other relevant information (print or graphic) into their own backpack or library. Any portion of a backpack can be shared with other students within a given college or university, or school with students at another affiliated colleges, universities, or schools if the researcher or teacher gives permission.

When students want to submit their concept maps or V diagrams for review by their teacher and researchers they submit them directly electronically via the Internet using their account on Exploring Minds. Teachers, professors, and researchers have access to all the features and metacognitive tools available to the students.

Administrative Tools is designed for teachers, coordinators, and director to create, edit, and delete groups (classes) or subgroups within groups with participating members. The Grade Book section permits access to student or participant records of transactions that occur during a semester or year (e.g., assignments, V diagrams, journal postings, etc.). There is also a Profile section where students can change their password and username, enter relevant information (e.g., address, telephone number), and anecdotal information including a photograph. Only anecdotal information is made public and can be viewed by any participant. The Profile allows the teacher, coordinator, or director to access participant records.

Features

Once logged into the restricted section a home page appears that contains newly posted items arranged by group (class). These are messages, journal entries, announcements, threaded discussions, and attachments. Once each message or journal entry is accessed, the teacher or student is taken to the Communications section where the message appears and the option of writing a response that is sent directly to the initiator is accomplished. Likewise if an attached document or V diagram is sent, they are accessed and viewed in the Communications section of the site and can be printed as a hard copy. Every message, once viewed and responded to, disappears from this screen and automatically stored in the Grade Book section under Records. These records are arranged by groups and students alphabetically and each individual's entries can be retrieved by clicking on the name.

A prominent feature of Exploring Minds is a reflective portion containing a journal for students to enter their thoughts and feelings of course content, and an exchange section whereby ideas can be posted and feedback received from professors, researchers, and teachers. Once comments are made and sent back to them, the students then read the response by clicking on the message appearing on the Welcome page. A record (date and time) of each transaction is automatically noted in the students' journal section and also in the journal of the teacher or professor. A notebook is provided to better organize notes taken for a class, a report, or paper. This notebook acts as a storage area and serves the same function as a regular notebook. The difference being that it can be accessed through wireless communication systems such as a laptop computer and information can be gathered from various Internet sources and locations.

Exploring Minds contains an interactive concept mapping component that reveals a visual representation of student thought processes with feedback directly placed on each respective map. A hierarchical concept map is a visual representation of an individual's thought processes. It is a word diagram that is portrayed visually in a hierarchical fashion and represents concepts and their relationships. Students, teachers, and researchers use concept maps as a way to visually display and share ideas using CMap developed at the University of West Florida. Maps developed by participants in our program are stored and accessed on our Exploring Minds server. The V heuristic developed by Gowin (1981) to enable students to understand the structure of knowledge has evolved into an Interactive V Diagram section of the network having a Quick Help menu and a link describing the V components with explanations of the epistemic elements. Also included are instructions for entering information on the V. Information is entered onto the Interactive V Diagram by clicking on the respective field of the arrayed elements and then typing the data. Once the fields on the V template have been completed, the user can review the entries and then electronically submit the information to our base site as an attachment. When received by the teacher or professor, the V diagram is reviewed and comments are made directly on the submitted V. These comments are then sent back by the reviewer to the sender who is then able to read the comments.

A backpack section serves as a repository for student work in progress and contains a files section for importing video, simulations, articles, or any type of pertinent electronic transmissions that is needed by a student. A drawing of the backpack is portrayed with communication, journal, notebook, files, V diagram, and concept map links. These are visually displayed and linked for access.

The teacher has a briefcase from which to navigate the interactive features of the Exploring Minds Network. The features contained in the briefcase that are linked are: grade book, calendar, notebook, journal, V diagram, communications, files, and concept map.

Both the teacher and the student have a study. The study provides a venue by which the teacher creates the reference materials needed for a particular class. Sections of the teacher's library include the files section, reference
documents, photo gallery, electronic journals, URL links to relevant sources, movies, articles, and reports. The students can use access these sources and include them in their own library. These items are then stored in the teacher library for student access and retrieval. Likewise, students can use the study and have their own library to collect information and materials for a project, report, or research paper. In this teacher library the materials and references are displayed for student access and retrieval. By clicking on each respective category a display of the requested materials appears and can be viewed or downloaded. The student library enables the student to categorize pertinent information relevant to a specific work within a class or research project.

Conclusions

Exploring Minds provides faculty with a system to communicate more effectively with their students. In addition to the management features (class assignments, class roll, personal calendar, announcements, grade book functions, and course material), the teacher or professor is able to react to student notebook postings on a regular basis and thereby monitor students’ thoughts and feelings instead of waiting for end-of-the-semester evaluations. These interactive dialogues, together with visual displays of the concept maps and V diagrams, serve to negotiate the learning process and better serve meaningful understanding between the professor, teacher, and students during the semester or school year.

The uniqueness of Exploring Minds is the active engagement that occurs between teachers, professors and their students afforded through the use of the notebook, concept maps, and interactive V diagrams. In essence, teachers and professors are active learners with their students, and facilitate the learning process by guiding students in their inquires, evoking discussions, and involving their students with other affiliated schools whose students may be engaged in similar research/study topics. Exploring Minds provides a learning context that encourages students to think about learning and enables them to learn principles instead of learning prescriptions that they may not understand or partially understand.

Acknowledgements

This paper is supported by the Center of Excellence in Information Systems at Tennessee State University and by NASA through the Tennessee Space Grant Consortium NGT-40021, Network Resources Training Site (NRTS) NCC5-96, and NASA Center for Automated Space Science NCC5-511. Oakwood Systems was contracted to write the programmatic system for this network.

Digital Data: Strengthening the Study of Educational Technology

Savilla I. Banister
Division of Teaching and Learning
Bowling Green State University
USA
sbanist@bgnet.bgsu.edu

Researchers, educators, and businesspeople are engaged in various crusades to encourage or discourage the use of computer technologies in schools. While most of the dialogues in these arenas rely most heavily on the media of verbal and written communication (text), the technologies of the twenty-first century provide other communicative media possibilities, including the use of video, audio, and images, to present and exchange information. An example of a type of research and communication that utilized multimedia technology is examined here.

A year-long study was conducted at a small, urban elementary school, focusing on student and teacher perspectives of computers in their classrooms. Conclusions of the study in traditional textual form were combined with multimedia, CD-ROM technology to produce an interactive compilation of data from the research. An exploration of this product presented during the SITE 2002 Video Festival provided attendees the opportunity to examine this type of inquiry artifact and explore the possibilities embodied in such a process.

Incorporating audio and video data into the research design helped to extend the potential of “thick description”. During the times I have shared images, and audio and video clips with the teachers participating in the study, or colleagues interested in my research, they have been very positive in their responses. Actually hearing the emotion and inflection in a teacher or student’s voice as they share their ideas, or seeing the students working in the computer lab helps to support the written text. I believe these elements contribute to the trustworthiness of this research. The CD-ROM appendix containing a collection of this data can be used as verification for the descriptions presented in the text, and also as a prototype for others interested in incorporating multimedia in their research designs.

The presentation and integration of images, audio and video included on the CD demonstrates how data in various formats can be preserved and made available to the scholarly community. By selected “Audio/Video Data” from the menu on the CD, one can navigate to data examined in Chapters Four, Five, and Six. In the Chapter Four section, one can click on “Peer Tutoring” and watch two kindergarten boys in the computer lab guide each other through a new application. In the same section, an audio clip of an interview with Ms. Roberson contains her explanation of how the kindergarten students “help each other” on the computers. In the Chapter Six section, the audio clip of Ginny describing the emotional and physical pain involved in the class’s keyboarding lessons is included. In these instances, hearing the tones of voice and seeing the facial expressions of the students enriches the descriptions presented in the text. Such representations allow the reader to juxtapose written interpretations with actual scenes and voices from the research site, encouraging critical review.

In the video clip of Mrs. Sprong’s Accelerated Math class work, located in the Audio/Video section, Chapter Five, not only can viewers watch the class process, but they can also see this researcher walking through the room, taking notes. The researched is also visible in the “Centertime” video clip, in the Chapter Four section. Her voice can be heard posing questions on the various audio clips. These examples give the reader a chance to further evaluate the processes used in collecting the data.

Mixing data types can also provide a unique view of a phenomenon under study. In the Audio/Video section of the CD presenting Chapter Five, a link entitled “Printer Problems” is provided. This particular clip combines a time-lapsed video clip of Mrs. Sprong’s AM class during the time when the printer stopped functioning; the audio track paired with the clip contains excerpts from a later interview with Mrs. Sprong explaining what transpired when she attempted to get technical support for this problem. Combining these two elements gives the reader a more powerful view of the frustrations students and teachers experience with technologies.

In these ways, the study is expanded and enhanced with digital data. With more publications embracing the electronic format each year, it is possible that journal submissions could include such digital data for distribution, linked with the written text online. Such provisions have the potential to challenge and deepen critical inquiry.
Learning communities:
a kaleidoscope of ecological designs

Abstract. This panel brings together scholars and educators who have worked for many years on fostering technology-enabled learning communities with an emphasis on classrooms and teacher education. The session will focus on issues of design for learning communities, examining existing cases of network-enabled learning communities in the classroom, the school, and the school of education. One driving question for the presentations and discussions is: "To what extent learning communities can be engineered, designed, fostered, and to what extent they are a complex organic entities that come about and evolve on their own?" The specific perspectives presented are: a) Knowledge building communities in the classroom, b) Learning communities in pre-service teacher education, c) The social infrastructure framework for learning communities, d) A networked learning community for teacher education at the national level; the case of Norway, and e) The school as learning community; Issues of leadership and organizational change.

This panel brings together scholars and educators who have in common the fact that they have worked for many years on fostering technology-enabled learning communities with an emphasis on classrooms and teacher education. A number of features are beginning to emerge from their work, in line with the work of Ann...
Brown (Brown, 1997) and her colleagues. This panel session will focus on issues of design for learning communities, examining existing cases of network-enabled learning communities in the classroom, the school, and the school of education. One driving question for the presentations and discussions is: “To what extent learning communities can be engineered, designed, fostered, and to what extent they are a complex organic entities that come about and evolve on their own”. Because of this tension, our position oscillates between that of the engineer—to build learning communities—and of the ethnographer—carefully observing and documenting a massively complex phenomenon that largely pre-exists and overwhelms the observer. Depending on where we stand along this continuum of positions, we are at times concentrating on what to do to achieve a certain quality of learning communities in teacher education, at other times wondering what conceptual tools are required to appropriate the complexity and quasi-chaotic nature of the learning communities we see unfolding. And what are the desirable and achievable affordances of technology in such a socio-cognitive engineering project? The experiences shared during this panel will illuminate such questions.

1- Knowledge building communities in the classroom. Mary Lamon & Marlene Scardamalia

The knowledge building classroom shares many of the processes of the classroom as a learning community; but it is more concerned with how students advance beyond present knowledge. They do this through the creation of new theories or the improvement of old ones through innovation, testing, and revision of ideas. Knowledge building classrooms, in their search for constructing cognitive artifacts (new knowledge, new representations, explanations), function in much the same way as scientific research teams operate. These research teams aren’t only trying to learn about existing theories, they are trying to advance those theories.

Can you create a knowledge building classroom without information and communications technology? Possibly, but we think that today’s technologies make it possible to teach in new ways—to do things differently or even to do entirely different things. One significant way that information and communications technology makes a substantial difference is that it opens up dialogue within communities for a substantive period: Ideas that are thought of and then forgotten can be revisited, revised, added to, and perhaps risen above (Scardamalia, 2000). In support of discourse that transforms a learning community into a knowledge building community, Bereiter and Scardamalia and their team created software, Knowledge Forum®, a problem-centered collaborative knowledge medium that operates over a computer network (Scardamalia, Bereiter & Lamon, 1994). This computer system, perhaps unlike others, was based on cognitive science and socio-cognitive studies about how expertise develops and grows.

2- Learning communities in pre-service teacher education. Therese Laferriere

Twelve principles emerge from this multi-year, multi-site design experiment to foster and sustain learning communities in teacher education in Canada and
abroad focusing on ICT integration to curriculum and collaborative learning. Designexperiment in four different contexts. Key trajectories of these principles are: from material connectivity to social networking, increased or sustained crossings of institutional and cultural boundaries, and the gradual deprivatisation of pedagogical practices.

3- The social infrastructure framework for learning communities. Katerine Bielaczyc

Focuses on the social support structures that teachers achieve around computer-supported collaborative tools in order to create environments for classroom learning communities. This "social infrastructure framework" allows us to frame and analyze practices that foster learning communities.

4- A networked learning community for teacher education at the national level; the case of Norway. Morten Søby & Vibeke Kløvstad.

Will present the perspective of a national level, with emphasis on the design of web-based tools for the community of innovative teacher education institutions in Norway.

5- The school as learning community; Issues of leadership and organizational change. Alain Breuleux

This perspective concerns the specific case of educational institutions as learning communities. The key institutions that are examined are the schools and schools of education, and their relevant aspects are: A driving purpose and an actively shared vision, a repertoire of practices (in particular intellectual practices and governance practices aimed at building and sharing knowledge), and systems of values and beliefs. The notion of institution includes different levels diverse realities: from the one-classroom school in the village, the school district, the college, the school of education, and emerging new forms of school networks and institutional alliances between the above. A related issue is the connection and desirable alignment between these different types and layers of institutions, with their specific ways of becoming learning communities. Learning communities at the school or school of education levels will be distinct from other learning communities by a focus on organizational change and, in particular, on issues of leadership. Important questions will include: What is the role of institutional leaders in the strategic transition towards learning communities? How can institutional leaders themselves constitute learning communities that specifically focus on building, learning and sharing leadership practices?

Abstract: The explosion and infusion of technology into the educational environment has lead to a multitude of new research tools that are available for conducting research. Personal digital assistances (PDA’s) are one of these new exciting technologies that can lead to research that taps areas and constructs previously unexamined. Additionally, PDA’s may allow data collection that is more instantaneous and focus on the moment when an event occurs. This articles reviews the uses of PDA’s and how it may be applied to various research areas.

The explosion and infusion of technology into the educational environment has lead to a multitude of new research tools that are available for conducting research. Researchers have been using the Internet for the past few years to collect large data sets and explore areas that were not feasible using more traditional research approaches. The continued development of technology has lead to another technological breakthrough, namely, Personal Digital Assistances (PDA’s) that may open many more avenues for research in the educational and other realms. This paper provides an outline of the uses of PDA’s in research and hopefully brings to awareness the potential of PDA’s in research.

The use of PDA’s in research may over time reveal many shortcomings of traditional paper-and-pencil assessment instruments. Research has shown when individuals recall past experiences, people tend to remember peaks of emotional intensity, or the most recent things, or are influenced by the context, or how they feel at the moment they are completing the assessment instruments. With this in mind, researchers that collect data after events have occurred or ask individuals to report about behaviors and experiences in the past may not be getting accurate data. In response to this researchers are calling for a change in the collection of self-report data. Researchers have suggested that two major changes need to be done to overcome these potential problems and influences. One is that researchers need to collect data at the moment, which takes the time factor into account instead of waiting to collect data about that particular moment at some later data. Second, data collection needs to take into account the environment, thus data collection should occur in the environment where the phenomena is occurring. The use of
programmable PDA's may be the research tool that can overcome the shortcomings of more traditional paper-and-pencil data collection.

Personal Digital Assistants (PDA's) have come to market during the past five years as a storm. Initially, only one or two hardware companies made and sold the products. Now virtually every hardware maker, plus several companies that make only PDA's have multiple products on the market. Additionally, as the competition has grown between companies the capabilities and software available for PDA's has grown exponentially. At the current time PDA's are programmable, have expansion slots and can handle large volumes of data. Due to programmability, survey's can be developed for research and the information collected can be downloaded into data sets that can be used for statistical analyses. This is only the tip of the iceberg, the true potential of PDA's in research lies in the ability of the researcher to collect data at various times or intervals. PDA's can be programmed to cue the research participant to fill out a survey on the PDA at predetermined times, or at random intervals during the day. Additionally, the research participant can be instructed to complete surveys on the PDA during or immediately after an event of particular significance. Through the use of PDA's data collection can occur in real-time within the environmental context of their daily life.

The advantage of PDA's is not just limited to research. PDA's may have widespread implications in the educational realm and for the treatment of many problems. In the educational realm students can purchase PDA's or be provided with PDA's as part of a course. The instructor can then provide students with notes, outlines, and reminders when assignments are due. Additionally, the instructor can have the PDA programmed to help students develop a study schedule and on what materials to focus on. The implications in the educational realm appear endless at this point and need further investigation. In terms of treating problems applications can be developed and used to cue individuals regarding their efforts to change destructive habits of thought and behavior. Additionally, the treating professional can provide the individual with a host of information on a PDA that can be used by the individual to reinforce and encourage treatment compliance between actual meetings.

The use of PDA's in research and treatment is not an easy task and several issues need to be address and tackled before employment should be undertaken. First, researchers should ask, is there a more convenient and cost-effective way to collect the desired data. If there is a more cost effective procedure for collecting accurate data, that avenue should be pursued. Second, can the PDA be programmed to collect the desired data. Due to size of screens and internal memory, questionnaires need to be short and concise. In conjunction with this since collection of data may occur continuously or various intervals during the day, the short the questionnaire or data asked of the individual the less intrusive will be the data collection procedure and higher compliance will hopefully results. Third, training be provided to subjects on how the PDA works and what needs to be done to have the subject collect the data for the researcher. If these questions can be effectively dealt with, it may be feasible to employ PDA's in the research endeavor.

Once the decision has been made to use PDA's the researcher needs to program the PDA with the survey's or other instruments that will be displayed. Numerous programs available and it would behoove any research to explore the options available and chose a software package that best fits the need for data collection. After that has been accomplished the time frame for data collection must be established, such as daily, three times a day, etc. At this point the PDA needs to be programmed to provide a reminder to the subject to complete the survey or instruments at the desired times.

With the PDA's programmed and ready to go, the researcher now needs to recruit subjects for the research and train them in the use of the PDA and what will be expected of them in the research process. It should be noted that at this point it necessitates that enough PDA's are available for each subject that will be participating in the research. Once subjects are fully trained and understand the uses of the PDA and what is expected of them it may be beneficial to pilot the data collection process to look for possible difficulties that need to be overcome before final data collection commences.

Once the final data collection procedures have commenced the researcher needs to provide technical support to individuals in the study and ensure the continual operation of the PDA's. As individuals complete the research project they turn in the PDA and the researchers is able to download the data collected to a number of programs that will allow analyses of the data and would return to more traditional ways of conducting research.

As can be seen the use of PDA's can be time consuming and difficult to accomplish, but the trade-off to examine areas that have not been previously examined can be tremendous. This paper has discussed some of the issues surrounding the use of PDA's in research and treatment and we hope that we have raised awareness of the potential uses of PDA's in research. The use of PDA's in research and treatment is just beginning to emerge and shows promise as a tool that can go along way to enhance may fields in the social sciences.
College Website Review and Revision

Terence W. Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, Jacksonville, FL USA.
tcavanaugh@unf.edu

Abstract: Websites are becoming increasingly important for schools as support for teachers, administrators, counselors, students, parents, and the community. Jamie Mackenzie (1997) offers four reasons for maintaining effective school websites: introducing visitors to the school; pointing students to useful web resources; publishing student work; and collecting data on curriculum projects. Developing or redeveloping a school's website can become a complex process and it requires careful planning. Investigating who will use the site, what information users will require or appreciate, and maximizing useful ways to present the information are important steps. Who will use the site also brings up the important question of who can use the site? Any revision of a website must include accessibility issues for their content. The US government and the W3C consortium has accessibility guidelines for websites that will assist school website reviewers and designers in adapting their sites so all users have equitable access.

Need

An education college website should have as its mission to recruit, support, and inform current and future students and faculty about the college and the profession, while modeling educational principles. In interactions with users of a local College of Education website, it was determined that the site had become outdated and did not fulfill its mission effectively. The dean assigned the task of revising the website to the college technology committee, and a member was selected as the coordinator for this revision.

In a college that has deaf studies and special education programs, an additional concern was accessibility for disabled users. To that end the college wanted to make sure that its website would model proper application of accessibility guidelines as promoted by the W3 Commission and the US government's Section 508 of the Rehabilitation Act concerning Electronic and Information Technology.

Revision

Guidelines directed by the W3 Commission indicate that to achieve a minimum conformance level of “A,” a site had to meet all of the priority one elements concerning the following conditions:

- Provide content that conveys essentially the same function or purpose as auditory or visual content;
- Ensure that text and graphics are understandable when viewed without color;
- Clearly identify changes in the natural language of a document’s text and any text equivalents;
- Ensure that tables have necessary markup to be transformed by accessible browsers;
- Ensure that pages are accessible even when newer technologies are not supported or are turned off;
- Ensure that moving, blinking, scrolling, or auto-updating objects or pages may be paused or stopped;
- Ensure that the user interface follows principles of accessible design: device-independent access to functionality, keyboard operability, self-voicing, etc.;
- Use features that enable activation of page elements via a variety of input devices; Provide context and orientation information to help users understand complex pages or elements; and
- Ensure that documents are clear and simple so they may be more easily understood (Web Content Accessibility Guidelines 1.0, 1999).

From the initial analysis of our site it was determined that improvement was needed in alternative text tags, use of framesets, and identification concerning the languages and html formats on the individual web pages.

Research was started to find tools to assist in evaluating the site to improve accessibility. There are several tools available, many of which have no cost. Some of the free tools that were examined were Bobby from
CAST, HTML & CSS Validator from W3C, A-Prompt from the University of Toronto, and the 508 Accessibility Suite for Dreamweaver. It was decided to use A-Prompt as the evaluation tool because of ease of use and because of its assistance in identification of problems, as well as in guiding and assisting in their correction. An excellent listing of tools to assist in evaluating and repairing sites for accessibility is the Evaluation, Repair, and Transformation Tools for Web Content Accessibility from the W3C Web Accessibility Initiative at http://www.w3.org/WAI/ER/existingtools.html.

The next step was to find out specific ways that users felt the site was not fulfilling its mission. The initial part of this investigation included a series of interviews with faculty members and students to find out what they found useful about the current site, what problems they had, and how they felt that it could be improved. This information was then taken to a professor teaching a course on educational web design. The professor and her students in that class participated by taking the information gathered from the interviews, their research on effective web design, and their own experiences with the college's website and creating an evaluation instrument for the site as a class project. This educational website evaluation instrument contained questions relating to: the design of the site, including the visual elements, layout and ease of navigation; usability and readability, ease of use, user satisfaction; educational value of the appropriateness of the content for its purpose and audience. Also there were open-ended questions concerning new needs, organization, and information. The instrument was given to a variety of individuals ranging from faculty, students within the college, upcoming students, and even high school students who were visiting campus.

From the analysis of the instrument results, the following areas needed adjustment or addition. The college should provide information concerning pre-college requirements about what to take and do for the first two years as an undergraduate. There should be information available about faculty including their teaching and research areas, contact information, links to their web pages and email accounts. Navigation needs to be clearer concerning divisions or sections within the college and their programs and services. A design component that was found needing was to make sure that all college pages had descriptive meta-tags, ensuring that they may be found more easily through search engines.

Each phase of the redesign was reviewed and approved by the college's technology committee using mock up web pages, navigational concept maps, survey and interview results, and accessibility needs. A more efficient method was developed for faculty members to submit content changes through their department. This format is an accountability system for the changes, and a method for responding back to the person making the request. From our college site review process we feel education college sites should achieve accessibility by meeting W3C and ADA compliance standards to reach at least the "A" rating put forth by the W3C commission for accessibility.

Conclusions

College sites should provide information not only to current students, but to prospective and future students. This information can include the programs that are available and the number of hours and courses required for programs, images or photographs of students and facilities spread throughout site, the college mission and vision statement, course descriptions, and especially pre-college information including necessary courses to take during the first two years, important forms, dates, required tests, and any other relative information.

There should also be a notable faculty presence on the college site. At a minimum there should be short pages for all faculty that provide information about the faculty to students and other stakeholders. The faculty pages should include the faculty members’ teaching areas, their research areas of interest, how to contact them (including building, office, phone, e-mail, etc.), a link to faculty members’ personal pages. Also it is important to include with the faculty the adjuncts that teach at the college.

A committee of the college must direct the maintenance and structure of the college’s website. Faculty members need to have input and knowledge of procedures regarding concerns, such as errors on pages, or the possibility of adding new pages or sections. A clear set of directions is needed about site changing procedures. The site committee should include persons who have ongoing interactions concerning the college; it should not be left totally with people who are not intimately aware of the climate and concerns of the college.
Using ‘No Tech’ Activities to Teach about Technology and Issues of the Online World

Dianne Chambers & Michael O’Brien
Science and Mathematics Education
Faculty of Education
The University of Melbourne, Australia
d.chambers@unimelb.edu.au  m.obrien@edfac.unimelb.edu.au

Abstract: Whole class or large group activities using learning technologies can be difficult when IT resources are scarce or in high demand. In response to this challenge creative ‘no tech’ teaching activities are used that powerfully explore concepts and issues encountered in the online world. In this paper we describe several activities that have been used successfully with teacher education students and with children to develop an understanding of high tech concepts and of issues encountered in the online world. These activities can be used before students go online, to complement online activities, or if no online access is available. These activities demonstrate how students can develop a rich understanding of high tech issues without access to high tech resources.

Introduction

Although many teachers would like to use learning technologies with their students it is not always possible, for instance when IT resources are scarce or in high demand or, in many schools, for whole class or large group activities. This is true not only in developing nations where access to computing equipment may be limited, but also in countries like the United States and Australia where certain schools, institutions and sections of the community have reduced opportunities to participate in the new information-based economy. A 1999 report of US Department of Commerce concluded that Americans on the wrong side of the so-called Digital Divide are about 20 times more in danger of being “left behind” (Irving, 1999). One response to this situation has the teacher demonstrating the available technology at the front of the class, with students looking on, and perhaps taking notes, but not actually engaging with the concepts presented. A challenge, then, for teachers with limited access to high tech resources is to find or develop activities for students that will actively engage them and enable them to gain an understanding of, and confidence about, concepts relating to online technology. In addition, the authors believe that well-designed ‘no tech’ learning activities can be more powerful in developing conceptual understandings than use of high tech equipment. These ‘no tech’ learning activities and teaching strategies can powerfully explore terminology and issues encountered in the online world. To be effective, these activities must engage students in learning. Following are several ‘no tech’ activities about concepts relating to the Internet and issues encountered when going online that we have used successfully with teacher education students, with children, and with practicing teachers. These activities are effective because they start with existing reference points students understand. Abstract concepts such as hosts, packets, glitches, security, anonymity, confidentiality, potential perils of ‘chatrooms’ and even cyclical redundancy checking become understandable when students used concrete objects such as balls, pens and paper, and each other to explore these issues. By actively engaging in their own learning students gain an understanding of issues relating to being online and how the Internet works, in ways that passively listening to a teacher – or watching a multimedia presentation – cannot. It has been found that, whatever the level of access to technology, these activities develop a good conceptual understanding of the topic, generally much richer than if high tech resources had been used!

Learning about Online Communication

PaperNet is an activity co-developed by one of the authors (see O’Brien & Nicola, 1998) that uses pen and paper to explore issues of online communication. Through participating in the activity participants will understand issues about online chat and email, even of they have never been online. In this activity each participant is allocated a number that represents their email address and participants sit in a large circle facing outwards. Each individual knows their own number and the range of numbers used, but not the email address (number) of the other individuals involved (that is, everyone is anonymous to begin with). The participants send messages to each other, written on paper and addressed (with a number) to the other participants. These messages are delivered by people inside the circle representing the network (the ‘networkers’).
Because, initially, no one knows who anyone else is, those taking part gain an understanding of being participants in a chat-room. Students can choose to reveal who they are or choose to represent themselves as whomever they wish. In general no guidance about identity is given to participants — the questions about identity and anonymity are raised by the participants as they play the game.

Later, the participants sit facing inwards and repeat the exercise. Because they now know with whom they are communicating, it is more like sending and receiving email. It has been found that some ‘networkers’ peek at the messages — this leads to discussions about privacy and censorship.

During and following the PaperNet activity, very complex issues are raised by questions and are discussed and explored. Issues that have arisen in the discussion during and after this activity include:

- Privacy — did the ‘networkers’ read the messages? Should they?
- Censorship — should the networkers check the contents of messages for suitability? Should they? Must they? Should the networker be blamed for delivering an unpleasant message?
- Identity — was everyone honest in representing themselves? How hard was it to pretend to be someone else? Can we rely on what people tell us online? Should we give our personal details out over the Internet? Should we? Must we?
- Anonymity — what freedoms are there when anonymous? Can these freedoms be abused?
- Safety Online — what things can we do to make using the Internet safer?
- Bandwidth — how could we get over ‘log jams’ of messages?

When undergraduate education students participated in the PaperNet activity and following the debriefing discussion, they were asked to reflect on how participating in such an activity might help a novice user’s understanding of online communication. Reflections by undergraduate students included:

"The illustration and parallel between the game and the reality of email is really concrete and visible. It is solid demonstration, rather than a teacher just talking about it."

"The activity makes a sophisticated “invisible” procedure visible, accessible and easier to understand. The working demonstration of email can integrate into the participants’ preexisting knowledge."

Following are some comments by children aged 10-12 years who played the PaperNet game as a classroom activity. At the time none had used email or online chat.

"I liked the first Internet game the best because no one knows who you are and you can annoy people."
"The Blind game was the best because I couldn’t see who I was writing to."
"I liked the second game because I got lots and lots of mail."
"It was hard being a networker, there was so much mail to deliver I couldn’t handle it."
"Someone asked me if I was a boy or a girl, and I said that I was a boy when I’m really a girl. It was fun pretending to be someone else."

Learning about how the Internet Works

These activities are from Stephen Gard’s excellent book The Internet: A Resource for Australian Schools (Gard, 1998). This book is a fabulous resource for teachers, whether they have access to high levels of technology or no access to technology.

The Robust Nature of the Internet

In a game called Internetball the participants stand in a large space in a grid pattern. Each participant represents a host in the network and the ball represents a message being passed through the network. The aim of the game is to pass the ball (message) to an adjacent (or nearby) person and get the ball from one end of the grid (network) to the other. Once participants have an idea of how a message (ball) gets passed through the network via the hosts (people) you can create ‘glitches’ by, for example, getting all green eyed boys to squat down and no longer be a functional part of the network. An alternate path for the message must be found when hosts become afflicted by these ‘glitches’ and become non-functional. This activity demonstrates the robust nature of the Internet which is a highly reliable system for data communication, because if one host in the system is knocked out, there is always another to turn to and the message will get through

Error Checking of Data

Another effective (and fun) learning activity from The Internet: a Resource for Australian Schools (Gard, 1998) is Packet Panic, a game that demonstrates how data are passed as ‘packets’ and are error-checked to ensure that the whole message has been passed and that its parts are reassembled in the correct order at the receiving end.

To begin, play the childhood game where a person is given a message and it is whispered to the next person and so on until the last person tells the group the message they received which, after passing through a succession of players, is
usually different to the original message. Discuss the unreliability of sending messages in this way and how the Internet would not function adequately if data were sent in this manner.

To play Packet Panic get students to create a short sentence (four to six words) that gives a simple instruction such as “Take off one shoe” or “Stand on one foot”. The message is then written onto cards with one word per card and the number of the word in the sentence also on the card. The last word in the sentence has the additional word ‘end’.

The cards are shuffled and given to another group (who does not know what the message is). One person has the cards (the ‘sender’) and the rest of the team (about six people) are in a line with a few metres (yards) between each participant. The first person (the sender) reads one card, goes to the next person in line and whispers the contents of the card (the ‘packet’ of information) to her, such as “off, 2”. The second person verbally ‘passes the packet’ to the third person up the line, and so forth. When the words gets to the last person (the receiver) he writes down the words received and says what he heard back to the previous person in the line. The message then makes its way back to the sender. If she receives back the same message that she sent, then she puts that card aside, knowing that that part of the message has been received correctly. She then sends the words on the next card. If the message that returns is not the same as the one sent then she resends the message. [Other packets of information (words on the cards) can be sent before the confirmation of the previous has been received, but is not recommended early on or chaos may break out!] The receiver reconstructs the original sentence by putting the words in the correct order and knows how many words there are in the sentence from the ‘end’ data. Regardless of the order the words are sent in or any errors occurring in sending some of the words, the checking by the sender means that each message will eventually be received correctly. The receiver then follows the instruction to show that the message was received. (This activity can also be set up with teams racing to correctly send a message.)

Where Packet Panic differs from the common children’s game is that the ‘sender’ and the ‘receiver’ maintain a dialogue (via the team) in which they compare notes about what has been sent and any lost or damaged packets are resent until the message is complete and correct. The activity demonstrates that modern data transmission techniques ensure almost error-free message handling (cyclical redundancy checking). This is a concept that would be difficult for most children to develop an understanding of, yet this activity illustrates this complex topic in an easy to understand way.

Conclusions

Activities such as these create a scaffold of understanding and can be useful both when IT resources are scarce or for topics where off-computer activities provide a richer learning environment about high tech issues. There are many concepts relating to IT use that are better explored for understanding when not at a computer, but rather through the use of low tech or no tech activities as illustrated above. The types of discussions raised by these activities are very rich and explore topics that may otherwise be invisible. By engaging in learning activities such as these, students create a scaffold of understanding by operating within paradigms they are comfortable with. Abstract concepts can be explored, discussed, and dissected. Technology novices can gain confidence and awareness of what awaits them in the online world before they have access to a computer or the Internet.

How One Educational Technology Professor Integrates Teaching, Research and Service

Alice Christie, Arizona State University West, U S

This paper describes how community service, research and teaching can be fully integrated by an educational technology professor by creating a partnership with a K-6 school. It describes the partnership development process, the grant-writing process, and the implementation process. Roadblocks that threatened the partnership are discussed as well as suggestions for overcoming these obstacles. Specifics about the integration process are discussed in depth.

The partnership between a university and a local elementary school serves a low SES population with few home computers and little Internet access. This project uses existing facilities to provide an after-school Community Technology Center where students, parents and other community members can have access to computers, email, the Internet, and computer instruction. In addition, many teachers in the school lack the skills to use technology effectively within their classrooms. The university professor will provide training to remedy this problem. Classes and access to the Community Technology Center are free to all community members.

This collaborative partnership is advantageous for all stakeholders: elementary school students and teachers will benefit from using the Technology Center after school hours; school and district administrators will satisfy parents wishing greater access to technology for themselves and their children; community members will benefit from access to computers and computer instruction; university undergraduate and graduate students will have opportunities will observe K-12 technology integration; several graduate students serving as research assistants will gain knowledge of qualitative research methods; and the university professor will conduct an extensive research study on students, teachers and parents using technology in a community setting. This project therefore provides the university professor with a strategic way to integrate teaching, research, and service.
The GWeb Portal is a centralized online environment developed to fulfill the varied needs of The George Washington University students, faculty, alumni, staff and friends. The ability to integrate email, online student registration, courseware software, enterprise data and other existing resources into a comprehensive single-sign-on portal allowed for greater application interoperability, extended usage, and enhanced University wide communication.

The GWeb portal is based upon a mix of academic and personal services to encourage use and promote community interaction. While the University's main purpose is to facilitate academic study, GWeb recognizes that the bond between the student and the University extends beyond the classroom. Considering that bond, services of personal nature, such as weather from around the globe, movie show time listings, comics, and classified ads provide resources that would otherwise require users to search elsewhere for these features. The aggregation of the GWeb services increased usage and therefore the effectiveness of communication between the University and its constituencies.

Today, thanks to its proven infrastructure, more and more applications are being built on top of the GWeb architecture to facilitate the University's operations and academic learning.

Currently, GWeb includes the following features:
- Role-based configuration. Users are presented with applications and communication that are relevant to their affiliation within the University (i.e. student, staff, faculty, alumni, or guest).
- Entertainment: GWeb modules include news from washingtonpost.com, weather from around the world, comics, horoscopes, movie show time listings, live broadcasts of GW's radio station, real-time cameras from around campus, and classified ads.
- Role-based polling and surveys. Users are presented with polls and surveys that are relevant to their affiliation within the University (i.e. student, staff, faculty, or alumni).
- Content management and distribution. Organizations and departments within the University can post news and events on the portal and have the same content syndicated out to their own website on the WWW server.
- Online directory: Users can search email and campus addresses for faculty and staff.
- Access to external applications. The portal provides single sign-on to Email, library catalogues, and Prometheus (the University's courseware application).
- Secure distribution: Faculty and staff can now obtain instant, secure access to their personal identification numbers for accessing SCT's BANNER over the web.
- Leave tracking system. Provides GW employees with a method for requesting and tracking leave.
- Employment listings and employment applications. Allows users to browse and apply online for GW employment opportunities.
- Training registration: Allows users to manage GW systems training and other short-term courses.
- Bookmarks and Web Notes. Users can bookmark web sites or save the contents of various web pages through GWeb. These bookmarks and notes can then be shared with other GWeb users and accessed from any computer.

Metaconceptualizing Knowledge: The Challenge for Teacher Education

Charles Dickens, Department of Teaching & Learning, Tennessee State University, USA, cdickens@tnstate.edu

Abstract: The challenge today in teacher education is not to teach about technology, or with technology. It is, rather, to facilitate a different conception of what constitutes knowledge. Current concepts are still driven by an image of reality that was created over three hundred years ago. The Cartesian and Newtonian assumptions about a universe that can be known by knowing the nature of its component parts is no longer viable. The model for our present understanding of reality is one of particles, uncertainty, and tendencies. This paper explores the relationship between the digital universe and the physical and the necessary changes in our accepted concepts of the principle concepts that we take for knowledge.

What is knowledge? What do teachers need to know about knowledge? Why are these non-trivial questions for twenty-first century teachers?

A few decades ago, the premier learning theory adopted in schools was a behavioral one. Learning was defined as an observable change in behavior. Knowledge was assumed to be discrete and generally factual. It was a substantive body of information that appeared to exist independently from those who taught it and those who were to learn it.

In the late sixteenth and early seventeenth centuries the locus of control for this body of accepted knowledge shifted from the world as interpreted by the Church to a world being redefined by man. Space and time were inextricably and mathematically linked by Descartes’s coordinate system of analytic geometry. Bacon’s formalization of inductive logic opened the way for the development of science as the only trustworthy path to true knowledge. Newton’s remarkable “laws” of motion were mathematically proven and empirically verifiable.

The paradigm of the enlightenment’s world view, contributed by M. Descartes, was that the universe was like a great clockwork. It had a mechanical order that could be discovered by considering its component parts. Knowledge of the whole could be apprehended by studying and assembling its parts.

Knowledge was subject to change, of course, but it was a systematic change that substituted some parts for others. The changes did not challenge the underlying assumptions of the clockwork metaphor.

Changes wrought by twentieth century science did begin to chip away at this image of reality. Einstein’s relativity reorganized space and time and their relationship to each other. Physicists and mathematicians were creating a radically different view of the underlying structure of reality that has yet to be assimilated into our collective consciousness. We still cling to the Cartesian and Newtonian view and the relative security and certainty it offers us.

In education, Descartes and Newton’s legacy was evidenced by the public adoption of a behavioral theory of learning as recommended best practice a quarter century ago. Behavioral psychologists like B. F. Skinner proposed what were purported to be “laws” of human behavior, just as Sir Isaac had thought he was doing for physical science. Today, however, we consider best practice to be based on a constructivist view of learning, especially in recommendations for integrating the use of technology with classroom practice (Grabe & Grabe 2001, Jonassen 2000, Jonassen et. al. 1999).

It is rather ironic that one of the forces that drove the recent shift of focus in learning theory was research into artificial or “machine” intelligence, once a very small and arcane branch of computer science. Models
of thinking in the form of sophisticated computer programs were used to test theories about human thinking and problem solving.

Today we have in our homes and schools computers that are far more powerful than those used to develop the first A.I. programs and early “expert systems.” We are becoming a wired society and part of a global culture of a metaphorical “cyberspace.” Having this technology in the schools means more than the need for teachers to learn new methods of instruction. It is a defining technology that has the potential for altering the ways we think about ourselves and our world. This means teachers will need a radically different notion of the nature of knowledge than they have had. It also means that their students will need to develop their own understandings of what knowing and learning are that will better serve them in the future.

In closing, I want to share a selection of definitions by experimental architect Lebbeus Woods (1991):

DETERMINATE FIELD: a geometrical field pre-determined by a self-consistent set of rules of operation; e.g., the Cartesian field.
FREE FIELD: geometrical field unpredictably determined by the complex flux of conditions within the field; e.g., the field of non-linear systems.
NETWORK: an ephemeral, freely evolving, unpredictable dynamical four-dimensional pattern.
CIRCUS: a cybernetic state of free interactions; a community of autonomous performers, continuously re-formed by the independent choice of each; a feedback loop; a recursive mechanism.
PHENOMENON: a description of experience.
CONSTRUCTION: the invention of reality.
EXPERIENCE: transformation of reality through perception.
FREEDOM: a state emptied of pre-conceived value, use, function, meaning; an extreme state of loss within which choice is unavoidable; a condition of maximum potential, realized fully in the present moment.
STRUGGLE: the essential condition of freedom.
KNOWLEDGE: the invention of the world in all its complexity and multiplicity of its phenomena.

The winner of the future is not the one with the most toys, but the one who plays with them the best.

Title: Integration of Informatics Concepts and Practices into an Existing University Curriculum

[subtitle: There's no way we can fit another course into this program!!!!]

Within a four year Baccalaureate program of Nursing Education, this educator is interested in successfully integrating several computer skills and a knowledge base of information about the use of computers in healthcare, known as nursing informatics. After five years of informally trying to get students in this nursing program “practice ready” with acceptable computer literacy, knowledge base and skills, this educator recognized the need to formalize the integration of four levels of computer knowledge and practice into the existing nursing program. This paper is the description of the results of that integration project. Although this presentation will refer to a nursing curriculum, these ideas could be relevant to most post-secondary courses where students need to incorporate computer skills into their programs as accessory to their professional development.

This short paper will briefly describe

- the rationale for integrating this subject material into the curriculum as opposed to presenting it in a 3 credit course format.
- the objectives for the exercises and assignments chosen to help students know and practice their computer skills.
- the expectations of student performance at each of the four levels.
- the faculty development necessary to implement the integration.
This paper will be of interest to educators concerned with practical ways to:

- assess student computer comfort and skill levels,
- interest students in using computer skills, and
- prepare students to go out into their career with foundational computer skills and comfort with technological advances.

Resources available with this short paper presentation will include a sample of assignment criteria and guidelines for implementation of computer concepts and practices expected at each level.
The Advantages of an Active Text

Abstract: Business colleges have become increasingly disenfranchised with the way Business Calculus courses have been taught and with subject matter included within the course. Over the past year we have developed a text for our class that we make available on a CD. This provides much flexibility and allows us to implement several innovative ideas. Because the text is active, we have inserted hyperlinks to current web data sets that the students manipulate. We have also made compressed videos of examples and exercises found in the text. These videos are available on the CD and hyperlinks to the videos have been included within the text. These ideas could be generalized to courses other than Business Calculus. One could also use these ideas to make his/her own video tutorials without writing a new text.

Introduction

As mentioned in the abstract above, business colleges across the country are beginning to question the worth of Business Calculus as a required course. Several years ago the College of Business at Appalachian State University was among this group. It was then that the mathematics department started using Excel extensively in this course and started focusing on the needs of students in this course. Over the course of this last year the authors set out to improve upon this course by designing an innovative, new text entitled Networked Business Math.

The course already required extensive computer use with Excel and Maple, a computer algebra system. It was natural to try to make use of the power of computing in this new approach. The text, at the time this article was written, is a complete one-semester text for Business Calculus. It was first available via the web but is now available on CD.

Because this text requires the computer just to be read, we were able to make it an active text. Exercise sets at the end of each section have hyperlinks to solution sets. Exercises have hyperlinks to current data, e.g. census or labor statistics data, and thus these exercises remain current. The main innovation is that most examples in the text contain a hyperlink to a video file. This file shows students how to work the example and students can also work along with the video.

In this paper we will discuss, in more detail, this text and its innovations. Students' reactions and comments will also be included. Finally, we will point out ways in which others can use some of these ideas without writing his/her own textbook.

Exercises and Solution Sets

Because the text is active, students have links within the text that access web sites containing current interest rates, current U.S. income data, labor statistics, census data, etc. This, of course, is an impossibility with a printed text. An example is included below:
Go to http://www.census.gov/govs/www/state.html and select a year for the Summary table. Download the “Summary Table Spreadsheet.”

(a.) Using the state population as the x-coordinate and the total revenue as the y-coordinates, choose 5 states (not your own), plot the data, and find an equation of a curve of best fit.

(b.) Plug in your state’s population and predict your state’s total revenue. How accurate was your prediction?

(c) Repeat a and b above with 20 states

Huge data sets, which are current and applicable to the majors, can be downloaded and then uploaded into Excel within a matter of seconds. As long as the census bureau updates their web page, this problem is a current problem. Also, some self-constructed data sets within the text have been embedded in such a way that students can copy and paste the data into Excel quickly and without copy error. This results in more instruction time and also allows for more intricate and detailed examples within the text.

The exercise sets at the end of each section also contain hyperlinks to solution sets. If the homework requires the use of Excel, the solution file is an Excel file. If the homework requires the use of Maple, the solution file is a Maple file. Because many students do not have a copy of the Maple software, html files can be accessed to show Maple solutions to the homework. These files are truly solution sets and not just answer sets. Students can explore and manipulate their files, in order to check their solutions and, of course, these files are included on the CD.

Video

As stated above, most examples have hyperlinks to a video file. A typical example has the following format:

Example 1: Copy the linear data above and find the line of best fit. See sec1_4_1.qt. for a video on this concept.

These video files are included on the CD and must be viewed with Apple’s QuickTime Player, a free download from Apple’s web site.

These videos offer students and teachers many advantages. The pedagogical advantage is more classroom instruction time. If a course requires the use of computer software, classroom time must be used to teach the software syntax. Because the videos show the software “in action,” students can see the syntax for themselves and view the cause-and-effect relationship of the commands. The instructor, therefore, does not have to re-explain the syntax, and more time is available for actual course instruction.

The students also reap benefits. These videos should appeal to the visual, auditory, or tactile learner. The students can run the video and software simultaneously. Therefore, a student can work along with the video and learn the material and the syntax. If the video progresses too quickly, the student can pause, rewind, or rerun the video.

These videos are also 24-hour tutors. Students do miss class from time to time or they just miss concepts while in class. Learning class material that has been missed can be difficult. With the use of these videos, students have some help to that end.

Response To The Text

On the lighter side students have commented that it is nicer to carry a 5-oz. CD as opposed to a 10-lb. book. Students who have missed class have pointed out that the videos were a tremendous help in learning missed material and keeping up-to-date with the rest of the class. Student response to this approach has been quite favorable. In fact, two students led a departmental colloquium in April 2001, in which they discussed their (favorable) views of the text.

We have been using this text since January 2001. Since then, about 600 students have used this text at ASU and one community college teacher has used it during the Fall, 2001, semester. Because of the student volume and nature of the text, an (almost) typo-free text has been created.
Students' impressions and comments have been very positive thus far. They appreciate the fact that applicable topics are covered, and some students have reported to us that they have used Maple in other business classes. Because of the use of Excel and Maple, more "real-world" type problems and functions can be analyzed. Students have also expressed much appreciation for the videos and the benefits that they provide.

**Generalizations**

The authors realize that business calculus is not the only class for which computer software is used. Some of these ideas can be implemented into any class that uses computer software, without having to write your own textbook.

First, understanding how the videos are made is necessary. These videos were created with SnapzPro², available at http://www.AmbrosiaSW.com, which is essentially a screen capturing software tool for Macintosh computers. For those using a Windows PC, a similar program, HyperCam, is available through Hyperionics. These programs allow the user to capture between 1 to 30 frames per second and embed audio. The authors use 5 frames per second and the file size is approximately 500KB per minute of video. Most videos are between 2 to 5 minutes in length so, as a result, video downloads are relatively short, even with a 56K connection. However, the computer that one uses to produce the videos needs to have sufficient speed and memory or the video will lag significantly behind the audio. The authors used a Macintosh PowerBook G3 with 333MHz and Mac OS 9.0.

Because this software is a screen capture, virtually any software can be videoed. With this software a teacher can produce his or her own videos and make them available via a web site. Videos less than six minutes in length can be downloaded relatively quickly with 28-56 kb modems. Thus, as long as students have internet access, they have video access. In fact, the authors first used this approach before the new text was written. The authors managed the course using WebCT and it was natural to use this as a storage area and access area for the videos.

Statisticians within the ASU Mathematical Sciences department have started using this type of video to model some statistical software. Instructors can make their own tutorials or work selected exercises from their current textbook. Instructors could write their own supplementary exercises and make them available through the web with links to video. There are many possibilities and instructors can make it as intricate or involved as they wish.

**Conclusions**

A textbook on CD should be more than simply a transfer of words from one file format to another. It should be an interactive textbook. Networked Business Math allows for this. With the click of a mouse students can access huge data sets or solution sets. With another click of a mouse students can access video and can participate by modeling what they see in the video. In this way the text is truly interactive and students can do much more than passively read the text. In fact, with many math texts students do not even engage in passive reading of the text. This text and style attempts to draw the student into active learning of the material.

As stated above, these approaches need not be confined to Business Calculus. Statistics software, geometry software, computer algebra systems, etc. can be explained through video. An instructor need only post their video tutorials in a web-accessible space and students have 24-hour help.
Web Design through Traditional Subjects

Joanne Fevergeon, Teacher

adharkar@macromedia.com

Abstract: Web design is a new subject for many teachers. Although Web design teachers have the ability to teach this course, they have not generally come from a Web design background themselves. Having the knowledge or background to teach such a course can be difficult. New teachers of Web design can draw from more traditional subjects, where they might have more expertise.

Web design requires understanding information and its underlying conceptual structure to create Web sites that convey the information in a way that promotes learning. Although it is a new communication medium, teaching Web design can provide an exciting method that combines traditional subjects with the latest communication technologies. Web design can be used to teach subjects such as History, Art, and English and vice-a-versa.

History
Students encounter large quantities of information on the Internet. To be thoughtful consumers of this information, students must learn to discern its validity. The research students conduct and the products they create for the Web also need to contain valid and justified content. Students can learn to assess validity by following the processes they use in other subjects such as history. For example, when documenting historical accounts, expert historians conduct the search for validity by verifying the authenticity of the source, checking for bias, and using corroborating evidence. Similarly, students can utilize these professional methods to distinguish valid Web information from false content. In this session, we will do a number of activities to judge validity by analyzing Web site information with respect to bias, sourcing, corroboration, and currency.

Art
Graphic design on the Web incorporates basic rules of design. Principles of art and design overlap when designing for the Web. Students can be taught traditional art methods to apply to the Web forum. Art principles such as color, balance and the rule of the thirds will help students better understand graphic design.

English
The Web contains written work that is different from writing for print work. The information on the Web must fit into a smaller space and capture the attention of the user immediately. When learning to write in English classes, the topics covered help students organize information and provide specific information. Differentiating these two forms of writing can help students better understand writing for the Web. Teachers linking Web writing to writing in English class can help students easily transition to Web writing. Learning to write for the Web differs, but having strong writing to begin with will help students transform their writing for the Web.

Conclusion
The transition to Web design requires the acquisition of new skills for teachers and students, however the transition can be made smoother by incorporating the use of traditional subjects. Web design, although a new field, can be taught in conjunction with familiar subjects that will produce similar skills. These skills can then be built up beyond their traditional roots.
A Comparison of Online and Regular Learning Contexts in a Course for Teacher Education Students

Asghar Iran-Nejad
Yuejin Xu
Educational Psychology Program
University of Alabama
United States
airannej@bamaed.ua.edu

Abstract:
This paper explores whether online and regular learning contexts differ in their influence in the course of a semester-long intervention aimed at changing the learning conceptions of the students enrolled a multi-section educational psychology course for teacher education students.

Introduction
Changing teacher’s conceptions of learning and knowledge is currently viewed by teacher educators as an important component of pre-service and in-service teacher training programs (Cochran-Smith & Lytle, 1999). The way we conceptualize learning has a profound influence on the approach we may take in further learning and teaching. However, little is known about what affects the development of learning conceptions and how different learning conceptions interact with learning contexts and types of instruction. The study reported here explored a semester-long approach to teaching educational psychology to pre-service teachers aimed at getting them to reconsider their own conceptions of learning. The study also explored how well online cooperative learning contexts compare with traditional cooperative learning contexts. Additionally, we explored a new type of instruction which not only provided procedural learning opportunities but also opportunities for indepth grounding of student learning in their prior experiences.

Theoretical Framework
Iran-Nejad (1990) identified three qualitatively different levels of learning conceptions as reflected in existing learning theories. The first level is internalization of external knowledge by means of maintenance rehearsal in which learning is viewed as the storage of ready-made objects. The second level is internalization of external knowledge by means of constructive elaboration in which learning is more likely viewed as the construction of objects via ready-made patterns. The third level is the wholetheme reorganization of the learner’s own intuitive knowledge base in which learning is like inventing new designs using one’s own intuitive knowledge base. This third level was the goal of instruction for indepth grounding. Such instruction includes the interaction of multiple sets of factors. One set of factors influencing learning has to do with learner’s own active and dynamic self-regulation processes (Iran-Nejad & Chissom, 1992). Another related set of factors results from interaction in social and cooperative contexts (Vygotsky, 1978). And yet a third set of factors deals with variables having to with the kinds of learning activities facilitated through instruction. In normal academic learning these factors are expected to work together naturally to bring about future learning. Moreover, following the biofunctional theory (Iran-Nejad & Gregg, 2001), we hypothesized that wholetheme learning facilitate the development critical learning.

Methodology
The students in six different sections of an educational psychology course for teacher education students were randomly (a) divided into groups of 4 to 5 students each and (b) assigned to two cooperative learning contexts. In one context, students met in regular groups in their classroom to engage in cooperative learning activities. In the other conditions subjects used the computer to interact using the same learning activities, computer forums, and online interaction using WebCT. In addition, the students in three of the sections were provided with procedural learning instructions. Students in the other three sections received procedural learning opportunities plus grounded learning opportunities aimed at whole theme learning as defined above. A conception of learning inventory was used to measure changes in participants conceptions of learning. A multiple choice test measuring different levels of critical reflection was also used. Finally, the learning activities were compiled by the students into a reflective learning portfolio, which will be used as a source of qualitative data.

Results and Discussion

This paper reports the quantitative data from the learning inventory and the multiple choice test. Qualitative data is discussed in the presentation. The scores from each of the three subscales of the Conception of Learning (LC) inventory were summated. A mixed design ANOVA was conducted on the pre-test and posttest inventory scores with three levels of learning conceptions (LC1, LC2, LC3) as a within-subjects factor, two levels of instruction as a between-subject factor, and two levels of cooperative learning as a between-subjects factor. Would the participants in the computer cooperative learning groups in any form of relevant disadvantage as compared to those in regular cooperative learning groups. No significant main effect or interactions involving cooperative learning were found. The multiple choice test contained three types of items. Regular items measuring domain-specific content, critical reflection items based on domain-specific content, and critical reflection items measuring cross-domain inference. A potentially important finding was that the interaction between cooperative learning and instructional intervention was significant only for cross-domain multiple-choice items. No differences were expected between online and regular cooperative learning, and none were found. The finding that the participants in the grounded instruction did better in regular cooperative learning and worse in online cooperative learning was surprising. This finding is interesting, especially since the mean performance for both grounded instruction groups was higher than regular instruction groups.

Abstract: Integration of technology and basic computer literacy into our colleges and universities is undoubtedly a necessity. However, little consideration in the literature has been given to specific needs of the student. Educators need to consider the level of incoming technology literacy, and career field of the student when implementing technology training to ensure that individual needs are met without overloading the student. Universities have a responsibility to insure that the integration of technology into courses is not done recklessly, and that all students have an equal opportunity for success.

In today's technology driven world, the integration of technology and basic computer literacy into our colleges and universities is undoubtedly a necessity. However, little consideration in the literature has been given to specific needs of the student. While some students may enter college with the basic technology competencies needed to successfully complete course work, others are often required to master technology that may have little relevance to their particular field of study. The level of computer experience and knowledge necessary varies drastically from job field to job field. Simply requiring students to acquire knowledge of a preponderance of software programs, may be a detriment rather than an asset to college students. In order to adequately prepare college students for a career, without overloading them with non-essential technological skills, universities need to focus on the individual student's specific needs. The main concerns addressed in this article are the relationship between course content, technical proficiency, and influence on social skills.

Virtually all employment opportunities for college graduates require (and even expect) a certain level of technological experience. To meet this challenge, many universities are either infusing the instruction of various computer programs into course curricula, or simply requiring the student to use a variety of technology mediums to complete assignments. Many universities now even require students to own or lease a personal computer that meets the universities' own recommendations. According to Harry Matthews, Chair of the Academic Computing Coordinating Council at the University of California – Davis, "computer ownership levels the playing field for all students" and also assures instructors that on-line assignments are accessible to all students (Justice, 2000).

The fact remains that not all students are on a level playing field. In 2000, only half of all college freshmen arrived on campus with their own computers. These college freshmen were proficient in using
Windows, word-processing software, electronic mail and the Internet (Olsen, 2000). Unfortunately, this suggests that the other half of college freshmen may not have the aforementioned proficiencies, and are at a disadvantage when compared to their fellow students that do own computers. Ultimately, the amount of time for the student to learn the subject material does not change. If the student is not already familiar with chosen medium, he or she may be faced with a significantly larger workload than the technological savvy student. Conversely, if the instructor allots class time for technology instruction, the result may be the subsequent omission of certain course material. There is a struggle being achieved a balance between technology, course content, and social skills learning.

There is no doubt that universities must ensure that students are technologically literate before graduating, since more jobs than ever before require proficiency in technology. Therefore, universities must make an effort to assure that all students are truly on “equal footing” throughout college, and can progressively grow together in their continued, expanded use of technology. An additional issue is the needs of non-traditional students. Many non-traditional students have part or full-time jobs as well as families at home. They simply do not have “extra” time to attend workshops outside of their regular classes.

The vast differences in the abilities of both traditional and non-traditional incoming students dictates a need for intervention. A computer proficiency assessment for incoming students, prior to admission, could identify a need for remedial computer instruction. A class in the use of microcomputers could facilitate an even playing ground for all students. Another way universities could address these needs is by covering computer literacy in freshman seminars as a part of adjusting to college life.

It is also important that the rapid infusion of technology into universities is not executed at the expense of social skills training. Careers in fields such as psychology, where face-to-face skills and the observation of non-verbal cues, are essential to success, an overemphasis on technology could be detrimental to the overall education of the student. According to Rogers (1992) “There must be a warmth of relationship between counsellor and counselee if any progress is to be made”. For many individuals, learning the intricacies of computer software and technology may be considerably less important than daily social skills training and application. Early research by Gove and Geerken (1977) indicated that when people have more social contact, they are happier and healthier. Furthermore, research has indicated that there is a positive relationship between social skills and academic achievement (Feshbach and Feshbach, 1987). Universities that require instructors to implement technology into courses need to consider the student’s social development and career path.

Today’s college student is faced with not only learning traditional course content, but also required to attain proficiency at the use of a variety of technological mediums. Oftentimes professors are using technology such as a web page to supplement course instruction. Students who are less technology literate than their peers are either forced to spend additional “study time” learning how to navigate through a new web site, or forgo the web site material. Hence, if students are overloaded with learning technology, this may be accomplished at the expense of valuable course content. Technology overload may also be affecting the student’s social skills training. Many careers require “face-to-face” rapport building skills. Courses that traditionally focus on this type of training may be less beneficial for the student, if class time is dedicated to technology instruction. It is not the intent of the authors to suggest that technological infusion is counterproductive to the student’s education. However, universities have a responsibility to insure that the integration of technology into courses is not done recklessly, and that all students have an equal opportunity for success.

The Dichotomy of the Conquering Hero: Searching for the Pedagogy in the Teaching of ICT

A C Jones, University of Sunderland, School of Education, Hammerton Hall, Gray Road, Sunderland, United Kingdom SR2 8JB
Email: chris.jones@sunderland.ac.uk

Abstract
There are I believe a number of approaches being taken to the teaching and learning of ICT in English secondary schools. Many teachers of ICT are not specifically trained in the subject and so are using tried and tested pedagogies borrowed from their own experiences in the teaching of the specialist subjects in which they were trained. Some of these teachers are imposing their own view of what ICT is about and how it should be taught. Some are recognising that ICT has concepts, knowledge, skills and abilities that need to be taught - but not being sure how to go about teaching these are falling back on a skills transmission model that is appropriate in vocational skills training but which underdevelops the things that students 'need to know'. This paper looks at the strategies that are being employed and looks at where a perceived pedagogy for ICT is emerging.

Is there a pedagogy for ICT?

The teaching of ICT in secondary schools in England has been highlighted as having many weaknesses. Reports on the development and application of ICT in schools during the 1990s highlighted problems with resourcing and the slow-response times to new initiatives (Cox & Johnson, 1993. Stevenson, 1997). The OFSTED report which focused specifically on the inspection of IT teaching in England during 1995/6 identified IT as the least well taught subject in the curriculum (Goldstein, 1997). The situation has changed a little over time, but standards in ICT remain highly variable throughout the country; and do not compare favourably with standards in other subjects.

Achievement remains unsatisfactory ... in one-quarter of schools in Key Stage 3 and in one-third at Key Stage 4. (Ofsted, 2001)

Goldstein (op. cit.) highlighted the need for the development of a critical pedagogy for ICT. In referring to a critical pedagogy he was mindful of the difference between the teaching of IT skills, the development of IT knowledge, the understanding of ICT concepts and the application of knowledge, skills and understanding in a variety of contexts. For each of these approaches to the development of capability in ICT teachers needed to be aware of the specific teaching and learning methodologies that were appropriate and should be critical and reflective in their choice of pedagogy. He reminded us, also, that in order for the pedagogical and managerial development of ICT as a subject to be successful schools would need access to "high quality national and local support" (p3). He goes on to say that:

Lessons should be learnt from earlier stages of successful curriculum development in IT in this country, when such support entailed opportunities for teachers and teacher educators to sustain professional networks which addressed the teaching of IT and its uses in the curriculum (p3)

His message appears clear; without support and direction, teachers of ICT begin to "think that technology is the most important factor ... and overlook the pedagogical objectives' (Mason, 1998), and are deflected from starting to think about their practice in terms of appropriate theories of learning and teaching (ngfscotland). The 'technology trap' is one which is at once both appealing and dangerous: personal competency in ICT is a pre-requisite for pedagogical competency (you need as a teacher to know how to use the hardware and software to develop conceptual awareness), but the students in school need also to develop their personal
competencies before they can use the ICT effectively as part of their learning repertoire - and as such you as
the teacher can stick simply to the teaching of personal competency and not get into the development of
conceptual awareness and understanding in your students.

There is certainly merit in that train of thought. Skill development often begins the process of conceptual
development. The problem that we have with the teaching of ICT and the development of IT capability is that
teaching and learning in ICT often does not go very much further than the teaching of skills based courses.
So the pedagogy does not, very often, go much beyond drill-and-practice where students merely follow sets of
instructions (or work through workbooks) which outline exactly which key presses and manoeuvres a student
needs to go through in order to meet the defined task requirements.

The impetus for such approaches to teaching and learning in ICT derives from the technology itself and the
pragmatism which lies behind the belief that functional competency in the use of the software alone is what
constitutes an effective curriculum in ICT. The pragmatism here is one which ensures that students are
successful in functional operations: they can do. They might not understand - but if we only test their abilities
to carry out a limited range of operations then understanding is not necessarily important.

If we are to get any closer to a defined and accepted pedagogy of ICT (Goldstein, 1997) we need to analyse
and define what is, or perhaps what should be taught as part of the ICT curriculum. We need to identify
clearly the components of that curriculum and to identify and describe measures that need to be taken in order
to ensure that the delivery of that curriculum is fit for the purposes we require of it.

In her analysis of teaching and learning in ICT, Webb (2000) identifies significant difficulties. The
development and transmission of knowledge is "crucial to the pedagogical reasoning process" (Shulman,
1987), but in the ICT teaching community the match of experience and practice to the categories that
Shulman defines is not a good one. It is clear from experience that many teachers of ICT lack a well defined
subject knowledge (Preston, et al., 2000) and the definition of the subject in the National Curriculum
specification for ICT, is couched in terminology which is generic enough to cope with the rapid changes in
technology over time, but as a consequence has less clarity than other subjects. Webb (ibid.) analyses the
relationship between the pedagogical content knowledge and how the subject itself accepts and utilises
general pedagogical knowledge and concludes that they are:

less well defined for ICT ... and the fairly limited research base of students' problems and misconceptions in ICT means that the knowledge of learners and
their characteristics is limited.

This issue about the language of pedagogy and ICT is central to much of the debate, as is the dichotomous
relationship between skills and concepts. Ofsted (op. cit) identifies the 'lack of systematic networking of
leading teachers and schools' and those programmes which focus 'on the individual teacher's skills in using
specific software' as being analogous with the failure to develop an 'effective subject pedagogy using ICT'.
The tendency also to 'focus on technical matters' when supporting the role of ICT co-ordinators has
undermined efforts to 'engage in professional and curriculum development' (p5).

Passey (1998) identifies a need for teachers to begin to see ICT in the same way that their students do, and in
coming to see the technology as part of their natural teaching and learning repertoire which will support their own
development of a pedagogic competence in ICT. What is interesting in his view is that he firmly places the
development of pedagogic competency before that of functional competency.

McCarney (2000) in summarising conference responses to the issue of pedagogy and ICT stated simply that
'there is a clear need to develop the pedagogy of ICT in the curriculum'. Grant (2001) also comments upon
the lack of 'an agreed language regarding a pedagogy for ICT'. In doing so, she highlights the significant
failure of the education community to deal effectively with the demands made upon it as a consequence of the
development and application of a curriculum that is loosely defined and that is dependent on timely responses
to technological change.
Identifying the language of the pedagogy is important here. Grant (op. cit), Goldstein (op. cit) and Webb (op. cit) all refer to the way we as teachers talk about and define what it is we are doing in terms of our teaching and learning. Part of this is about identifying clearly what we want our students to learn - the content of the curriculum; and a significant part getting to the 'agreed pedagogy' must be about identifying clearly how we should go about teaching this content.

Responses to technological development, be that the introduction of new hardware or the updating of software, often leads to a temporary de-skilling of the user and a consequent demand for specific operational training that is designed to support functional competency. A study of teachers' skill development in Greece (Makrakis, 1997) determined that personal skill acquisition are almost irrelevant without the development of pedagogical knowledge and understanding at the same time. In the context of Shulman's (op. cit.) knowledge categories competence in using ICT tools is skill application and demonstration without "the pedagogical organisation and presentation" (Makrakis, 1997 p167). Atkinson (1997) goes further and elaborates on the relationship between the technology and the potential for the development of a pedagogical construct indicating that technology lends itself to skills development without the concomitant development of underpinning concepts and knowledge:

Technological systems are prone to under-theorisation and are often predicated on implicit pedagogical assumptions that do not necessarily stand up to rigorous scrutiny. (p 102)

Selinger (2000) acknowledges, in her analysis of the use of multimedia in schools across Europe, that "virtually all countries recognise that development cannot be effective unless attention is given to teacher training"; and that any teacher training undertaken should focus in on the pedagogical application of ICT. Her analysis was further developed by Freeman and Holmes (2001) in their review of national policies for ICT. We have seen in England that the approach taken by the DfES to the development of teacher knowledge and skills in ICT through NOF training has come under criticism from Ofsted (op. cit.) and from teachers themselves (creativenet, 2000). This criticism lays the blame for the lack of appropriate development in ICT firmly at the door of the DfES. The "weakness of government in providing for change" was seen to exist, among other reasons, because there was a distinct lack of will to prioritise the teaching of ICT, and that in over half of schools ICT is neither fully implemented, nor evaluated (Jones, 2001 creativenet, op. cit.)

This lack of national vision and application is not a purely English phenomenon. McKenzie (1993) relates that, even after ten years of computers in American schools, "there is some evidence that we have failed to integrate the use of technologies by all teachers ... in ways that are meaningful, natural and powerful".

Plotting the route for finding both the perceived and projected pedagogies for ICT is not straightforward, though there are clear markers that we can lay down to help us to trace our route. Classroom mythology describes a situation in which enthusiastic students who are willing to learn and who enjoy the structured and staged approach to the development of ICT skills people ICT classrooms. The argument would continue to state that if children enjoy their learning and if we can see that there is a "greater improvement in ICT standards than in any other subject" (Ofsted, op. cit.) then there is nothing inherently wrong with the teaching and learning methodologies employed in ICT classrooms.

However well stated this argument might be the research into effective teaching (Hay McBer, 2000) identifies clear approaches for the development of successful pedagogy in all classrooms that is not, as yet, being applied in ICT classrooms. The issue of in-service training is part of the solution, and should be focused not on the development of operational skills but on the pedagogical knowledge required to develop children’s learning as fully as possible (Hemmings, 1998). There are other important issues that need to be drawn out here. The majority of teachers of ICT began, as I did, as teachers of other subjects and moved into ICT either as the curriculum changed and ‘they had expressed an interest in it’, or because they had a gap in their timetable that needed filling. As a consequence there is a large number of teachers of ICT as a specialist subject who have brought with them a pedagogy from their training and experience of teaching another subject. They have general classroom knowledge, but lack the content knowledge, curriculum knowledge and the pedagogical content knowledge (Shulman, op. cit.) to be fully effective in their roles. These terms are important in beginning to identify what it is about teaching a subject that is different for each subject, and are therefore
central to the analysis of what it is that differentiates pedagogies. General classroom knowledge relates to the knowledge that teachers have which enables them to manage classrooms and to relate to the students that they teach. Content knowledge is equivalent to subject knowledge and should be seen as an important and essential partner to curriculum knowledge which is the understanding that the teacher has about the structure and content of the curriculum as defined by external agencies such as examination boards and the National Curriculum. What pulls all these strands together is the development of pedagogical content knowledge which exemplifies the whys and wherefores of how to teach the subject effectively.

There are difficulties too in that the National Curriculum specification for ICT is vague in its use of terminology, and is perhaps best described as a wish-list for student development in ICT. It describes what a student should be able to do, but not as in most other subjects, what they should know. This has led to the development of on-line, interactive or prescriptive schemes of skill development and application that foster a classroom pedagogy of what might be termed as ‘ultra-facilitation’. Here the role of the teacher is purely that of monitor and assessor. It is the use of software that drives the learning; the focus on the task is supreme and the teacher’s input to the lesson is minimal. Such approaches are, I would argue, part and parcel of the pedagogical dilemma facing teachers of ICT. There are ‘successful’ commercial schemes that offer certification and structure to teachers, schools and students which require very little in the way of actual subject knowledge on the part of any of the participants. Under these circumstances, why is pedagogy important at all? Schools can fill the students’ time constructively, they can meet targets for student achievement, and they can deploy teaching staff effectively using existing resources.

One might counter this with the argument that quality assurance systems that monitor the effectiveness of the educational process will promote student learning and enable teachers to identify curriculum weaknesses and to move forward in a cycle of school self-improvement. This might well work in other curriculum areas but in ICT the inspection framework at school report level is not forceful enough in responding to its own judgements when schools are failing to meet National Curriculum requirements for ICT delivery (Jones, op. cit., Goldstein, op. cit., Ofsted, op. cit.).

There is a distinct need to develop the curriculum content of the ICT curriculum and to specify the range of teaching and learning experiences that children should expect to benefit from as a consequence of schooling. (Webb, op. cit.) This is beginning to happen since the publication of the QCA schemes of work for Key Stages 2 and 3. Very little analysis of the impact of these schemes has taken place. In a very quick hand count, of the 57 teacher trainees beginning their school practicum element in October 2001 only 4 were going to be involved in any form of teaching ICT in a framework which corresponded to that published by the Qualifications and Curriculum Authority. Subject knowledge is the main barrier here to pedagogical development and change in ICT classrooms. The focus on functional competency, which enforces particular pedagogical concepts such as drill and practice, could be minimised if teachers teaching ICT but qualified in other subject areas were “encouraged to study the theoretical aspects of the subject rather than focusing predominantly on practical issues” (ibid.).

The development of the ICT capable school, one which acknowledges the curriculum importance of ICT and which invests in the training and development of staff in ICT, is an important step towards defining the pedagogies appropriate for the ICT classroom. An approach to the development of ICT in schools has been identified by a UNESCO project (unesco, 2000) and has proposed four stages of school development and defined the learning pedagogy appropriate/characteristic of each stage:

<table>
<thead>
<tr>
<th>Teacher centred</th>
<th>Factual knowledge based learning</th>
<th>Learner centred learning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Didactic</td>
<td>Teacher centred</td>
<td>Collaborative</td>
</tr>
<tr>
<td></td>
<td>Didactic</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ICT as a separate subject</td>
<td></td>
</tr>
</tbody>
</table>

Table 1. Approaches to ICT Development in Schools (ibid.)
This perhaps allows us to plan our journey. Many schools would however misinterpret the focus of the table and place themselves in a higher domain than would be appropriate based on an analysis and observation of teaching styles. If we build this model into the four stages of pedagogical informing (Woods, 1993) then we can see that, although the context is appropriate (ICT has dedicated suites), the lack of a fully defined content in the lower school, and the lack of open and grounded inquiry pose barriers to progression from one pedagogical domain to another. It is my belief that many schools would claim to be applying the concepts of learner-centred learning and that because ICT was already a separate subject that they were progressing from application to integration. Indeed, we can see elements of integration taking place as far as the facilities and resources are concerned, but in relation to pedagogical development most schools are stuck between emergence and application, and until teachers are more familiar with and confident in the concepts which underpin ICT they are not going to progress into the development of a pedagogy appropriate to ICT, and will continue to apply those pedagogies which are clearly not serving themselves or their students well.

Topic: Concepts and Procedures

Abstract:

Unlike the highly individualized mapping process developed and popularized by Novak and Gowin, the Jones-Steinbrink model produced invariant maps with recognizable conceptual patterns. This outcome allowed researchers to produce concept maps and related instructional materials in an orderly, systematic manner that allowed students to efficiently and effectively learn the concepts presented in science and social studies lessons.

Proposal:

This paper presents a summary of the research and development efforts in graphic conceptual organization of curriculum materials conducted at the University of Houston-Clear Lake by Robert M. Jones and John Steinbrink during the 1980s. In a series of projects conducted by masters degree candidates, they were able to identify and validate four basic conceptual patterns in nonfiction science and social studies textbooks. Using the four basic patterns which they labeled main idea-supporting detail, summary and generalization, process or sequence and cycle, they and their graduate students were able to conceptually map all lessons and chapters in contemporary science and social studies textbooks. Unlike the highly individualized mapping process developed and popularized
by Novak and Gowin, the Jones-Steinbrink model produced invariant maps with recognizable conceptual patterns. This outcome allowed researchers to produce concept maps and related instructional materials in an orderly, systematic manner that allowed students to efficiently and effectively learn the concepts presented in science and social studies lessons.

The graphic technology software available in the late 1980s consisted mainly of drawing programs and each individual element of the concept maps had to be drawn. Jones developed a series of coded templates in an attempt to improve this situation but the process was still slow and expensive in terms of human resources and time. This resulted in the development of only a small number of demonstration lessons and units. The technology was so complicated and time consuming that researchers found it easier to hand draw the maps using flow chart templates.

Recently several new generation programs with excellent conceptual mapping capabilities have been developed and are currently readily available for use by curriculum workers and teachers. This paper presents several lessons from a contemporary science textbook that have been conceptually mapped using the Inspiration software. Lesson concept maps with reading organizers, conceptual worksheets, aligned review and assessment tasks and other graphic teaching/learning products are presented. These products utilize the Jones-Steinbrink patterns and can be easily constructed using Inspiration. In addition to solving the technology problem faced by the earlier generation of researchers, the current software allows the instructional materials to be quickly and efficiently produced.

The Inspiration software also allows for the utilization of advanced interactive techniques that were conceived of but could not be demonstrated by the early researchers. For example, the lesson concept map can be presented in an uncluttered manner using only a few descriptive words for each conceptual element. By using the note feature of the software, each element can be opened to present descriptive text to the learner. This should allow for focused reading and concept pattern recognition by learners. Numerous other features of the software and their use in conceptually organizing curriculum materials are currently being investigated. These are presented and discussed.
Focus First: Strategic Planning and Front-End Development of an Online Teacher Resource

Cathy Bonus Lalli
Northeast and Islands Regional Educational Laboratory
The Education Alliance, Brown University
United States
Cathy_Lalli@brown.edu

Abstract: This paper addresses the critical steps that contribute to the strategic planning and front-end development of a new Web site. The process included an interdisciplinary team that worked to define the project in terms of purpose, objectives, target audience, and style, using modified versions of established Web development guidelines. The team also gathered information that would define and prioritize the content. This process was undertaken in a way that economized limited resources in the early stages, but allowed for future expanded development.

Background

As part of a contract award from the U. S. Department of Education, the Northeast and Islands Regional Educational Laboratory (LAB), a program of The Education Alliance at Brown University, agreed to develop a Web site entitled "Teaching Diverse Learners." This award was due in part to The Education Alliance's expertise in the areas of equity and diversity and a long history of technical assistance experience that has contributed to the knowledge-base of effective practices in classrooms, schools, and districts.

Preliminary Planning

An interdisciplinary Web site action team was assembled to begin defining the project. The team, consisting of equity and diversity experts, an editor, and an educational technologist, followed a modified version of Web development guidelines ((Lynch & Horton, 1999; Burdman, 1999; IBM, Design section, Web Guidelines). The task of planning the site began by addressing the strengths of the organization. Based on these strengths and informed opinion, the Web site action team drafted a rough mission statement and tentative objectives for the potential site. Then, a competitive analysis of nearly 100 equity-related Web sites was conducted to identify their purposes, nature of content, and intended audiences. This information was used to identify gaps among existing diversity Web sites and to align a gap with the expertise of The Education Alliance, in an effort to avoid a duplication of existing resources.

From the results of this analysis, the action team discovered that there was little information available to assist teachers of English language learners (ELLs) in the classroom. With this information, the team was able to identify the primary target audience for the Web site and to modify its purpose and objectives.

Needs Identification

Once the primary audience was identified, the action team administered a needs assessment survey to define user interests and needs. Surveys were distributed to teachers through Equity Assistance Centers across the country. The results of the survey would drive the content to be developed, help in setting measurable strategic goals for the site, and inform the final refinement of site purpose and objectives.

At the same time, the action team discussed design concerns with the technical development team. These concerns were around the issues of accessibility across platforms, older hardware and software, and dial-up connections. All team members had a clear understanding that this site would be designed in a minimalist style that would maximize access for those using low-end technology. In addition, the team established that the content would be developed in a Web-friendly style that was clear, concise, direct, and professional.
These steps were essential to finding the focus that would guide the production process of a new Web site. They provided a solid foundation for defining the audience, purpose, and style of the site, and continue to be used to guide ongoing content development.

Site Development

Priorities for first-year development included a simple architecture that would adapt easily for future expansion. The content development of the site and the maintenance of its interactivities were initially undertaken with limited resources. Therefore, a "Layers-of-Necessity" model (Tessmer & Wedman, 1990) was adopted for the site in order to facilitate a modest launch and to accommodate future development, as additional resources became available. In addition, the minimalist style of the site in its initial stages was consistent with the evolving concept of the model from simple to complex over time.

The efficient use of time and resources limited the extent of testing in the early stages. Prototype and user testing were economized (Nielsen, 1999; Tessmer & Wedman, 1992) in order to focus time and expertise on content and technical development. However, user reaction to the prototype helped to guide the development of usability heuristics for the final product.

Summary

New technologies have simplified the development process for Web sites, making it possible for anyone with a computer and online access to author a site. The downside of this convenience is a proliferation of well-meaning, but unfocused sites. Strategic planning for the "Teaching Diverse Learners" Web site provided a definition and blueprint that served as a foundation for the initial and future development of the site.

The steps included:
1. Forming an interdisciplinary action team to define the project
2. Identifying the strengths of the organization and drafting a rough mission statement and objectives for the site
3. Conducting a competitive analysis of related sites
4. Identifying a gap in existing resources and aligning the gap with the strengths of the organization
5. Defining the niche and target audience
6. Assessing needs and interests of target audience to identify and prioritize content
7. Refining purpose and objectives
8. Determining design concept, style, and strategy for technical development of site
9. Soliciting user reaction to the prototype design to guide product development
10. Defining user heuristics for the final product.

Teaching Multimedia Design Using the “Tri-Component” Scenario Model and Associated Methods

Jean-Marc Laubin
Laboratoire des Sciences de la Communication
Université de Valenciennes et du Hainaut Cambrésis, France
jmlaubin@calasoft.com

1. Introduction

Despite the fact that many computer science students master complex techniques, like programming and technology integration, they are still unable to cope with the demands of multimedia project design. Clearly more emphasis should be placed on concept development given that content production is more a question of good ideas and targeting, than pure technical expertise.

The first part of the paper examines the challenges that the behavior of inexperienced students poses when they start to create a multimedia application. The second part looks at the basis of what makes up a multimedia application and the way in which its design is taken into account by our “tri-component” scenario model and associated methods. The final part demonstrates how using this method can help teachers deal with some of the challenges of teaching multimedia creation.

2. Problems Encountered by Students Starting a Multimedia Project

2.1 Misidentification of the scope of the “multimedia” concept: When asked, “What does the word ‘multimedia’ mean to you?”, my computer science students regularly use one of the following answers: images and sounds on a computer; images, sounds and texts on a computer; images, sounds and interactivity on a computer; or images, sounds, texts and interactivity on a computer. The example of books, and more particularly roleplaying gamebooks (e.g. http://directory.google.com/Top/Games/Roleplaying/Gamebooks, retrieved 12/27/2001), is usually not identified by students as a possible “multimedia” system. Then there is the case of my engineering students who thought they were creating “multimedia” products because they were producing a 3-D film.

In fact, the use of images, sounds or even the computer are criteria that are neither necessary nor sufficient to define the specificity of a “multimedia” system, as will be defined below (section 3.1).

2.2 Inappropriate vocabulary for communicating within a team and misidentification of project levels: The word “interactivity” is used very often and with different meanings leading to frequent confusions such as the mixing of several phases of work. The word “interactivity”, for example, is used in place of “interface elements” (e.g. “Here the interactivity is a button that can be clicked”). In fact, the concept of interactivity is related to the nature of messages exchanged and not to the way they are emitted or acquired.

2.3 Confusion between specification and implementation: Very soon into the project many of my computer science students verbalize their intentions, for example, by saying things like “the user can click a ‘Stop’ button to exit the activity”. This kind of specification already suggests an implementation (a button). The problem here is that this over-hasty decision may not necessarily be the most effective one.

2.4 Omission of the specification phase: Using a non-directive approach (Rogers 1973), one of my three students groups, last year, was working on the subject “What can an adaptive Web-TV be?” and they encountered several problems in not following the recommended method. Error 1: Due to an inappropriate definition as to the nature of multimedia, they had decided, without further reflection, that a Web-TV is a mere Web site where users can view videos on demand which could possibly be “interactive”. Error 2: In Week 2, I discovered the students had shot some videos without a written out script. They had rushed to the camera because, it seems that, it was an “attractive activity”. Error 3: Having first neglected to create a scenario, the students finished with tons of unused rushes and presented an incomplete reply to the initial question, resulting in a good final report but a very poor prototype.
3. The Tri-Component Scenario Model

3.1. Basis of the model - an operational definition of multimedia applications based on their communicational functions: "A multimedia application is a conceptual activity consisting of a pre-formatted informational content and allied explicitation procedures. It is destined to be exposed to the meaning and actions of one or of several interactors via an interactional loop. This is made up of two non empty information flows, one of which enters while the other exits, each of which consists of one or several mono- or pluri-sensorial canals" (Laubin 2001).

3.2. The structural outline of the tri-component model: The model of representation of, what can be called, the “tri-component scenario model” (Figure 1) ensues directly from the above definition of “multimedia” and is proposed for the design of multimedia projects, both as a methodological aid and as a basis for software tools that implement it. The model is influenced by the work on “Multiple Intelligences” (Gardner 1996) and covers all the design aspects of the Scenistic Approach (Leleu-Merviel, Vieville & Labour 2002).

The multimedia product is presented as a communicational object with particular features that can link up interested parties (authors and interactors) in an asynchronous way. The schematic representation of the tri-component scenario model is a direct transposition of the definition as a formalized model of setting the scene (scénarisation) after having taken into account two current features of multimedia applications. These features are not linked to the definition, as they are absent in certain cases (namely in books), but they have demonstrated their qualitative importance (Durand et al. 1997b) in the two following ways.

First, there is the capacity to memorize a context when the work is put into practice (namely the paths of the interactor) without which one would have to list exhaustively all the possibilities of the scenario. This leads to a myriad of combinations in the number of situations that could be described, and in so doing this can hamper the author’s work. This necessitates a "status vector" (see section 3.4 below) in our model.

Second, there is the crucial element that characterizes the ability of multimedia applications to change the content of their memory according to specific rules. These rules can be related or not to the interactor’s behavior and necessitates a generative component in our model.

Figure 1. Structural outline of the tri-component model

Besides the three components (Fig. 1), the scenario includes a formalised description of the data collection as well as the structural specifications (the document is broken up into fragmented elements logically organised at different levels).

There is also a status vector that is the only mechanism of memorization and inter-communication available for the three components.

The interactional loop is entirely defined by the expositional and scenational components (C1+C2) which describe the input and output flow of information of the external canals of communication.

---

1 Definition: By interaction is meant a series of exchanged “messages” between interactors in a given “communicational” (see below, Footnote 3) context (Watzlawick, Helmick & Jackson 1967, sections 2-2, 2-41). The concept of interaction can also be defined as a “system”, where interactors are engaged, or have engaged, in defining (negotiating) the nature of their relationships (idem, section 4-22).

2 The point being that intelligence is not unitary but complex and multi-facetted. For Gardner a human being can be intelligent in various ways, and this includes linguistic intelligence, musical intelligence, logical-mathematical intelligence, spatial intelligence, bodily-Kinesthetic intelligence, intra-personal intelligence, and inter-personal intelligence.

3 Definition: For Watzlawick et al. (1967, sections 2-23, 2-34) communication is not just transmitting a message. It also implies a certain level of commitment and is defined in the way the sender sees his/her all-encompassing relationship to the recipient of the message.
The expositional component (C1, see fig 1) describes all that can be sent to the interactor. This is done by way of basic directives that send signals to different output canals. The proposed model is very open, and does not specify the way the basic directives must be described. This can refer to the corpus data of a multimedia product. For example, “Play IntroSound on the Sound output canal N° 2”, or “Display film Intro.mov on the help window of the main screen”, or even “emit smell maritime_pine.od for 10 seconds on the Smell output canal”.

The scenational component (C2, see fig 1) (Durand et al. 1997a) describes the potential flow of information from the interactors to the multimedia application. This is done by using the notion of an “actional link” (what the interactor can do) defined in terms of four major elements: a) a condition under which the link exists, expressed in terms of the status vector; b) the title of the link; c) the consequence of the link; and d) as an option, the appropriate communication canal (if not present the link is said to be “abstract”). The consequence of the link lists the ways, by the order of priority, that the application can react to an interactor’s choice. Each case is described by a context (conditions about the status vector), by the new resulting fragment and by the modifications of the status vector.

The generative component (C3, see fig 1) describes the rules of intrinsic development of the multimedia application. It is essentially made up of fragments called “generators” that do their work as background tasks and can require complex calculations. Basically they can read and modify the status vector or modify the corpus data used by the application. The proposed model remains open without specifying the way of describing the generators. Besides the generators themselves, the generative component also includes the activation instructions of the generators.

3.3. Structure of the scenario document: Without entering into details here, the scenario is broken up into fragments, which consists of the basic communicational unit. One can distinguish two types of fragments. First, the “Multi” fragments are linked to the interactional loop and can contain the directives of the expositional (closely linked to the notion of audiovisual scenario) and interactional components, as well as the activators of generators of the generative component. Second, the “Gen” fragments are the generators themselves that cannot send or receive signals to and from canals, but modify the internal state. There are also, two mechanisms to structuring the scenario document, one is supra-fragmentary (chaptering) and the other is intra-fragmentary (temporal synchronization).

3.4. The status vector, mechanism of communication of the three components: The purpose of a status vector is to memorize all information that needs to be kept or transmitted among the components. It is through it that one can see the idea of synchronization among the different components. The status vector is made up of seven sections to administer various elements from contexts that are different in their very nature. Each section can be read or updated by different components in a very precise manner, but this feature cannot be gone into in this paper for reasons of space. Suffice it to say there are:

- Two sections concerned with the profiles of the interactors:
  - The constants of the profile (or interactional constants) e.g. “I am a certain age”
  - The variables of the profile (or interactional variables) e.g. “User never chooses red links”
- One section concerning rhetoric control:
  - Global evaluation statements e.g. “Acquiring the notions of chapter 3 done”
- Two sections are concerned with the manipulation of data by the different components:
  - States of the communication canals e.g. “No sound received on input canal Sound N° 1 for 48 sec.”
  - Content Variables e.g. “Key to room X in inventory”, “Chapter 3 consulted”
- Finally, two sections deal with the follow through of the interactor’s path, and serve to memorize the presence, the order, or the number of the passage of given fragments. The situation is modified by the two components that administer the interactional loop, while the histories are automatically generated without any intervention from the three components.
  - Situation (current fragment)
  - Instant history and statistics e.g. “Link # x of web page xx.html selected seven times

4. Contribution of the Tri-Component Model to Teaching Multimedia

4.1 : How does the tri-component model help solve the problems we have identified?

Misidentification of the scope of multimedia: Our model establishes clearly the type of product that students have to take in account in creating a multimedia project. The model is closely linked to a systemic approach for designing multimedia products. It can also help to ensure the successful achievement of pedagogical goals: The status vector description is essential and allows one to check if students have a real understanding of the situation that they are building. Interactors’ actions should have multi-level goals, and both the control and communication processes
have to be well defined, the former by the generative component and the later by the expositionnal and scenational components.

Inappropriate vocabulary for teamwork and misidentification of project levels: Returning to the example used in 2.2, as part of a Scenistic Approach, the “tri-component” model allows for a more unambiguous and appropriate vocabulary among team members, for example, “The user will have the ability to stop” (abstract input channel, primitive at scenario level). For this purpose the interface is a mouse-clickable area on the screen (interface level) in which a message “Stop” must be displayed (output channel, primitive at scenario level) taking the form of a button with the text message as title (implementation or production level).

Confusion between specification and implementation: One can enrich the interface level by a verbalized choice (using voice recognition technology) with everything else staying the same. Taking the example above, the interface is both a mouse-clickable area on the screen, and a verbalized choice that recognizes the word “Stop” (interface level). In this way one can present a unique abstract scenario with several possible implementations.

It is vital to ask students to start with writing a scenario first so to help them focus on the design and to split their work into smaller and simpler tasks. The scenario can eliminate the dangers of students “designing as they go along” and it allows subsequent evaluation, both by the teacher and by students, to see if the implementation is happening according to the initial specifications or not.

Omission of the specification phase: In Week 2, the “Web-TV” group’s work was partially saved by an in-depth explanation of the “tri-component” model and then by asking them to produce the required scenario documents to guide the team along for the rest of the tasks to be done.

4.2. Discussion

In this section we present how our model is used and how it compares to several other works. At the very beginning of a project, or preferably one month before it starts, the «tri-component» model can be presented along with a classification of the various cases of the interactional loop (interactional degree), of the generative component (generative degree) and the ability to use and recontextualize parts of the information.

The student’s projects are organized at a group level, with each group having 12 to 14 students. The whole project is conducted as a situational problem (Delattre 1993, Dewey 1938/1968) which has a very general theme as a starting point and whose final goal is to produce a working prototype. The pedagogical aim is to construct knowledge by self-discovery and by using several kinds of tools in being aware of constraints, limits and errors. It also involves measuring the gap between intention and final result. Every step is learner-centered with the teacher having to continuously reevaluate the degree of success, the quality of the communication within the students group, the needs of specific tools (software, development kits, computers and audio-visual equipment). The main difficulty for the teacher is to guarantee the right type of success for the project, and in some cases s/he has to convince the students to break down their objectives into smaller, more manageable ones. This approach, inspired by Bruner’s (1966), has proven successful with six groups during the last two years.

The tri-component method is used at the beginning of the multimedia creation course and is compared to methods dedicated to design work like those of Landow (1994) and Levy (1992). Our method offers an easier teaching framework. First, the students note down all their ideas in an unstructured document. Second, the students fill out a skeleton scenario to cover all the required aspects reusing their initial ideas. Third, the students add any missing content. Fourth, they define in detail the status vector content and associated tasks (communication, rhetoric control, etc.). Fifth, the scenario is validated by simulation tests. All these steps are then iterated (spiral method).

The tri-component model formalizes the writing constraints of the objects in the designer’s universe (places, characters, objects, etc.) and their interaction with the user. It also allows a pragmatic and step-by-step work on the multimedia product. Another very important point is the syntax of the language used to support the model that provides a scenario-based approach viz Wimberley (1996), Garrand (1997). However, their scenario models are not appropriate and need alternative choices (Laubin et al. 1999). The chosen format and syntax for our underlying ZebraWriter language (Laubin et al. 1999), whose updated specification will be published later this year, satisfies the following characteristics, in order of importance: easy reading, self-explanatory text, good simulation capacity, a good navigation capacity, easy update procedures, tool for structuring and rhetoric construction control. The next step will be to introduce into the project process a writing and prototyping software that implements the ZebraWriter language and provides various functions for scenario analysis and validation.

4 For Bruner (1966) a theory of instruction should: (1) be focused on learners’ needs, (2) present a body of knowledge in a way that is understandable to learners, (3) propose a systematic approach to presenting instructional resources and (4) be clear about the system of rewards and sanctions.
The method can also be applied to teacher education both for inexperienced multimedia teacher in the same way as described above for students as well as for inexperienced teacher wishing to produce a multimedia version of their courses. Indeed for this latter case the tri-component method can enhance existing constructivist inspired pedagogical approaches.

5. Conclusion

The underlying idea of using the “tri-component scenario model” for multimedia teaching is to ensure a good methodological environment for helping the teacher and the students to succeed in a very open situation-problem. In these kinds of projects the most important is not the result but the encouraging the appropriate strategies to achieve set tasks, such as to:

a) explore a multimedia problematic (ability to construct step by step from scratch and to later structure and refine)
b) delimit a feasible goal according to the time given (the fragmented structure help identify and measure sub-tasks)
c) organize the work and communication within the student groups (the scenario is a common specification and reference document)
d) finalize an actual multimedia work done (the use of ZebraWriter associated language provides a prototype on paper without any other work and production steps can start fairly late when the prototype is fully validated)

Abstract: During the last two years as a project coordinator of computer science students experiments were conducted into the teaching of multimedia design. This has led to the observation that many students are not able to cope with the initial phase of designing a multimedia project. Our proposal for solving this basic problem is based on a constructivist approach related to the Scenistic Approach in our research laboratory. The approach is learner-centered and focused on strategies that students develop for the project. Learners start with a step-by-step creation of a detailed scenario that they wrote for a multimedia application according to the “tri-component formalized model”. The second phase is the realization of the project when the group has to organize itself according to the diverse abilities of its members. For the future these methods appear to be particularly useful for experienced teacher educators in the multimedia arena.

afgsm@uaa.alaska.edu

Abstract: The I.T. skills needed by the students we teach demand experiences which are outside the educational mainstream.... (We need) an education commensurate with each student's ability to learn. (Sandra Kaplan)

My session seeks to focus on the individual relationship between the teacher and each student, with special reference to Martin Buber's "I-Thou" relationship and to move away from the I-it/I-them" way of education. This is the means to fulfill any student's greatest need - to be loved and respected for who they are - an individual person who is different. It is my convinced belief that this is the starting point in serving students effectively to enable both the teacher and the individual student to make meaningful contributions for the future. It is in fact to fulfill the conference’s goal as expressed in its title. In the interactive session, I will begin by inviting the teachers to examine the assumptions that underpin their philosophy – with special reference to their understanding of reality, truth and values in their own lives and then in the lives of their students. In this connection, educators will be challenged to be aware of the importance of relevance for the future and also discuss ways to determine each student’s needs for the future.

When these have been explored, then, their relationship to education, with particular reference to the conference’s educational goals, content, method and values, will be dealt with in detail. In view of the wide range of geographic, social and economic backgrounds of teachers attending the conference, (and the students they serve) each teacher will be assisted to create a one page summary that can serve as the basis of their educational technology philosophical framework to ignite their students' potential at their schools. The session will encourage each teacher to harness personal qualities, interests, experiences and expertise to create this clearly defined framework and, at the same time, be flexible to meet the needs of a diverse population. Accordingly, the essence of the session is to place excellent and relevant tools in teachers' hands -- tools that can equip them with the knowledge of what clear plans to utilize in serving each individual student.

I am convinced that the “why” of education greatly facilitates and enriches the “what” of education and technology.
Abstract  By the earliest definition (Dodge, 1995) a WebQuest is "an inquiry-oriented activity in which most of the information learners work with comes from the web." WebQuests are defined first as being "inquiry-oriented," but are they truly an example of inquiry or are they something else? The majority of WebQuests fall under Herron's (1971) category of structured inquiry, but there are higher levels of inquiry desired by educators that are difficult to promote using the WebQuests model. Based on a spiral path of inquiry, Web Inquiry Projects (WIPs) are designed to promote such higher levels of inquiry, specifically Herron's levels of guided and open inquiry.

Introduction

In early 1995 the WebQuest was developed by Bernie Dodge and Tom March as a way to help learners focus on using online information rather than looking for it. By the earliest definition (Dodge, 1995) a WebQuest is "an inquiry-oriented activity in which most of the information learners work with comes from the web." WebQuests are defined first as being "inquiry-oriented," but are they truly an example of inquiry or are they something else?

Defining Inquiry

The answer to this question might depend on how you define "inquiry." It has been said that if you ask ten different educators to define "inquiry" you are likely to receive eleven different definitions. In an effort to produce a definition that represents the needs of every content area, the Exploratorium Institute for Inquiry (1996) developed the following definition: "Inquiry is an approach to learning that involves a
process of exploring the natural or material world, that leads to asking questions and making discoveries in the search for new understandings."

An inquiry approach to learning can look markedly different depending upon content area. In the social studies, inquiry might require learners to analyze primary source materials in developing an understanding of historical events and how they are relevant to today. Inquiry in science might involve learners in observing and describing some natural phenomenon that is new to them, or in testing scientific hypotheses through systematic laboratory investigations. No matter the content area, regardless of the role inquiry plays in any given learning situation, it should give learners an opportunity to solve real-world problems, overcoming authentic obstacles in solving these problems.

On one extreme, this process can be significantly scaffolded, requiring learners to follow a prescribed path toward a preset solution. On the other extreme it can be open-ended to the point of being defined and solved completely within learners’ interests and efforts. Between these two extremes exists intermediate levels of inquiry. Teachers and curriculum developers have a tendency to project more inquiry into their instructional activities than is warranted. Accurately determining the level of inquiry reflected in a particular activity is, therefore, a critical first step to inquiry instruction. Although not currently in widespread use, Herron (1971) developed a simple and practical rubric for assessing the degree to which activities promote student inquiry. Based partly upon the writings of Schwab (1964), Herron’s Scale describes four levels of inquiry, each differentiated by the information and support given to students prior to or as they complete the activity.

**Four Levels of Inquiry (Herron, 1971)**

1. **Confirmation/Verification** — students confirm a principle through a prescribed activity when the results are known in advance.
2. **Structured Inquiry** — students investigate a teacher-presented question through a prescribed procedure.
3. **Guided Inquiry** — students investigate a teacher-presented question using student designed/selected procedures.
4. **Open Inquiry** — students investigate topic-related questions that are student formulated through student designed/selected procedures.

When an activity is evaluated for its level of inquiry, a simple table establishing what is given to the learner determines at which level of inquiry the given activity resides—the less given to the learner the higher the level of inquiry (see Table 1).

**Early Internet Inquiry: The WebQuest**

While WebQuests are touted as being “inquiry-oriented” activities, just where in Herron’s inquiry hierarchy do they fall? Originally WebQuests were intended to be structured inquiry (Level 1), as students are given a task (problem) and a process (procedure) to complete the task. Of the WebQuests produced to date, many do not qualify as “inquiry-oriented.” In fact, a portion of what creators are labeling as “WebQuests” can easily be confused with less sophisticated, non inquiry-oriented Internet Scavenger Hunts. These “non-inquiry” WebQuests typically require learners to answer given questions, usually listed on a worksheet, and going to specific web sites to answer these questions.

The San Diego State University WebQuest Page includes a database of links to hundreds of created WebQuests. The WebQuests listed in this database were pre-screened for quality but were not investigated as to which level of inquiry each resides. Recently, 75 sampled WebQuests were investigated,
25 from each major schooling level. From this sample, zero WebQuests were Level 3, 12 were Level 2, 45 were Level 1, and 3 were Level 0. Additionally, 15 did not qualify as being inquiry-oriented, but instead qualified as Internet Scavenger Hunts. Unfortunately the widespread acceptance of WebQuests as a valuable educational tool has, in some cases, compromised their original purpose.

Table 2: WebQuest levels of inquiry

WebQuests were developed as an early step in answering the question, “How can Internet resources be effectively used in the classroom?” When the WebQuests concept was created over six years ago, there was no formal method of using the Internet to support “learners’ thinking levels of analysis, synthesis and evaluation”—important components of inquiry-based learning. WebQuests can, if created and used correctly, promote inquiry-oriented learning, particularly structured inquiry (Level 1). WebQuests will continue to serve as an important component of web learning, but it is now time to take the training wheels off and consider where the WebQuest concept can lead, especially with regard to promoting higher levels of inquiry-oriented learning.

Guided inquiry (Level 2) requires learners to design and select procedures, and open inquiry (Level 3) also requires that learners formulate their own topic-related inquiries. With no preset procedures and perhaps no teacher-defined questions to drive an activity, is it possible to develop a model similar to WebQuests that is more open-ended?

Some Early Thoughts on Web Inquiry Projects (WIPs)

Web Inquiry Projects (WIPs) are intended to meet this need. Promoting higher levels of inquiry in the classroom requires that less specific guidance be given to students. This fact alone makes it difficult to produce a model that is used by students in the way that WebQuests are used. Therefore, WIPs will be used primarily as a teacher resource, providing loose structure and guidance to teachers wishing to make good use of the wealth of available uninterpreted online data. Such data can be found at thousands of web sites, an excellent source being Digital Resource Centers (Center for Technology and Teacher Education, 2001). Digital Resource Centers “have the potential of transforming university teaching and learning” and “are relevant for K-12 education.” Such collections include the Library of Congress’ American Memories, the Virginia Center for Digital History’s Valley of the Shadow, the National Climatic Data Center, and the U.S. Census. Social studies teachers might use a WIP to help teenage students use primary source materials to determine what life was like for a southern family during the Civil War (Mason & Carter, 1999). A science teacher might use a WIP to help students use historical rainfall data to determine whether or not El Niño had an affect on their local weather during the winter of 1997-98 (Bell, Niess, & Bell, 2001). WIPs created from these examples are available at http://edweb.sdsu.edu/wip.

WIPs are intended to be used as inquiry roadmaps for teachers desiring to promote higher levels of student-centered inquiry, specifically by leveraging uninterpreted online data to answer inquiry-oriented questions. Unlike WebQuests, which provide students with a procedure and the online resources needed to complete a predefined task, WIPs will place more emphasis in having students determine their own task, define their own procedures, and play a role in finding the needed online resources. The WIP concept is based upon and designed to support a spiral path of inquiry (adapted from The Inquiry Page, 2001). WIPs will provide teachers with six stages of scaffolding as they lead students in a web-enhanced inquiry project. While an inquiry-oriented activity might start at any of these stages, WIPs will be designed to initiate student inquiry at the Reflect stage.
The six stages in this path, including the proposed role of WIPs in these stages, are as follows:

Stage 1
General description of stage: Teachers leverage previous activities or start anew by sparking students' interest in a topical area. At this stage teachers are to provide a hook, causing students to reflect upon the topic.
Student Role: Reflect on previous or new material.
Teacher Role: Provide a learning hook.
WIP Role: Provide ideas and resources for topical hook.

Stage 2
General description of stage: Based in the students' interests sparked by the hook, the teacher leads students to ask questions related to the topic.
Student Role: Ask questions related to topic.
Teacher Role: Keep questions on topic.
WIP Role: Provide potential topical inquiry-oriented questions.

Stage 3
General description of stage: After questions have been asked by the students, the teacher assists them in defining the procedures for investigation. Here the teacher's role is to ensure that the procedures are rigorous enough, according to the rules defined by each content area, to provide adequate evidence to support potential answers.
Student Role: Define procedures.
Teacher Role: Ensure procedures are rigorous.
WIP Role: Define potential procedures, including type(s) of data needed.

Stage 4
General description of stage: Students seek online data that will be used to answer their questions. At this stage the teacher must provide guidance on the relevancy and reliability of data. Here also, the teacher might participate with students in finding resources or have pre-selected resources in mind in the event that resources are difficult to find.
**Student Role:** Investigate data.
**Teacher Role:** Assist students in finding and assessing credibility of data.
**WIP Role:** Provide list of potential resources of online data.

**Stage 5**

**General description of stage:** When data is found the teacher must ensure that students have facility with the tools needed to manipulate data. If numerical data must be manipulated then students will likely need facility with a spreadsheet application. If data is non-numerical, then concept mapping or database software might be required.

**Student Role:** Manipulate data.
**Teacher Role:** Teacher provides data manipulation tools and training using tools.
**WIP Role:** Provide an example of manipulated data.

**Stage 6**

**General description of stage:** No conclusion is meaningful unless communicated appropriately. After students have manipulated the data, they discuss and defend their results with each other and the teacher. Here the teacher must support students' efforts in presenting their results in writing, through graphical presentations, and through rhetoric. At this point, new inquiry-based questions might be asked as students reflect upon their results, restarting the process.

**Student Role:** Discuss and defend results.
**Teacher Role:** Teacher supports students' efforts in presenting and defending results.
**WIP Role:** Provide example of defended results. Provide example of new inquiry-oriented questions.

**Conclusion**

In the last five years WebQuests have proven to be useful in promoting Herron's Level 1 of structured inquiry. At a time when educators struggled to provide an effective way to make good use of the Internet, the WebQuest model supplied the scaffolding needed by both students and teachers. WebQuests will continue to be an important component of inquiry-oriented learning.

Being heavily scaffolded, WebQuests prevent learners from participating in higher-level inquiry activities. Now that both teachers and students have more facility with the Internet, scaffolding from the WebQuest model can be removed, leading us to Web Inquiry Projects. If used appropriately, WIPs will help educators promote guided and open inquiry, Levels 2 and 3, respectively.

Curriculum, Competence, and Confidence:
A 3C Approach to Teacher Preparation for Technology-integrated Practice

Michael Nord
Willamette University Department of Music
mnord@willamette.edu

Abstract: Effective teacher preparation addresses issues of curriculum, competence, and confidence. Interactive in technology-integrated classroom practice, these "3C"s should be actively intertwined and accounted for in teacher preparation pedagogy. This paper outlines a 3C approach used in both graduate level music teacher preparation classes and in-service workshops. The approach is rooted in the notion that good teaching, not simply good machines, makes for meaningful technology integration.

Overview

Schools are embracing the integration of technology. Teachers and students have the potential to engage in meaningful activities previously unavailable. Music technology, for example, offers practical classroom access to authentic materials and processes that had previously been limited to those with highly specialized skill sets and instrumental resources. Regrettably, schools are not yet enjoying the full potential of technology. This is, I believe, particularly true with regard to music. Impediments to the effective integration of technology into classrooms may be structural or pedagogical in nature.

Structural impediments to the integration of technology include a lack of current hardware and software, lack of appropriate space, limited access to computer labs, administrative disinterest, and insufficient technology support (Hasselbring et al, 2000; Young et al, 2000; Drost and Abbot, 2000). Pedagogical impediments center on lack of the teacher preparedness to confront the new paradigm of technology-integrated practice (Dunnigan, 1993; Dudt, Yost, & Brzycki, 2000; Whetstone and Carr-Chellman, 2000; Uszler, 1996). The overlap of these structural and pedagogical impediments manifests itself in the lack of opportunity for preservice teachers to observe the kind of in situ modeling that will inevitably affect their future practice (Moursund and Bielefeldt, 1999, Carlson and Gooden, 1999).

Those of us who are teachers of teachers have limited opportunity to directly confront the structural impediments that exist in various locales. However, we should strive to prepare teachers for the highest levels of technology integration because of the value it brings to schools.

Effective teacher preparation addresses issues of curriculum, competence, and confidence. Interactive in classroom practice, these "3C"s should be actively intertwined and accounted for in teacher preparation pedagogy. As with strands in a rope, a fray in one leaves the others vulnerable. Tripartite models have been described in relation to both the teaching of elementary classroom teachers to teach music (Jeanneret, 1997) and to teach with technology (Merideth & Steinbronn, 2000). This paper will outline a 3C approach as it has been used in both graduate level music teacher preparation classes and in-service workshops. The model is rooted in the notion that good teaching, not simply good machines, makes for meaningful technology integration.

The 3C's

"Curriculum", as used in this discussion, encompasses content and pedagogy. Technology offers new opportunity with regard to both of these curricular dimensions. There is a ring of truth to the old aphorism: "We teach like we were taught." In other words, all of our behavior as teachers is modeling. Therefore, teacher education should model practice consistent with that which the teacher educator wants her students to bring to their classrooms (Jeanneret, 1997; Dudt, Yost, & Brzycki, 2000). That practice should account for technology potential in the crafting of a new curricular paradigm, rather than simply...
plugging the computer into an old one. Teachers, not technology, must craft the new paradigm (Riel et al., 2000).

Technology-integrated teaching requires that teachers develop their own strength in technology use (Pan, 1999; Uszler, 1996)). “Competence,” as used in the 3C model, refers to a teacher’s practical ability to use and troubleshoot both hardware and software. In many, if not most, schools technical assistance is not readily available. Staff responsible for technology maintenance and training is typically spread thin. Children in classrooms with teachers who are self-reliant are more likely to have consistent access to current working technology. Developing competence must also include developing the tools for managing classroom technology use (Duran, 2000).

“Confidence” refers to teachers’ sense of personal ability and preparedness to the use of technology. Teachers who do not themselves feel comfortable or capable with computing are unlikely to integrate it in any significant way. Whetstone and Carr-Chellman (2000) note that preservice teachers did not see the importance in their own roles in classroom implementation. Significant gender differences exist with regard to self-confidence with technology (Bauer, 2000; Weinman & Haag, 1999).

Curriculum

We want our education students to enter the profession with an inclination to take a step back and ask: “What aims and goals do I have for my students, and how might technology contribute to them.” Naturally, as their models, we must do the same, pointedly making content, pedagogy, and the thinking behind our choices explicit. The model we provide will serve our students as a point of departure in their own practice.

Modeling is the single most potent communicator of pedagogy. We teach them “method” by doing with them something analogous to what they will do with their students. In a sense we are trying to nurture their perceptions to both sides of the teacher/student experience, first by putting them in the “role” of their future students, and secondly by later giving them opportunity to put each other in that role. Organized reflection is the glue that binds the pieces. The operative concept is to do what you would have them do in their future classroom, rather than describe what you would have them do.

For a music curriculum, Wiggins (2001) advocates the goals of musical literacy, proficiency, and independence. Like other constructivists she suggests that students achieve these goals through problem-centered interactions with authentic materials (Brooks & Brooks, 1993) or situated learning (Duffy & Jonassen, 1992). Specific topics return at ever increasing levels of complexity and interaction (Bruner, 1960; Thomas, 1971). With these perspectives as a philosophical base, the 3C approach focuses on using technology to provide unique opportunities for exploration and problem solving in the materials of music. In other words, music technology is most potent when used as a “tool” (as opposed to as a “tutor”) allowing students to engage and manipulate the basic building blocks (see Thomas, 1971) of musical works; pitch, timbre, rhythm, form, and dynamics. Classroom teachers craft the focus, sequence, and design of problems. Figure 1 below illustrates some general examples.

</tr>
</tbody>
</table>

Figure 1: Curriculum content progression.
Successful integration of technology requires that teachers take students beyond the immediate cognitive and musical products of their interaction with that technology. The lesson, from the perspective of our students being in the role of their own future students, is not over when the machines are turned off. Organized examination of their products (technological or otherwise) is a central element of constructivist practice. Finally, they need to be guided through a reflective review as what happened in their role as "students" and its implications for their future practice.

**Competence**

In order to successfully integrate technology into their practice, teachers need to know how to use and choose hardware and software. They also must have a repertoire of trouble shooting skills. They must have technique in technology classroom management. In the 3C approach these issues are addressed in lessons and "in process." A good rule of thumb is to take nothing for granted.

With regard to hardware lessons, a number of my own students reported that actually assembling a system in class was invaluable to them, even if they had done it at home. MIDI based music systems are especially complex with their extra hardware and software. A thorough review (and consistent use) of terminology is valuable. My experience suggests doing all of this at the beginning of a semester.

With regard to software lessons, going through installation routines is also valuable. Again, MIDI systems have extra layers of complexity.

Situating learning is the key. Students develop competence by using, and often struggling, with software and hardware. Our goals should center on our students gaining independence. While we are modeling a constructivist curriculum approach that they might use with their future students, they are similarly engaged on another level aimed at their own technology skill development.

Some ideas follow:
- Start with unstructured time to "play."
- Don't hand out step by step guides. This teaches them to type, not develop independence.
- Demonstrate a technique or tool and then present them with a problem to solve.
- Be a guide and scaffold, but let them work through their own difficulties.

It is here where the "in process" dimension is at the forefront. For example, after "play" (read exploration) have them demonstrate their discoveries. Everyone discovers something, and the pool of discovery is usually greater than any one individual or team comes up with. Treat "I don't know how I got here" as an invitation for the class to figure it out together. Have individuals or teams present their solution process as well as products. Create an atmosphere where students are comfortable questioning and answering each other. Students should be constantly teaching their peers. The inevitable freezes, glitches, and miscues of technology should be viewed as opportunities for the development of troubleshooting skills. Guide students, but do not solve technology problems for them. Where a student is unable to navigate a particular issue, or that issue is one that you want the entire class to have experience confronting, bring them into the search for a fix. Bear in mind that the goal is to teach them strategies for independent trouble shooting, rather than simply providing a top 10 list of problems and solutions.

We want our students to be independent in their ability to choose software. Once more we need to equip them with a strategy rather than a list. In focused lessons, students must be familiarized with the notions of usability, acceptability, and efficacy. Teams of students can be provided with a question guide that they use to evaluate specific software. Both general and contextual perspectives should be taken. Students can also be asked to formulate and share their thinking behind new questions addressing usability, acceptability, and efficacy. In process, planned and spontaneous examination of the three categories should take place in the context of the activity students are engaged in at that moment.

A final area of competence described above is management. Obviously there is a great difference between the university lab and the elementary school music room. Absent the opportunity for in situ modeling/observation opportunities, our students will rely on the modeling we provide in our classrooms, and the anecdotes we can share from our experience. Familiarizing them with the use of management software will be useful. Opportunities for students to take the role of teacher in your classroom, followed by group and individual reflection may be your single most potent means of nurturing their development of management skills.
Confidence

Technology confidence must be actively nurtured in the teacher education classroom, intertwined with the curriculum and competence issues. Confidence is an empowering sense of personal ability in negotiating curriculum and competence issues. While it is a natural by-product of the independence described earlier, we must be active in assuring that it is there. The 3C approach takes the view that one doesn’t teach confidence, one teaches for confidence. Students must first internalize the notion that it is not the machines that teach, it is they who are teaching with the machine as their tool. In other words, it is they who are in control of the situation. Situations get out of control because of inadequate lesson planning and implementation, and/or technical difficulties.

Lesson planning and implementation is addressed by the models you provide (see Jeaneret, 1997) and the process of reflection that accompanies each experience. Model use of, and create formal reflection time for the “try it yourself first” strategies. We should exemplify the habit of first ourselves trying the creative problems we will assign students. This will not only prepare us to more effectively guide their troubleshooting and negotiate unexpected outcomes, it will provide opportunity to share your own work in the planning, implementing, assessing. Sharing your experience, and especially its hang-ups, will help them change the “it’s me” stance to an “it’s the nature of the beast and I know how to work with it” stance.

Computers crash and behave erratically just as chalk breaks and nails scratch the board. Confidence with regard to technical issues is addressed by students developing personal learning and troubleshooting strategies through guided confrontation of technical problems in their own and classmates’ work. The teacher educator must assure that all students learn to solve their technical problems, and assist others. This requires a commitment and patience on the part teacher and class. Be particularly vigilant with female and older students. Taking care of problems for your students may allow them, and probably you, more comfort, but it diminishes their independence and thus confidence. Nonetheless, as always, balance and sensitivity should guide decision-making.

Confidence in confronting lesson planning and implementation, and/or technical difficulties is synthesized by our students through their actively assuming the role of teacher to their peers, and multi-leveled roles as students. All students must experience all roles. As their teachers, we must be vigorous in our sensitivity to their concerns and devise focused strategies that give them practical experience in confronting those concerns. Let no one passively (or as Holt might suggest, actively) slip by.

Promoting a realistic multi-dimensional sense of confidence in our students will contribute to a school classroom atmosphere where children are freed to explore with technology, guided by teachers unintimidated by the unpredictable.

The 3C Approach

Teachers of technology-integrated education courses should consider curriculum, confidence, and confidence when developing their syllabi. This applies to planning for both individual lessons and for their sequence. While lessons may emphasize one strand, we teachers of teachers should always account for each of the 3C’s and aim for their seamless integration.

Conclusion

A discussion of technology and teaching must reflect the notion that it is not merely the presence of technology, but rather it is the means by which it is engaged wherein lies the potential for improvement in learning. The 3C model seeks to operationalize the view that effective teaching is more likely to occur when teachers have been nurtured in their own capabilities, the sense of their own capabilities, and the processes and products of meaningful lesson building.

The ideas in this paper represent a synthesis of theory and practice as explored by my own teaching in graduate and professional development classrooms. The approach will be applied in undergraduate classrooms next year. While some former students report that they have successfully integrated technology into their own classrooms, formal study remains to be done. Research should look at the integration of technology, efficacy of that integration with regard to the achievement of teaching aims and goals, and the manner in which the 3C teaching approach affected those issues.

The PDCA Model: A Basic Evaluation Tool

Catherine A. Offutt, Outside Evaluator, University of New Mexico – Gallup, USA, melcat@nm.net
Connie J. Casebolt, Business Dept., University of New Mexico – Gallup, USA, conniejcaunm.edu

Abstract: The PDCA model allows any grant-funded project to make a comprehensive bridge between the project logic model to the daily workflow model of managing for success. The PDCA model offers an organized way to explain the processes through which the project has evolved and points directly to methods, which are either effective or ineffective. The PDCA model of formative evaluation provides Project Managers, Partners, Evaluators, etc. with a document which keeps the information about a given project organized, timely, and comprehensive.

Most grants require both formative and summative evaluations to be performed over the life of the funded project. Most recipients of grant funds struggle with the efficient application of evaluation methodologies, within the scope of the funded project. Few agencies prescribe the specific formats for conducting evaluation. Striking the proper balance between process evaluation and impact/outcome evaluation can be tricky and time consuming. A method, which follows the flow of the project, yet allows for critical evaluation and restructuring of problem areas can be most helpful.

PDCA stands for Plan, Do, Check and Act. The PDCA model allows every project, whether it is a PT3, Technology Challenge or in a totally unrelated area, to make a comprehensive bridge between the project's logic model to the daily workflow model of managing for success.

Collaborative partnerships appreciate this model because it allows each Partner to showcase their contributions while keeping them informed of the activities of other Partners. Further, it provides a basis, when used in conjunction with a project logic model, for optimizing creative solutions to problems as they arise within the project scope.

The PDCA model offers an organized way to explain the processes through which the project has evolved and points directly to methods, which are successful, as well as those which are problematic. The project's federal Program Manager can easily see what has been accomplished and what remains to be completed. Additionally, areas, which are difficult to manage, can be identified and technical help can be applied where necessary. The PDCA model facilitates the creation of interim and annual reports to funding agencies.

The PDCA model should, ideally, be completed at the time of grant application and used to facilitate the funder's review of the grant proposal. However, the PDCA model can also be completed following the grant award. The objectives of the proposal need to be translated from the grant application to the PDCA form and then a step-by-step listing of activities necessary to accomplish each of the objectives are listed and prescribed a responsible party and timeframe for accomplishment. Each item that is developed will be assigned a status, as of a given date, which tells the reviewer which issue the item pertains to and what priority the item has been assigned. Then each item within the PDCA model is periodically (usually quarterly) evaluated, based on reports of activities conducted and logs of dosage data. Once an activity and/or objective is successfully accomplished, the procedure becomes standardized, the success shared with others and the status of “Resolved” is assigned. Should the activity not be accomplished given the initial strategic plan and assignment of resources, the “ACT” column becomes the place where new ideas and revised strategic plans can be documented until success is achieved.

Utilization of the PDCA form of process evaluation helps Project Directors/Managers develop, organize, implement and monitor the multiple objectives of any given project. Used in conjunction with the project’s logic model, the PDCA form also facilitates the identification of problem areas, the engineering of a new strategic plan for solving such problems, and highlighting areas where technical assistance from the funding agency may be beneficial.

This model is easy to use and lends itself to capturing the ebbs and flows of project management over time. Mostly, the PDCA model keeps the flow of information about a given project organized, timely and comprehensive.
**PT3 Project Performance Improvement Tracking Log as of 10/31/01**

**MISSION:** To support the transformation of teacher preparation programs into 21st century learning environments that prepare technology-proficient educators to meet the needs of 21st century learners.

**VISION:** To improve the knowledge and ability of future teachers to use technology in improved teaching practices and student learning opportunities, and to improve the quality of teacher preparation programs.

**GOAL:** To modify and enhance the current early childhood, elementary and secondary teacher preparation programs offered through the University of New Mexico – Gallup Campus.

Abstract: Certain processes of coding electronic discussions have been shown to improve the quality of argumentation styles in online discussions. This paper addresses a) a teacher education course in physical education where cognotes are used to prompt students to consider more substantive electronic discussion interaction b) an inclusive education course “aligned in time-frame” to the physical education course such that the transfer of skills to other courses (without prompting) can be judged.

Introduction

Since its inception, electronic discussion has been used primarily to offer an asynchronous environment for casual exchange of ideas between students. In recent years this has evolved to more thought-provoking exchanges promoted in part by improved professor interaction.

With regard to evaluation, early uses of electronic discussion amounted to participation grades which gave little credence to the quality of the discussion. Efforts to improve the quality of discussion have included the design of analytical rubrics that gauge broad styles of student interaction. For example if a student responded to an instructor’s prompt and raised a new question they may be awarded a passing grade for the electronic discussion.

Current Practice

Acadia University created in 1997 an institutional network called Acadia Courseware Management Environment or ACME where students participate in electronic discussion groups (hereafter EDG’s) within undergraduate courses. Most recently, MacKinnon & Aylward (2000) have designed a macro-based coding system for electronic discussions called cognotes. These cognotes highlight specific aspects of critical thinking and higher-order argumentation styles. To date, several limited studies have been undertaken namely: (1) teacher-coding of student discussions in a science education class (Aylward & MacKinnon, 1999) and (2) student coding of peers in a middle school education course (MacKinnon & Bellefontaine, 2001). Results from this last study has indicate that cognotes as a teaching strategy has the
potential to improve communication patterns within a context where students apply the codes electronically to evaluate their peers.

The purpose of this study was to further examine the link between our electronic EDG's and critical thinking necessary for substantive student discussion. Part A of this study addresses a teacher education course in physical education where the cognotes are used to prompt students to consider more substantive electronic discussion interaction, rather than actually applying the codes electronically. Does the introduction of cognotes as a teaching strategy prompt students to improve their electronic discussion communication patterns? Part B of this study addresses an inclusive education course “aligned in time-frame” to the physical education course such that the transfer of skills to other courses (without prompting) can be judged. Do students who have been introduced to the strategy improve their electronic discussion group communication patterns in others courses? Are these communication patterns more substantive than those from students who have not been introduced to the cognote teaching strategy?

Part A: Electronic Discussion Group Setting With the Introduction of Cognotes

Setting

This study began within a teacher education course in physical education where students were invited to construct new meaning about teaching from engaging in electronic discussions stemming from learning activities experienced in class related to physical education content and teaching strategies. Students, in groups of 4 or 5, initially engaged in an electronic discussion prior to being introduced to the cognotes developed by MacKinnon & Aylward (2000). “Cognotes” are used as student prompts to consider more substantive electronic discussion interaction. Students (a) were introduced to cognotes, (b) distinguished between critical categories and (c) created their own statements for each category in a teacher-led exercise. Students were then invited to assess an earlier EDG using the coding system as a scaffold to determine the nature and level of their entries. The process of self-assessing one’s entries was also part of the assessment system at the close of each of topic with the intent to challenge students to ensure that they were engaging in high-level discussions by the end of the semester. Data was gathered from all 52 students in the Bachelor of Education Elementary Program (B.Ed.) enrolled in this Physical Education in Inclusive Elementary Schools methods course. Data consisted of all EDG entries captured from the first and last electronic discussion prompt introduced in class during the fall semester.

Analysis

An inductive analysis of student entries was conducted based on the coding system developed by MacKinnon & Aylward (2000). This analysis indicated that a significant number of students offered their unsubstantiated opinion as opposed to engaging in more substantial argumentation patterns such as cause & effect, compare/contrast, idea to example/example to idea etc.

“Phys Ed teacher should teach overall fitness awareness, basic skills that will help students be active, and develop a positive attitude towards a physically active life (opinion). In teaching Phys Ed. An instructor needs to be able to match the skills and activities to the lesson to the physical capabilities of the students (opinion). Activities should be fun with the focus on students learning skills rather that on performance (opinion).”

Students also sent messages agreeing with others people’s messages and essentially only repeating what someone else said.

“Sandra ... I thought your point about teaching physical education as a life style not a subject was excellent especially in light of the fact Canadian Children are becoming increasingly inactive” (agreement).

Meanwhile there were instances where students did support and extend their ideas. “Learning, whether it takes place in the classroom or in the gym is more effective when it is fun (opinion). When learning is fun students will be more engaged and are therefore likely to retain what was taught (building a point). Thinking back on early school experiences, I remember even now the good, fun learning times such as the puppet play we put on to retell a story. I don’t recall as much on what was taught to me in the lecture format except that it was boring and I spent more time watching the school clock waiting for the bell than that doing any real learning. I don’t’ think its is a question of whether we should develop skills or have
fun. A better question would be, how do we as educators incorporate fun into our lessons so that more learning can be accomplished?"

On a few occasions it was clear that students were not only providing support for their way of thinking, they were furthering the discussion by building on points that other students had previously made. "Dan made a great point. P.E. and fun should go together (agreement). If the activities are fun, the children will enjoy learning the skills and develop a better outlook on skill development and active living (building a point). For me, gym was always fun. Some drills may have been more tedious, but if they were made fun with a competitive edge. Students would enjoy and look forward the classes" (idea to example).

Table 1 shows the distribution of discussion patterns in the electronic discussion for the Physical Education Methods course.

Table 1: Distribution of elementary program students according to their discussion group patterns within the Physical Education Methods course.

By comparison to earlier work done by Aylward & MacKinnon (1999) these results are not surprising. In the aforementioned research above, students were not evaluated on the quality of their participation. They were encouraged to participate in EDG's in more substantive ways however, their response to this was not reflected in a grade. This is in contrast to the work of Aylward & MacKinnon (1999) where in fact students were graded based on a hierarchal "cognote" grading scheme. The Physical Education course data then corroborates the dilemma that MacKinnon (2000) posits, i.e. grading the discussion may provide incentive to improve argumentation styles but is the impact long-term? This then leads to the question of whether improved discussion patterns transfer to other courses. This then constitutes the second component of this paper.

Part B: Electronic Discussion Group Setting Without the Introduction of the Cognotes

Purpose

Part B of the study of electronic discussion groups (EDGs): 1) searched for evidence of transfer of discussion skills from one course to another without prompting students using coding categories (Group A), 2) examined inherent skills in a control group that had no prior instruction (Group B), and 3) examined skill growth over time in both groups.

Study Groups

Group A were B.Ed. Elementary Program students (n = 16) concurrently enrolled in the Physical Education in Inclusive Elementary Schools methods course and in the Issues in Inclusive Schools foundation course. Group B were B.Ed. Secondary Program students (n = 43) enrolled in the Issues foundation course but not in the PE methods course.

Both courses used EDGs and as noted, Group A students were introduced to cognotes and their particular use in stimulating higher levels of critical thinking in the PE course. However, no such instruction was given to either Group A or B in the Issues course beyond the mechanics of using EDGs and the value of critical thinking in
their work. All entries from the first and last topics assigned in the electronic discussions comprised the data for this analysis.

Analysis

Using the coding system developed by MacKinnon and Aylward (2000), the analysis grouped students’ EDG entries according to the following response types. P1 indicated off-topic or faulty logic; P2 indicated agreement with others, expression of opinion, asking a question, simple compare/contrast with no significant new information; P3 indicated clarification with new information, building on a point, making inferences, describing cause/effect consequences, ideas illustrated by examples, and examples leading to new ideas, that is essentially carrying the conversation forward to a higher cognitive level. The growth in discussion skills (as defined here) over the duration of two electronic discussions is noted in Table 2.

Table 2: Skill Growth: Topic 1 Discussion to Topic 2 Discussion

Skill growth in both A and B Groups was shown by increases in (P3) higher level responses, decreases in (P2) lower level responses, and countered by slight increases in off-topic (P1) responses. However, Group A consistently had a higher percentage of P3 responses and a lower percentage of P1 responses than Group B, indicating a greater initial skill level in Group A as well as continued skill growth.

From Table 3, over time, response frequency for Group A showed a slight increase, while a definite decline was noted for Group B.

Table 3: Response Frequency: Topic 1 to Topic 2

Discussion

It appears as though some students are retaining the electronic discussion skills gained from one course and applying them in another. Despite being prompted with the variety of patterns they might access, many students are choosing not to seriously improve their electronic discussion. From earlier work (MacKinnon, 2000) it seems quite evident that scoring the EDG quality could significantly enhance the number of students that consciously improve their argumentation patterns.

**Acknowledgements**

This work was supported by several Innovative Teaching Grants (Acadia University) as well technical assistance from the Acadia Institute for Teaching and Technology. The opportunity to present this work has been afforded by Acadia University/AITT.
Scientists at Vanderbilt University Medical Center work in teams each day to conduct valuable medical research. The Sci-Tech Research Project encourages middle or high school students to assume the role of various types of medical research scientists working in research teams at Vanderbilt University Medical Center. Students participate in this classroom project by establishing teams of four and choosing to be Primary Investigator (Ph. D. or M. D.), Lab Director (Master Degree), Lab Technician (Bachelor Degree) or Fellow/Graduate Student (Ph. D. or M. D.) within their team. Only one Ph. D. and one M. D. is on each team. Students must determine which position they want to hold within the team, recognizing the qualifications and responsibilities of each position.

Vanderbilt medical researchers present hypotheses to each team. Students work in teams to test the hypotheses within a designate period. Vanderbilt research scientists will use videoconferencing technology in order to communicate with the Sci-Tech Research Teams answering questions and providing guidance. Each group will use a Compaq IPAQ handheld to record findings and create a presentation based on these findings. The culminating activity includes team members of the Sci-Tech Research Project visiting a science lab in the Vanderbilt University Medical Center, presenting their findings to the researchers who posed the hypotheses and meeting their research scientist counterpart.

Participating in this project incorporates skills related to understanding the scientific method process, utilizing technology to collect and record data, team building, speaking to a group, utilizing technology to present findings, and skills related to the hypotheses, which are curriculum connected. This teaching strategy combines project-based learning, technology and reality-based teaching in an effort to increase student interest not only in science and technology but also in pursuing careers in the health sciences.
Ethics in Technology: Crucial Considerations
Fidel M. Salinas Ed.D.
Denise M. Smith, Ed.D., CCC-SLP

This study posits ethical issues in a technological world and their impact on education, business, industry, and government. Major topics included in this discussion include:

1. Ethics in curriculum development for Face-to-Face or Distance Learning environments on the Internet. Survey of Intellectual Property, explores the following: Who owns what, where, and when, domestically, and on a global basis?

2. Impact of licensing technological applications in a Global economy and on individual and social behaviors beyond software piracy.

3. Technological ethics issues and their impact on education, both, in academic institutions, and the industrial communities.

4. Global perspective of the impact of technology on the emergence of requirements for a new code of ethics on Global free speech, privacy rights, libel, slander, and Netiquette practices.

Intended audience members for this presentation are educators and administrators pre-K through adult.
A New Dimension of Teaching in Digital Learning Environments -
Teaching Teachers to Teach Between Schools

Abstract: The integration of information and communication technologies and, in particular, the increasing presence of the Internet in teaching and learning, challenges traditional educational considerations of time, distance and location. It also challenges traditional notions of the school. The ubiquity of information and communication technologies in education systems enables teachers and learners to form new teleteaching and telelearning relationships. The development of Internet-based technologies and the choice these provide of synchronous and asynchronous teaching and learning has encouraged some teachers to reconsider the organization of schools as well as the nature of their classroom work. This paper considers issues in the integration of information and communication technologies in teaching and learning for the organization of schools in the context of a shift from distance education to telelearning. A case study of senior high school students in selected small, rural Canadian communities who have been provided with opportunities to learn university-level Science and Mathematics within virtual classes located within a digital intranet provides the background for this paper.

Introduction

The urbanization of the Canadian landscape along with falling birth and fertility rates have combined to pose a threat to the ability of small rural schools to offer a high quality education program to the school-aged children they serve (Dibbon and Sheppard, 2001). As rural communities and schools decline in size educational policy makers often question their viability and as a result new educational structures suitable for delivering quality education to rural schools are being developed. The introduction of telelearning in schools in Canada, as in other developed countries, has been particularly noticeable in rural areas and has been largely influenced by declining enrolments and limited fiscal resources.

The rapid growth and educational application of the Internet has led to a challenge to traditional ways of teaching and learning at a distance that were based on paper and the postal system. TeleTeaching is Internet-based and does not require the degree of central control that distance educators have traditionally had. Teleteaching at the present time involves a search for appropriate pedagogy to enable teachers and learners to gain maximum advantage from the devolved, flexible and increasingly collaborative ways of organizing learning that are now possible between teachers and learners in multiple networks.

TeleLearning for Rural Canadian Communities

Thirty one percent of schools in the province of Newfoundland and Labrador are designated “small rural schools” (N=122) and 75 of these have fewer than 100 students. Seventy of the small rural schools in this province are classified as “all-grade” (K-12) which means that they must offer a senior high school program that meets the provincial certification standards. The concern expressed by educators in many of
these small schools is that they do not have the capacity to provide quality programs in all areas of the school curriculum. Therefore, the large proportion of small schools located in rural communities requires special consideration in the development of new, electronic educational structures. The search for appropriate new educational structures for the delivery of education to students in rural Newfoundland and Labrador has led to the development of Digital Intranets, within which virtual classes have been organized. In the process of developing teleteaching within digital Intranets, several challenges have had to be met.

**Preparing Advanced Placement Science and Mathematics for the Internet**

The development of Advanced Placement (AP) Web-based courses in Biology, Chemistry, Mathematics and Physics took place within subject area teams. A lead science teacher in each discipline was paired with a recent graduate in each of the disciplines of Biology, Chemistry, Mathematics and Physics who possessed advanced computer skills including web page design, Java and HTML. The lead teacher and the graduate assistant were advised from time to time by Faculty of Education specialists at Memorial University of Newfoundland in each curriculum area and, where possible, scientists from the Faculty of Science. The extent to which each web-based course was developed by a team of four people varied. Most course development took place through interaction between lead teachers and the recent graduates. Although at times professors had different opinions as to the most appropriate approach to the design of the courses, this model enabled the four courses to be developed over a sixteen-week summer recess period in time for the 1998-1999 school year. Minimum specifications were adopted for computer hardware and network connectivity. All schools involved in the project had DirecPC satellite dishes installed to provide a high-speed down-link. In most rural communities in this part of Canada, digital telecommunications infrastructures do not enable schools to have a high-speed up-link to the Internet. Appropriate software had to be identified and evaluated for both the development of the resources and the delivery of instruction within the Intranet. Front Page 98 was selected as the software package. Additional software was used for the development of images, animated gifs and other dimensions of course development. These included Snagit32, Gif Construction Set, Real Video, and similar packages. Many software packages were evaluated and finally WebCT was selected. This package enabled the instructor to track student progress, it contained online testing and evaluation, private Email, a calendar feature, public bulletin board for use by both instructor and student, a link to lessons and chat rooms for communication between teacher and student. For real-time instruction, Meeting Point and Microsoft NetMeeting were selected. This combination of software enabled a teacher to present real-time interactive instruction to multiple sites. An orientation session was provided for students in June 1998, prior to the implementation of this project in September. Students had to learn how to communicate with each other and with their instructor using these new technologies before classes could begin.

**The Development of a Digital Intranet**

The electronic linking of eight sites within the Vista School district to collaborate in the teaching of AP Biology, Chemistry, Mathematics and Physics created a series of open classes in rural Newfoundland that became known as the Vista School District Digital Intranet. The creation of the Vista School District Digital Intranet was an attempt to use information and communication technologies to provide geographically-isolated students with extended educational and, indirectly, vocational opportunities. This has been part of a broader pan-Canadian initiative to prepare people in Canada for the Information Age (Information Highway Advisory Council, 1995, 1997). The development of the Digital Intranet within a single school district involved the introduction of an open teaching and learning structure to a closed one. Accordingly, adjustments had to be made in each participating site so that administratively and academically, AP classes could be taught.

The Vista school district initiative challenged the notion that senior students in small schools have to leave home to complete their education at larger schools in urban areas. By participating in open classes in real (synchronous) time, combined with a measure of independent (asynchronous) learning, senior students were able to interact with one another through audio, video and electronic whiteboards. Because this
Intranet comprised a single school district and because the students lived within 60 miles of each other, from time to time they were transported to a central location where they were able to get acquainted with each other and their tele-teacher. While AP courses are a well-established feature of senior secondary education in the United States and Canada, it is unusual for students to be able to enroll for instruction at this level in small schools in remote communities.

From Closed to Open Teaching and Learning Environments

The major change in instruction for the students in the first Digital Intranet in Newfoundland and Labrador was the provision of learning in a flexible manner, building around the geographical, social and time constraints of individual learners, rather than those of the traditional school. Students from eight different communities had the opportunity to study advanced science subjects and mathematics as members of open classes from their small, remote communities. Instead of meeting in traditional classrooms, the Digital Intranet provided students with simultaneous access to multiple on-line sites, as well as the opportunity to work independently of a teacher for part of the day.

The advent of the Digital Intranet had implications for students who began to interact with teachers and their peers in a variety of new ways. Many students experienced difficulty expressing themselves and, in particular, asking questions in open electronic classes when they did not know their peers from other small communities. The organization of social occasions for students learning science in open classes in the Intranet helped overcome these problems. The need to prepare for classes before going on-line became increasingly apparent to both teachers and students if the open, synchronous, science classes were to succeed. As the commitment to come to class fully prepared increased, students became more comfortable with one another and inhibitions such as asking questions on-line were overcome. Also, as their studies progressed, the students were increasingly subject to scrutiny by their peers as they responded to questions and concerns through chat-rooms, audio, video and with their AP on-line teacher. In future, interaction in the Vista Digital Intranet will be both synchronous and asynchronous.

The need for increased technical support for this new, open structure has become increasingly urgent for teachers and students who are using information and communication technologies to teach and learn across dispersed sites. Both have to be provided with expert advice and instruction in the use of new applications. A particular problem has been the difficulty in securing and maintaining instructional design expertise in the preparation and upgrading of courses delivered through the Intranet. Since these instructional design experts are not available to the school system on a full-time basis tele-teachers need to work closely with instructional designers on a skills transfer program that will enable these tele-teachers to keep their courses up to date and relevant.

Teaching Between Schools (Sites) in Rural Communities

In the process of developing teleteaching and telelearning within Digital Intranets in rural Newfoundland and Labrador, teachers, learners and administrators had to adapt to a new, electronic educational structure in which teaching and learning took place between, as well as in, it's constituent participating sites.

In the open teaching and learning environment of a digital intranet, participating institutions academically and administratively interface for that part of the school day during which classes are being taught. This is a different educational structure from the traditional and, by comparison, closed educational environment of the autonomous school with its own teachers and its own students. There is a potential conflict between a school as an autonomous educational institution serving a designated district and schools which become, in effect, sites within electronic teaching and learning networks. Issues related to governance, teacher allocations, teacher and student scheduling, work load and training and development will need to be resolved before open teaching and learning model can be fully adopted.

149
Page 89
Principals and teachers appointed to the closed, autonomous learning environments of traditional schools frequently discovered that the administration of knowledge requires the development of open structures within which they are increasingly expected to collaborate with their peers located on a range of distant sites. Some now find that the positions to which they were appointed in traditional (closed) schools have become, in effect, locations within new (open) electronic schools and some of the teachers actually split their teaching assignment between the open and closed model of school.

An essential aspect of the development of open electronic classes is the coordination of both hardware and software between schools. Without coordinated technology, schools cannot fully participate in electronic networks. However, the purchase of appropriate hardware and software is a matter of confusion for many principals, teachers and School Boards who seek support and advice. Many rural schools with open electronic classes realized that the successful administration of a network required local technical support. Unless adequate technical support systems can be established, electronic networked classes could be curtailed by teachers who could argue, with justification, that there is insufficient back-up to justify their investment in telelearning.

In small and remote Canadian communities the assurance of adequate technical backup is often particularly difficult to provide for teachers and their senior students. In schools in Newfoundland and Labrador, the majority of which are designated rural, telelearning often depends on the goodwill of one or two teachers with enough technical knowledge to develop and maintain school networks and to troubleshoot when malfunctions occur.

Pedagogy for TeleLearning

Although it has yet to be shown that open Internet-based classrooms suit the needs of all students, particularly those at junior levels, they do provide rural schools with choice in the way they can access educational and, in particular, curriculum opportunities. Teaching in classrooms that are electronically linked to other sites requires different lesson preparation and delivery skills from teaching face to face. For teacher–student interaction in a new electronic structure to be effective, the strengths and weaknesses of the new environment have to be understood by everyone who participates.

Students often have more independence in managing their learning in open electronic classes but must have to be assisted by teachers in the setting of goals, the meeting of deadlines and in evaluating their progress. Teachers are effective in open electronic classes if they can be flexible in ways they enable students to participate in on-line lessons. Audio-graphic networking has in the recent past provided schools participating in regional electronic networks with a simple and flexible way of accommodating the diverse needs of learners (Stevens, 1994). The student's need to concentrate on the audio lesson to fully participate in it when conducted in an open electronic class between several sites was noted by several participating schools in earlier research in New Zealand (Stevens, 1994). Students cannot anticipate when they will be asked a question over the audio network, something that encourages preparation for classes conducted with teachers and peers who are not physically present (Stevens, 1998; 1999).

The nature of Tele-learning requires dedication and discipline on the part of learners and they must be motivated to complete and participate in all aspects of the learning program. As a result, high quality interaction with learning materials and interaction between teachers and other learners is essential for effective learning. With the right support, tele-learning has the potential to open new and exciting worlds to more and more students, at all levels.

Strategies and protocols for on-line teaching have to be developed between participating schools if all students are to be able to fully participate. The introduction of a rural school to an open electronic network considerably improves its resource base for both teachers and learners but does not solve all of its problems. It is often difficult to coordinate the timetables of networked schools and a considerable measure of inter-institutional and intra-institutional cooperation is required to develop detailed and effective plans for collaboration.
There are several immediate pedagogical challenges to be considered for effective teaching in a Digital Intranet: Teaching face-to-face and on-line are different skills and teachers have to learn to teach from one site to another. This is fundamental to the success of teleteaching. Teachers have to learn to teach collaboratively with colleagues from multiple sites and educators have to judge when it is appropriate to teach on-line and when it is appropriate to teach students in traditional face-to-face ways. These judgements have to be defended on the basis of sound pedagogy.

Conclusion

The introduction of inter-school electronic networks has added a new dimension to education in Canada and is bringing new challenges for teachers and learners (Collis, 1996; Hobbs and Christianson, 1997) and administrators. The teachers and researchers who are collaborating in the development of new electronic structures for delivering education to dispersed, rural sites in Atlantic Canada are very conscious of being pioneers.

In rural Newfoundland and Labrador the open learning model challenges the closed model of schooling by questioning the need for appointing all teachers to schools, rather than, in appropriate cases, some teachers being appointed to networks of schools. It questions the appropriateness of learners engaging solely with their peers within their own, physical classrooms, and, it questions the very notion of the school.

Technically, tele-learning is defined as the asynchronous or synchronous (real-time) delivery of training and education over the Internet to an end-user's computer or Internet appliance. Philosophically, tele-learning signals a shift of epic proportion in the way we will approach learning in the future. If we are prepared for the opportunities this type of learning presents we will be better prepared to meet the needs of all our students. If not, we may miss or delay the greatest potential changes in learning and the subsequent empowerment of people that the world has ever witnessed.

Abstract: This presentation provides information garnered from a post-faculty development workshop survey regarding the use of evaluation rubrics. Rubric discussions at the UT-ITESM faculty development workshop (in June 2001) focused on six facets of understanding, seven steps to rubrics development, and the employment of rubrics as an alternative assessment method. This paper presents the post-workshop survey and results, as conducted by the researchers, while workshop participants’ rubrics samples and assessment strategy suggestions will be presented during the oral presentation.

Introduction

Evaluation of online collaborative learning has been the subject of increased attention in recent years. Online collaborative learning involves both task and social aspects of learning. A long tradition of methodology and approaches regarding task evaluation, including knowledge and skills, exists. Social aspect evaluations, including communication and group collaboration, present special challenges to instructors, and opinions regarding online learning evaluation cover a wide spectrum. Some commentators have proposed "the need for standardized evaluation," while others have emphasized the importance of considering the context and the characteristics of users (Crawley, 1999).

Rubrics are "a type of scoring guide" used to assess more complex and subjective performance, according to Mary Rose (1999). She said rubrics provide "authentic assessment" so the evaluations of student performance are "closer to the challenges of real life than isolated tests." Rubrics that "communicate detailed explanations ... not only benefit students in making them more conscious about their own learning outcomes and process," she said, but teachers also benefit by their ability "to provide an objective basis for assigning grades" and to "involve students more effectively in the evaluation and assessment process" (Rose, 1999). A plethora of literature in support of such measurements abounds. Topics discussed include using rubrics as an alternative assessment (Marzano, 2000), as assessments of authentic and contextual learning (Huffman, 1998), and as performance assessments in an outcome-based system (Mitchell, 1997).

This report was initiated by an instructional designer serving as a facilitator of a three-week cross-discipline and cross-institutional online collaborative learning workshop, ITESM Summer Institute, and is based on a collaborative effort of two workshop participants, a high school principal and a higher education school administrator. The major objectives of this report are to explore workshop participants’ perspectives toward the use of rubrics as an alternative assessment tool following their engagement in using rubrics for self, peer, and product evaluations after collaborating in groups. A post workshop survey was conducted to investigate participants’ perspectives, experiences, and attitudes toward its future use. A few rubric samples produced by some workshop participants are also presented and analyzed.

ITESM Summer Institute – Discussions on Evaluation

On May 28, 2001, forty-eight ITESM (Monterrey Institute of Technology and Higher Education System) faculty members from throughout Mexico gathered at the University of Texas in Austin for the “ITESM Summer Institute.” Hosted by U.T. Austin, this intensive three-week professional faculty development workshop emphasized the integration of technology into curriculum and instruction. Three major aspects of the workshop were cooperative learning, collaborative learning, and faculty development.

The discussions on evaluation were conducted by one of the three major workshop speakers, Dr. Paul E. Resta, a professor at the University of Texas at Austin. Various perspectives and approaches in using rubrics were explored. Workshop discussions included the relevancy, validity, reliability of using rubrics, as well as design
considerations and strategies involved in rubric use. According to Resta, an awareness of the varying levels of student understandings is essential when planning the use of rubrics to evaluate online collaborative learning; he identified six facets of understanding to include explanation, interpretation, application, perspective taking, empathy, and self-knowledge.

In collaborative learning settings, students need to explain and communicate their ideas by making their knowledge public. They also must be open to review, discussion, and revision of their ideas within this setting. Through dialogue and discussion, students are able to achieve deeper understandings of conflicting ideas. The second facet of understanding is interpretation. Students need to hear meaningful stories that relate to their real-world experiences. In collaborative learning settings, students need to make their interpretations and understandings public while instructors should provide opportunities for clarifying and contrasting interpretations while promoting exploration and examination of self and others’ interpretations. Through this process of exposure to multiple interpretations, students are enabled to modify their interpretations.

The third facet of understanding is application. Learners should ideally be able to demonstrate what and how they have learned and employ their knowledge in complex contexts. Through the provision of real world problems and authentic, collaborative, and complex context within the learning environment, learners should be able to more effectively apply their knowledge and skills within the context of peer monitoring and cognitive apprenticeships. The fourth facet of understanding is the ability to take critical and insightful stands and the ability to provide reasoning and evidence to explain a particular phenomenon. In a collaborative learning situation, students are exposed to diverse viewpoints and conflicting ideas. Instructors who are able to facilitate critical analyses assist students in recognizing the strengths and weaknesses of their ideas, ultimately enabling more meaningful learning to occur.

The fifth and sixth facets of understanding are empathy and self-knowledge. Given the presence of divergent worldviews, students must be able to discern others’ values and understand others’ viewpoints when collaborating. Through discussion, assumptions are made explicit and further discussion and learning is enabled. The collaborative learning instructor should indicate the limits of the individual’s personal understanding and encourage multiple perspectives and dialogue among collaborators, with one of the end results being that all students should come to the realization that they are blinded—to some degree—by ignorance, prejudice, or habitual thought patterns. Based on such understandings, the instructor should have a better understanding of rubric utilization, inclusion factors, and rubric incorporation into instruction.

Seven steps to rubric development were discussed. These are: (1) Determine learning outcomes; (2) Keep it short and simple (include 4-15 items; use brief statements or phrases); (3) Each rubric item should focus on a different skill; (4) Focus on how students develop and express their learning; (5) Evaluate only measurable criteria; (6) Ideally, the entire rubric should fit on one sheet of paper; (7) Reevaluate the rubric (Did it work? Was it sufficiently detailed?). Dr. Resta suggested that instructors should select an authentic and engaging collaborative learning project that results in a real product. In considering the relevancy of the project, the instructor should specify curriculum areas covered and how they relate to students’ academic and/or professional goals. The instructors should focus on elements of knowledge that are important and worthwhile to students. Other considerations include: having a clear idea about “learner outcomes;” “learners’ entry skills and knowledge;” “project goals and expectations;” and considering how to promote students’ higher-level cognitive and critical thinking skills such as reasoning, analysis, problem-solving, critiques, and reflection. In addition, the instructor should promote creativity and divergent thinking by challenging students in authentic activities where students engage and solve problems collaboratively. In determining the rubrics development procedure, Dr. Resta suggested that outcomes should be considered first. The rubric statement should be “short and simple.” Items listed should have a particular focus on essential skills and knowledge. In addition to comprehending and mastering knowledge and skills, it is essential that students are able to communicate their ideas and understandings. The instructor should “focus on how students develop and express their learning,” and provide proper guidance.

To assess online collaborative efforts, Dr. Resta suggested that self, peer, and product evaluation should be included. Collaborators should be held accountable to each other in order to enhance optimal performance. In order to enhance accountability, members’ contributions and quality of work need to be assessed by peers. Instructors should also provide comment sections so students can provide rationales for their rankings and qualitative ratings. In order to enhance product evaluation, individual and group products should be assessed. Instructors should also
require students to maintain a portfolio of their contributions, specify items to be included in the portfolio, and identify criteria to be used for portfolio evaluation, Resta said.

**Rubrics for Assessment**

The merits of using rubrics for assessment are well-documented. Caroline McCullen (1999) refers to rubrics as excellent tools that offer a way for every student to succeed. Students can refer to a specific project or learning activity rubric and discern their ability to work at some level of proficiency. At the same time, students can discover for themselves modes to enhance future performance and proficiency in similar learning activities or projects. Rubrics also provide a way to make subjective activities such as group work, research processes, and presentations objectively evaluated (McCullen, 1999). Social skills and group behaviors are often not amenable to assessment and objective means of evaluating these skills and behaviors are often lacking. Rubrics allow teachers and students to easily outline and evaluate levels of proficiency.

Rubrics can be employed as both an evaluation and a teaching tool. Standards can be set for students’ work and used as guidance to assess students’ progress and performance. Finson & Ormsbee (1998) said that rubrics refer to specific guidelines on how to score all or parts of an assessment or activity. They identified two forms of rubrics: analytic and holistic. “Criteria that determine the specific type of rubric designed or selected may include the focus or intent of the assessment, the type of instruction preceding assessment, and personal preferences of the individual doing the assessing,” they said (p. 80).

Analytic rubrics are used to award points for very specific responses. Analytic rubrics are extremely objective because teachers critique each student response and score the response according to established criteria. These rubrics are more process-oriented than product-oriented. Holistic rubrics are used when overall quality is the focus of assessment. Holistic rubrics are more product-oriented than process-oriented and are primarily concerned with the total performance or product rather than with the individual steps taken to arrive at the final product. In its purest form, a holistic rubric is not used to award points; instead, student products are simply rated according to designated indicators.

**A Post-workshop Survey about the use of rubrics**

A multiple choice survey was conducted by this study’s researchers to discover workshop participants’ prior knowledge and use of rubrics as well as their plans to use rubrics for evaluation in their instruction. Participants’ plans to use rubrics to evaluate group collaboration, tasks, or overall performance were also surveyed, as were their specific plans on rubric use, the relative likelihood of using rubrics for students’ self-evaluation, peer-evaluation, or teacher-evaluation, and the target populations of rubrics employment.

**Method**

The main purpose of this survey is to gain an understanding of participants’ prior knowledge of rubrics and to survey their learning of rubrics through workshop experience in self and peer evaluation using pre-developed rubrics. Further, how workshop participants intend to apply what they have learned about evaluative rubrics in their classroom teaching were explored.

The survey, conducted through a free online survey Web site (http://www.freeonlinesurveys.com), was sent to 46 workshop participants (two of three researchers were not included in this survey). Only 15 responses were obtained because most attendees were on summer vacation. Survey results were automatically calculated and shown on the Web.

In addition to the multiple-choice questionnaire, participants were also asked to provide additional comments via e-mail, telephone, or on-line chats with the researchers. Rubric samples produced by three participants during the workshop were obtained.

Survey questions were in Spanish because 95 percent of the workshop participants are native Spanish speakers. The survey questions were translated into English.

**Translated Survey Questions and results**

1. Prior to attending the UT-ITESM Summer Institute, were you using rubrics as evaluation tools? Choose only one option.
a. Yes (26%)
b. No (73%)

2. Do you anticipate using rubrics as evaluation tools in future courses? Choose only one option.
   a. Yes (100%)
   b. No (0%)
   c. I don't know (0%)

3. If you do anticipate using rubrics as evaluation tools in future courses, which aspect of the task/project/activity will your rubric focus on? Choose all the options you consider applicable.
   a. Process (group collaboration) (53%)
   b. Results (Product) (40%)
   c. Results Presentations/Evaluations (40%)

4. If you do anticipate using rubrics as evaluation tools in future courses, what do you want to evaluate? Choose all the options you consider applicable.
   a. Abilities (80%)
   b. Attitudes (86%)
   c. Values (46%)
   d. Knowledge/Content (100%)

5. If you do anticipate using rubrics as evaluation tools in future courses, how many levels of competencies do you anticipate using? Choose only one option.
   a. Two (0%)
   b. Three (26%)
   c. Four (73%)
   d. Five (0%)
   e. Six (0%)
   f. Seven or more (0%)

6. If you do anticipate using rubrics as evaluation tools in future courses, under which of the following modalities do you anticipate using your rubric? Choose all the options you consider applicable.
   a. Self-evaluation (26%)
   b. Peer evaluation (53%)
   c. Teacher Evaluation (93%)

7. If you do anticipate using rubrics as evaluation tools in future courses, at what educational level do you anticipate using your rubric? Choose only one option.
   a. High School (26%)
   b. Peer evaluation (40%)
   c. Teacher Evaluation (0%)
   d. Continuous Education (0%)

Results
Survey responses indicate participants’ consensus on the value of using rubrics for evaluation and suggest that UT-ITESM Summer Institute attendees are united in their perception that using rubrics in collaborative learning is an effective motivator. Of the 15 participants who responded, 60 percent planned to use rubrics with high school students and 40 percent planned to use rubrics with undergraduate students. The results show that only 26.67 percent of the participants had used rubrics as evaluation tools prior to attending the Institute and that the majority (73.33 percent) had not been familiar with the use of rubrics prior to the workshop. Following the workshop, however, all respondents indicated planning to use evaluation rubrics in their courses.

Regarding task aspects and anticipated rubrics use, about half (53 percent) said they would use the rubric to evaluate the group learning process, 40 percent would use rubrics to evaluate results or products, and 40 percent...
would use rubrics to evaluate students' presentation of their products. These results demonstrate that while the majority of the participants plan to use rubrics as a tool for evaluating group work, some remain focused on such tangible end products as tests or papers. Many of the teachers' responses, nevertheless, reflected an interest in examining group interactions and collaboration. Many participants said they anticipate using rubrics to evaluate teacher-set benchmarks of proficiency. This demonstrates that many participants anticipate teaching in a more structured environment where cooperative learning is utilized, but not the more loosely structured collaborative learning environment. According to Panitz (1996), a collaborative learning approach differs from cooperative learning mainly in the way the learning environment is structured and in the teachers' control of activities.

Regarding future use of rubrics for evaluation, all respondents indicated planning to evaluate knowledge and content; 46 percent planned to evaluate values, 86 percent planned to evaluate attitudes, and 80 percent planned to evaluate abilities. All respondents endorsed the idea that rubrics are an appropriate evaluation tool for assessing content and specific knowledge. The majority thought that rubrics might also be used to evaluate observable behaviors, competencies, and attitudes. Regarding who should conduct evaluations, 93 percent said that teachers should conduct evaluations, 53 percent said that peers should conduct evaluations, and 26 percent said self-evaluation should be employed. This suggests that most participants will continue to evaluate their students on their own, while some will incorporate peer evaluations and students' self-evaluations. Three or four levels of competencies were the only respondent choices, in terms of the levels of competency to be evaluated in designing rubrics, with 73 percent preferring four competency levels and 26 percent preferring three competency levels.

Conclusions

Based on the post-workshop survey responses and participants' rubric samples, it appears that participating teachers are seriously considering using rubrics as an alternative assessment in their classes. These evaluations, participants indicated, extend not only to evaluating students' product, but also to evaluating communication processes and abilities, as well as the ability to present ideas and products. Participants endorsed the inclusion of a wide array of aspects besides knowledge and skills, such as ability, values, and attitudes. Evidence was found to indicate an evolving concept of who should assess students' performance. Participants realized that assessment is not solely the teacher's responsibility, but that peer- and self-evaluation should also be employed. In general, ITESM participants exhibited their new found understanding that rubrics are not only an evaluation tool, but also an instructional tool to be used for scaffolding students' learning, monitoring students' performance, and promoting meta-cognition and critical thinking.

A reform process is currently underway at ITESM, Mexico, centered on emphasizing a student-centered approach, values and attitudes in teaching, and the implementation of technological integration. The institute expects its faculty members to understand the learning process, the relationship between knowledge and the social-emotional aspects of learning, and the role of technology in learning. The institute expects teachers to demonstrate progress in their instructional design utilizing strategies learned, resources explored, and realization of the changing roles of teachers. Throughout the investigation of the paper, we discovered participants' evolving attitude toward evaluation and their willingness to incorporate rubrics for various types of assessment in their classrooms.

THE CRUCIAL ROLE OF INFORMATION TECHNOLOGY AND
KNOWLEDGE-ECONOMY FOR TEACHER EDUCATION

Tsung Juang Wang
National Taipei University of Technology, Taiwan
(e-mail) tjwang@ntut.edu.tw

ABSTRACT:
This paper describes the current status of restructure development in technological and vocational education. The discussion covers Knowledge economy (K-economy) along with "global village" needs, and is supported by information about technology standards combined with notions of curriculum, career, ethics, and tradition. The concepts of Information Technology (IT) and K-economy development require input from all mankind, but teacher education professionals can play a particular role here; their reform motivation can often be a decisive argument for their education and workforce development.

Introduction
Life-long learning is the key to education in the 21st century; schools must depend on the directions they plan to take. Such decisions can be difficult especially when schools find themselves faced with the influx of rapid changes, both in society and in the school environment, characterized by the many changes that "move in so many different directions" (Drucker, 1992; 351) so no matter which direction one takes and what pressures we receive from different sectors, education needs to be customized, school-based, relevant, readily available and learner-centered. For this to happen, the place of technology is vital in providing the tools to access information from all corners of the earth, yet this information is useless unless the teachers help the students to turn this into knowledge, and through reflection in time.

In order to answer the challenges of the coming knowledge economy, Taiwan's education system needs to undergo wholesale reform. However, educational reforms need to be accompanied by adjustments in the education system. What are the main difficulties currently being encountered by Taiwan's educational reforms? What kind of social foundations should we be laying for future education?

As the age of the knowledge economy approaches, how should we reform education so as to best answer its challenges -- particularly the reform centering on education legislation? Educational reform in Taiwan has been going on for over a decade, and in fact, its overall direction complements some of the particular needs of the age of the knowledge economy very well indeed.

The Inter-relationship of K-economy and IT in Taiwan
As the technology, the systems, and the economics of education reform advance, we must not lose sight of what education is for. The argument began with is about its moral purpose. The recent economic adjustment is in many ways a blessing in disguise. It reinforces our conviction that we must diversify our economy and promote high-tech, high value-added industries. It is also a timely reminder that our ability to respond to the challenges of the future world depends on how well we can equip our young generation today. We firmly believe that the starting point is education. But, what is the education needs in the new millennium, life-long learning, creativity and devolution of our education system? Our education system must ensure that all our students are information technology (IT) literate, with some of them having the potential to become leaders in the field. This is because IT and the teacher education have changed and will continue to change the world in profound ways with lightning speed. We live in an information age, which offers immense opportunities. And our students have to learn to embrace them.

There must be flexibility in the education system to promote diversity and excellence, and nurture creativity in our students. The system must allow room for schools and educators to innovate, and to respond to the changing demands of parents. It should encourage competition among education providers, and give all stakeholders a proper say in the delivering process.

K-economy and IT Impact upon the Teacher Education
In a knowledge-based economy, the ability of our people to continually learn and upgrade their skills and knowledge is vital to our development and competitiveness. At the basic education level, we offer adults part-time courses ranging from primary to senior secondary. On the vocational side offer part-time skill upgrading courses.
At the tertiary level, we have an Open University, which plays an important role in our efforts to promote life-long learning.

In the past, our education system was very intolerant of different opinions, and shut out non-mainstream educational patterns, and so as we advance towards the age of the knowledge economy, we must put special emphasis on the social foundation that the knowledge economy must have. At the same time as promoting cooperation between industry and education, should we also set up a mechanism to allow participating researchers, or even all of society, to have the chance to share in the fruits of investment in public resources? Then again, that's maintaining social justice, and the knowledge gap may produce many social problems, and so we should formulate some measures, such as making the internet even more widely available, and even cheaper, maybe even expand opportunities for digital education by making it free of charge, and so cut down on the occurrence of related problems.

Educational reform continues to expand in quantity, but we've still yet to see much of an improvement in quality, and the key reason for this is that in the past, compulsory education only ensured nine years of schooling, it didn't promise that you'd have learnt anything after these nine years, and so many junior high school graduates would be doing their military service without even being able to write their names very well. It's very important that we solve problems to do with teaching staff, teacher education. Our teachers are using yesterday's knowledge to teach today's children how to handle the society of the future, and if teachers don't treat further self-improvement as a duty and an obligation, how will the students that they teach be able to answer the demands of contemporary society?

In ongoing policy discussion of educational reforms, people emphasize the impacts of globalization and try to make every effort to adapt their education system as well as curriculum and pedagogy to prepare for it. Unfortunately they often ignore the necessity and importance of localization and individualization or they put these three processes in a contradictory position. Without localization in education, they will be unable to meet the local needs, involve community support, and enhance site-level motivation and initiatives (Kim, 1999; Cheng, 1996). Without individualization in education, all efforts of reforms will be unable to meet the needs of students and teachers and to motivate them to be effective in teaching and learning. In other words, they will not be able to elicit the necessary initiative, imagination, and creativity from school members and community members, and to make contribution to the process of globalization, not just receiving its impacts. Therefore, globalization, localization, and individualization all are necessary components in current educational reforms.

Conclusion

We need to rethink and re-engineer our school education and teacher education. If we believe our world is moving towards multiple globalizations and becoming a global village with boundless interactions among countries and areas. Our new generations should be expected as a contextual zed multiple intelligence person in such a fast changing and interacting global village. The development of the society should be multiple towards a learning multiple intelligence society. The aims of education should be to develop students as a multiple intelligence citizen who will creatively contribute to the formation of a multiple intelligence society and a multiple intelligence global village with multiple developments in technological, economic, social, political, cultural, and learning aspects. If IT is to bring a real added value to education, then its success lies in the innovative methods for designing, planning and conducting network actions in which innovation lies not just in the mere presence of a new technology but rather in revising certain teaching processes or in creating new ones based on the new technology. Furthermore, IT in most of the countries was seen as something that should be added on to the curriculum rather than an integral part of curriculum planning.

Utilizing *Blackboard* to Engage Teacher Candidates in Higher-Order Thinking

Saundra L. Wetig  
College of Education  
University of Nebraska at Omaha  
United States  
swetig@mail.unomaha.edu

Abstract: The infusion of technology into classroom activities has been demonstrated to enhance student learning (Christopherson, 1997; Roblyer, 1998). The value added comes from the potential for anytime/anywhere learning, student communication, and increased access to multiple sources of current information. During the Fall 2001, a web program titled *Blackboard* was made available to all students and faculty members across the University of Nebraska at Omaha (UNO). This paper highlights how *Blackboard* will be implemented in a level I field experience course in the College of Education for the Spring 2002 semester. This work-in-progress is not an empirical study, but instead, an attempt by the instructor to help students think more critically regarding classroom observations made in a level I field experience course.

Background: *Blackboard*  
Today's education landscape is characterized by a greater demand for anytime/anywhere learning. As we move into the 21st century, technology has become a significant part of how we train teacher candidates. The new millennium requires teacher candidates to practice both the art and science of teaching in new and different ways. During the Fall 2001 semester the UNO Information and Technology Service (ITS) provided faculty and students with the opportunity to utilize the web-based server software system titled *Blackboard*. *Blackboard* serves 5.4 million active users, with more than 1,900 ‘live’ institutions. UNO is one of eleven educational institutions in Nebraska utilizing *Blackboard*. A sample of tools available through *Blackboard* include:

1. **Calendar** – Users may manage their course, organization, institution and events through this tool.
2. **Tasks** – Organizes projects, defines task priority and tracks status.
3. **Course Documents** - An area to place documents of various types for students to view.
4. **Assignments** – Lists the due date and description of class work. Quizzes and exams can be placed in this area for students to access.
5. **Discussion Board** – Instructors may add forums, and allow students to read messages that are organized into threads. Students can read and respond to both the instructor’s posts and the posts of other students in the class. This is a great tool to promote discussion among students about class subject matter outside of class. Participants do not have to be logged on at the same time.

Integrating *Blackboard* into an Instructional Systems Course  
The College of Education (COE) at UNO has undertaken a review of its course offerings in response to emerging national standards. The faculty of the college has designed a program for teacher education candidates that utilize a systematic, experience-based approach to develop and demonstrate requisite knowledge, skills and dispositions. The outcome of this curriculum is “The Teacher as Orchestrator of the Learning Environment.” Instructional Systems is a course, which acquaints teacher candidates with the basic aspects of curriculum design and implementation. Topics integrated into the course include: a) instructional delivery strategies based on the assessment, prescription, implementation, and evaluation (APIE) model of the COE, and b) educational technology selection, design, production, utilization and evaluation. Instructional Systems seeks to help teacher candidates understand the role of a teacher as the orchestrator of the learning environment and the integral part these topics play in that role.

Students in Instructional Systems are required to complete twenty observational hours in an assigned school setting. The placements are made in socio-economic diverse elementary, middle, and high school settings. Throughout the twenty hours, teacher candidates are required to complete field reports.
The field reports are guided by questions based on the clinical aspects APIE model. Candidates turn their reports in as word-processed document to which they receive feedback only from the instructor. During the Spring 2002 semester student reflections will use on-line submission through the Discussion Board tool.

Data Collection Through Blackboard’s Discussion Board

Discussion Board will be utilized as an additional communication tool, moving students beyond routine class discussions. Following observations and participation in the schools, teacher candidates will be required to respond to threads (set up in forums) based on the elements of APIE. Students will post their responses to each thread in Discussion Board. In addition to personal posts, each student will be required to respond to three classmates threads. An example forum based on the elements of assessment and prescription:

1. Element: Assessment: Topic: School and Learning Environment
   DESCRIBE the environment of the school itself (hallways, teachers’ lounge, administrative offices, classrooms, etc.).
   OBSERVE the classroom environment (teacher’s desk, students’ desks, seating arrangements, walls, windows, attitudes, etc.).
   ANALYZE the answers you wrote to the first two questions above. DISCUSS both the possible advantages/disadvantages to the two environments. Provide insight as to how your future learning environment might look like.

2. Element: Prescription: Topic: Classroom Procedures and Routines
   DESCRIBE the schedule for each day of the week in you classroom.
   DESCRIBE the routines used each day (lining up for recess, lunch, naps, etc.).
   ANALYZE the structure and routines of the day and explain how and why you think they are conducive to learning. If you think the procedures inhibit learning, explain why and how.

The discussion board will be used in a manner similar to a virtual chatroom. A benefit of Blackboard is that it was designed for asynchronous use. Users do not have to be available at the same time to have a conversation. A key feature of the discussion board is that user conversations are logged and organized. Conversations are grouped into forums that contain threads and all related replies.

Conclusion

During the next semester efforts will be concentrated in engaging teacher candidates in higher-order/conceptually based dialogue based on the their observations and the observations of their classmates in a level I field experience. By requiring students to engage in self-reflection and evaluation it is hoped they will begin making connections regarding the pedagogical aspects of assessment, prescription, implementation, and evaluation.

As we move into the 21st century, we have an obligation as teachers to help our teacher candidates become higher-order/conceptually based learners/thinkers. It is critical for teacher educators to continue personal modeling of technology as an aid to instruction and as a tool to engage students in higher-order/conceptually based dialogue. Jackson (1986) says in his discussion on transformative teaching, “it is essential to success within that tradition that teachers who are trying to bring about transformation changes personify the very qualities that they seek to engender in their students” (p. 124). It is hoped that as teacher candidates are engaged in purposeful, yet guided online dialogue that they will begin in their own ways to become higher-order/conceptually based learners in the experience.

Abstract: Although technology continues to flourish at an unprecedented pace and influence society, its impact on society and individuals is just beginning to be investigated. As a result of technology becoming an integral part of everyday life, research findings indicate individuals are experiencing a great deal of related stress and anxiety (technostress) concerning technology. Presented are breathing techniques that help individuals cope effectively with technostress and a rationale of why they work.

Political, social, and economic issues, as well as technological advances, are generating major changes in individuals' behavior and society. In this age of computers and electronic media, researchers have been investigating the impact of technological changes on individuals. This paper will illustrate an effective way of coping with technostress by helping individuals understand the importance of breathing.

Modern life has become so complicated, harried, and crowded that individuals feel as if they must constantly scurry to survive. Developing world events, concerns about the future and technologically driven everyday life have created tremendous strain on society, and specifically for individuals using or expected to use technology. Physical, social, and mental boundaries essential for our well-being are being constantly assaulted by technological stimuli. Individuals' senses are being bombarded with technological sounds and sights (beeps, pagers sounding off, cell phone ringing, and unsolicited conversations at any time and place digital alarm clocks, programmable toasters, smart credit cards, ATMs, computers, Internet, video games, VCR programming, etc.) leaving us irritable, distracted, unable to concentrate. Technological bombardment has generated tremendous technostress for some individuals.

Negative consequences of technology and computers may be pandemic. Yet, stress is not limited to technoeposure or threat of exposure. Timothy Jay (1981) discusses extreme forms of technostress, i.e., abject fear of computers, and coined the term “computerphobia.” Weil and Rosen (1997) found that one-third of university students...
were computerphobic. Craig Brod (1984) coined and defined the term technostress as “a modern disease of adaptation caused by an inability to cope with the new computer technologies.” However, Weil and Rosen (1997) think of technostress as any negative impact on attitudes, thoughts, behaviors, or body physiology caused either directly or indirectly by technology. Individuals must begin to learn and make use of ways to help feel less frustrated and pressured, while coexisting with the rapidly expanding world of technology.

Individuals struggling with technological changes respond with extreme muscle tension and instinctive restricted breathing which causes individuals to breathe shallowly, more in the chest than from the diaphragm, reducing oxygen intake and exhalation of toxins. Aware of this process, many eastern philosophers believe that natural, healthy breathing is a powerful antidote and coping mechanism for mediating everyday stress. Natural breathing techniques can be applied and used in almost any setting at nearly any time thus decreasing and controlling technostress levels. Individuals must relearn how to breathe correctly, set aside effective breathing time each day and make deliberate, conscious choices to regain their natural way of breathing. This involves awareness of, focusing on faulty breathing patterns and replacing them with correct, healthy ones. Correct breathing before, during, and after any experience, situation, or simply while sitting at the computer will facilitate calm, warm and energetic feelings. Thich Nhat Hanh(1975) indicates that mindfulness is the life of awareness which we can master and use to restore our breathing. Breathing is a natural and extremely effective tool that can help focus ones mind and maintain mindfulness. As the mind becomes scattered or the body becomes tense, one may use healthy breathing to take hold of life and moderating technostress.

Even though the healthy breathing process appears to be elementary many do not do it when it can be most helpful; yet, the resultant advantages of relearning to breath can have a profound effect on individual lives. In today’s technologically advanced society, mastery of breathing is extremely important for living. The dynamics of breathing and various breathing techniques available deserve much more attention in Western society. Wilkinson, Buboltz & Mathew(2001) presented numerous breathing techniques for easing test anxiety. One breathing technique example, a few minutes devoted to “slow diaphragm respiration” (SDR) invigorates the body and shifts thoughts to a relaxed state. A person can make use of SDR while sitting at the computer desk. SDR begins by closing the mouth and breathing deeply through the nostrils. One places a hand on the diaphragm just below the ribcage and takes deep breaths so the hand moves out and back as the lungs inflate and deflate. The shoulders should not lift, but remain stationary. While paying close attention to what happens, one draws in breath and lets it out. If while practicing one encounters excitement or nervousness about breathing, simply relax and think of something pleasant for a moment. After thinking of something pleasant, and when breathing has slowed to normal, resume the exercise. The slowing down respiration technique has very important implications for alleviation of muscle tension, anxiety and reducing technostress.

Abstract: Individuals are being bombarded with new and ever changing technologies in today’s society. Research appears to have focused primarily on the use of technology to enhance education and productivity. Little research has focused on how, for some individuals, technological usage may have a negative impact on their attitudes, thoughts, behaviors or bodily physiology. This article reviews the development of Technophobia and the use of Wolpe’s Systematic Desensitization methodology to help individuals overcome their computer fears.

Today, there is more technology than ever before existing at home, at work, and play. Individuals are being bombarded with new and ever increasing changing technologies, just to make it through a routine day. However, there are millions of individuals who are not comfortable with technology. The purpose of this paper is to illustrate how increased technological usage has created for some individuals, technophobia. In order to help these individuals overcome their technophobia, Wople’s Systematic Desensitization has been found to be an effective method to help individuals overcome their fear of computers or other phobias.

The increasingly sophisticated technology (in the workplace, home, and play) involves the use of machines by all individuals. Technologies are altering people’s lives in a very positive way for most individuals. Yet for others, technology is having an adverse effect by creating stress in their lives. Jay (1981) found some individuals had an extreme fear of computers and coined the term “Computerphobia.” Later, Brod (1984) coined the term “Technostress” for individuals having difficulties with technology and defined it as “a modern disease of adaptation.” However, Weil and Rosen (1997) do not consider it a disease but define it as “any negative impact on attitudes, thoughts, behaviors or body physiology that is caused either directly or indirectly by technology. These authors perceive “TechnoStress” as an irritation that individuals feel as their boundaries are constantly being invaded by technology. In their investigation of individuals experiencing technostress, Weil and Rosen found that people’s reactions to technology typically fall into three “Techno-Types” (1) Eager Adopters love technology, first to buy new technology equipment, and find it
challenging and exciting. These individuals expect to have problems with technology and solve the problem or find someone that can. Eager adopters usually make up 10 to 15% of society; (2) Hesitant “Prove It” does not find technology fun or challenging, hesitate to invest in technology and have to be proven its worth to use it. If you can convince them they will consider it. Hesitant makes up 50 to 60% of society; and (3) Resisters avoid technology; they want nothing to do with it; they feel intimidated and embarrassed as well as inadequate when handling new technology. In fact, any difficulties make them run further away each time sometime else goes wrong. The resister makes up 30 to 40% of society. The Resisters are individuals who have strong fears toward technology (technophobic).

For some individuals technological changes create problems that prevent them from becoming technological competent and were called “Computerphobic.”; however as other products of technology has become common, the term evolved into “Technophobia”. Both these terms describe an individual’s negative reaction to technology. An excellent example of a technophobic individual was illustrated in Wilkinson’s (1997) article entitled, “An educators journal toward technical competences”. In his striving to become technologically competent, several stages evolved that were identified and recognized as helpful for individuals overcoming fear of computer usage. They are: (1) need for a firm commitment to learn about computers; (2) recognizing the importance of learning computer language; (3) purchasing and reading of computer books for additional technical knowledge about computers hardware, software and operating systems; (4) research required, knowledge accumulated and learning needed for purchasing a computer, and (5) applying acquired computer skills to work, home and play. These stages are useful and illustrate indirectly the gradual and systematical desensitizing process necessary for reducing computer fears.

Essentially a person’s attitudes, emotions and behaviors toward technology play an important role in a person becoming “Technophobic”. A key question is “What can be done to help these individual handle their fear of working with computers?” Systematic desensitization is a therapy developed by Joseph Wolpe to inhibit fear and suppress phobic behavior (a phobia is an unrealistic fear of an object or situation). His method of treatment can be used to help individuals overcome their fear of technology. Wople’s treatment is based on Pavlovian conditioning principles and represents an important application of classical conditioning. Wolpe’s therapy uses relaxation to counter human phobias is called systematic desensitization. Basically, systematic desensitization involves an individual using relaxing while imagining the fear-inducing stimuli that prevent productive behavior. To help an individual overcome their fears, Wolpe used a series of muscle relaxing exercises. These exercises involve tensing and then relaxing a particular muscle. The person tenses and relaxes each major group in a specific sequence. The assumption is that tension is related to fear and so using tension reducing exercises is relaxing and helpful in overcoming a phobia. The desensitization treatment consists of four separate phases: (1) individual are instructed to construct a graded series of fear inducing scenes related to computers and ranks them in a hierarchy that produce the lowest level of fear to those that produce the highest level of fear; (2) training the individual to learn to relax (3) actual counter conditioning involves instructing the person to relax, then to imagine as clearly as possible the lowest scene on the hierarchy of computer fears, and (4) assessment process involves testing of the effectiveness of desensitization by having the individual encounter the fear object.

Comparing Themes of Critical Reflection from Face-to-face and On-line Discussion in a Course for Teacher Education Students

Yuejin Xu and Asghar Iran-Nejad
University of Alabama
United States
yxu@bamaed.ua.edu

Abstract: Electronic discussion is found to be better than face-to-face discussion in promoting equal participation among students and in increasing language ability. However, few studies have been conducted to examine whether the use different mode of interaction makes a difference in critical reflection among learners, especially among teacher education students. The purpose of this study is to compare and contrast students' on-line discussions recorded in WebCT Chat room and face-to-face audio taped discussions.

Introduction
Comparing and contrasting two modes of learners' interaction, that is, face-to-face and electronic, has been an evolving focus in the field of language acquisition (Kelm, 1992; Kern, 1995; Warschauer, 1996). Electronic discussion is found to increase more equal participation within students. Moreover, "students used languages which is lexically and syntactically more formal and complex in electronic discussion than they did in face-to-face discussion" (Warschauer, 1996, p. 7). However, does the use of different mode of interaction make a difference in critical reflection among learners, especially among teacher education students? This study addresses this question by analyzing students' real-time online discussions recorded in WebCT Chat room and face-to-face audio taped discussions over a period of a semester following a ground theory (Madill, Jordan & Shirley, 2000). To our knowledge, the present study represents the first attempt to explore the effect of face-to-face and on-line discussion on critical reflection.

Concept of Critical Reflection
As pointed out by Imel (1998), there has been a lack of a common definition for critical reflection, which actually led to the interchangeable use of the terms reflection and critical reflection. However, many people would agree that critical reflection "involves actively monitoring, evaluating and modifying one's thinking and comparing it to both expert models and peers" (Lin, Hmelo, Kinzer & Secules, 1999, p. 43). To engage in critical reflection, learners need "move beyond the acquisition of new knowledge and understanding, into questioning (of) existing assumptions, values, and perspectives" (Cranton 1996, p.76). Two dimensions are central to critical reflection: problem recognition (PR) and solution recognition (SR) (Iran-Nejad, 1998). Good reflective practitioners should be able to demonstrate either keen examples of cross-domain problem recognition anchored in within-domain solution recognition or keen examples of solution recognition anchored in within-domain problem recognition. In other words, learners need not only know what to know but also how to know and when to know.

Critical Reflection and Technology
Technology can play an important role in supporting learners' critical reflection. In their paper, Lin, Hmelo, Kinzer and Secules (1999) proposed four ways that technology can scaffold reflection, namely, process displays, process prompts, process models, and a forum for reflective social discourse. In the first three ways, reflection is more regarded as an individual activity, whereas in the last one, reflective social discourse, "it is clear that reflection can also be a social activity and can be influenced by a community" (p. 53). WebCT ® is a kind of software that offers real time online chat as well as other features. With its capability to trace record and display what have been input by its users, WebCT chat offers a great opportunity for learners to interact and reflect and to generate more
reflective social discourses. Therefore, we hypothesize that WebCT Chat could excel or at least match the traditional face-to-face mode of interaction in group discussions for critical reflection.

The Study

Participants

The participants in this study were 8 students enrolled in an educational psychology course for teacher education students participated in this research. They were randomly assigned to one of two groups. Both control and experiment group were using the same syllabus, having the same amount of instruction, and doing the same tasks (a portfolio, a midterm, and a final). However, in the control group, students were assigned class time to conduct face-to-face discussion on group mind-changing experiences. Their discussion was audio taped and later transcribed. Whereas in the experiment group, WebCT recordable Chat rooms were created for each group to chat over the internet on their group mind-changing experiences.

Procedures

First, each participant wrote a general reflective essay. Then, they shared their reflective essays among their group members either via email or hard copy. Second, as they read their group members essays, they wrote down all the questions that came to their mind. Third, they prepared two paragraphs, proposing a group mind-changing experience for consideration during the group discussion. One paragraph discussed the prior-to-change thinking of the topic and the other paragraph the thinking after the mind-changing. Finally, each group met for a discussion (face-to-face vs. real time on-line chat) to exchange questions and decide a common shared topic for their next reflective essay.

Analysis

Transcripts in WebCT Chat and in face-to-face discussion were collected as our data. They were first compared by the amount of time, amount of discussion (words), turns. Then, they were read and re-read to identify categories, themes and the position in the aforementioned two dimensions of critical reflection.

Findings and Conclusions

Our analysis yielded few positive findings. As far as the time, amount of discussion (words), turns, are concerned, the face-to-face group generated more discussion than the on-line chat group in less time. Moreover, compared to the online chat group, the face-to-face group had more turns among its group members. The Appendix shows one recorded group discussion in WebCT Chat, in which we can see that the chat was actually dominated by one participant.

Concerning the themes, categories, and examples in critical reflection, we didn't find any major difference in two groups so far, which actually contrary to our hypothesis.

Yet, we really cannot conclude that face-to-face is better than on-line real time chat to support critical reflection because this study has some limitations. One major limitation is the small sample size. Also, it would be better if other measures of critical reflection are adopted and used.

C-2>>I think that the desire to learn influences the ability to learn and I think that someone who does not desire to learn to become a good teacher would not learn to become a good teacher
```
that goes back to the topic of art vs. science, is that teacher capable of teaching and does he or she have an influence or skill that can help our kids learn.

also, do all good teachers have relatively the same teaching methods, or can they still be as different as night and day.

teaching is something you have to want to be a part of.

teaching is not necessarily good for the gander.

don't think that anyone who does not have a love for teaching is capable, if you don't want to do it, you won't do a good job of it.

that is correct someone has to want to be a teacher and i feel you can not make them want to teach but i did not want to be a teacher and here i am at 23 with a degree in business.

you are old!!!!

old and dirty.

nobody has the same teaching skills, everybody is different.

would say style instead of skills, we should all learn the same skills.

you're mean.

so lets decide on a topic you guys.

i think we should do good v. bad.

what part of it?

i would say style instead of skills, we should all learn the same skills.

true, but is that enough to make a paper.

nobody has the same teaching skills, everybody is different.

style instead of skills, we should all learn the same skills.

true, but is that enough to make a paper.

ok ok ok ok.

let's write those papers.

sounds good to me.

let's write those papers.

sounds good to me.

write a paper on how much emphasis is put on personality at different age levels and how that reflects back to art vs science.

write a paper on how much emphasis is put on personality at different age levels and how that reflects back to art vs science.
Internet in Chinese Education, Where to Go?

Abstract: This paper will study (1) the various stages of Internet access in China: from censorship to limited self-autonomy, (2) instructional use of the Internet in China, (3) the digital equity issues which hinder the instructional use of Internet in China. Further suggestions will be made regarding healthy development of the instructional use of the Internet in China. They include: Internet policies, funding, digital access, and the geographical balance of technology distribution.

From Censorship to Limited Self-autonomy

The instructional use of Internet in China has come a long and hard way. Its development can be subsumed into three stages: (1) censorship, (2) half-censorship, and (3) limited self-autonomy. Starting from 1993, there were a series of changes in government policy regarding the use of technology in education, including the Internet. Realizing that technology, especially information technology, was the key to productivity and national economic growth, the Central Committee of the Communist Party of China issued the Guideline to Educational Reform and Development and shortly afterward, enacted the Education Law of the People’s Republic of China in 1995. Both emphasized the need for reform in the existing education system and that the government should support the use of broadcasting, television, and other distance education avenues to create an environment for life-long learning (Chen, 1999).

A recent study shows that from 1994 to 1997, the government appropriated major funding to network infrastructure construction. Four major network systems were established: CHINANET, China Science Academy Network, Golden Bridge Network by the Ministry of Education, and the Ministry of Information Industry (He, 1998). These network systems connected more than 300 universities, colleges, and research organizations. They also provided network services that connected provinces throughout the nation. In the meantime, the Internet access became no longer a privilege that belonged only to a few research institutes and universities. More people were able to communicate via email through their Internet Service Provider and surf the Internet at home or at work, although such access was still under government control with sites filtered and censored.

As China became more and more involved with the world economy, exchange and communication with Western countries and organizations have increased exponentially in the areas of commerce, culture, and academic research. In April 1997, the government sponsored the National Conference on Information Technology in ShenZhen, a liberal and open city in southern China. Chinese Vice Premier Zhou Jiahua spoke at the conference emphasizing that (a) the central and local governments put the management of information and the construction of database for information management at the top of their agendas, and (b) schools and education organizations developed Web-based instruction and Web-based assisted materials for students in the classrooms (He, 1998). As a result, Internet business flourished. More Internet Service Providers (ISPs) became available. By the end of July 2001 there were ten major Internet Service Providers in China with UNTNET and CNCNET being the two leading Internet Service Providers in China. The government has also loosened its Internet policy allowing foreign investment in Chinese telecommunication services although the government ordained that it must own at least 51 percent of shares in any Chinese IT company.

The opening of the Internet market granted, for the first time, Chinese people self-autonomy in the use of the Internet; it not only allowed people to access the Internet but also to develop their own instructional materials on the Internet. The statistics by China Internet Network Information Center (CNNIC) indicate that the Internet users in China have increased from 620,000 in 1997 to 26.5 million by July 2001 (CNNIC, 2001). In the meantime, the Internet market becomes more diversified in terms of the domains registered under the CN.

Nonetheless, the growth of Internet market and the self-autonomy granted to people are accompanied by an increased restriction and regulations imposed by the Chinese government. In April 2000 the Ministry of Education (MOE) of China published Provisional Regulations on Modern Day Distance Learning. At the same time, the Ministry of the Information Industry issued Measures for Administration of Places of Business for Internet Access Services. Both documents “regulate and guide” the Internet activities in China. The Provisional Regulations by MOE stipulate, for example, that the online school activities must be governed by the Measures for Administration of Places of Business for Internet Access Services. Both documents “regulate and guide” the Internet activities in China. The Provisional Regulations by MOE stipulate, for example, that the online school activities must be governed by the Measures for Administration of Places of Business for Internet Access Services.

Internet in Chinese Schools

The instructional use of the Internet in China has also undergone ups and downs. With no exception, it has been under strict supervision by the Ministry of Education of China. The survey studies by China Internet Network Information Center (CNNIC) from 1997 to 2001 indicate that Internet growth has been slow in education. In fact, the percentage of EDU domains under CN has been...
decreasing within the last few years. In spite of that, the Internet as an instructional tool has found its way in the classrooms of both higher education and elementary and secondary education.

At colleges and universities, the Internet is used in instruction in several different ways. First, it is used as an assistive tool for information search and communication. Instructors like to use email to communicate with students and encourage them to use the Internet to search information for their projects. Second, the Internet is used as an alternative avenue to traditional course delivery. In Nanjing University, for instance, the Department of Foreign Languages and Literatures developed a proprietary Web shell-ware which enables the instructors to develop their online ESL courses. Third, there is in recent a trend to form collaborative exchanges between the Internet and the classroom. Eight major universities led by Nanjing University, have developed an Internet based educational network system for information sharing and collaborative learning.

Like higher education, elementary and secondary schools use the Internet as a tool for information search and communication. The Internet is essentially an extension of the school library. Although there is a demand from teachers who prefer to have their own instructional web page, few teachers know how to build their own instructional pages. Some provinces started a pilot program by establishing a centralized technology hub which provides technical support to local schools. For example, the Educational Technology Center in Fujian Province has created an Internet program that has ignited far-reaching reform throughout the country. The project includes an online expert teacher database of master lesson plans and supplemental instructional materials that teachers in local schools can access for use in their classrooms. The Center also offers online courses to high school students who, upon completion of the courses, will be awarded a high school diploma accredited by the Province (Zhang, 2001).

Nonetheless, the instructional use of the Internet in China is uneven in terms of distribution, accessibility, and digital equity. The access and equity issues have been one of the major concerns that hinder the Internet development in education in China.

**Distribution.** China has an uneven distribution of technology and resources. Geographically, the coastal cities and provinces are well developed with more advanced technology and infrastructure, and therefore have better access to new technologies than the inner cities and provinces. The CNNIC January 2001 report showed that the nine coastal cities and provinces accounted for 70.55% of total 265,405 websites in China (CNNIC, 2001). Obviously, the imbalance of technology resources in distribution gives rise to the issues of accessibility and digital equity across the country.

**Accessibility.** The issue of accessibility is one of the major issues in Internet instruction. First of all, people in the inner land have fewer chances to access latest technology than people from coastal cities and provinces. Secondly, the universities have better access to the Internet than the secondary and elementary schools. A study shows that the college students, including 23 year technical colleges account for about 65% of Internet access, whereas secondary school students account for 23%, with only 6.44% for elementary, and 5.66% for others (CNNIC, 2001).

**Digital Equity.** The digital equity is another important aspect in instructional use of the Internet in China. The divide in economic status creates a divide in digital access. The economically well-off have a better chance to have computers at home, whose off-springs consequently become more computer literate than those who do not own home computers. Gender is another equity issue. The CNNIC January 2001 report showed that the male had accessed Internet more than the female with male 69.56% and female 30.44%.

**Conclusions**

The instructional use of the Internet in China is still in a developmental stage. Where it should go and how it should go are issues that need to be addressed immediately. We believe that a healthy development of the instructional use of the Internet in China should take following steps: (1) the government should adopt a more open, less restricted Internet policy for free information exchange and communication; (2) it should reduce the geographical differences to create an equal opportunity for people to access the information they need; (3) more funding for secondary and elementary education is needed with a focus on educational technology enhancement and the opportunity for people to access the digital technology regardless of gender, age, social and economic background.

It should be recognized that China has made great efforts to improve its education system, provide opportunities for more people to receive education, and invest in technology infrastructure in both higher, secondary and elementary education within last ten years. Such efforts could be more effective if it examines the existing issues from a global point of view, take substantial steps to loosen its control on Internet use and support the instructional use of Internet in all areas.

eskridge@thinkquest.org

Hilary Maybaum and Robert Sibley
ThinkQuest
United States
maybaum@thinkquest.org
sibley@thinkquest.org

Abstract: ThinkQuest for Tomorrow's Teachers is a collaborative partnership among ThinkQuest—a non-profit educational technology organization—and a consortium of teacher-preparation programs, K-12 schools, and businesses. It is supported in part by a catalyst grant from the U.S. Department of Education's Preparing Tomorrow's Teachers to Use Technology (PT3) Program. Now in its second grant year, the T3 consortium includes 14 colleges from across the country. The consortium seeks to promote the practice of learner-centered, constructivist pedagogy in which education students, their higher-education faculty, and others are colleagues in the learning process. We envision teacher educators modeling a learning environment in which inquiry, exploration, and knowledge adaptation and creation are critical modes of learning.

Introduction

ThinkQuest for Tomorrow's Teachers (T3) brings a new approach to educational technology use and integration by creating a core group of trained and committed teacher-preparation faculty who, in collaboration with academic leadership and administration, can engage their students in the ThinkQuest “Guiding Partner Approach” to constructivist learning. By combining the practice of this student-centered pedagogy with a structural approach to curriculum-based and Internet-enriched activity design, the T3 program aims to provide an ideological basis for systemic change in education practices by emphasizing exploration, collaboration, and facilitation among teacher-education faculty, pre-service teachers, in-service teachers, and elementary and secondary students.

Program Components

The T3 program is grounded in several components that, taken together, comprise a holistic approach to the integration and use of digital and Internet technologies as tools in the teaching and learning process. First and foremost is the ThinkQuest Guiding Partner Approach (GPA). The GPA consists primarily of two interwoven concepts: students and teachers as junior/senior colleagues in the learning process, and the use of flexible frameworks for instructional design (Harris 1998). The approach focuses on preparing technology-proficient teachers to collaborate with students on educational activities that greatly increase the probability of long-term learning. Critical to the GPA model are techniques for establishing an environment that will encourage and facilitate "elbow-to-elbow" collaboration between teachers and students.
In conjunction with the GPA, the ThinkQuest Pre-Service program component brings teams of pre-service teachers, in-service teachers, and college faculty together to create (1) web-based educational resources for use by K-12 educators, and (2) online learning projects for K-12 students. The program also encourages pre-service and in-service teachers to simultaneously collaborate with teams of elementary and secondary students in creating meaningful, educational Web sites.

Publishing and dissemination are important goals not only of T3, but also of the overall (Federal) PT3 program. The T3 Web site (http://t3.thinkquest.org) is among the primary means of addressing this programmatic goal. The purpose of the site is to disseminate project information, including methodology, partner programs, student project results, discussions, research, reflective writing, evaluation information, and resources in the areas of technology and pedagogy.

Results To Date

The program completed its first year in May 2001. Five higher-education partners participated in at least one T3 training workshop. The GPA was adopted and used by 35 faculty members at the five sites in 2000-01, and over 80 pre-service teachers created web-based learning activities that were published at the T3 Web site. Many of the faculty worked directly with their pre-service teachers to create web resources that can be used with K-12 students or by other teacher-preparation programs. Evaluation results (CER 2001) suggest that over 70% of the pre-service teachers that participated in the program felt they were prepared to integrate technology into their classrooms in the future. In addition, several participating sites forged partnerships with K-12 schools to promote the GPA in classrooms.

At the beginning of the second grant year (Summer 2001), ten additional Schools, Colleges, and Departments of Education (SCDEs) were accepted as consortium partners. These partners represent a broad geographic and demographic diversity, which will test the program in the most authentic settings and among teacher educators who are not considered technology innovators. There are currently 14 teacher-preparation partners in the T3 program. Year 1 partners are Eastern Connecticut State University, City College of New York, Western Michigan University, and University of the Pacific. Year 2 partners are Barry University, Hampton University, Haskell Indian Nations University, New Mexico State University, Oakwood College, Prairie View A&M University, Southern Oregon University, Trinity International University, Turtle Mountain Community College, and University of Washington. A four-day, hands-on workshop in Indian Wells, CA, in Fall 2001 provided an opportunity for faculty leaders from both Year 1 and 2 partner sites to meet and exchange ideas. There is great enthusiasm and commitment among these partners, which form the catalytic core of the program’s success to date.

Page 113
More than one hundred papers comprise the Distance Education section, this year. Selected from a significantly larger body of proposals, these reports, taken as a whole, illustrate the breadth and impact of distance education within the broad scope of educational practice. The programs for this section remind us once again that technology in education often means distance education, and that distance education means, primarily, Internet delivery. Nonetheless, the spectrum of papers illustrates a field of practice and scholarship that is emerging with great diversity and energy.

Within these presentations, there are initial reports of experience with distance education in many different disciplines and at several levels, from elementary school, through post-secondary instruction and lifelong professional development. Though the discovery of distance education remains a relatively constant theme in this section, the level of sophistication reported by the discoverers reminds us that skill levels of every practitioner, including those who have just begun, are being raised. "Rereducing the professor and the student: Lessons learned..." illustrates the ways that distance education plays a significant role in the overall professional development of the professorate. One suspects that the continued contributions of organizations like ISTE to the expectations of professionalism in distance education have helped everyone, even those just beginning, incorporate technology considerations into an overall vision of professional practice.

Not all experience is naïve, however. "Faculty use of Blackboard... at two mid-western universities" or "An online solution to educational technology leadership certification" illustrate that the research base is broad enough to include multi-institutional and regional data sources. "A framework for senior/community college partnership..." and "Supporting partnerships and school improvement with collaborative learning..." describe the ways barriers fall between kinds of institutions, as well, when distance education concerns surface.

"Preparing teachers for digital distance education" and "Facilitating online professional development" illustrate a broad shift towards distance strategies for staff development. Throughout the papers, we are reminded that learning with technology is learning about technology. Likewise, papers such as "Teaming: A catalyst for transforming distance education teacher preparation programs" and "The use of open and distance education in facilitating change in managerial development: The Mexico experience" explore professional development functions that are plainly impossible without sophisticated distance education systems - and sophisticated education technology professionals to manage them.

Reports of new offerings illustrate that the field is growing in breadth. Many of the reports here demonstrate that it is growing in depth, as well. Distance education experience is beginning to serve as a crucible of theory development. It is apparent from "Semantic knowledge factory," "Establishing a learning community of media design and art schools," or "Teaching through tragedy..." that theoretical innovation spans most, if not all, disciplines.

This is the first year that the Annual has been able to feature a broad selection of papers that address the power and problems of distance education in reaching persons with disabilities. While those vital issues are addressed in other sections, "... A global infrastructure... for the physically challenged" or "Design of student model centered Web based adaptive learning system" begin with distance education as media of learning for all students. Many papers, including "Synchronous remote Internet conferencing with deaf and hard-of-hearing students" and "Using Robolab software and Lego hardware to teach computing concepts to deaf and hard of hearing high school students" explore the power of distance education when sound is not enough.

"Different assessment methods for deaf and hearing on-line learners" reminds readers of the myriad considerations of assessment that distance settings provide. From the beginning "Assessing readi-
ness of distance learning students" to "Considerations in evaluating network-based learning systems," experience and techniques related to gathering or using data in distance settings is considered at every level from public schools to leisure learning. Significantly, the emphasis in assessment has moved from comparing distance to face-to-face instruction or supervised examinations. Now, researchers are gathering information and constructing theory related to the kinds of probes that are appropriate to distance learning, in itself, and are producing "A rubric to encourage and assess student engagement in online courses," or "A strategy for analyzing online communication," among many others.

Theory, indeed, is emerging from other areas than assessment. "Creating, implementing, and sustaining community in ... distance education" or "Asynchronous online discussions: facilitating critical thinking skills ..." describe learning outcomes, unique with distance education, that bespeak a view of social learning that is fundamentally different from most face-to-face instruction. "Action research on socio-constructivist pedagogy in Web-CT" or "The transformation, reform, and prospect of distance education in Taiwan" begin a long-needed discourse about distance education as both object and tool of social reconstruction theory.

Of course, curriculum and theory all rest, to some extent, on infrastructure and budget in technology-facilitated environments. Many papers, like "Diseño, elaboración y ejecución de cursos virtuales de bajo costo," and "Distance learning: Eliminating the digital divide" or "Delivery of Web based ... courses using a freeware version of Blackboard." Funding sources make up a significant part of the treatments of "The role the New Opportunities Fund ... has played in the UK," and "Establishment and improvement of the distance learning project at Inter-American University of Puerto Rico, Bayamón campus" describe knitting together institutional resources from many different institutions.

These hundred papers, taken together, reminds readers that distance education is neither a special environment for education, nor a special application of technology. Rather, the field is rapidly acquiring a theoretical structure, policy expectations, teaching or assessment strategies, and pedagogical conventions of a complete educational system. From first encounters to distance institutions, and workshops to comprehensive student services systems, distance education establishes or reveals new ways of teaching, reinforces old values of knowledge, and establishes communities of learners in ways that thrill us all. As you will find as you read this section, among the most thrilled are those authors who share with us all their adventure of discovery.
Improved Communication Through Online Discussion

Gertrude (Trudy) Abramson
Graduate School of Computer and Information Sciences
Nova Southeastern University
United States
abramson@nova.edu

Abstract: An interactive, asynchronous forum makes an excellent alternative classroom for graduate learning. Earlier experience as a reader and writer do not suffice for maximizing the potential of the forum for higher-level learning based, in large measure, upon meaningful discussion. This paper shares the pragmatic, research-based experiences of graduate students who strived for better communication as co-moderators and participants in short, three-week online discussions.

Introduction

Technology has progressed to the point that most educated adults have access to and use the Internet. E-mail, instant messaging and chat rooms are some of the more popular tools. There is an unstated assumption that use of these tools prepares one for meaningful participation in online class discussions. Interactive online classes should not be chat rooms. Even in this hypermedia environment, online class discussion needs to be carefully structured and supervised if higher-level learning is to be attained.

Graduate Online Learning Courses

Although this paper addresses coursework at the doctoral level, the lessons learned herein can be applicable to the masters' level and even, in some cases, to undergraduate studies. Each three-credit doctoral course at the Graduate School of Computer and Information Science (GSCIS) at Nova Southeastern University (NSU) runs 22 weeks, beginning with 20 hours on campus during the first week. Because all students are gainfully employed and most have family responsibilities as well, terms are lengthened to allow for life events.

Following the proliferation of the World Wide Web, when Mosaic became Netscape, students requested courses in Internet-based learning. In summer 1998, we offered our first class in Online Learning Environments (OLE). It covered just about everything related to distance education and almost immediately, we learned that there was much more to this new phenomenon than could be addressed in a single course. Therefore, in winter 1999, Instruction Delivery Systems (IDS) was introduced. It took a while to delineate the territory of each course. At this time, OLE addresses distance learning programs and communications issues and IDS, teaching and learning online. A third course, Online Assessments and Measurements (OAM) is still in the design phase awaiting the hiring of a professor with extensive expertise in both educational technology and psychometrics.

Online Communication in the OLE Course

Asynchronous, online discussions make possible revisiting remarks that had formerly disappeared into air, reflecting on one's remarks and on those of others and, most important, thinking in a collaborative environment. It is difficult to separate the process of discussion from the process of teaching and learning. During the earlier iterations of the OLE course, discussion leaders kept morphing into classroom teachers, which caused discussion participants to assume the roles of learners in under-designed instructional processes.

Half of the summer 2001 OLE course was devoted to research and practice with online communication in round table discussions. Several readings were suggested to help participants get into the appropriate mindset. For example, Funaro and Montell (1999) present guidelines for using online discussion based
upon 12 pilot iterations of a forum as a communications tool as an embellishment of traditional classes. The greatest value of their work is the specificity of items provided for reflection and experimentation. Williams (1997) offers online moderator guidelines and community-building tips based upon the WELL (www.well.com), self-described as one of the world’s most influential and cherished virtual gathering places. The WELL uses the term host a conference as we use the term moderate a round-table discussion. The reading cited by the largest number of students was Beaudin (1999) who identified various techniques recommended and used by online instructors for keeping online learners on topic during asynchronous discussion. In addition to the techniques, he discussed factors that affected their selection.

As teachers, we are aware that when a learning experience requires the cooperation of the learners, the success of the experience is uncertain. However, nothing can be learned in a vacuum and in order to practice one’s moderating skills, one must have participants. Each student was required to co-moderate a distant scholarly discussion and to participate as a discussant in three others. The co-moderator route was chosen in order to maximize opportunities for online communication and to ensure that discussion were not brought to an abnormal end because of life events. Forty students participated in the 20-hour on-campus meeting in July 2001, 35 of whom completed the collaborative, distance learning experience that ended on December 6, 2001. On the few occasions that co-moderators disappeared before the discussion was conducted, other teams readily included the abandoned peer.

Two online classrooms (asynchronous interactive forums) served as learning spaces for the course. The nomenclature is simple: The forum is the greater entity such as the classroom, a thread is a discussion topic, a message is a new statement within a thread, and a reply is a response to a statement. Enrollment in a class entitles one to password-protected forum entry. Anyone may initiate a thread, message or reply. Everyone has edit privileges but only the professor may delete.

The General Forum (GF), served a variety of purposes. In traditional terms, it was the classroom where new learning began, open discussion ensued and assignments were presented, elaborated upon and questioned. There was a monthly communication thread and even a café for casual conversation. It was up and running from the first day of the term and provided immediate, meaningful opportunity for new students to become comfortable in a structured online learning environment. Posting to the GF was optional. Active participation’s only reward was personal and professional growth.

The second forum, Round Tables (RT), was restricted to the research-based, practical experiences (discussions) and a single thread for discussion issues. All online round-table discussions were required to be relevant to some aspect of online learning. Each round-table discussion was initiated and completed within a specified three-week period. The first week was set aside for sign-up and reading of the linked documents. During the two remaining weeks, the co-moderators were charged with presenting discussion provoking questions and encouraging increasingly deep levels of response. At the conclusion of the third week, the co-moderators had a week to collaborate upon and post a summary message on the discussion thread. A copy was posted to the GF in the Conference Summary Thread.

At the on-campus meeting that preceded the online learning experience, students were given time to circulate, meet in small groups, and come up with topics of possible interest. Following that, the class convened as a group and responded to the different ideas. This experience was not a commitment but an opportunity to get a sense of general interest and appropriateness. It was also a very significant part of building the community that would continue working together online.

**Performance Assessment of One’s Own Experience**

There is an enormous difference between memorizing theory and turning it into useful practice. Graduate students should take ownership for their learning processes but it is very hard to convince people that the ultimate objective is other than to please the instructor. The purpose of the round-table exercises was to provide each student with multiple opportunities to balance experience and research. A four-step process was identified:
1. Literature relevant to online communication had to be reviewed.
2. Moderating and co-moderating had to be experienced.
3. Participating in different discussion with different moderators had to be experienced.
4. The three parts had to be put together into a reflective process so that the end product became professional growth.

The remainder of this paper focuses on the reflections as presented by members of the class. Initials are used to identify the students and to protect their privacy at the same time.

RS: All of the forums began with an introduction of the moderators, participants, and forum topic. One provided photos where were helpful in connecting posted opinions and ideas with a face (Boettcher & Conrad, 1999).

JL: Communication improved as a sense of community began to develop. The inclusions of first names appearing in the actual postings of a discussion are a sign that communities are beginning to emerge (Poole, 2000). As these communities emerged discussions seemed to flow more smoothly and quickly. Classes begin to negotiate substantive issues, ideas, and concerns with others who had common interests and goals (Edens, 2000). With other classmates responding, students receive much more extensive feedback than could be provided by the professor or moderator alone (Levin, 1999).

BG: The four round tables in which I participated successfully implemented Beaudin's (1999) "best practices." Each round table provided introductory information regarding the selected topic, participation criteria, and discussion questions. Discussion summaries were posted at the end of each week of the session. The discussions were highly interactive, the topics were interesting, and the resulting knowledge-base was extensive. I believe the high quality of forum contributions was a direct result of well-formulated initial discussion questions along with mentor-supplied re-focusing questions (Beaudin, 1999) when appropriate. In addition, each round table narrative included the professional background and experience of the co-mentors. At the end of the registration week of each session, the photos of round table participants and co-mentors were posted. These activities demonstrate the importance of and adherence to the principle that discussion moderating takes place in both a professional and a social context (Collison, Elbaum, Haavind & Tinker, 2000; Rossman, 1999).

NT: Through the power of asynchronous dialogue, I was able to join the discussion whenever I was best cognitively suited to do so (Abramson, 1999). I had enough time to decide how best to respond and which individual I wanted to direct my response to, in order to make the best possible contribution to the discussion (Funaro & Montell, 1999). I learned more than I thought I would from my peer's knowledge, opinions, remarks, questions, and experience. My peers were very respectful of each other, and they made an effort to understand alternative viewpoints (Poole, 2000).

JP: In retrospect, I learned tremendously from this experience. Although I have participated in a variety of online discussions, from a state-wide online conferences to daily distance education interaction with students, this exercise in mentoring illuminated more than just the admiration of best practices as mentioned above. Specifically I noted seven distinct lessons learned: Nothing takes place in a vacuum. Ask good questions. Listen actively. Involve everyone. Be flexible. Dare to venture into unknown territory. Relax.

SV: Moderators of online discussions should clearly define the topic for a discussion. Knowlton and Knowlton (2001) and Fabos and Young (2000) suggest that both the quality of communication and the interest level of participants deteriorate when moderators do not clearly solidify the scope of a discussion. In each of the round table discussions for this course, the initial postings made by moderators in week one included purpose statements about the session topics. Another successful strategy employed by the round table moderators was the use of leading questions posed by moderators in their opening postings. Discussions generally initiated with replies to these questions.

SS: Studies have shown that online forum participants want prompt feedback and specific comments posted in a timely fashion (Rossman, 1999). In preparing responses as the moderator, I was challenged to
differentiate between participating and encouraging, steering and monopolizing. Rossman observed that online courses are not conducive to lecturing and that instructors who facilitate learners' mastery of course objectives by encouraging discussion of topics related to the assigned reading are typically more effective than those who post lengthy presentations. Keeping this in mind, our moderator team encouraged short three to four paragraph discussions. In responding, we limited ourselves to add-on information rather than creating mini-essays. If I felt I might be lecturing, I reviewed my posting and changed some of my statements to questions rather than giving or creating answers.

PF: I serendipitously tripped across Dehler and Possas-Hernandez (1998) who reflect the positions espoused by Dr. Abramson. They aver that computer-mediated communications (like our forums) provide a fertile medium in which to cultivate the construction of knowledge, both shared and individual. Also, that experiential learning contributes to the full mastery of a domain. They conclude that the depth and richness of the learning experience depends on collaboration, diversity, and multiple perspectives. This mirrors my experience in this exploration of online discussion via the forums in our class.

BG: As I reflect on the "round table" assignment of this course, I am impressed with the completeness and the holistic appeal of this assignment. As learners, we had the opportunity to observe and experience the "best practices" of forum moderation modeled effectively in the general forums; each of us was able to participate in four student-forums (once as a co-moderator and three times as a participant); and finally we reflected on our experiences. As a teacher in a traditional classroom, I am constantly challenged to design class activities that effectively promote learning (the assimilation, integration, and implementation) of the concepts and principles under study. I found this assignment to be an extremely effective activity. This assignment was carefully crafted and exceptionally constructed in order to promote a rich educational environment for all of us.

Assessing the Readiness of Distance Learning Students

Dr. Mac Adkins  
Distance Learning Center  
Troy State University Montgomery  
United States of America  
mac@tsum.edu

Abstract: Is distance learning appropriate for all learners? How does a learner know if it is an appropriate choice? To assist students in determining their level of readiness to study at a distance and to assist institutions in identifying students who might be at risk of not succeeding in an online environment, an online assessment device has been constructed. READI—Readiness for Education At a Distance Indicator is a tool to help learners and their advisors assess the student’s readiness for learning at a distance. The READI tool is not intended to make an absolute decision as to whether or not a student will succeed as an online learner. However, the student’s scores will give them an idea of their strengths in the four different components READI measures: reading comprehension, technical competency, individual attributes and learning styles. When the student uses the READI tool, they receive immediate feedback concerning their scores along with a guide to interpretation. In this presentation the presenter will share how this tool is being used by Troy State University as well as other institutions to assess learner readiness.

Are you ready to take a distance-learning course? Are your distance education students best prepared to learn at a distance? Is distance learning for you?

Emerging advances in instructional technology, particularly the Internet, have caused higher education institutions to reconsider how they deliver courses and use space. This paradigm shift from a classroom model to a technology-delivered model has particular significance for distance learning. There is a group of learners who, due to work, family commitments, disability, or geographical location, are unable to attend campus and therefore choose to study at a distance. This application of instructional technology has resulted in a world-wide explosion of on-line courses. But is distance learning appropriate for all learners? How does a learner know if it is their best choice?

Having worked in distance learning for over a decade I have observed that distance learning is congruent with the needs and talents of many students, but is not appropriate for others. As Dean of Distance Learning at Troy State University Montgomery I developed a tool I call READI—Readiness for Education At a Distance Indicator. READI is a tool to help learners and their advisors assess the student’s readiness for learning at a distance. The READI tool is not intended to make an absolute decision as to whether or not a student will succeed as an online learner. However, the student’s scores will give them an idea of their strengths in the different components READI measures. When the student uses the READI tool, they receive immediate feedback concerning their scores along with a guide to interpretation.

In this presentation I will share how this tool is being used by Troy State University as well as other institutions to assess learner readiness.

READI measures four components:
- Reading Comprehension
- Technical Competency
- Individual Attributes
- Learning Styles

181
Geoffrey Cox (Cox, 2000) noted that Stanford has been doing forms of distance learning for more than 30 years. He observed that “Data drawn from these programs show that distance education works. We know from substantial experience that under the right conditions, not only is distance education comparable in quality to traditional education, but in some cases it is more effective. The conditions are important: students must be capable, highly motivated, and familiar with enough background to be ready to receive new ideas and knowledge. They must have good coaching, though not necessarily teaching, they must have the opportunity to interact with each other. When these conditions are met, learning takes place.” Cox’s comments mirror the four measurable components of READI:

Capable – Reading comprehension
Motivated – Individual attributes
Familiar – Technology competency
Coaching – Learning styles

How READI Works

The web-based tool assesses students’ likelihood for succeeding in an online learning program. READI indicates the degree to which an individual student possesses attributes that contribute to success in online learning, including:

- Self-motivation
- Time-management skills
- Self-discipline
- Reading comprehension
- Persistence
- Availability of time
- Ability to use a laptop, printer, software, and the Internet.

READI does not rely on simple self-assessment questions with obvious “right” and “wrong” answers. Rather, through a sequence of activities measures the degree to which students possess the traits needed for success in studying at a distance. READI provides an immediate score and diagnostic interpretation of results to the student and to their prospective school.

Benefits to the Educational Institution

The literature shows that maintaining high retention rates in distance education programs is a significant challenge for distance learning program. One of the significant variables is student readiness and appropriateness for studying at a distance. READI serves as an early warning device to identify students that might be at-risk of dropping out of distance education programs.

Educational institutions invest heavily on attracting and recruiting students. But when students quickly drop out of the program there is little return on the investment. READI allows schools to identify the students who are likely to drop out and it then provides resources for remediation so that the student can succeed.

Benefits to the Student

Students also invest thousands of dollars in their education. Many of them are hesitant to study at a distance for fear that they might not do well. READI helps them to recognize their strengths and provides resources to strengthen their weaknesses. A student who is confident of their READIness is much more likely to enroll.
Other Features of READI

Reporting – Each participant receives an individualized report indicating their personal READI score. This report compares their results to others in their defined group. School counselors receive a summative report detailing overall usage as well as individual READI scores.

Solutions – If the instrument determines that a user is not ready to study at a distance, links to potential solutions and resources are provided. At this point the student’s admissions counselor may also provide additional resources.

Ease of Interpretation – The results are not presented in confusing columns of numbers and figures, but in easy to interpret charts and graphs. Participants receive colorful charts indicating their level of READIness in reading comprehension, technical competency, individual attributes, and preferred learning styles.

Delivery of web-based and web supported distance education courses using a freeware version of Blackboard

Wendy L. Arneson
Clinical Laboratory Sciences, University of Texas Medical Branch, Galveston, TX
wlarneso@utmb.edu

Dean L. Arneson
College of Pharmacy, Nova Southeastern University, Ft. Lauderdale, FL
deana@nova.edu

Abstract: Delivery of distance education courses can be challenging in terms of timely delivery of course materials and instruction. Another challenge is facilitating student communication within student groups and with faculty. By providing material and exercises prior to class and conducting virtual classroom/synchronous webchats, web-based distance courses can be more interactive for students and help to facilitate critical thinking and problem-solving skills. A free web-based instructional delivery method, Blackboard Version 5.0, can meet many of these needs. This electronic instructional delivery method eliminates the time and expense of mailing or sending materials by facsimile. This system can also be used for administration of quizzes within specified time frames, and immediate feedback can be delivered to the student and instructor. Virtual office hours can be conducted via the webchat/virtual classroom feature and there is also a link to external email. External links to recommended websites can be used for additional reading resources. Use of Blackboard provides many benefits that can allow for efficient delivery of distance education courses within the confines of budget guidelines, particularly when distance education is new to the educational institution.

Introduction

Post-secondary education perspectives have changed over the past few decades. Changes include shifts in enrollment patterns, changing demographics of students and faculty and greater demand for anytime/anywhere learning. Fulltime resident student enrollment is declining in many educational programs. More students are adult learners that want to advance their present positions and require advanced education and training. However, many of these students are unable to accept full time or daytime pedagogical roles due to the need to remain employed in the community in which they reside. Predictions of the number of students desiring post-secondary education by the year 2005 is a 20% increase from current numbers. Many students, however, will expect anytime/anywhere learning to meet their educational needs. Employment expertise will often require better communication and problem-solving skills. Meanwhile, shifting of faculty responsibilities may require more time devoted to teaching during non-traditional hours as they meet these enrollment needs. More frequently, institutions are investing in computer technology and distance education to meets these needs rather than on classrooms.

Converting courses to distance education does require some thought and re-design. One can not merely post the lecture notes and exercises, give periodic examinations and expect the majority of students to succeed in mastering the skills they need to acquire. This didactic approach is successful in developing critical thinking in only a few students who have previously acquired proficiency. Problem-solving must be taught through a variety of methods and using the computer as a delivery tool will not automatically teach these skills. In fact, using the computer as a delivery method may create more barriers than by using face-to-face demagogical practices. Professors need to become designers of learning experiences, especially when using the computer as the delivery tool. Likewise, care in instructional design must be taken so that the product is not full of "bells and whistles" that are distracting and don't add to the value of
the education. Learning experiences should involve guided practice with feedback, case study or other problem-solving exercises and directions in gathering and using information.

A sense of community is missing with distance education in that students usually lack the face-to-face communication with other students and the instructor. If students also fail to receive feedback for the mastery of skills and knowledge in the course, they become discouraged and drop the course or the entire program. Likewise, if students experience difficulty using the technology and a sense that they are the only one experiencing problems, they will drop out. Students expect a seamless online environment that unifies student life and academics. Using discussion board, email, homepages, an online calendar and instant messaging can all help to create a sense of the academic community and to form networks with faculty and other students in order to resist attrition.

Features of Blackboard

Blackboard Version 5.0, can meet many of these needs to include: course creation, student enrollment, student/faculty email, bulletin board and virtual classroom usage, storage and retrieval of syllabus, lecture handouts and assignments, quizzes, grade book and use of other tools. This system is user friendly for faculty and students. Easy to use tools allow for the delivery of materials (text documents or slide shows) to distance students over the internet in many formats including but not limited to html. This electronic delivery method eliminates the time and expense of mailing or sending materials by facsimile. Case studies can be posted on the discussion board and students can collaborate to solve the problems via email or webchat. Guided practice can facilitate critical thinking with synchronized chat using the white board to illustrate points and bring in internet sites during virtual classroom time. Blackboard can also be used for administration of exams within specified time frames, and immediate feedback can be delivered to the student and instructor. Productivity tools are also provided to allow the student to have an address book and an online calendar to track their tasks. Other tools allow students to search for other courses provided on Blackboard and access resources such as online searches.

Communication Challenges

Challenges faced in the conversion of classroom-based courses to web-based involve communication. A common cause of attrition in distance education is due to students feeling isolated from the instructor and other students. Including opportunities to chat with the student at a distance and mechanisms for quick feedback via email or instantaneous feedback via instant messages can improve communication and help students to stay motivated and be successful in learning. Blackboard provides these features and the virtual classroom can be subdivided into separate rooms for small chats and private conversations between the instructor and one student even within a virtual classroom setting. Virtual office hours can be conducted via the virtual classroom feature and link to external email can provide communication when synchronous messaging is not necessary. By linking with a previously established email system rather than providing an internal email, it limits the number of communication tools that an instructor and student use.

Summary

Demands for distance education continues to rise. The delivery of distance education courses can be challenging in terms of timely delivery of course materials, didactic instruction and for facilitating student communication within student groups and with faculty. Blackboard 5.0 as a course-delivery system, is user friendly for both faculty and students with easy to use tools allowing for the delivery of materials over the internet in many formats including but not limited to html. This electronic delivery method eliminates the time and expense of delivering teaching materials and examinations via the mail or facsimile and can facilitate better communication between faculty and students in order to help decrease attrition that is typical of distance education.

Prosocial Behavior in Online Instruction

Jason D. Baker, Ph.D.

Abstract

A significant body of literature has supported the assertion that communication in the classroom is central to the learning process. Prosocial behaviors, such as nonverbal and verbal immediacy, have been found to promote affective and cognitive learning in traditional instructional settings. The short paper presents the results of a study that examined the effects of instructor verbal immediacy on affective and cognitive learning in the online classroom. The results of this study found that students who rated their instructors as more verbally immediate expressed greater positive affect and higher perceived cognition than students taught by less immediate instructors. These results are consistent with similar studies in traditional courses and reinforce the influential role of the instructor in the online learning environment.

An understanding of the significance of prosocial behaviors in the online classroom has benefits to instructor and student alike, as practitioners could improve their course development and delivery in light of these results. Furthermore, such information goes beyond the “no significant difference” studies that continue to appear in the literature and would serve to validate an intuitive perspective held by many online instructors. Therefore, this presentation will not merely address the results of the study but will use them as a framework to suggest improvements to online pedagogy. Building upon these results, I will offer suggestions as to how to improve the effectiveness of the online learning experience through instructional design, pedagogical strategy, and social facilitation. This presentation will weave my experience, as both an online instructor and distance learner, with the results of the study to assist those who seek to effectively teach online.
Defining the Role of Student Involvement When Teaching with Technology: The Non-Traditional College Student

Martha Beasley, Lees-McRae College, US

In the process of defining the role of student involvement when teaching with technology, one must have an understanding of the student's needs. In the realm of higher education, we teach with a focus on both the traditional and non-traditional college student. The traditional college student is between the ages of 18-21, and in the midst of acquiring social and academic maturity, and a basic knowledge of the power, impact, and basic capabilities of technology on today's world. The range of technological knowledge of the traditional student varies between Internet surfing and chatting to demonstrating proficiency using highly technical processes. This proficiency will continue to increase in the traditional student, as K-12 schools continue to enhance, encourage, and advocate technology in the classroom setting. The non-traditional college student (approximately 40 years old) tends to be highly motivated and task-oriented due to the seriousness and circumstances of voluntarily enrolling in college. These circumstances entail real costs to the student such as time, employment, family, and finances. Most non-traditional students know a great deal about life, relations, and dealing with a wide range of experiences. A goal in education today is to meet the needs of all students, both traditional and non-traditional.

As we attempt to meet the needs of all students, we can find commonalities among the traditional and non-traditional student. Many times the needs of the traditional student include structure, guidance, and understanding throughout the student's college experience. Ironically, the non-traditional student possesses these same needs, but simply for different reasons. Common expectations of both kinds of students include information that is up-to-date, courses that are flexible and that accommodate different learning styles, guidance on what and how to study, opportunities for application, feedback, humor in the learning environment, and variety in course activities (Moore and Kearsley, 1996). Another common driving force for both the traditional and non-traditional student is the desire to graduate with a degree that will serve the student well in an ever changing world. Suggestions for direct student involvement that help to promote a high-quality educational program as students prepare for the real world may include such ideas as a teaching and learning center for multimedia training, a writing lab, laptops for students, and student involvement in the remodeling, networking, construction, and implementation of projects. Another method of meeting these needs, demands, and expectations is through distant learning course work.

In the process of making this transition to distant learning programs, institutions tend to grapple with various issues. The overall goal is to deliver a successful, high-quality education to students. Institutions inquire about the role of the student in the process, since the goal of a high-quality education centers around the student, both traditional and non-traditional. This includes a design or perhaps, redesign of what students bring to the "table of learning". For example, the once passive learner is required to become an active, autonomous developer of knowledge (Parker, 1997). Far more responsibility is placed on the learner and the classroom moves from a teacher-centered approach to a student-centered approach. As the approach changes, the task becomes multidimensional by a change in attitude, skills, and the ability to interact with the technology.

Kasworm (1992) suggests three stages in the continuum for implementing a student-centered approach for student success in technological course work. Stage One centers on teacher-directed interaction, which is highly structured, as students are introduced to the technology. Brief question and answer sessions are encouraged in order to assure pedagogical and social attributes as the student moves in the direction of autonomy.

Stage One allows interactivity in many formats including teleconferencing, videos, or conference calls. The goal is for the student to become self-directed through in-depth discussions that are richly sculptured by the professor.

Stage Two addresses student skills, as the learner advances from lower level thinking skills to higher order skills. The professor assists in guiding the student away from reliance on the instructor to the role of decision maker. McGiven (1994) believes that in order to promote a successful distance-learning program, one must focus on the student's ability to critically analyze and interpret information, and to interact and elaborate on concepts.

Stage Three, the final stage of a successful technological program, centers on high student autonomy and low instructor dominance. The professor's role is that of a guide and facilitator, while the role of the student is that of an active learner and participant. The professor continues to encourage and guide the student throughout the course.

All of these stages were part of the vital planning in creating an Educational Psychology course for 15 non-traditional education majors. These students displayed typical qualities of the non-traditional student, especially in
the lack of confidence when faced with a distance-learning course in their program of study. In order to make this experience a successful course, initial professor-directed activities were built in to the scheduling of the progression of the course and assignments. These students were a formed cohort and had taken in-class courses together prior to the distance-learning course. They were able to associate a name with a face and personality throughout the online discussions. Three face-to-face meetings were built into the course, including an initial, introductory meeting, a mid-term exam and review time, and a final exam and assessment time of both the course work and the distance learning experience itself.

Initial attitudes about the course arrangements ranged from excitement and high motivation to learn in a new and different manner, to real doubt and lack of confidence in each individual’s ability in the realm of technology. The course was purposely set up to begin as a highly teacher-centered and directed course and to gradually transform into a student-centered format. This was accomplished predominately through the use of online discussion forums and changing from professor directed questions to student directed topics and discussions based on the readings.

The course turned out to be successful in many ways. All 15 students responded in all assignments and made A’s and B’s in the course work. Perhaps the biggest success in the course was displayed through the confidence of the students in their final remarks such as, “I can’t believe I made it through this course. I knew so little about technology, computers, and especially a distance learning course!” Others remarked about how much fun the course had become, and still others who were reluctant to speak out in class felt proud that they were able to vocalize opinions on an equal level with more assertive students! All students commented on how convenient this sort of arrangement was for their typical non-traditional student schedules. All 15 students balance such responsibilities as full-time/part-time jobs, families, and adult responsibilities. As they responded to assignments and to each other, the recorded time of student involvement was usually around 10:30 P.M. to 1:00 A.M. This proved to be a real plus for the students, as they attempted to balance everything in their busy lives.

Overall, this distance-learning course proved to be a real success, but I attribute the success to following McGiven’s general guidelines for creating a course that advances from a teacher-centered atmosphere to one that is almost completely student-centered. I also feel that the preset meetings and the fact that the students already knew each other through previous course work helped to create a free environment for genuine responses and feedback regarding individual opinions and spontaneity in the online discussions. For example, one student summed up the experience by stating, “Our discussions online were much like those we have in class, and knowing the people you are participating with is a tremendous help. I liked reading everyone’s ideas and feel that I came away from the class with a great deal more understanding than I would have had I only read the materials and taken the tests.”

Due to the changing needs and roles of students, changing approaches in education help to foster a student-centered process of learning for both the traditional and non-traditional student. As demonstrated in this particular online distance-learning course, the role of the student focuses on technology proficiency and responsibility for acquiring new knowledge.

New Mexico Tech is a small (1,500 students), state sponsored research university in central New Mexico. It sits on a traditional campus offering specialized classes in science and technology in the traditional manner. But with competition increasing in recruiting qualified freshmen, transfer students and graduate students, something non-traditional was going to have to be done: distance education.

History
Distance education was not necessarily a new idea. But implementing a viable program was. Over the years distance education became the longest four letter word on campus. Distance education would take time and money, resources that were better spent on research or other projects.

There were many failed attempts at distance education over the past years. Committees were organized and disbanded. Facilities were built using surplus materials, and consortiums were organized as delivery partners. Tech was doing distance education, but was missing the drive and support needed to take the next step. There was no reason to the programming, no reason for the classes offered, and no direction. Instructors saw distance education as time prohibitive. There was a question as to who would own the program rights. And there was little incentive monetarily and professionally for developing any type of program. There was also no marketing. There were no classes to market, and therefore no market for classes. Distance education had become mission impossible.

Developing a Concept of Distance Education

As other universities became more competitive, and as enrollment dropped, the university realized it was time to look at distance education once again. But even though distance education seemed to have many of the answers, there were still many hurdles from the past to overcome. For starters, there was no administrative organization. There was no superstructure. And there was still a concern from the faculty about workload and ownership. And since Tech was so far behind other universities in delivering distance education programming, it did not make since to try and compete against already established classes such as English and other undergraduate type programs. Besides, Tech has a unique blend of classes and programs, many of which are not offered anywhere else. Therefore, the university began to take inventory and identify classes and programs that were not only unique to Tech, but would create interest beyond the campus. The concepts identified came from energetic materials, mineral engineering, and science teaching, areas of which unique classes could be developed and offered.
Next, a team of distance education visionaries was put into place to create a department for distance education. This team went to work identifying markets, researching cost-effective delivery methods, developing infrastructure, establishing policies and procedures and contemplating non-traditional calendars to meet the needs of students. A decision was made to market programs and not just classes. The team set out to do public relations work with the faculty. They had to identify and address the concerns of the faculty and convince them of the benefits of distance education. This has been done by the establishment of committees, holding facility open houses, regular reports to the faculty council, and the writing of a distance education contract with the input of faculty members that is favorable in areas of compensation and assistance in course development. As programming develops, as quality improves, and as other faculty members see what distance education is doing for other programs and the university, attitudes are changing and more and more individuals and departments are wanting to participate.

Distance Education Takes Shape

Distance education at Tech is still in its infancy. There are still many questions and concerns that need answered. Distance education at Tech is growing faster than ever. There are growing pains. Unforeseen problems arise almost daily, but with teamwork and vision they are mostly resolved. The organization is developing and team members are identifying their roles. But despite the growing pains, distance education is becoming a viable program and is beginning to meet the needs of students, community and the university. Today, New Mexico Tech is producing and delivering courses using video tape, video teleconferencing, and the internet in real time to sites all over the country. Today it is possible to earn a Master’s degree at Tech through distance education. And distance education at Tech will continue to grow as more plans and programs begin to take shape. The vision of distance education at New Mexico Tech is gaining life. It has allowed the university to reach beyond its physical boundaries. Distance education is no longer Mission Impossible, it is quickly becoming Mission Possible.
Student Perceptions of Austin Peay State University Online Courses

Linda Brake, M.A. Ed
Ed. S. Graduate Student
Austin Peay State University
Clarksville, TN USA
tlea@midsouth.net

John Mark Hunter, EdD
Associate Professor, College of Education
Austin Peay State University
Clarksville, TN, USA
hunterm@apsu.edu

Abstract
Austin Peay State University began offering online courses in Fall 2000. After a year of courses evolving rapidly, instructors and administrators felt confident in their ability to present instruction using this medium. Could this confidence be supported by analysis of students' perceptions? Research questions included: (1) Has the change in service delivery from face-to-face classroom instruction to online instruction led to a satisfied student? (2) What student qualities are prominent in leading to a satisfied student who operates in our online environment? (3) What are students' attitudes toward online courses they are currently completing? A non-experimental descriptive study using an online survey determined student perceptions. Results were transferred to numerical measures to determine a perception score. Higher scores signified a more positive perception toward web-based learning. The conclusions drawn from data are that the overwhelming majority of respondents have strongly positive perceptions toward their online learning experience.

Background Information
Remaining current with technological innovation and meeting student needs has become crucial to the competitiveness of higher learning institutions. The pedagogy by which institutions of higher learning now offer instruction to students continues to evolve and change into some new and different models. The causative factor of this is twofold. There has been a dramatic increase in the nontraditional student population, and institutions of higher learning have responded to this changing student body, with it's attendant change in needs. Secondly, the broad availability of technological advances has provided an opportunity for more and more schools to take their courses into sophisticated online environments that previously were open to only a few elite institutions. The combined effect has been to fuel the phenomenon of changing the service delivery model of instruction at colleges and universities.

Statement of the Problem
Austin Peay State University (APSU) has seen a dramatic, rapid rise in the online course offerings and number of students enrolled in online classes. What are students' perceptions of these courses? Is the administration alone in believing the instruction and experience is positive for the students who choose this medium? The higher education community must gauge success based, in part, on the satisfaction and perception of the students they serve.

Review of Related Literature
Nearly fifty-five percent of all four-year public institutions of higher learning offer complete degree programs through online courses (Bataineh 2000). Current literature has much to offer us concerning student perceptions of online learning around the world. From longitudinal studies with over 15,000 participants (Rekkedel 1999) to small research projects involving just seven students (Sorg & McElhinney 2000), research has overwhelmingly found students with positive perceptions of learning over the Internet. An in-depth analysis of current research indicated some very prominent factors that are involved in determining whether students' perceptions are positive or negative. By far, the variable of interactivity on
three different levels defined the strength of students' perceptions. Other factors include computer knowledge base (Solloway & Harris 1999), prior experience (Ewing-Taylor 1999), community-building online (Kolloff 2000), and gender (Sanders & Morrison-Shetlar 2001). The literature also is rich in attempts to identify traits among individuals who are successful in their online experiences and how those traits can be used as indicators for predicting student success.

Methodology

The research sample was derived from the total population of students enrolled in online courses at APSU in the Fall semester of 2001 (approximately 450 students). The researcher developed a 25-question survey that included demographic information, computer skills and online habits, and a Likert-type response scale about perceptions toward online instruction. Completed surveys were compiled to determine perception scores for each student and each item on the survey. The instructor of record for each of the online courses (18 individuals) was asked to give their students the opportunity to participate in the online survey. Results were emailed directly to the researcher.

Results

The decision of which courses and sections would be given the opportunity to participate was left to the instructors of those courses. While several of the eighteen faculty members asked their students to participate in the online survey, most did not. One was found to have offered an incentive to his students to participate in the study. Twelve percent (n = 56) of the students who were enrolled in online instruction participated by filling out the online survey. It is not known how much of the online population was given the opportunity to participate.

Nineteen of the 56 respondents rated their courses in the top ten percent of the range; there were no scores in the bottom ten percent. The median score is 58 out of a possible 68. Seventy-five percent of the respondents scored above the mean (52). In depth analysis of the data is ongoing and will be completed before definitive conclusions are drawn from the study. However, a preliminary analysis makes it clear that the results are skewed strongly to the right; this is seen as an indication of positive student perceptions toward their online experiences at APSU.

Distance Learning Program Review

Cathy Cavanaugh, Ph.D. Curriculum & Instruction, University of North Florida, USA. ccavanaugh@unf.edu

Abstract: Recently the college of education faculty and administration at a regional state university stated that the college needed a thorough review of its policies, procedures and plans regarding distance learning. The college's technology committee collected data to establish the college's history, current status and goals. Faculty members were surveyed to learn about their individual experience and interest in distance learning, and to learn about the issues they felt were important to resolve as the college moves ahead in distance learning. The data was used to draft a 3-year plan and a 6-year plan for distance learning at the college.

A strength of distance education is its potential to focus the learning process on the student. Courses and programs that emphasize their focus on the student's strengths and needs will succeed in attracting students. In order to build their reputations and keep students, courses and programs must reach quality goals. Instructors have concerns regarding the identity and honesty of the students doing the work in distance education courses. A survey of 850 Americans by the American Council on Education found that 43 percent think distance-learning courses do not measure up to those offered in person (Evelyn, 2001).

In its December 2000 report to Congress, the Web-Based Education Commission made high quality online educational content one of its seven critical issues. In order for a student or institution to determine whether quality has been achieved, quality must be defined. A primary goal of educators is developing independent learners who can capably apply their knowledge to new situations. To ensure that distance education offerings meet this goal, providers must identify desired learning outcomes and instructional methods. Quality indicates that instruction is effective and appropriate. The definition of quality may include quantitative elements such as completion rates, student performance, and student evaluations of the learning experience. Qualitative dimensions may include ratings of teaching-learning events, materials, learning process, pace, activities, content and options offered to students (Cavanaugh, 2001).

During the 2000-2001 academic year, college of education faculty and administration at a regional state university stated their belief that the college needs a thorough review of its policies, procedures and plans regarding distance learning in order to ensure that we continue to provide quality programs and to uphold our reputation for attention to students' needs while expanding our ability to serve the community. To begin the process of managing distance learning in the college, we gathered data to establish the college's history, current status and goals. The college Dean and department chairs designated the college's Technology Committee as the group to oversee the process. The committee selected a member with distance education experience to lead the process, with a student assistant. To learn the extent of the college's past involvement in distance learning, a history was compiled. The history listed the names of courses taught via distance technologies and information about the year and term, instructors, students registering, students completing, and student performance and satisfaction information when available.

The baseline history showed that over the four academic years during which the college offered distance learning courses, 23% of the college's full-time faculty members had taught distance learning courses. In the university, fewer than 5% of faculty taught distance education courses during that time period. In fact the college of education began offering distance learning course two years before any other college in the university. Between 1998 and 2001, the college offered 30 distance learning courses, compared to 16 offered by all of the other colleges combined. The college has served 375 students via distance learning. Throughout the 4-year period, the numbers of courses and students involved in distance learning at both the college and the university levels have steadily trended upward. The historic information indicated that distance education, while new to the college and to the university, has become more important in meeting our educational missions. Clearly, there is interest in continuing to develop our distance learning program. However, during the four years that distance learning has been available, there have been no standards or quality controls applied to courses, delivery or students, at either the college or the university levels. As interest and involvement in distance learning grows, concern over maintaining quality grows.
The college distance learning review entered a stage of assessing the current status of distance learning. Full-time faculty members were surveyed to learn about their individual experience and interest in distance learning, and to learn about the issues they felt were important to resolve as the college moves ahead in distance learning. An open-ended email survey was distributed, and follow-up interviews were conducted to ensure that each faculty member had an opportunity to participate.

Survey items pertained to past or current courses taught using distance elements, distance elements used (email, Blackboard chat or discussion, web-based projects, teaching via audio or video, other) for enhancing or replacing classroom instruction, interests in teaching a future distance learning course either fully or partly distance, college courses that would be well taught using fully or partly distance learning approaches, college courses that should not be taught using distance learning, benefits to the college and our students of expanding our distance learning offerings, concerns about the college expanding distance learning offerings, and issues that are most important to resolve as the college moves ahead in distance learning.

During the survey period, background information was collected regarding distance education policies and procedures in place or in development at the university's other colleges and at other colleges of education in the state. The colleges' Dean's office and web pages were consulted to learn how distance education was managed. Data was gathered regarding whether the college has a faculty review board, a guidebook, or policies regarding decisions about distance learning courses and instruction. Copies of any available materials were collected.

Faculty survey results and college inquiry information was compiled and summarized in a report that was submitted to the college Dean, department chairs and the technology committee. The data about past distance learning offerings and current faculty status was used by the technology committee to draft an outline for a 3-year plan and a 6-year plan for distance learning at the college. The outline is shown below. The college's comprehensive distance learning review is currently entering the action phase, in which a detailed policy and plan will be developed by a representative group of faculty members.

Plan for distance learning at the college of education
I. Policy regarding appropriate courses for distance environments, and procedures for adding distance components to courses
   Including Faculty proposals, Proposal review process, Rationale for distance component, Quality assurances, Faculty support in developing courses, Student screening
II. Infrastructure and support needs
   Including Equipment, Facilities, Faculty support, Student support
III. Plan for building student enrollment in distance learning
   Including Quality courses and instruction, Student satisfaction and success, Meeting community needs, Appropriateness of communicating distance learning opportunities to students locally, statewide, nationally and internationally

Design of Student Model Centered Web Based Adaptive Learning System

Pinde Chen  Kedong Li
Institute of Education Technology
South China Normal University
GuangZhou, China
pinde@scnu.edu.cn likd@scnu.edu.cn

Abstract: Web-based education systems are becoming increasingly popular in recent years; however, most of the systems developed so far use static hypermedia as the manner of representing contents. It's a challenge to develop advanced Web-based education applications that can offer both adaptivity and intelligence. This paper will review some related works in this area and present a design of advanced Web based learning system that support adaptive presentation, adaptive navigation and adaptive help.

1 Introduction

The first comprehensive review on adaptive hypermedia system can be found in (Brusilovsky, 1996, p. 87, in 2001 the author continued tracing research progress in this area (Brusilovsky, 2001, p. 87). Since 1996, Most of adaptive hypermedia are education hypermedia which are inferred in (Brusilovsky, 1996, 2001).

As for adaptive collaboration support, an example in this area can be found in (Greer, 1998, p. 494). This paper reported an Intelligent Helpdesk system which integrated two cognitive tools: CPR (Cooperative Peer Response) and Phelps(Peer Help System).

In this paper we will present a web based learning system which integrate adaptive content with adaptive help centered by student model.

2 Designs

Our schema is a student model centered integrated learning system feature adaptive presentation, adaptive navigation support and adaptive help. The system structure can be depicted as Fig 1.

The data part of a web based learning system is made up of course fragments, instruction strategies, domain model & course structure, student models. Student Model consists of user's knowledge level, learning goals as well as their background. User's knowledge level is an overlay model. For each domain model concept, an individual overlay model stores a value which is an estimation of the user knowledge level of this concept.

An adaptive engine will be used to generate web page dynamically based on values in the User Model and other data listed above when the curriculum is delivered via web; the pages demonstrate the features of adaptive content and adaptive navigation.

Help system is a tool that resides on a page. When a student ask for help, help information is generated according to the position of current question as well as knowledge level of the User Model. The system utilizes entries in forum & FAQ which are indexed by concepts of Domain Model and course fragments to generate personalized help information.

The help system can also consult a discussion forum; each topic of the forum is indexed by concepts in Domain Model. When user wants to submit a question, the user must select one or more concepts (from the list). The system can use the user input to make sure that all FAQ and contents of discussion forum are correspond to the (user selected) concepts.

3 Progress of the work
Our work is still in the early phase; our goal is to implement a suite of tools to help instructors to produce such an online course easily without writing programs. These tools include:

- Tools of define domain concepts, learning goal and background knowledge
- Tools of define class structure
- Tools of define rules of page construction
- Tools of define prerequisite concepts and output concepts
- Tools of create exercises
- Adaptive engine
- Help engine
- Discussion group on indexes for domain concepts

By this system, the teacher will be easily to develop an online course which is an adaptive education media. In addition, there is a adaptive help tool available. Other common tools can also be linked to this course. All of these tools provide a leaning environment for the students while they learn via Internet. We believe that our work will be beneficial to web based distance education.

Teaching through tragedy: 
Use of dynamically created websites to maintain communities of learning.

Michael L. Connell, Ph.D. 
University of Houston 
United States 
mkahnl@aol.com

Abstract: During the Summer of 2001 the University of Houston, together with the rest of the Houston community, suffered through one of the most devastating storm events in memory – Tropical Storm Allison. At the time of Allison's arrival the author's summer courses were two-thirds complete and everyone was looking forward to a smooth completion of a successful term. As a result of Allison's impact the university's main campus was shut down for a one-week period, and university servers supporting instructional tools went off-line.

This paper will describe how these courses were able to successfully maintain their direction via a pair of dynamically created emergency websites. These websites successfully maintained a community of discussion within the class and enabled the completion of the remaining projects. This paper will outline the background leading to the collapse of the normal instructional infrastructure, the mechanisms and logistics of creating an alternative instructional infrastructure, and a discussion of its effectiveness.

This proposal was first thought of during August of 2001. In the chilling climate following September 11th it is comforting to know that even when normal systems are not present we can still fulfill our instructional calling.

Introduction

We often take for granted that there will be a minimum of support for our instructional efforts. At a bare minimum we would expect a classroom, some type of regularly scheduled meeting time, and a supporting technology infrastructure for web-based activities. During summer of 2001 at the University of Houston we had none of these due to the impact of Tropical Storm Allison. The university itself had been closed due to massive flooding (much of the downtown Houston area was underwater click on: http://hometown.aol.com/mkahnl/Courses/Tech_Math_II_S2001/cathys_powerpoint.htm to see a few pictures showing the extent of the devastation), the university technology infrastructure was off-line (talk to Jerry Price, I am sure he can tell you a few stories!), and students were in survival mode and their resulting schedules were chaotic at best.

Technology to the rescue

This paper will describe how a pair of emergency websites, literally created on the fly, together with extensive phone conversations kept the courses alive. These sites were not fine tuned creations, but serviceable constructs responding to the needs of the moment. The author during this period often found himself up at 5:00 am with a cell phone in each ear and a voice transcription unit plugged into the computer. Despite these many trials feedback from students indicated that they felt they had more one on one feedback given in the class then other courses they had taken on campus.

The paper will further describe some of the logistical challenges of maintaining contact (one student threw a 200' telephone cord across an alley to a neighbor’s apartment which still had phone service!) as well as describe differences in student product when compared with more traditional offerings of the courses. I will finish by including student comments on the courses. I am planning on including the url’s for the emergency websites so that others can see what was done.
Abstract: At the decade of the 90’s the use of the Personal Computer – PC, became common due to the fall of its price. The spread of PC’s all over the world and its connection through networks, Internet and Ethernets, made this equipment a mean of communication used by people from different parts of the world. This achievement enabled a faster and even more effective communication (e.g. chat, e-mail, net-meetings, etc) (see Barradas & Guerra 2001). Many were the areas that benefited from the spread of PC’s and the new Information Technologies (IT) implicated, namely the areas of education and formation courses. With Internet and due to the growing necessities of the common citizen, nowadays is possible and it is being even more stimulated the long distance learning; this has been one of the emergent concerns of the latest scientific meetings as (Technical meeting, 2001).

Introduction

It is common to hear about long distance learning using IT (as it is the case of some virtual Universities) [1]. In the following sections of this paper we will present some projects developed in Escola Superior de Tecnologia de Castelo Branco (EST). The aim of these projects is to improve the teaching of engineering subjects. This improvement isn’t only related with contents but also with the logistic support needed by students with less availability to be in campus, such as worker-students. In this paper we refer to some important items needed to approach both teachers and students from distant places.

Interface through www pages

The School has actualized online information of all subjects that integrate the curricular plan of the Computer and Computer Science Engineering courses as we can see in (Fig. 1a) [2]. For each subject the students have access to the teacher’s contact (email, etc), to the subject’s program, evaluation regulations, technical and didactic information, bibliography, etc. It is without doubt an extremely positive mean of communication between teachers and students; it allows the direct contact between them once the student has finished his graduation. Therefore the page allows former students to get knowledge actualization; it’s also useful for those trying to get a higher education, as they know previously the contents of the subjects they will study.

Supporting teaching tools

A didactic Compact Disc (CD) is being developed whose contents are related to the control area subjects (Digital Control, Dynamic Control and Computer Control), as showed in (Fig. 1b). The CD will serve as a teaching support in EST and in other Engineering Schools where these subjects are part of the curricular contents. There is also a logistic component, www page, whose gold is to improve the CD ROM’s effectiveness. Through this page the support is guaranteed to the components in need of actualization; it also allows taking doubts

BEST COPY AVAILABLE

199
related with the referred subject. Users' suggestions are collected to improve both CD and www page. Control Teaching Multimedia Tools – FEMECO (Marques et al. 2001) is the name given to these tools. The referred page serves as a student support; it has additional information, which allows communication with the teachers of the subjects, whom can also elucidate doubts. Therefore it contributes to a better learning and enables communication amongst instructor and student. The page is frequently actualized in order to enable effective support.

![Course web interface](image1)

![FEMECO CD](image2)

![WebMat](image3)

**Figure 1:** Supporting teaching tools

Other www sites are being developed to improve teaching of different subjects such as the case of Mathematics (Fig. 1c). Other software is being developed to allow remote control of practical experiments and used in long distance laboratory experiments, this is particularly important for engineering courses (Chasqueira et al. 2001).

### Special teaching

Information Technologies are a paradigm of society. However, there are some neglected groups as it is the case of handicapped people with greater access problems. In order to offer knowledge to a group of those ill-favoured people, it was developed in EST a support teaching integrated system for people with hearing deficiencies (Valente & Guerra 2001). The greater advantage of this application is the integration of both spoken and written languages with sign language. Although it was developed for students it also enables parents and teachers to use it to transmit knowledge. This is another of the new information technologies applications developed in EST.

### Conclusion

In this paper we present a summary of the new information technologies techniques, used in long distance learning, developed in EST. We also include tested strategies to motivate students to the technological courses, Computer Science and Computer Engineering, lectured in Castelo Branco-Portugal.

Teaching Research Methods Online: Course Development and Comparison to Traditional Delivery

Reagan Curtis, Ph.D.
Educational Psychology
College of Education
Northwestern State University of Louisiana
United States of America
Email: reaganc@nsula.edu

Abstract: The development and evaluation of an online Educational Research and Evaluation course for Master's level students in a College of Education is described. Rationale for the course’s highly structured design and the inclusion of a synchronous group discussion component in an otherwise asynchronous course is discussed. Students’ performance in the 2 sections of the online course is compared to a traditional section of the same course. Results indicate that students performed equally well when applying their knowledge in written papers, but that the traditional testing situation put those students at a disadvantage compared to their online counterparts.

I have three goals in mind as I write this paper. The first is to describe the development of an online version of an Educational Research and Evaluation course for Master’s level students in a College of Education. Both the number of courses offered and the number of entire degree programs offered online doubled between 1995 and 1998 (Phillips, 1999). Research methods courses are required in most Master's degree programs across the country. As many universities strive to offer online degrees, research methods courses will increasingly be nominated for conversion to online delivery formats. A description of the process of designing and implementing such a course will provide insights for those who are or will be involved with online delivery of similar courses. My second goal for this paper is to go beyond a description of the course development process to provide insight into how online delivery compares to traditional formats for research methods courses in education. I will describe data from three groups of students: those enrolled during the first semester online delivery was offered, students enrolled during the second semester online delivery was offered, and those enrolled in a traditional section during the second semester online delivery was offered. The third goal for this paper is to describe how teaching the course online one semester informed how I taught it during the second semester. While many forces push for increased online delivery of courses, it is important to ask how these courses compare to traditional methods of instruction. I believe there is a trade-off between online and traditional delivery formats so that the benefits and drawbacks of each must be weighed.

Online Course Development

Consistent with the first of my goals for this paper, I will describe my particular experiences in the process of online course development. Let me first relate my reasons for moving into online delivery for Educational Research Methods. This is a course that all students who receive a Master’s degree in education from Northwestern State University, and many other universities, must complete. It is traditionally a very demanding course for students and one that most students leave for the end of their program. It is also one of my passions and along with statistics is a course that I think students can really learn to love if it is delivered properly. Finally, at Northwestern State University, Educational Research Methods was a course that had not been taught online before. I knew that several complete degree programs would become available for distance education students if this course was offered. I realized that under these circumstances someone would be developing this course for online delivery and I decided that my background and love for the course made me the ideal candidate. I started my journey through the online adventure by signing up for 33 hours of training funded by the Learning Without Travel initiative on distance delivery methods available at Northwestern State University.
These methods included using compressed video to present instruction where students could see and hear their instructor and receive feedback in real time. This system has some definite advantages, but also has the drawback of forcing students into a particular timeslot and physical location for instruction. Frankly, I was not convinced that dialog with a 1-2 second delay was really enough of an advantage over asynchronous delivery methods to warrant restricting students to a particular time and physical location for instruction. In my mind, they might as well make the trip to a university for a traditional course if that was the best we could do.

I decided that truly asynchronous Internet delivery was my delivery method of choice. This meant using the Blackboard delivery system. I received training on how to develop, design, and manage a course using the Blackboard delivery system. The training went a long way to preparing me for the course, but there was much more that could only be learned by doing. One of the many truths I learned in those training sessions was that preparation is everything. In traditional delivery formats, the professor has much more room for on-the-fly adaptation as they assess their students’ progress. That type of assessment and adaptation is not possible without face-to-face interaction. Preparation becomes your only substitute.

Preparation in the structure of the course; preparation for every contingency you can conceive of because others you haven’t thought of will arise.

I spent several months preparing and designing my course before it opened for student enrollment. As I began, there were several ideas I knew I wanted to incorporate into this course. Those ideas had origins in my graduate training in educational psychology and found substance through the training sessions I was able to attend. I am greatly indebted to Darlene Williams for her expert training and willingness to help me in bringing these ideas and goals into reality through the Blackboard delivery system.

First, I knew that I wanted the course to have a clear structure that led students through the material. I knew that other instructors in other courses preferred to post most of the assignments at the beginning of the semester and allow students to work at their own pace. I don't think Educational Research Methods is the kind of course that this is appropriate for. The material is difficult and complex for students. I think that a guided tour with a more analytical or piecemeal approach is warranted. Of course, students have to be able to bring it all together in the end, but I think they need to perfect the components first. I had in mind the cognitive apprenticeship kind of model discussed by Barbara Rogoff and Jean Lave (Rogoff, 1990) and the idea of a more knowledgeable guide through the Zone of Proximal Development that Lev Vygotsky (1978) described. This model is sometimes described using the metaphor of an apprentice tailor learning to complete a garment. I would allow students to work on small pieces of the garment and guide them as they perfected each piece before they would tackle a complete garment on their own. For Educational Research Methods, that complete garment was an empirical research proposal complete with an in-depth literature review, specific methods, and detailed measures. A research proposal that would allow students to go out and collect data for a thesis the very next day if need be.

A second idea that I knew I wanted to incorporate into this course was the use of small group discussion. This was at first nothing more than a vague goal. I thought that group discussion among peers in an asynchronous course had the potential to replace much of what was lost by not having face-to-face class meetings. Threaded discussions are a common way of trying to facilitate group discussion in asynchronous courses, but I didn't think they would be enough. For one thing, threaded discussion lists have a reputation for being difficult to sustain. I knew that I would be using threaded discussions, but wanted to supplement them with more real time types of interactions. With this goal in mind, and Darlene’s expertise reassuring me that it was possible, I decided to require students to form into small groups with designated times to meet in the Virtual Classroom section of Blackboard. This introduced a synchronous component to the course and I was unsure how students would react to the requirement.

With these ideas in mind, I put together a course where just about every week involved reading a chapter from the textbook, reading my lecture notes on that chapter, meeting in the Virtual Classroom to discuss issues with classmates, and posting questions or comments on a threaded discussion board. The final research proposal was broken down into 5 sections and a draft of each section was due about every other week. I then read these drafts and provided detailed feedback on how to improve them for the final version due at the end of the course. Weeks that did not have drafts due usually involved taking a quiz on the reading assignment for that week. These were open-book, open-note quizzes, but were also timed so students had to be well organized. Finally, I included a midterm and final exam that students downloaded and had 3-4 days to complete before emailing me their responses.
Online Course Delivery

Delivering this course turned out to be quite labor-intensive. I thought that the amount of up-front work that went into designing the course would make the actual delivery less intensive compared to a traditional delivery format. This did not turn out to be the case, but if I had not put that effort in at the beginning, then delivering the course would have been completely overwhelming. As it was, I averaged at least an hour every day just answering emails and questions from the threaded discussions. Each week, I also graded quizzes and sent feedback on the correct answers or reviewed proposal drafts and sent detailed feedback on how to improve the final version. The amount of work that I put into delivering this course was about the same as that I put into delivering traditional sections. The difference was that much more planning had gone into it before instruction ever began.

You may be wondering what could take up an hour a day answering emails and discussion lists. For the first few weeks of the course, students had three overriding concerns. Firstly, some had difficulties with email and Internet technology. I learned quickly that some students were well suited to taking a course online, while others needed a great deal of "basic training" in skills such as sending emails with attachments, saving word processor files in different formats, and navigating a web site. I believe strongly that there are some students who belong in online courses, while others simply do not have the prerequisite skills. I don't mean that this latter group cannot perform in an online course, but simply that they would be better served in the traditional classroom. Even for those with a strong technology background, online courses can be challenging as evidenced by this email excerpt:

I have been unable to email you all day. I faxed my final exam, since our server at school has been non-functioning, and when I got home and tried to email from my regular browser, that also had problems. I am trying this route. I hope this is acceptable (anonymous student).

Both the professor and the students must be flexible and able to problem solve with technology in order to make an online course work. For me, this flexibility included accepting assignments by several routes, being able to read files in several different formats, and being able to respond to emails and phone calls promptly.

A second early concern involved questions about how to navigate the course site. Navigation difficulties were generally fairly easy to resolve. It was just a matter of clearly explaining how I had organized the course site. Students entered the site on an Announcements page. All assignments were on a separate page and listed according to their due date. The assignments for each week were posted at the end of the previous week. This page explained where they needed to go to find links to lecture notes, threaded discussion boards, the virtual classroom quizzes, explanations of proposal drafts, or whatever was needed to complete that weeks assignments. The course syllabus and other general course documents were posted on a course content page.

Students third concern in the first few weeks involved the Virtual Classroom discussion group assignments. Many emails and threaded discussion postings from students indicated that they had signed up for an Internet course precisely to avoid that sort of time constraint. Still, I maintained that they could find 2-5 other students and meet at anytime during the day or night. The groups were finally formed, albeit with a good deal of grumbling. I asked students to send me transcripts of their synchronous discussion sessions in the Virtual Classroom and responded to any unresolved questions from those. It turned out that, by the end of the course, most students indicated that the discussion groups were their favorite part of the course. It allowed them to get to know their peers, to discuss the content in a way that they had not done in any other online courses, and to get feedback from me for anything that their peers couldn't help them figure out.

Once these concerns were resolved, the course delivery ran fairly smoothly. I still had emails to answer, threaded discussions to respond to, and Virtual Classroom transcripts to read, but student questions became mostly content oriented as they became familiar with the technology and structure of the course.

Comparison to Traditional Course

The third goal for this paper is addressed by focusing on students' work and feedback relative to the Educational Research and Evaluation course as presented in each delivery format and across two semesters. The data include all and only regular course assignments: quizzes, tests, journal article critiques, drafts of a research proposal, e-mails, group discussion logs, etc. Students were asked to provide consent for their course performance to be used in this comparison. The online course was first delivered in Spring 2000, which is a 16 week semester. Forty-nine originally enrolled. Of those, 12 withdrew and 14 of those
that completed the course agreed to participate in this study. The online course was modified and delivered again during a 9 week session in Summer 2001. Thirty-six students enrolled, of which 3 later withdrew. Of those that completed the summer course, 16 agreed to participate in this study. I also taught the course in the traditional classroom format during the summer. Twenty-three students enrolled for this section and 1 later withdrew. Nineteen of the 22 that completed the course agreed that their performance could be reported in this paper.

A comparison was done of the proportion of total points earned in the course across the three sections. Students in the first semester online course averaged .93 (SD=.03) of the total points available. During the summer session, students in the online section averaged .91 (SD=.05), while students in the traditional section averaged .88 (SD=.07). An ANOVA showed a significant effect of section \( [F(2, 46) = 3.74, p = .03] \). Scheffe post hoc analyses \( (p<.05) \) revealed that this significance was driven by the difference between the first semester online course and the traditional summer section while other comparisons were insignificant (See Table 1). This difference between the summer traditional section and the spring online section may be due either to the online versus traditional delivery format or to the 9 week versus 16 week session. In trying to better understand this difference, students' performance on their major assignments was examined.

### Table 1: Total proportion of points, proportion on critique and proposal writing assignments, and proportion on midterm and final exams for each section.

</table>

* Significant \( (p<.05) \) difference across course sections.

The proportion of points earned on a critique of an empirical research paper ranged from .90 (SD=.11) for the first semester online to .94 (SD=.04) for the traditional section in the summer session. For the final research proposal assignment, this range ran from .86 (SD=.13) for the traditional section to .89 (SD=.05) for the first semester online. ANOVA's examining the effect of section on the proportion of points earned for these writing assignments showed no significant differences between sections (See Table 1). This is very interesting. Students in both sections were able to write equally solid journal article critiques and research proposals. The ability to critique published research and to write a research proposal were primary goals for this course. They involve students applying their content knowledge of research methods to the real world contexts of both evaluating existing research and designing new research studies. The online course appeared equally facile at allowing students to attain these goals.

The case was different for the exam scores. The first and second online sections earned .89 (SD=.05) and .90 (SD=.05), respectively, on the midterm and .90 (SD=.06) and .86 (SD=.06) on the final exam. The traditional section earned .71 (SD=.15) and .63 (SD=.15) on the midterm and final exam, respectively. ANOVA's examining the effect of section on students' midterm and final exam \( [F(2, 46) = 20.24, p<.000] \) and \( [F(2, 46) = 34.08, p<.000] \) scores revealed significant differences. Scheffe post hoc analyses \( (p<.05) \) showed an advantage favoring both online sections when compared to the traditional section.

There is an obvious reason for this difference. Students in the online sections had several days to complete the exam in which their textbooks and notes were ready at hand. Students in the traditional section had to take the exam in class without using their text or any notes. While this clearly explains why the traditional students did not score as well, it also raises an important question. If both online and traditional students critiqued journal articles and designed empirical research studies with equal facility, then how do we interpret the difference in their exam scores? It seems from their papers that both groups had equal mastery of the material, but the testing situation precluded traditional students from displaying their knowledge. This may be seen as an argument for open book/note testing or as an inherent advantage for online instruction where instructors are all but forced to create open book/note exams. Even though the traditional students were at some disadvantage regarding their tests, the differences in overall course grades were slight. This difference was only significant when compared to the first online section and not to the second. This seems to argue against it being driven by test scores, because both online sections had the advantage there, and for it being driven more by the length of the session, 9 versus 16 weeks.
Insights

Besides the argument for open book/note testing and the conclusion that the online course seemed to allow students to apply research knowledge just as well as the traditional course, there are other insights to be gleaned from the development and delivery of this online course. First, and perhaps foremost, is that online courses are wonderful for some students, but inappropriate for others. Along with this I believe that students (and perhaps instructors) do not always realize what qualities make someone suitable for online courses. These qualities include an ability to work independently and to motivate themselves; an ability to learn complex material from text, written explanations, and graphic representations; and a certain baseline technological savvy. Those who need external motivators, learn better through face-to-face interaction, and/or are frustrated using computer, email, and Internet technologies would be better served in a traditional classroom. They will find that the online course is simply more challenging than its flexible time schedule is worth.

These considerations should also be turned to evaluating courses as to whether they are appropriate for online delivery. I believe that at least three questions should be asked before an online course is developed:

1) Are the goals or content of the course such that student motivation is likely to be low?
2) Is face-to-face interaction crucial to meeting the goals of this course?
3) Is the student population for the course likely to be technologically unprepared?

If the answer is yes to any of these, then the course should not be developed for online delivery.

A second insight is related to the workload involved in teaching online. As I talked with colleagues who don't teach online, I sometimes got the impression that they thought it was easier than traditional sections. That not having to show up to lecture each week meant that there was less work and less preparation time. What I found instead was that the lecture time was more than replaced with answering emails, responding to discussion threads, and reading Virtual Classroom chat logs; and that the preparation time was moved back so that it primarily occurred before the semester ever began. I found that teaching online required me to do much more technological problem solving, to be more flexible in responding, and more available to my students than when I taught a traditional section. That said, I found that teaching online was an extremely stimulating experience that made the extra, or at least different, workload well worth it. At the end of it all, this comment from one of my students sums up both my experience and what I hoped to impart to those in my courses:

This semester has been a true learning experience for me. I have learned much both about research practices and about myself as a result of participating in this course. I have a better grasp of the components of an effective research study, the process involved, and the time required (anonymous student).

Virtual Learning? Enhancing teaching and learning through ICT

John Cuthell, MirandaNet, UK

Information and Communication Technologies present students with a constantly developing toolbox. Students use the tools to construct artefacts from a range of sources and inputs. The end product - a frozen point in a shifting panorama of possibilities - asserts their identity. These post-modern magpies use skills and concepts to combine source materials that meet the needs imposed by their teachers and tutors. The surface gloss confuses and dazzles: what is original? Where are the sources? Which (if any) is attributed? The question of whether the learning and skills embodied in the artifacts are transferred to conventional learning raises other questions.

The conventions and assumptions of institutional learning have become increasingly at variance with the praxis of the learners, whose style is that of bricolage, based on the hardware and the software to which they have access. The content and form of students' learning is inscribed within the artefacts which they produce. Knowledge and outcome are synonymous for them: they have become cyber bricoleurs.

Students with computers have become owners of the means of their knowledge production, and hence of their cultural capital. The symbolic capital which issues from this is virtual: the simulations transient: constantly updated. The standards and expectations of the education system sit uneasily with the values of the digital auteurs who form the vanguard of the postmodern economy.

At a time when e-learning is seen as a solution to the needs of both industry and the education system, the work and words of these students may shed some light on the ways in which it takes place.

The work of these autonomous learners in the classroom and at home is examined and related to the curricular framework in which it takes place. Can their teachers assess the originality of the work, or are they dazzled by a surface gloss which they can never achieve. Do the ways in which these students learn complement or clash with the assumptions of their teachers?

The use of a number of online services to support teachers is examined. These range from services which simply provide the equivalent of online worksheets, through those that support the teacher in the delivery of the curriculum by offering a highly diverse set of resources and student activities, to those that provide ‘one-off’ curriculum enrichment activities.

The research basis of this paper is a six-year longitudinal study at an 11-18 school of one thousand eight hundred students. The research investigated the impact of ownership of computers on work, learning styles and concepts of Mind on students and teachers.
Facilitating On-line Professional Development
Suzanne de Castell, Simon Fraser University
Jennifer Jenson, York University

In today's "knowledge economy," institutions of higher education struggle to keep up with the demands of lifelong learners, driven as these are by shifting economic and political conditions both nationally and globally. Significant among these new demands is the insistence that practicing teachers upgrade their technology skills in order better to implement and integrate computers in the classroom. This project seeks to articulate in greater depth and detail than any list of "best practices" can provide, a well-established professional development program for practicing teachers which makes use of both traditional and on-line delivery methods. Through a rich, fully elaborated study of a range of instructional forms (including on-line, classroom-based, workplace-based and peer mentorship methods) we seek to understand and specify what hinders and, most importantly, what enables learning and instruction in web-based environments.

In all the ways we have, in the past, understood alphabetic literacy as the keystone for affording in practice the rights affirmed in principle to education for all, it is necessary now to understand contemporary technological changes as these continue significantly to alter the terms and conditions of access to public educational goods. Although we know a good deal about the role, functions and uses, and forms of pedagogical support for traditional text-based literacy in the provision of educationally valued knowledge, we urgently require an up-dated conceptualization of functional literacies and their optimal development – one which is capable of taking seriously into account the impacts and implications of new learning technologies for information, communication and expression.

Despite the eagerness with which new media, computer technology and on-line delivery systems have been widely embraced across Canada, educational institutions have failed adequately to study the pedagogical conditions for attaining in practice what are too often merely presumed in principle to be actual educational efficacies and outcomes of e-learning technologies and resources. In the rush by postsecondary institutions to put courses on-line, we are only just now, post hoc, beginning to be critically attentive to research which examines educational outcomes of online learning and teaching (see, for example, Bonk, 1998; Bonk, Kirkley, Hara & Dennen, 2000; Owsten, 1997). Moreover, in light of increasing recognition of the actual inaccessibility of on-line instructional content to a range of "targeted" users (in this case, in service public-school teachers in university-based courses), forgotten have been familiar – and essential – educational questions. Primary among these is the question central to our own research: when it comes to on-line learning, what kind of help helps?

As a result of the omission of critical questions about curriculum and instruction in online learning research, what works to facilitate learning with web-based tools and resources is largely not known or when it is purportedly known, "best practices" (Jenson & Lewis, 2001) are unproblematically generalized from case studies which are in fact small-scale, subject/context specific, and of short duration. This means that much of the research
currently available on web-based learning is little more than a "snap shot" of a single course which has been placed on-line.

The purpose of the research described in this paper is to improve the teaching of fundamental technology skills and knowledge by advancing our understanding of optimal uses of technology in education, in both curricular and pedagogical terms, in online, face-to-face, and mixed mode environments. The issues which drive this work, accordingly, are those which have largely been ignored in the competitive rush by universities to offer courses online: (1) the design of research-based, custom-built yet scalable, user/community-specific and context-specific curriculum (and not merely the "adaptation" of existing generic course content to web-based, most typically template-driven forms) (2) identification and evaluation of the full range of potential pedagogical supports for in-line learners, especially users new to learning in this medium, and (3) a persisting obstacle to sustainability of technology implementation in education: identifying conditions which facilitate the effective practical application and transfer of knowledge by and among teachers, both within and across the school as a workplace.

Abstract: This paper is a review of literature on the impediments to distance education on the learners' part. The authors believe that an understanding of the impediments to distance education on the learners' part will help teachers from at all levels (preservice, inservice, higher education) not only to set more realistic expectations from students but also to design their distance courses in a way that meets the learners' needs. Distance education is identified as "student centered" by many researchers and thus much of the research in distance education is from students' perspective. The distance education literature presents various barriers to distance learning from the students' perspective. The authors review these barriers and present them under six categories: the learner's comfort level with technology, technical shortage, level of interaction, the level of learner's psychological readiness, cultural/individual characteristics, and environmental factors.

Introduction

This paper is a review of literature on the impediments to distance education on the learners' part. The primitive form of distance education was correspondence. Since then, the form of distance learning has become more sophisticated with the use of communication technologies, including satellites, telephones, cable-television systems, computers and the Internet. The definition of distance learning in the US Department of Education glossary is "the use of telecommunications technologies, including satellites, telephones, the Internet and cable-television systems, to broadcast instruction from one central site to one or more remote locations." Although learning at a distance has existed for several decades, both the characteristics and the medium of distance education have dramatically changed due to technological advances. Educators encounter new teaching methods and forms to serve a diverse student population. In distance education teachers have different roles than they do in traditional education. In addition, there are numerous obstacles to successful distance education. Some of them are new, but many of them have existed since distance education was born (Berge, Muilenburg, 2000).

We believe that an understanding of the impediments to distance education on the learners' part will help teachers at all levels (preservice, inservice, higher education) not only to set more realistic expectations for students but also to design their distance courses in a way that meets the learners' needs. Wood (1996) and Galusha (1997) imply that knowing student characteristics and demographics helps distance teachers understand potential barriers to success and allow them to plan distance education in order to optimize student performance, retention, success, and potential barriers to learning.

Distance education is identified as "student centered" by many researchers. Therefore, much of the research in distance education is from students' perspective. Many researchers present various barriers to distance learning from the students' perspective. The author of this paper reviews these barriers and presents them under six categories: the learner's comfort level with technology, technical shortage, level of interaction, the level of learner's psychological readiness, cultural/individual characteristics, and environmental factors.

The first category, comfort level, refers to the learner's lack of technical literacy to be able to use the course media, negative attitudes toward technology, and lack of training or support from the educators.
The second category, technical shortage, includes the requirement of course materials that are cost-
prohibitive for the learner, poor online connections, shortage of software, platform dependent media, and
inaccessibility of materials such as extensive graphics.

The level of interaction refers to the learner-teacher and learner-learner interactions. Feeling isolated and
"faceless teaching" (minimal feedback from the teacher) are the barriers in this category.

The level of the learner's psychological readiness includes barriers such as lack of motivation, resistance to
change, lack of time management skills and discipline, weak goal commitment, lack of orientation, and fear of
failure.

Cultural/individual characteristics refer to cultural differences, e.g. the learner's awareness of teacher
expectations, the learner's disabilities that keep him/her from meeting the course requirements, language barriers
across cultures, time zone differences, and learner's lack of prerequisite knowledge on course content.

Environmental factors include lack of family support, lack of peer support, lack of time, noisy study
environment, changes at work, unexpected responsibilities at work, and family problems.

**Literature Review**

Removing the barriers created by institutions is crucial especially in reaching adult learners, learners in
rural areas, and learners with employment restrictions or physical limitations (Machtmes, Asher, 2000).

Galusha (1997) classifies barriers as student, faculty, and organizational barriers in distance learning.
Garland (1993) classifies obstacles to distance learning as situational, institutional, epistemological dispositional
obstacles to distance learning. Garland (1993) suggests that situational and dispositional barriers are related to
learners' life situation, psychological and sociological personality such as attitudes, confidence, learning style, and
motivation.

In the reviewed literature barriers to distance learning on the learner's part were identified as follows: Lack
of learner training, "faceless" teaching, lack of learner motivation, poor online connection, extensive graphics,
cultural differences, lack of interaction, feeling isolation, lack of technical literacy, resistance to change, lack of time
management skills and discipline, lack of family support, lack of peer support, lack of time, stress, poor grades,
weak goal commitment, fear of failure, lack of prerequisite knowledge about course content, noisy study
environment, lack of orientation, environmental conditions, illness, family problems, changes at work, unexpected
responsibilities at work, information overload, language barriers across cultures, fear of technology, fear of
foreseeable replacement of faculty, high cost materials, lack of support service, and resistance to change (Brown,
1996; Wood, 1996; Galusha, 1997; Truman, 1995; Berge, 1998; Lehman, 1998; O'Toole, 1999; Whitworth, 1999;

**Learners' Comfort Level**

"A feeling of alienation and isolation" was an obstacle reported by distance learners (Galusha, 1997).
Whitworth (1999) states that in a learning situation in which the instructor is not physically present, both the
students and instructors feel isolated from each other. Lack of motivation is one of the obstacles for distance learner.
Obsborn's (2001) and Garland's (1993) studies show that learners who have lower motivation are at risk students in
distance education. Truman (1995) states that lack of time management skills and discipline are obvious barriers for
distance learners. The learner's "resistance to innovation" is also an obstacle in distance education (Berge, 1998).

**Technical and Support Service Shortage**

Inappropriate tutorial assistance and having difficulty in reaching tutors are obstacles for a distance learner
(Garland, 1993). These barriers can be a psychological problem for some students who are hesitant to initiate contact
with others. Galusha (1997), Berge&Muilenburg (2000) state that the lack of support, services such as providing
tutors, academic planners and schedulers, and lack of technical assistance are obstacles for distance learner.

Another obstacle observed often with distance learners is a lack of suitable study materials for distance
students. Wood (1996) notes that study materials must take into account the significant portion of students who
enroll with little or no experience of in distance learning. These students are at risk of dropping out unless they
develop study survival skills as rapidly as possible (Wood, 1996). Lack of training is another obstacle for the distance learner. Galusha (1997) and Palloff&Pratt (2001) note that if clear guidelines are not presented, the distance learner can be confused and disorganized and the learning process will suffer. Berge (1998) concludes that the most critical obstacles reported in the survey that he conducted were resistance to and fear of changes, and lack of access to resources and people.

Level of Interaction

O’Toole (1999) explains that studies emphasize that student-teacher contact is critical to the success of the distance learning process. Galusha (1997) and Garland (1993) state that perception of poor or timeless feedback and lack of communication with the teacher are main obstacles for the distance learner. Rumbe (2000) summarizes that learners without support are likely to delay completion of a program or dropout. A lack of frequent feedback was defined an often encountered obstacle by O’Toole (1999).

Level of Learner’s Psychological Readiness

Distance learners often feel lack of confidence in terms of learning. Galusha (1997) defines that lack of confidence is founded in individual and institution-related issues such as financial cost of study, disruption of family life, perceived irrelevance of their studies, lack of support from employers, insufficient support from tutors, course too time consuming, difficult in contacting tutors, change of employment, fees being too high, and feeling isolated. Insecurities often result in higher discontinuation rates among distance learners (Brown, 1996). In addition, lack of clear goals, the stress of multiple roles, learning style problems, adult pride, lack of prerequisite knowledge, lack of content knowledge are shown as barriers for distance learner in Garland’s (1993) study.

Cultural, Geographical and Individual Characteristics

Geographical isolation has been identified as one of the major barriers for the distance learner. Galusha (1997) notes that contacting academic and administrative staff, obtaining study materials, and borrowing library books are major geographical problems for distance learner). A study from Wood (1996) shows that this may lead to feelings of inadequacy and insecurity, and a lack of confidence in distance learners’ own abilities. O’Toole states that the learner’s cultural background is an obstacle often encountered.

Environmental Factors

A poor learning environment, such as lack of family and peer support, is one of the obstacles for the distance learner as well as the traditional learner (Garland, 1993). The learning environment is critical for adults who have a lack of self-confidence. Garland (1993) classifies situational barriers as poor learning environment, lack of support from family or peers, and uncomfortable study environment.

Discussion

The dramatic growth of distance education courses and the size of the adult learner population bring problems that require great attention by both distance educators and administrators.

We believe that the discussed barriers have various sources, yet some of them interact with each other. Some barriers create others, or some barriers strengthen each others’ effects. Thus, a distance teacher should be aware of all existing and potential barriers a student may have in order to design the course accordingly. We suggest that each distance course should begin with barrier inventories. Understanding real and perceived barriers on the learner’s part to effective distance learning and teaching may help to find the best ways to overcome obstacles. Without knowing the barriers, it is not possible for distance learners to effectively learn. There is no doubt that the fewer barriers there are to distance learning, the more learning and learner satisfaction there will be.

Reaching Teachers through Distance Education

Mary C. Enderson
Department of Mathematical Sciences
Middle Tennessee State University, USA
mcenders@mtsu.edu

Abstract: This paper addresses how one institution makes use of distance education to offer mathematics and mathematics education courses in its Master of Science in Teaching Program. The courses are offered through a compressed video format where there is two-way communication and interaction with students and faculty. Providing courses in this manner has proven to be quite successful for students on campus as well as those off campus (at the remote sites). It has also been found that students who are at the remote sites perform just as well, if not better, than those on site.

Brief overview of Distance Education

Distance education, a term that may be interpreted in a number of ways, basically means offering courses/classes via an electronic medium. The method of delivery – audio, video, email, tele-conferencing, video conferencing, web-based – is often what varies from one situation to the next. While such learning environments may appear different than the traditional classroom, the interactions and learning that occur are just as powerful.

The United States Distance Learning Association (USDLA) has reported on studies that have been quite consistent in finding that distance learning classrooms show similar effectiveness results as those reported under traditional instruction methods. Additionally, studies often point out that student attitudes about distance learning are generally positive (USDLA, 2001). With such factors at the forefront, one program, the Master of Science in Teaching (MST) Mathematics, has been quite successful in offering courses through a compressed video (video conferencing) format for mathematics teachers or teachers who have an interest in mathematics. In what follows, I present some of the factors that influence how courses are offered in this program, how faculty support has provided such courses for students, and how students have operated successfully in such learning environments.

A Master’s Program in Mathematics Education by Way of Distance Education

The USDLA has reported that distance learning must be an important aspect of higher education due to its timely and cost-effective means of continuing education and lifelong learning. It also elucidates that it is imperative in today’s society to bring together learners from widespread locations for live interactions and relationships. With the aid of a video classroom designed with two-way communication, the MST mathematics program at Middle Tennessee State University (MTSU) has been able to accomplish this. The program has allowed a number of teachers in the rural middle Tennessee area to complete graduate studies in the area of mathematics by providing courses through a video conferencing format. The “on-sight” classroom is the central location for courses where the instructor delivers the course. There may be students on site who are able to come to the campus to take courses, where other students are off campus. There may be anywhere from one to five remote broadcast sites that have off campus classrooms for students to meet at for specific course times throughout the semester.

Preparing courses offered by distance education is a major undertaking that many faculty or instructors are not well aware of until the process begins. One study, conducted by the NEA (2000), found the following:

- Over half (53%) of distance learning faculty spend more hours per week preparing and delivering their distance education course than they do for a comparable traditional course.
- Those faculty who have taught the distance education course eight or more times, spend more hours (48%) rather than fewer hours (21%) on their course.
- Most faculty (84%) do not receive course reduction or compensation for teaching a distance education course.

These points bring out that fact that while offering courses through this manner are important in reaching a greater number of students, faculty who prepare such courses are often having to commit a great deal more of their time to present such courses. The Higher Education Program and Policy Council of AFT (2001) found that some faculty
spend anywhere from 66% to 500% more time in their course preparation. This often is a major point for "newcomers" not joining the ranks that teach via distance education.

An important part of preparing a course is making decisions on how to involve students in the course – particularly those at the remote or off campus sites. *Best Practices for Electronically Offered Degree and Certificate Programs* (2001) addresses the importance of developing a rich interaction between instructor and students and among students in the design of a program and its courses. Several points mentioned in this document have been confronted by instructors and individuals involved in the MST program at MTSU. Such issues include: (1) assurance of appropriate interaction, (2) instructor response to assignments and other coursework, (3) technologies used for interactions (e.g.: email, telephone office hours, voicemail, fax, classroom discussions by video), and (4) measurement of the success of course interactions. MST mathematics faculty have been able to meet such demands due to the method of delivery adopted for the courses. The video conferencing method allows two-way communication with visual images of individuals who have spoken. Thus, all classrooms are equipped with television monitors and microphones for this to occur. Prior to class meeting times, faculty have materials (in-class assignments, returned homework or graded assignments) delivered to the respective sites for students as well as setting up other means for them to receive needed materials (e.g., email, readings/documents obtained from the web). Once a course begins, students are prepared to be involved in the course in much the same way they would a traditional course. Each site is equipped with an overhead projection device for sharing or presenting materials as well as select sites having a computer station for using software such as PowerPoint and a connection to the Internet. Students are to ask questions or to share points of discussion – both of which are vital to the success of the remote sites. Even though all students are not physically in the same classroom, they can operate like they are in the same place with the video and audio features. While most courses meet regularly throughout the semester at the various sites, mathematics faculty teaching the courses often make a point of scheduling one to two Saturday class sessions where all students come on campus for class.

One might think that students “learning” how to exist in a distance education situation would be difficult. Instead, we have found the transition for students to be rather easy. Once students get over the "shyness" of talking by use of a microphone and seeing themselves on the television monitors, the rest almost falls into place. The learning environment becomes one rather than many. This is crucial to students feeling like they are a part of a class as well as vital to the success of our courses in the master’s program.

Hand-in-hand with student learning is student assessment. Since the student population described here is at the graduate level, they are expected to prepare and present work for the class – regardless of their location. All students are evaluated in the same manner and measure of course success is as challenging as that in a traditional classroom setting. Faculty involved in the distance education course offerings have found that this is an area that constantly needs to be revisited – especially in cases where testing occurs. Some agencies and organizations have documented that testing with qualified proctors at remote sites is often not available, and thus causes problems in obtaining accurate results.

Data collected from students involved in the MST distance education courses paints a success story, but also one much in line with the research on distance education. Findings indicate that students who are off campus perform just as well, if not better, than the students who are on campus. This is an important factor for continuing to offer such courses in this manner, as well as revising the presentation and delivery of such courses.

Offering courses through distance education is not just a “fad” in higher education. With the technological revolution upon us, we are faced with a means to make advanced studies available for more individuals. For one institution, MTSU, this avenue has helped support a number of teachers in improving their teaching and learning of mathematics, as well as maintaining a strong graduate program that continues to grow.

Use of Asynchronous and Synchronous Conferencing Tools: Implications for Teacher Practice

Dr. Teresa Franklin
Instructional Technology-College of Education
Ohio University
USA
franklit@ohio.edu

Selma Vonderwell
Instructional Technology-College of Education
Ohio University
USA
koc@ohio.edu

Abstract: A comprehensive understanding of online learning, tools and instructor practices can contribute to a much-needed knowledge base for effective planning and implementation of successful learning. This paper presents the implications of facilitating asynchronous and synchronous tools on teacher practice. The instructors have taught and applied these tools in a Technology Applications in Education course in which one instructor used asynchronous discussion tools and a weekly student online journal in her undergraduate classes and the other instructor used asynchronous and synchronous tools in her online classes with undergraduate and graduate students.

Introduction

Developments in computer technologies have opened ways for the redesign of teaching and learning. Online education is a new area promising active, self-regulated and reflective learning. When properly designed, the online learning environment can promote collaborative learning; improve interaction and participation supporting learner-centered rather than teacher-centered learning. The use of asynchronous and synchronous discussion tools has gained attention due to their potential to provide rich learning experiences and interaction among students and instructors. These tools have commonly been used to enhance collaboration, critical thinking, knowledge building, to create learning communities and to provide a means for the online instructor to develop active learning environments.

Research and literature on asynchronous and synchronous discussion focus on discourse analysis, type and quantity of interaction among the participants, instructional strategies used when implementing these tools as well as the roles of the instructor and students (Ashton, Roberts & Teles, 1999). The question remains as to how does the use of asynchronous and synchronous tools change teacher practice in the online environment? Teacher practice in planning and implementing instructional strategies plays a significant role in online learning success. This paper presents the implications of facilitating asynchronous and synchronous tools on teacher practice.

The Study

The instructors applied asynchronous and synchronous tools in their Technology Applications in Education courses. Sections of EDCI 203 Technology Applications in Education or EDCI 532 Technology Applications in Education (graduate equivalent) are required of all students pursuing a degree in the College of Education at a Midwestern University. In the past, the courses have been offered in a traditional setting. In 1999, 2000, and 2001 a section of each was offered each quarter online due to increased enrollment demands. In hopes of developing a learning community, the instructors decided to use the asynchronous and synchronous tools provided by the University. The instructors felt that this might help to simulate the same discussion practices, collaboration, interaction and feedback often found in the traditional classroom and alleviate the concerns about building a classroom community. The discussion tools included as part of the course were

The participants from the courses were divided into three groups in which a qualitative case study method was used to examine each course as a complete data source. All asynchronous and synchronous tools were provided to all faculty at the university in the development of online courses. The software used by this university was CourseInfo 3.0 and Blackboard 5.0 (www.blackboard.com). The instructors continued to use Blackboard set of software tools provided by the university in order to maintain continuity of tools/software throughout the study. The participants were grouped in the following manner to create a coherent understanding of the differences among the groups:

- **Group 1** participants were graduate inservice teachers and used the chat, email, listserv and discussion board as their asynchronous and synchronous.
- **Group 2** participants were undergraduate preservice teachers and graduate inservice teachers. These participants used email, listserv and discussion board as asynchronous tools.
- **Group 3** participants were undergraduate preservice teachers and used a virtual café, email, discussion board and electronic journals as their asynchronous and synchronous tools.

Data was collected from the following course sources: email between student and instructor, email between student and student when possible, chat archives, listserv archives, discussion board entries, and electronic journals. Data collection was ongoing and continued throughout the study. Instructors maintained a reflective journal of their concerns and changes during the courses as well. An examination of the chat, email, listserv, discussion board conversations and students’ weekly online journals offered opportunities for the instructors to evaluate and reflect on their own practice. All sources were evaluated and coded for common themes.

In an examination of instructor practice the following activities were noted. With Group 1, the instructor used both asynchronous and synchronous tools in her class that included a discussion board, email, listserv and synchronous chat. Each week online office hours were held in which students could chat with the instructor and ask questions concerning course work and other concerns. Part of the online office hours were set aside for individual conferences and other times were for open discussion in the class or team discussions. Questions were posted to the asynchronous discussion board were used to check understanding and to encourage reflection and discussion of technology topics common to preservice and inservice teachers. Email attachments were used to turn in assignments or to ask for a critique of work in progress. A listserv was used to ask questions between the online chats or to distribute information that the whole class should see.

With Group 2, the instructor decided to not include the online chat in the development of the course due to access problems with the university software and technical server problems. The instructor continued with the use of the discussion board to check understanding and to discuss technology topics common to preservice and inservice teachers. The listserv took on a much greater role as it was used to discuss weekly concerns and team discussions. All communications were asynchronous in this term of the course.

With Group 3, the second instructor used the asynchronous discussion board and student online journals. The instructor created learning teams composed of three to five students. The discussion team size was kept small and students were put into similar or same specialization areas. The instructor had intended to create small learning communities in which students discuss and analyze issues and concerns that deal with their specialization areas in regards to technology integration. This instructor implemented an online journal to collect feedback and student reactions. Minute Paper format is an assessment technique to provide rapid feedback to the instructor (Cross & Angelo, 1988). Individual online journal areas were created for the students to give weekly feedback to the instructor’s questions about the class and give suggestions in regards to what they are learning and the structure of the class.

**Findings**

The use asynchronous and synchronous tools in online learning have implications on teacher practice. These implications are pedagogical, social, managerial and technological. There were also differences found between graduate and undergraduate level concerning the implications of how they influenced teacher practice. When used appropriately, these tools can help the instructor to foster a learner-centered climate and allow the instructor to use a constructivist philosophy when interacting with students. Additionally, the teacher can facilitate these tools to check student progress and learning while continuous assessment and development of
the course. However, as well as appropriate use of instructional strategies, online teaching requires a great deal of commitment on the part of the instructor.

**Pedagogical Implications:** Teaching online requires design decisions that are appropriate to online learning. The instructors intended to enrich their students’ learning experiences through asynchronous and synchronous communication tools and to build a learning community model. Utilization of these tools were determined by the instructor’s pedagogical values and goals as well as the technical and technological capacity of these tools provided within the CourseInfo and Blackboard and other technology services at the University. The instructors made deliberate decisions on how to use these tools, how to provide feedback to the student(s) and how to obtain feedback from student(s).

When discussing the development of the courses and the use of the discussion thread the instructor of Group 1 and Group 2 had the following comments:

> While the undergraduates prefer to work in groups and correspond with those in their majors, the graduate students want to hear and read everyone’s answers it seems. I had originally thought that I would have everyone in small groups but the graduates complained that they wanted to know what the whole class thought about different discussion questions. While the undergraduates seemed content to be isolated, the graduates want to read everything.

The Group 3 instructor put in her reflective journal when deciding upon the use of threaded discussions these statements:

> I could have just created discussion questions for the whole class, but I thought by creating small groups that specialize in the same area, students are going to write issues that deal directly with their majors and they can learn from each other. I also would like to create a small learning community which they will share information with each other and ask questions to each other. The other reason I created small group areas is that when the data is too much to read as in the case the whole class posting info, this will create information overload and students will not tend to read each other’s responses. In my previous [face-to-face] class, I observed that students simply answered the questions. However, this could be just an assumption. The amount of interaction that might happen may depend on the type of the questions asked, the amount of moderation provided by the instructor.

Discussion questions and weekly online journals provided ways for the instructors to get feedback from the students’ and check student learning and progress. Instructors incorporated activities that emerged from student discussions and journal writings. For example, Group 3 instructor created a Frequently Asked Questions Area to answer student questions that emerged from student online journals and a Virtual Café where students can ask questions to each other and collaborated. Students offered suggestions and instructional tips in their journal writings.

Another implication of the online journal was that the format of the questions changed after the fifth week due to the feedback from the students. The students were initially asked to write what they have learned, what is remaining that they haven’t learned and if they have any suggestions for the instructor. The students told the instructor that they were tired of answering the same questions. The instructor changed the questions to questions that dealt more directly with integration of technology. This allowed students to reflect on the issue of how they could integrate technology into their teaching rather than focusing on technical skills.

**Implications for Management:** The Group 3 instructor aimed to create collaboration among students in each undergraduate learning team. Three of the discussion questions required each undergraduate team member to be either an editor or a judge. Each time one of the team members gathered the information other team members posted and edited those and create a technology poster or list the issues pertaining to the matter in hand. This created quite a confusion among the students. They were confused about how to handle collaboration online. One student wrote in her online journal:
The only difficulty that I have had this week is about the discussion board question. It seems rather hard to talk with the group. We are all pretty busy and it is difficult to actually write this paper over the Internet without physically seeing one another.

The instructor received several emails or phone calls in regards to how the students were to do their editorial tasks. After the first initiative, the instructor had to revise the questions and redesign to simplify the tasks of the students. Another challenge for the instructor was to have the students respond to the discussion questions and to remember to write their online journals. The instructor initially had planned to use eight discussion questions spread to ten weeks during the quarter; however, it was decided to keep it at six since the students were getting overload by the discussion questions.

Social Implications: The instructors tried to create a friendly social environment in which students could ask questions to the instructor and to each other. Teacher presence, concern and acknowledgement of students are important aspects for creating a learner-centered environment. One of the strategies used was to email students for progress check in a friendly manner. They asked students how they are doing and how the class is going for them even if the students did not ask any questions. Bonk, et. al. (2000) suggests that social actions such as instructor empathy, interpersonal outreach (e.g., welcoming statements, invitations, and apologies), discussion of one’s own online experiences, and humor can help foster a learner-centered climate.

Group 3 instructor used the online student journals to interact with the students as well as checking student progress and learning. It was observed that the students used the online journal as a way to connect with the instructor. Instead of emailing the instructor they asked their questions or made comments to the instructor within their online journal areas. The Group 1 and 2 instructor used the chat, email, and listserv to make student inquiry about student concerns and class issues. Students indicated on the course evaluations that the chat was the most interesting and had helped students connect to the instructor in a personal way.

Technological Implications: The technology available, specifically the course management software had enormous implications on teacher practice. For example, the instructors had to post each discussion question to each learning team one by one. Also, the online journals had to be created individually one by one. This required the instructor to spend a great deal of time. The variety of levels within the software created the need to take more time in moving among the various parts of the software.

Implications of Educational Level Differences: In examining the use of the different synchronous and asynchronous tools the instructors found the some interesting differences concerning not only the tools, but whether the participants were graduate or undergraduate students. Concerning the educational levels of the students, the instructors found that undergraduate preservice teachers approached the use of technology and coursework in very different ways. By in large the graduate inservice teacher asked more questions of the instructor in fact almost 2.5 more inquiries were made on assignments and critiques of work. The graduate inservice teachers were more likely to return to the synchronous discussion board and respond to each other’s responses to the questions than the undergraduate preservice teachers. The graduate inservice teachers would ask each other for help by use of the listserv often posting questions of the following nature,

[Graduate inservice teacher to the listserv] Does anyone have an idea why my printer is not working? It keeps printing only the bottom half of the words. I have replaced the print cartridges and paper... and reset everything. HELP!

[Graduate inservice teacher to the listserv] What software is everyone using to complete assignment #? Can someone tell me what she really wants us to do?

Not a single listserv question from the undergraduate inservice teacher ever asked a question of the whole class although they were encouraged many times to do so. The undergraduate preservice teachers would ask the instructor for individual help through personal emails.

The listserv was often used by the instructor of Group 1 and Group 2 to remind the students of upcoming deadlines. This often sparked a flurry of questions from the graduate inservice teachers and a sudden rush of assignments being sent. At times, it seemed that the reminders were the main prompts for questions and comments to the instructor by the graduate inservice teachers. They were very interested in asking fellow teachers about how they would handle an assignment.
This same attitude was also used in the asynchronous chat by the graduate inservice teachers. While the instructor would often begin the discussion or questions on the asynchronous chat, after about 10 minutes, the instructor found that the teachers would begin to ask each other questions and make comments about their teaching methods, schools, students and technology and only looked to the instructor for confirmation or another point of view. The chat was extremely lively with teachers [they did not know each other] discussing classroom issues as though they had known each other for years. Teachers would come in and out of the chat often leaving to take children to events and returning. The instructor began to have less and less of a role in the chat during office hours as the graduate inservice teachers took the lead in questioning and discussion.

With Group 2, the use of the listserv with the undergraduates had a very different outcome than was seen with the graduate inservice teachers. Seven of the sixteen undergraduate preservice teachers sent a message similar to the one below,

Dr. [Instructor], I have a syllabus and the assignment list with the dates things are due. Please do not send me anymore emails about when things are due. I can read the assignment list.

I have a list of when the papers are due. Don’t email me about this.

Quite surprised by these statements, the instructor promptly made a note that the seven students did not want to be reminded of when assignments should be completed and removed them from the distribution list.

Conclusions

Graduates and undergraduate behave differently in the online environment. This behavior affects the way the instructor presents and distributes information. While the course content remains the same, the methods used to encourage students to participate and develop an online community must be carefully crafted to meet the characteristics of the online student. While the instructors had expected that the undergraduates would be very used to the online environment and chat or participate in discussions easily, that was not always the case. The undergraduates were more interested in finishing the course to meet a graduation requirement than participating in meaningful discussion for the most part.

In this paper, we attempted to describe the implications of asynchronous and synchronous conferencing tools in online learning on teacher practice. Online teachers need to be committed to be available to respond to students’ questions and concerns and make the means for them to engage in meaningful learning. The teachers need to continuously check student progress as well as how they are doing while teaching online. Teacher presence is an importance issue for the students to feel they are not alone and everybody is a part of the learning process.

Online teaching is not simply posting assignments and discussion questions. It requires extensive planning and structuring and time. Online instructors need to be aware of the strategies and activities they can use with asynchronous and synchronous conferencing tools to engage students in active learning and to provide and receive constructive feedback.

Title: Critical Issues in Distance Education
Type: Panel
Panel Members: Thomas Frizelle - graduate student, Jesse Drew - graduate school, Sara Rinkleff - graduate student

The purpose of this panel is to discuss relevant critical issues in Distance Education. Critical issues reach far beyond personal experiences and educational systems. For this reason, the panel will be composed of visiting scholars and Iowa State University graduate students. We hope to provide a diverse and international perspective on critical issues related to distance education.

What are some of the advantages and disadvantages associated with the increased offering of Distance Education classes? During our time we plan to focus on several salient issues related distance education: student learning outcomes, motivational issues, pedagogical considerations and instructors intellectual rights. Our panel will present qualitative and quantitative research and offer questions for reflection.

We hope to increase understanding and awareness with other IT professionals concerning the above critical issues in distance education. As instructional technologists, we are faced with a daunting task, which has an awesome responsibility associated with it: how to create educationally meaningful learning experiences for students using technology responsibly. As with any new technology, it is long after a technology has been introduced that it either reaches its full potential or falls to the wayside. We firmly believe that distance education, and other technologies, have not been fully explored and refined. It is difficult to speculate when and how this epiphany will come about. One thing is certain, instructional technologists must be cognizant of both the changes in practice and more importantly the changes in values which distance education and other technologies bring to a culture.
Faculty Attitudes Towards Distance Education: Enhancing the Support and Rewards System for Innovative Integration of Technology Within Coursework

Ruth Gannon-Cook

Abstract: Distance education is an area of rapid growth at the university level, especially within the colleges, schools and departments of education (National Center for Education Statistics, 1999; United States Distance Learning Association, 2000). However, there are some faculty who are not jumping on the bandwagon and are taking a more conservative route towards considering the impact of distance education within their courses attitudes towards distance education: early innovators; hangers-on (late adopters); and, negative withholders (resisters) (Robinson, 1996). Each of these groups have concern not only for their students and the appropriate learning environment for their subject matter expertise, but also a concern towards the university rewards system.

Introduction

Since faculty members are key ingredients to both creating and teaching distance education courses, there is a need for research concerning faculty perceptions about distance education, and which factors could influence faculty participation. As postsecondary institutions expand distance education courses, it will become even more important to determine what motivates and inhibits faculty to participate in distance education.

The survey in this study originally consisted of several studies combined into the original survey and validated by Dr. Kristin Betts at George Washington University (Betts, 1998; Hunt & Crawford, 1999). This survey differed, however, in the dissemination of the surveys by sending the surveys to faculty electronically, using email listservs, and by establishing an Internet website to collect and gather data from respondents. Through the adaptation of the surveys to an electronic format, the study had the opportunity to provide the participants with electronic surveys, tools that reflected the technology of the study.

Rewards System

The rewards system, both written and unwritten, are of primary importance to faculty and their attitudes towards distance education. Types of rewards may also play an important part in how faculty responds to using and integrating technology into their
courses. So, while part of the concerns of faculty may be due to the time and energy required to focus upon the instructional design process (analysis, design, development, implementation, and evaluation), other concerns that may have stronger effects upon faculty members’ efforts may be going overlooked, reasons like tenure consideration and the efforts expended incorporating technology that are often overlooked in designation of tenure.

As is well known, each of the three aspects leading to tenure are of utmost importance, teaching, research and service, with the research, publication and grant writing elements being highly prized. The instructional design process that must be focused upon distance education takes valuable time and energy away from the traditional rewards system and, therefore, is of concern to both tenured and untenured faculty. A thoughtful revamping of the university rewards system concerning innovations and instructional design concerning distance education elements integrated into university coursework must be considered. A focus upon faculty attitudes towards distance education, the traditional rewards systems concerning tenure-focused faculty, considerations towards revising university rewards systems concerning tenure-focused faculty, and how innovative technological integration within university coursework may be rewarded within the university rewards system are addressed. Mixed research methods were used, incorporating both quantitative and qualitative data obtained from a dissertation survey conducted at a large urban southwestern university by one of the researchers in this study.

**Faculty Motivation and Distance Education**

The dissertation data used in this study divided the data into two categories of faculty motivation: internal and external, to see which motivators encouraged or inhibited faculty member’s use of distance education. Internal motivators included encouragement, team spirit, and collaboration. External motivators included tenure consideration, merit raises, compensatory time, and other types of external rewards.

This research study surveyed faculty to determine if factors such as academic division (school or college), age, gender, tenure-track and non-tenure-track status influence faculty participation in distance education. The study also examined whether other factors might motivate faculty members to participate in distance education or inhibit/deter faculty members from participating in distance education.

Research on motivation indicated that currently many universities uphold a "public relations" approach to participation by administration and faculty, or a top-down management style of information dissemination to faculty (Paul, 2000; Stribiak & Paul, 1998). This type of management style attempts to appeal to the intrinsic motivators to faculty members, but can create hygiene (negative) factors that can inhibit authentic participation (Herzberg, 1986). The "public relations" approach maintains: one-way communications; the status quo for existing arrangements; defining the citizen/employee as dependent consumer; and defining the educator as an autonomous professional (Anderson, p.576). Administrative interest in the needs of faculty and efforts to assist faculty and meet those needs could be helpful in establishing a precedent of administrative collaboration with faculty (Gannon Cook, 2000). Authentic participation
consisting of positive rewards, collaboration and team building could then build upon the foundation of collaboration and trust established with administration and faculty.

**Distance Education**

Distance education operationally defined for the purpose of this paper is “a planned teaching/learning experience that can incorporate a wide spectrum of technologies to reach learners at a distance and encourage learner interaction (GannonCook, 2001).” Distance education can be taught: in face-to-face (f2f) formats at remote sites; in instructional telecommunication formats; using computer-based technology, like the Internet, listserv(s), e-mail, cable TV, interactive CD-ROM programs; using other technology like telephones, faxes, videotapes, audiotapes; or using little or no technology at remote sites (Gannon Cook, 2000).”

**Authentic Participation**

Authentic participation can go a long way towards engaging and retaining faculty because if they know the commitment is there and is evidenced by multiple examples of what the administration is willing to do, the faculty members will be more willing to meet them somewhere between the extremes of each side. By demonstrating the support of the administration, by nurturing activities, and by providing a venue for faculty voice, the faculty knows that authentic participation is really taking place and is not mere rhetoric. But extrinsic motivators have a growing influence on faculty members, particularly with respect to the use of distance education. Tenure consideration had a top priority to those faculty members still in contention for tenure status. Other motivators like increased salaries, monetary stipends, and compensatory time, all contributed to the increased motivation of faculty members participating in the survey (Gannon Cook, 2001).

**Future Trends**

The trend of institutions offering DE courses will continue to expand due to increased consumer demand and cost-efficiencies offered by this type of course delivery. The review of literature revealed that factors that most influenced faculty to participate in the creation and instruction of distance education hinged on motivation, both external and internal. Many faculty already carry full or overload teaching and administrative workloads, so it is difficult to persuade them to carry additional work for distance education courses without some type of external compensation (Gannon Cook, 2000). External compensation for faculty could include additional money stipends, royalties, course releases, tenure consideration and faculty voice in decision making-policies. Recent studies suggest that, while internal motivation can be inspired, particularly by department chairpersons and deans who have taught distance education courses, and can be inspired by participating in design teams, the pride of accomplishment often does not
sustain continued distance education instruction without the reinforcement of some type of external motivation.

Conclusion

While there are still many challenges and issues to designing and offering distance education courses, it seems unlikely that the trend for distance education will abate at any time in the foreseeable future. The research on faculty motivation and which factors can influence participation in distance education will become increasingly more important as the demand for these courses continues to burgeon. Future research is recommended in order to track trends and to gather new data pertaining to faculty motivation and which factors influence participation or non-participation in distance education.

Abstract: As a fastest growing branch of distance education, Web-based learning is attracting more and more people. Interaction is an important factor that affects the learning process. It not only affects the learning effectiveness, but also the learner's motivation. To investigate the learner's motivational perspective of web-based learning materials, a posttest-only experiment was performed. The results from the experiment showed that college students who went through web-based learning materials implemented with elaborated immediate feedback outperformed those who learned the material through the regular website in the IMMS test. The interview data also supported the above conclusion.

Introduction

The World Wide Web is attracting more and more people and increasingly used as a medium to deliver instructional materials. Web-based learning is becoming a fastest growing branch of distance education. Many courses have been developed and distributed through the web. However, a significant number of web-based courses are predominately designed to transmit information to the learner and lack interaction (Alessi & Trollip, 2001).

As an important factor that affects the learning process, interaction not only influences the learning effectiveness, but also affects the learner's motivation. In web-based learning environments, there are three types of interaction: students interact with instructors; students interact with other students; and students interact with the learning content (Moore, 1989). In the learning process, interaction can be used to confirm if the desired learning happens; provide inquiries asking for additional materials; navigate through the learning materials; and combine existing knowledge with new instructional content. Many means have been used for the first two types of interaction: email, listservs, chatrooms, bulletin boards, and audio and/or video conferencing. However, studies focusing on student-content interaction in web-base learning environments have not been found in the literature. Many strategies can be implemented into the learning materials to increase the interaction between the learner and the learning content and to motivate the student learning. One of them is to use immediate feedback. By integrating immediate feedback to the learning process, the web-based learning material becomes more interactive and motivates students' learning. This study investigated the motivational effects of elaborated immediate feedback in a web-based learning environment.

Study

In this posttest only experiment research, student’s motivational perspective of web-based instructional materials was examined through an Instructional Material Motivation Survey (IMMS) (Keller, 1999). To have a deep understanding of learners’ attitudes toward the learning materials, an interview was also conducted after the learner finished the experiment. The subjects in the study were college students in various majors. The learning content is about copyright rules and principles, which is a very important topic for pre-service teachers. The control group went through the learning material presented in a regular website, which provided limited interaction between the learner and the learning content. The experimental group went through the learning material presented in a website which integrated elaborated immediate feedback strategy. In this group, the learner could interact more with the learning content by following the provided feedback information.
Findings

The data collected through the IMMS and interview were analyzed with statistical procedures. The results showed that students in the experimental group outperformed those in the control group in the overall IMMS test. The ANOVA test indicated that the difference between the two groups was statistically significant. The analysis of the four subcategories of IMMS also indicated that the learning material embedded with elaborated immediate feedback was more attractive, and the students in the experiment group felt more satisfied with their learning. The data from the interview also supported the above conclusion. All the interviewed students expressed very positive attitudes toward the embedded immediate feedback strategy. They thought that strategy motivated their learning, provided helpful information to lead them to review their learning, and reinforced what they learned. Therefore, it can be concluded that immediate feedback can motivate students’ learning in the web-based learning environment.

Abstract: The goal of the novel tool HERMA (enHanced E-learning Repository MAnager) is to improve the efficiency of the knowledge transfer process in web-based learning environments. The mechanism enables users to improve adaptive courseware enlargement and it supports the dynamic retrieval of the content, its presentation and navigation. Based on self-defined semantic parameters, which describe course and user specific factors, it generates dynamically context dependent, user relevant and always automatically updated background knowledge that relies outside the static repository by applying a smart search framework. HERMA places this dynamically generated background knowledge at the disposal of learners across distinct viewing modes while navigating through the courseware. In addition, HERMA may improve the process of course generation and maintenance. In our first application, HERMA is integrated in the Hyperwave eLearning Suite and interacts with the smart search framework xFIND.

Motivation

At the IICM we had long-term experiences in the fields of web based learning systems, for example (Dietinger et al. 1998b), hypermedia management systems like (Hyperwave 2001), dynamic background libraries, as stated in (Dietinger et al. 1998a), and knowledge discovery, as with (xFIND 2001). The praxis showed that within the learning process the sole application of a static course repository is not sufficient. This led us to propose that one of the key issues of modern web based learning systems is to reach a dynamically enhanced knowledge transfer.

The knowledge transfer process could be interpreted as a holistic phenomenon composed of two, mostly overlapping but essentially different, main streams: a) the teaching process, which concerns knowledge generation and delivery, and b) the learning process, which concerns knowledge acquisition. A wide range of problems caused by a huge and an increasing amount of information as well as by rapid changing knowledge are faced within both processes. A selection of those problems is discussed as follows.

Knowledge in virtually any subject is a dynamic entity itself. According to (Lymann et al. 2001) each year a dramatic amount of 1.5 EByte of unique information is produced worldwide. Course authors and learners have to keep up with permanently increasing and changing knowledge. Thus, a mechanism should be given to support trainers in gathering new knowledge and tracking the modifications. Learners should get informed dynamically of this up-to-date background knowledge during their learning process.
Another problem is that nested hyperlinks in static documents often lead to no longer reachable resources. A survey of hyperlink sources in research papers has shown, that some 20-30% become invalid links within one year (Lawrence et al. 2001). Thus, the delivery of content with embedded linkages should happen in a semantic and adaptive way. The system should provide an adaptive extension of the static repository for example by defining an itemized semantic-based background library. Furthermore, the system should ensure relevance, actuality and reliability of this background knowledge. This can be achieved by collaborating with a smart search framework, like xFIND.

The learning process is a not always predictable user dependent entity. Current systems provide distinct "adaptive" features to deliver user-tailored content. We propose that adaptive and goal-oriented knowledge generation and delivery should be supported in web based training systems in order to define semantic topic maps and to assign user expertise levels. This enhances the responsiveness of the system in order to reach a wider target audience. Our former experiences in user behavior within the learning process, as stated in (Pivec 2000), have endorsed that learners hold distinct learning methods. Some prefer to get informed of background knowledge directly within the content of the course, for example through embedded hyperlinks. Others prefer information at the end of each chapter, and so on. Thus, a mechanism to provide adaptive presentation alternatives for the dynamic background library should be enabled.

Furthermore, trainers should have the possibility to specify grouped topics that describe different background knowledge resources in accordance to the skills of learners. In addition, learners should get the freedom to define their own expertise level, to personalize their view of the dynamic background library and add their own sources of information.

Based on the motivations, facts and problems stated above we have set up a prototype implementation called ‘HERMA’. The enHanced E-learning Repository MANager HERMA may be seen as a smart dynamic background library that transparently monitors all the features to solve the problems described above. Thus, it improves most of the needs of trainers and learners within web based training systems. An optimized adaptability is reached due to its gradable features and its permanent presence through the entire knowledge transfer process.

State of the art

As Peter Brusilovsky stated in (Brusilovsky 1998), we advocate the criteria of assessing adaptability within web based training systems on dependence of the provided or absent adaptation technologies. A survey in the field of pre-existing learning environments as well as present research work led us to emphasize that current systems do not meet the needs of trainers and learners for adaptive technologies. Annotations, chat rooms, asynchronous messaging, dynamic navigation, personalized study spaces, courseware delivery platforms, curricula sequencing, progress tracking, static library and glossary, internal search functionality, virtual references, adaptive collaboration, meta descriptors, topic maps, metadata servers as well as self-assessment features represent only some of the existing modules interacting in current on-line learning environments. Nevertheless, problems arise after trainers have already published their courseware. At this point they have determined their strategy to reach a specific didactical goal. In order to reach different target audiences with various levels of expertise, they should have to enlarge the courseware physically on the system storage.

A similar problem could emerge during the course attendance, for example if enrolled learners are not able to manage the delivered knowledge in the expected time or manner. Because of that, we propose that courseware as well as additional background information (background library) have to be provided according to learners’ needs. HERMA solves these problems by exploiting novel features that allow constant reconfiguration and personalization of courseware and dynamic background library.

The static knowledge repository is the basic element of on-line learning systems. Apart of representing a static collection of ready-to-use digital materials, it should integrate an adaptive complement for assisting trainers and courseware authors while developing, presenting and maintaining the courseware according to the needs of learners and to the dynamically changing knowledge. This should happen all the time, during the whole teaching and learning process.

HERMA enhances the goal-oriented knowledge transfer process by enabling the development of a dynamically indexed background library of subject-relevant resources relying outside the static repository. Trainers may determine, after creating its static courseware, a set of topics referring to accurately described resources on the Internet. Relevance, actuality and access of this background knowledge are maintained
with the collaboration of the smart search framework xFIND.

The Basic Idea

The basic functionality schema of HERMA, as shown in (Fig. 1), depicts the different interaction layers and its dependencies through the knowledge transfer process. Background knowledge relying on the Web is dynamically accessed via the smart search service xFIND (exploiting Quality Metadata) according to the predefined items in the Semantic Knowledge Factory 'HERMA'. These items are essentially defined within expertise level groups and assigned to one or more course chapters. Thus, depending on the selected viewing, the requested page is dynamically generated and contains a list of valid items. Clicking on a delivered item, in (Fig. 1) symbolized by the arrow 'Activation', will lead to a search call of xFIND using the pre-stored item specific query term. The final result is a set of accurate, relevant, up-to-date documents.

From the point of view of the trainers, HERMA essentially provides an option for determining a set of topic specific items, which refer to a dynamically generated set of resources provided by xFIND. Each item belongs to a specific level of expertise, may be grouped with other items to a specific 'subject' collection, may have synonyms - which should be referenced in the same way as the topic itself-, and has a scope of validity within the courseware. From the point of view of the learners, HERMA provides the possibility of choosing its own level of expertise and one of four different viewing modes for displaying the currently valid elements while navigating through the courseware.

![Figure 1. Basic Functionality Schema of HERMA](image)

Prototype Implementation

The implementation of HERMA runs fully integrated in the Hyperwave eLearning Suite system, works hand-in-hand with its database objects (courseware and users stored on the Hyperwave Information Server), and accesses background knowledge from the Internet intercommunicating with xFIND. When learners demand a page of the static repository, HERMA dynamically parses it applying a smart pattern matching mechanism. It remembers each valid occurrence of the predefined items and delivers the content according to the personalized learner settings. An item within HERMA is defined as a combination of: a) descriptive information about a topic, which is stored as an xFIND specific query term, and b) metadata about the meaning and validity scope of the topic definition within the training system.
Trainers assign each item a user-specific expertise level. The name of the item is simultaneously the name of the Topic, for example ‘Internet’. Some Topics may also be collected in self-defined subordinate sets called Subjects, for example ‘Information Technologies’. After determining via (xFIND 2001) a satisfying list of accurate information from the Web, the xFIND specific query terms are stored within HERMA. These terms represent the semantic retrieval of background knowledge and ensure always up-to-date information from the Internet. Trainers define also the scope of validity for each Topic (one or a set of course chapters for which the topic is valid). A set of Synonyms corresponding to the Topic may also be defined, for example “Intranet”. Thus, the presentation of the semantically itemized background knowledge depends on the intention of the trainers and on the personalized learner configuration.

Learners may not only choose an expertise level but also one of the four provided Viewing Modes that are shown in (Fig. 2) and explained as follows: a) Embedded hyperlinks: the content of the demanded page is parsed and modified dynamically depending on the current settings. Each match is highlighted and hyperlinked to a proper xFIND-specific search request. This is shown in (Fig. 2) by the word INTERNET and its Synonym INTRANET (identical hyperlink information stands behind the icons beside those terms). b) End of page: A list of the matching items is appended ‘at the end’ of the page. In the example of (Fig. 2) both, the topic Internet and its Synonym Intranet, were found. Therefore, the corresponding Topic name is contained in the List of items immediately after the content. c) End of chapter: single pages are not modified. At the end of each chapter a dynamically generated HTML page that contains an alphabetical list of the chapter and level-specific items is provided. d) End of course content: a dynamically generated HTML page with a list of all level specific items is attached at the end of the course.

Conclusion

As shown through the paper, HERMA enhances dynamically the functionality of static repositories by providing smart features that improve accuracy, actuality and goal orientation of static courseware. The prototype implementation of HERMA has been successfully tested for the course
‘Knowledge Management’ at IICM, Graz University of Technology. Further research and development work will update HERMA’s functionality. Thus, a learner may not only use one global Semantic Knowledge Factory, but develop a personal one or share a self-defined one within a group of course participants. It is also planned to integrate HERMA in large distributed systems, where users of different environments, like universities, may mutually manage a multi-server Semantic Knowledge Factory.

A semantic-based dynamic mechanism with various interactions, as implemented with HERMA, assists trainers, publishers and learners along the whole knowledge transfer process: it assists actors during knowledge creation, structuring, delivery, maintenance, personalization, reconfiguration and acquisition. Knowledge delivery is adaptable to users’ needs without overloading system capacities. The separate treatment of delivery and storage of knowledge makes the system flexible, reusable and cost effective.

The smart reconfiguration feature of HERMA makes it possible to gradable conduct the activities of learners during the whole knowledge transfer process. This enhances the teaching process by means of an improved guided learning.

As stated in this paper, HERMA applies a smart pattern matching mechanism to each topic definition - and to its corresponding synonyms - during the content delivery process. This simple idea enables a single HERMA environment to manage also systems that support multilingual content delivery, by associating topic definitions with synonyms in different languages.

Rhetorical Approach to Assessing Online Discussion

Duane B. Graddy
Middle Tennessee State University
United States
dgraddy@mtsu.edu

Abstract The purpose of this paper is to assess the fruition of online course discussions by analyzing the transcripts of these interactions for a graduate survey course in economics. The method used to conduct the study is unlike other works in that it is lexical in nature. Dictionaries are used to develop quantitative measures of the linguistic characteristics of the online conversations. These rhetorical facts are used to assess the linguistics of general course discussions and a specific team discussion.

Introduction

A key element in successful online learning is full and fruitful participation of learners in group discussions. These collaborative forums provide the basis for devising shared goals, encouraging comments, using the semantics of the subject area, developing critical thinking skills, providing personal examples, asking questions, lending support to others, sharing responsibility for completion of assignments, and promoting feedback. Online discussions provide a means of enhancing cognitive skills as well as a method for assessing learning outcomes.

In these respects, online discussions are dynamic processes that develop over the life of a course. Knowledge is constructed in these collaborative forums through the process of social negotiations among the discussions' participants. Therefore, recognizable advancements in social and cognitive skills should be evident in the degree of content sophistication and the level of perspective taking by the learners. Various authors have characterized this collaborative learning process in different ways.

For instance, Jarvela & Hakkinen (2000) describe web-based discussion as an ontogenetic process. They use the five stages of Selman's model of social cognitive development to portray the evolution of online course discussion. (Selman, 1980) Palloff and Pratt see online involvement as ideally evolving from initial dissonance to content mastery and then to transformative learning. (Palloff, 1999) The cognitive analysis model of Henri (Henri, 1992) is built around four dimensions of interaction ranging from social interchange to revealing metacognitive skills. Gunawardena, Lowe, and Anderson (Gunawardena, 1997) theorize that the active construction of knowledge in online discussions moves through five phases. Rourke, et al. (2001) considers the issue from a model of community of inquiry. In this model, deep and meaningful learning occurs through the interaction of cognitive presence, teaching presence, and social presence. Others (Bonk, 1998) approach the development of online course discussion in the context of Bloom's cognitive taxonomy. With the sophistication of learner questioning evolving from the lower stages of cognition to the synthesis and evaluation levels.

The aim of this study is to use this rhetorical information to shed light on several important questions.
1. Does the character of the discussion change over the life of the course? Does the linguistic nature and tone of the conversation change as discussions develop? Is there linguistic evidence of moving from low-level discussion to deeper collaborative synthesis?
2. Can generalization be made about communality, accomplishment, optimism, and understanding from the rhetorics of the discourse? Are there key indicators of conversational sophistication?
3. Do the linguistics of the messages reveal anything about the learners and the learning process? Can linguistic indicators suggest anything about conversational sophistication of individual learners and about the entire class?
Methodology

This paper uses Diction 5.0 (Hart, 1999) to analyze the content of the online discussions. This lexically based program searches the content of online discussions for five semantic features as well as thirty-five sub-features. Each semantic feature is scored on the basis of thirty-five sub-features (dictionaries) according to a series of formulas incorporated into the software. The online discussions are compared to forty standard dictionaries and word lists in segments of 500 words. For discussions exceeding 500 words, the overall scores are the average of the individual 500 word segments. Custom dictionaries on microeconomics, macroeconomics, noted economists, and mathematical terms were also included in the database. No terms are duplicated between these dictionaries. The noted economists’ dictionary is a list of surnames of famous individuals in the evolution of economic thought. The mathematics dictionary includes basic mathematical terms used in the construction and discussion of economic models. The custom dictionaries focus on word usage in contrast to calculating a specific score.

Sample

The sample for this study includes thirteen graduate students in an MBA prerequisite course focusing on the fundamental principles of economics. None of the students had taken the principles of economics as undergraduates so this was their first formal exposure to the material. Three discussion forums are analyzes in this paper. The combined scores on participation in the forums counted twenty percentage of the students overall grade. The forums dealt with assigned topics. The first one centered on an article by James Fallows entitled “What’s an Economy For?” which compared the economic structures of Western and Asian economies. The California energy crisis was the theme of the second forum. The third forum, which was somewhat shorter than the other two, focused the use of the Federal government surplus for tax cuts versus additions to the Social Security trust fund.

Results

The results of the study provide evidence of the usefulness of rhetorical assessment. The ambivalence, hesitation and oversimplification of the early discussion was proceeded by communality and optimism in the later group interactions.

Abstract: This paper is a report on the findings of a study conducted with graduate level students enrolled in courses delivered through the medium of real-time audio-video teleconferencing via the North Carolina Information Highway. The purpose of the study was to investigate the quality of distance education courses, to determine the effectiveness of the delivery medium, and to examine the respondents' perceptions of the instructional strategies implemented in these synchronous learning environments. Input from experienced teachers who were pursuing a graduate degree regarding the learning environment and pedagogical strategies offered valuable information to the researchers. Findings reveal much insight into how distance learning courses can best be delivered in synchronous learning environments.

Introduction

One of the questions in distance education that we continually attempt to answer is: what constitutes effective teaching in synchronous and asynchronous environments? In search of the answer, the fields of education and technology have studied student perceptions comparing online to traditional lecture class quality (Ryan, 2000), the achievement of students in distance education and traditional classrooms (Schulman & Sims, 1999; Dominguez & Ridley, 1999), demographics of students taking online courses (Guernsey, 1998), staff training needs (Connell, 1998), support for faculty teaching (Bremner, 1998), and community and team formation in distance education classrooms (Berg, 1999) and numerous other subjects. We have also examined traditional versus nontraditional roles for the teacher and new paradigms for on-line learning (Bourne, McMaster, Rieger, & Campbell, 1997; Shneiderman, Borkowski, Alavi, & Norman, 1998). The need still exists to examine the role of the teacher and effective strategies for effective teaching. As Shneiderman (1998) wrote, “technology can be wonderfully empowering for teachers and students, (but) the relationship between human beings is still the heart of the educational process.”
Purpose

This study attempted to examine the relationship between teachers and students in distance education classes taught by university faculty from the college of education. Graduate students who were practitioners in various fields of education were the participants in these synchronous classes. It was anticipated that this pool of students would give insight into appropriate and inappropriate uses of various teaching strategies and techniques due to their expertise in education. A website with a discussion board was created to allow for interactions among students about: 1) the quality of learning, 2) effective teaching strategies, and 3) the effectiveness of the media of course delivery.

The Study

Conceptual Framework

The conceptual framework that serves as a philosophical basis for our institution posits that faculty and students come together as a community of inquirers to examine the aims of education and the nature of teaching and learning for achieving worthwhile educational goals. Teaching is viewed as a dynamic, goal-oriented, social activity, and learning is perceived as an active process of acquiring, assessing, and producing knowledge. We collectively embrace the exploration of new forms of teaching and learning through experimenting with emerging technologies. To this effort, we work as a community of practitioners who embrace the social constructivist perspective and encourage discourse from various levels of participants in solving educational problems.

The Participants

When the researchers in this study determined a need to engage graduate students in a collaborative effort to evaluate the quality of their learning experiences from courses offered through distance learning, two groups of students were selected. These two groups of students consisted of majors from the field of instructional technology and elementary and middle grades education who were currently employed in their field of expertise. The technology majors were enrolled in the course Planning for Technology in Education. It is one of the advanced courses students must complete for a graduate degree and K-12 licensure in instructional technology in North Carolina. The course emphasizes the development of technology plans at local, school, and district levels. In addition, the issues and processes of successful grant writing are explored. This course was taught simultaneously to two groups of students at remote sites and one group on the campus. The remote sites had computers for each student, while the main campus site required students to use a computer lab located in another building. Each site had a technician to assist with the overall operational details of the teleconference. A web-based supplement was also developed for the course that included an orientation, daily outline and assignments, resources and a threaded discussion forum. The instructor for this course had previously taught with this delivery medium. The elementary and middle grades education majors were enrolled in the course Connecting Learners and Subject Matter. It is one of the required courses for all education majors for the graduate level degree. The course emphasizes effective strategies for ensuring student mastery of content. This course was taught simultaneously to two groups of students with one group on the main campus and the other section at a site approximately 90 miles away. Each site had a technician who assisted with cameras, sound, equipment, and trouble-shooting when the technology difficulties occurred.

The North Carolina Information Highway (NCIH) program used in this distance learning study provided video teleconferencing capability to universities and public schools across the state. The "Highway" originally established for video communication today serves as the centerpiece of the states high-speed data network, supporting the data, voice, and video needs of all government at the state and local levels as well as school systems and other public entities. Using the high-speed backbone of the North Carolina Integrated Information Network (NCIN), our NCIH services provide broadband connectivity and setup of on-site video conference rooms to support a host of point-to-point and multi-point conferencing applications, including the distance learning medium used in this study.
 Altogether 73 students were enrolled in these two classes. The instructional technology majors were aware of the synchronous learning environment in advance. However, the students enrolled in Connecting Learners and Subject Matter were not informed in advance of the delivery system to be used. These students met for a sixteen-week semester and when the courses were complete, they were asked to provide feedback on their pedagogical and technological experiences. These students volunteered to participate in an open-item questionnaire that was designed to collect demographic data and feedback regarding the quality of their learning experiences in these distance education courses versus courses that did not involve this delivery system. Students also analyzed the effectiveness of teaching strategies used in these courses and the effectiveness of the NCIH. The survey was posted on a password protected website and required students to give permission for their comments to be used in a research study. Results were summarized and presented below.

Research Questions

Each graduate student enrolled in these two courses was invited to participate in a research project designed to assess the quality of the delivery system used in their class and to examine their perceptions of the instructional strategies used. The following questions were posted on a password protected website.

1. Contrast the quality of the learning experience in distance education courses versus on campus courses (interaction, instruction, assessment, etc.).
2. What teaching strategies have you found to be effective in distance education courses?
3. How effective was the medium for delivery of the class (ie. NC-REN, NCIH, web-based)?

Altogether 46 students logged onto this website and participated in this research project.

Findings

In the following narrative, the responses to the research questions are summarized. Specific quotes are used to highlight student perceptions.

Question 1

When students were asked to evaluate the courses delivered in synchronous environments using NCIH, the quality of instruction was perceived as high and being “as good or better than courses taken on campus.” However, students reported a strong preference for the professor to be at their site and felt that “instructors should be required to spend equal time at the various sites. Students miss a lot by not having direct contact with the instructor.” One student wrote, “…the quality of instruction is not diminished by the remoteness of the instructor and learner” and further stated, “We tend to work more cooperatively as a group because of the distance, therefore, depending on one another more.” Another student commented, “Distance education is a good tool if all people included work together to make it successful. I don’t believe it can be successful when the groups are looked upon as separate entities. We must be a whole.”

Several respondents commented on the limitations of distance education courses. “The frustrations of the technological problems... made this class difficult and often non-productive,” wrote one student. Statements such as the following were posted. “A few glitches occurred with the delivery because of the equipment.” “Time was wasted due to technical difficulties.” “As technology bugs are worked out, distance learning should improve.” These comments appear in the final research question as well.

In summation, while students prefer direct instruction with the professor, many would not have been able to obtain a graduate degree due to living a distance from the university campus. The convenience of this delivery medium has “truly benefited” the majority of students.

Question 2

Graduate students were asked to reflect on the effectiveness of the strategies used in distance education courses. The majority of students commented that small group discussions and cooperative
learning activities were the most “effective strategies used by the professor.” One student stated, “I believe that small groups discussing the topics and then coming together as a whole is the best strategy I have used.” This use of instructional time allows students to “get things accomplished without the hassle if technological problems.” Another stated, “Small group discussions kept the program personal and relevant.” “The instructors were adept at encouraging students to pursue areas of interest.”

One student commented, “Just like in a regular classroom, variety is key: Cooperative Learning, Videos, Power Point, Direct Instruction (providing that the technology is working). For two sites, it is effective to bounce questions back and forth so that you can get everyone involved and sharing.” “Power point and the overhead were good to supplement direct instruction” because visual learners need additional support. Literature circles used in the Connecting Learners and Subject Matter class was cited as a “very effective strategy” also.

Least preferred by students were lectures and large group discussions. For example, “whole group discussion was limited to the technological difficulties” of having cameras and sound focused on the speakers.

Question 3

Determining the effectiveness of the NCIH delivery system was the purpose of the third question in this survey. Students enrolled in Connecting Learners and Subject Matter reported more frustrations with the delivery medium than their counterparts in the Planning for Technology in Education course. Technical difficulties such as “...voice delays, freeze frames, and just being down were common to our classes this term.” Most students made comments such as the “...the NCIH was not successful in truly making the class a good learning atmosphere.” “I know that the technical folks here worked really hard; however, we have experienced technical problems,” and “NCIH has a lot of room for improvement.”

To the contrary, students enrolled in the technology course said, “NCIH has worked well. We’ve only had a few instances when connections did not work. The biggest problem was that voices broke down often and at times the volume from campus was very low.” One student reported that this delivery system had been used frequently and they had learned the value of flexibility.” However, one of thee students questioned the amount of money the state invested in this technology saying, “It would be better to just have web-based courses.” Another concluded that though there were technical problems, they far outweighed the safety concerns of having to drive 60 miles at night through winter weather, and the fee was affordable.”

In summary, both groups of students see NCIH as a good idea that will continue to be a part of graduate level education.

Summary

Given the results of this research, it is clear that there are still barriers impeding the success of distance education such as technical assistance and failures of equipment. It is also clear, however, that educators can create an effective learning environment, one that is influenced, but not driven by the technological media.

Students who were knowledgeable about teaching strategies reported that two major approaches were most successful in the distance education classroom. First, a cooperative group approach was reported as highly effective, allowing full participation by all students regardless of their distance from the instructor. A more constructivist approach to distance education classes, where students actively take part as peer leaders and instructors, may improve student learning. Instructors need to take on the role of facilitator, to an even greater extent, making sure all students have a voice in the class.

Second, students reported learning best when small group discussions and direct instruction were employed as long as the instructors used active, interesting audio visual aids and were well prepared for questions and follow up interactions. Distance education affords an instructor the ability to influence a
greater audience, sometimes as many as three to four classes simultaneously. This advantage may require the instructor additional time in preparation and perhaps even a full rehearsal of lectures.

Finally, students still want face-to-face interactions with instructors. Faculty may need to creatively address this concern with two-way video office hours, make visits to off campus sites, or change student expectations of a traditional classroom.

Discussion

Teaching is a complicated task even in the most favorable of conditions. Teaching and learning in a nontraditional environment requires both the teacher and learner to modify how they interact. The instructional strategies employed in distance programs must be examined from the perspective of the learner and the instructor. Instructors must be apprised of specific guidance based on research. By studying the perceptions of classroom teachers in their roles as students, we can delineate good from poor practice.

Using a Centralized Web Site to Support Distance Learners

lockeebb@vt.edu

Abstract: Supporting students at a distance can be quite a challenge, especially for programs that are completely web-based. Many times instructors must be responsible for providing not only instructional information, but also direction for students regarding administrative, technical, and logistical matters, all of which must be communicated in a clear and comprehensive manner. This paper overviews general support needs of distance learners and demonstrates how the Instructional Technology Program at Virginia Tech created a centralized web site to support learners in its online program.

Support Needs of Distance Learners

An essential aspect of any distance education project is the support services available to the students (Abate, 1999; Gibson & Gibson, 1997; Peters, 1998). Krauth (1999) asserts that students enrolled in distance education programs need the same types of student support services that are available to on-campus students, but that distance learners expect the delivery of these support services to meet their needs for flexibility and convenience. She also notes that special needs arise based on distance learners’ isolation and the fact that they depend heavily on technology for learning and accessing resources. Abate (1999) states, “think of all the offices on campus, all of the services provided for traditional students. All of these should be considered and made available in some fashion for students studying at a distance”.

An Online IT Program for Teachers

The Instructional Technology Program at Virginia Tech currently offers an online Master’s degree for professional educators. Termed ITMA (Instructional Technology Master’s Program), the initiative originates from the Center for Instructional Technology Solutions in Industry and Education. ITMA provides practicing teachers the opportunity to earn a Master’s degree without the need to enroll in our on-campus program. In addition, the program is structured around a set of outcomes that are specifically geared to these nontraditional students; these outcomes are based on technology standards developed by the International Society for Technology in Education (ISTE), as well as by technology standards recently implemented by the state of Virginia for instructional personnel. In order for faculty to assess whether or not students have acquired the knowledge and skills outlined in these standards, the
students are required to create an electronic portfolio that showcases their work throughout the program. Every course that our online students take relates in some way to the development of this portfolio, and the development process itself provides a meaningful learning context for the acquisition of these skills.

**Studio Support Services**

The portfolio idea also provided the context for the development of the ITMA Studio as the centralized support system for our online students. The "Studio" name stems from a desire to create a metaphor for an art studio as a location where many resources are available for creative development. The home page features a graphical palette of links leading students to various support resources designed to help them through the program. The resources available in the Studio can be grouped into several categories: portfolio support, program support, and peer support. Portfolio support is the main focus of the ITMA Studio. The Portfolio link provides access to a wide range of information about the electronic portfolio, including a complete list of requirements, links to related standards, and examples of previous student portfolios. Other portfolio support options provided by the Studio are links to tools and tutorials that are specifically chosen to help ITMA students acquire and learn the technology that will assist them in the creation of their portfolios. The Tools section includes annotated links to a variety of software programs that can equip students for the development process, while the Tutorials section provides assistance for students who are learning to use these tools.

Program support in the Studio consists of a help area that provides contact information for all of the faculty and staff involved in the ITMA program, including instructors, administrative staff, and technical support staff. This provides the simplest of benefits for students by allowing them to access important program information in one place. If they misplace a phone number or email address they know to consult the Studio for the information. The Help section of the Studio also contains links leading to important sections of the Virginia Tech web site, such as the library, the email pipeline, and students' personal accounts. Virginia Tech allows students to perform a wide range of tasks without ever setting foot on the campus.

Peer support is the third category of support addressed by the Studio. The first way this is accomplished is by providing a gateway for students to share work amongst themselves. This gateway provides a link to every student's portfolio, which allows both students and faculty to easily access everyone's work. We have also provided a chat room in the Studio to allow for synchronous communication between ITMA participants, without the delays associated with email or discussion groups.

Through a combination of resources, the ITMA Studio is designed to meet our students' needs for flexibility and convenience. By providing portfolio, program, and peer support, the ITMA Studio endeavors to be a place where students can resolve problems, develop their skills, and find social support at any time of the day. It is hoped that with the benefit of these resources each student will be able to create his or her own electronic "masterpiece."

The Professional Development Series: Web-based Staff Development for K-12 Teachers

Lisa A. Heaton, heaton@marshall.edu
Assistant Professor, Elementary and Secondary Education
Marshall University Graduate College, USA

Lisa A. Washington, lisa@rockman.com
ROCKMAN ET AL

Rudy Pauley, rpauley@marshall.edu
Assistant Professor, Elementary and Secondary Education
Marshall University Graduate College, USA

Abstract: Marshall University's Graduate School of Education and Professional Development has successfully offered a series of staff development courses for K12 teachers using the Internet for course delivery. Teachers may apply, enroll, and complete the courses in an online format. The courses are structured around a series of informative and timely topics pertinent to today's teachers. Participant response to this program has been highly positive as exhibited by the exit surveys.

Introduction

The Professional Development Series was initiated during the Spring 2001 semester for the purpose of providing staff development courses to in-service teachers across the state. Courses are web-based (using WebCT as the delivery platform) with no face-to-face class meetings. One course was offered during the first semester as a pilot for the course development, marketing, registration, delivery, and evaluation procedures. The program was expanded to include three courses during the Summer 2001 semester and four courses during Fall 2001.

All courses offer three professional development credits that teachers can use for recertification or "plus hours" for advanced salary classification. Courses are graded as Satisfactory/Unsatisfactory. Content is geared toward providing teachers with practical applications that can be integrated into their classroom instruction. The current selection of topics includes: Using the WWW, Web Design, Literacy, Character Education, and Multicultural Education. Approximately 350 teachers from 49 out of 55 counties and three other states have participated in courses during the first three semesters.

Getting Started

Course offerings are advertised using a variety of formats, including: direct mailing to school superintendents and principals, faculty senate personnel, newspaper and newsletter advertisements, and the Series website, developed for the Fall 2001 semester.

Initial inquiry by students is completed by phone, e.mail, or online. Registration is completed by mail or online. Once registration is processed each student is mailed a Welcome Packet that includes a letter from the instructor, an assigned username and password, course login directions, and a tip sheet with suggestions for increasing success in an online course. The eight-point tip sheet was added after the first semester pilot was completed. These tips will be shared during the presentation.

Course Setup

All courses in the Professional Development Series begin with an orientation module designed to familiarize students with the course setup and navigation and to introduce the use of the course communication tools that are essential for discussion and assignment submission. Some of the most popular course tools include mail, discussions, student grades, quizzes, presentation area, and content module—all built-in to the WebCT interface. As part of the orientation module, students complete practice assignments that require using mail to announce that they have started the course and using Discussions (the Bulletin Board component) to post a brief bio.
Since the registration period for each course lasts four to five weeks during the beginning of each semester, students begin and end the course at different times throughout a semester. To facilitate this open enrollment period, all assignments are self-paced. This self-paced approach is also intended to accommodate the busy schedule of the typical classroom teacher.

Course materials and assignments include readings, interactive practice exercises (quizzes), online discussions, and independent projects. The focus of each course is on practical applications of content within the K-12 instructional setting. Examples of the Orientation Module and the organization of course content and assignment pages will be demonstrated during the presentation.

One or more instructors, depending on student enrollment, are available to facilitate each course. The course instructors are available to answer questions, facilitate online discussions, and evaluate assignment submissions. The target policy is to respond to inquiries and assignments within 48 hours of submission. Instructors for each course provide students with ample feedback and opportunity to make corrections to any assignment submission that does not meet the Satisfactory requirement.

The final component of each course is the Exit Survey.

**Exit Surveys**

Nearly 280 teachers participated in four courses during the first two semesters. Of this number, 260 participants completed the Exit Survey. The Exit Survey is intended to serve two major purposes: 1) evaluating course quality and 2) gathering information for future program planning. Items include:

- The course content was applicable to my professional development needs. (Strongly Agree, Agree, Neutral, Disagree, and Strongly Disagree)
- The assignments were relevant to the course objectives. (Strongly Agree, Agree, Neutral, Disagree, Strongly Disagree)
- The directions provided throughout the course were clear and helpful. (Strongly Agree, Agree, Neutral, Disagree, Strongly Disagree)
- The instructor(s) for this course were responsive to my questions and assignment submissions. (Strongly Agree, Agree, Neutral, Disagree, Strongly Disagree)
- Approximately, how many hours did it take for you to complete the course? (5-10 hours, 11-15 hours, 16-20 hours, 21-25 hours, 26-30 hours, >30 hours)
- Would you recommend this course to other educators? (Yes, No)
- Prior to this experience, have you ever taken a web-based course? (Yes, No)
- How did you hear about this course?
- If you are interested in taking other Internet-based courses, what topics would appeal to you?
- Please make any additional comments.

Results from the first two semesters (260 participants) are available and will be shared during the presentation. Ninety-eight percent of participants indicate Agree or Strongly Agree to the applicability of course content to their professional development needs. The remaining 2% were neutral. Ninety-four percent of participants indicate Agree or Strongly Agree with the responsiveness of course instructors to questions and assignments submissions, with the remaining 6% indicating Neutral or Disagree. One hundred percent of participants completing the survey indicate that they would recommend the course they completed to other educators. Additional feedback provided by students in the “additional comments” and future course topics has been equally positive and informative for course revisions and development of future course topics.

**Conclusions**

The need for quality professional development programs for in-service teachers is tremendous, especially for teachers who live and work in rural, isolated regions. Teachers who live beyond the standard service areas of colleges and universities deserve an equitable opportunity to participate in professional development programs. With the increasing access to Internet-connected computers in all public schools and with the expansion of Internet Service Providers into rural communities, online programs like the Professional Development Series can help bring the educational opportunities to teachers in all areas of the state.
CONSTRUCTING THE ONLINE LEARNING COMMUNITY: AN EXAMINATION OF READER RESPONSE AS A MECHANISM FOR SCAFFOLDING

Jeannine Hirtle Ed.D., Curriculum & Instruction, University of Texas at Arlington, USA, jhirtle@uta.edu
Kelly Frankum M. Ed., Mansfield High school, Mansfield, Texas, USA, kbfrankum@yahoo.com
S.Janelle Quintans B.A., North Dallas High School, Dallas, Texas, USA, sjquintans@earthlink.net

Abstract:

Studies on the pedagogical implications for integration of technology within teacher preparation courses are emerging in a time when national surveys (Milliken 2000, ISTE 1999) decry the lack of adequate teacher preparation in this area. This study examines the pedagogical implications for the use of Reader Response in an online post graduate methods course. The resulting benefits of technological, social, and cognitive scaffolding are the anticipated results and the specific methodology examines closely how these are achieved. The significance of this work is that it could be potentially used as a model for processing expository text in online learning communities thus increasing the learning experience.

Introduction

One of the criticisms of distance education is that it limits the students’ education experience because of the anxiety and frustration due to the isolation inherent in the process. (Hara and King, 1999) Distress may occur while working on the Internet because of the complexities of working in isolation in regard to technological issues as well as course content issues. (Hara and King, 1999) This is indeed problematic as Brown and Duguid caution (1996) that learning does not occur independent of communities... Learning, at all levels, relies ultimately on personal interactions.

As a professor in a web-based distance education program, I work with students who have degrees and are seeking certification in teacher education through distance education. These nontraditional students are teaching on emergency certification or working in other jobs preparing to transition into teaching. Within these same classes, I also worked with students who have varying degrees of experience as teachers and are pursuing graduate degrees in education. Many of these students already are coping with the isolation of teaching and I want to alleviate frustrations and anxieties that potentially could affect their learning experience by designing courses I taught online with built in mechanisms for scaffolding student learning.

Framework and Review of Literature

Scaffolding in the learning environment is defined as the process of supporting students so they can accomplish tasks towards the higher end of the Zone of Proximal Development. This is "the distance between a learner's 'actual developmental level as determined by independent problem solving' and the higher level of 'potential development as determined through problem solving under adult guidance or in collaboration with more capable peers.'” (Wertsch, 1985, p.67-68). Vygotsky described this as "the distance between the actual development level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” (Vygotsky, 1978). This support can be provided through collaborative group work with more capable peers or through adult guidance. A great deal of scaffolding is provided initially, but is then slowly removed until the student is able to accomplish the same task on their own. An important aspect of scaffolding is that the task the student is asked to perform does not change to accommodate the learner. Rather, the learner is supported and guided until their schema have accumulated enough new information to enable them to perform the task on their own (Hodson & Hodson, 1998).

The mechanism for scaffolding I chose to build into this course design was the use of reader response with expository text as the framework for online discussion communities. Based on the work of Louise Rosenblatt (1994), reader response is generally thought of as a literary practice, generally utilized within a language arts course. Rosenblatt theorizes that readers transact with text incorporating their personal linguistic experiential reservoir (1994) and their cognitive, affective residue of past experiences (1985) to construct meaning in text over time. Rosenblatt believes that the reader responds by means of the meanings he or she brings to the text, as well as by means of the meanings which emerge in the process of reading (Bertoff 1988). While my courses contained expository text, as opposed to the literature that reader response is more traditionally used with, I believed this method of processing the reading, when shared in community, might provide an opportunity for students to scaffold their learning.

Using Rosenblatt’s theory of reader response with the expository text used in two teacher certification courses, coupled with opportunities for social interaction which connected students’ thought and language in an online environment, I wanted to see:

1. If scaffolding of learning would occur as a natural outgrowth of this process
2. And if it did, what forms of learning support would it provide.

Methodology

The research design for this study is an action research project, which pursues action (or change) and research (or understanding) simultaneously through a cyclic process. This process alternates between action and critical reflection and the continuous refinement of methods, data and interpretation in the light of the understanding developed in the earlier cycles (Dick, 1997). The methodology chosen was a case study involving two post-baccalaureate and/or graduate level online classes. The department where this study was conducted offered a Masters in Education with an emphasis in Reading online and offered a series of five curriculum and instruction courses, which could be used towards a Masters in Education and/or in preparation for teacher...
certification. The first author of this paper is the instructor for this course and the two co-authors, are teaching assistants. One of the coauthors, Frankum, has a Masters in Education and the other, Quintans, is pursuing a masters. Both coauthors are teaching in K-12 public education at the time of this study.

The data collected for this case study comes from four sources: documents related to the course, threaded message boards, e-mail, and student interviews. The course documents include the syllabus and online lessons. The online lessons contain directions for reader response discussions. They will be analyzed for statements that would encourage or discourage scaffolding. The last three sources will be analyzed initially for the elements of scaffolding as well as negative expressions and expressions of frustration.

Three sets of threaded message boards for each class are being analyzed. They were chosen from the threaded message boards from weeks three, seven, and eleven in the course. At this writing weeks three and seven were the only weeks available for analysis. So, this paper is an intermediate look at the data. After initial analysis of weeks three and seven by the three researchers, the following codes for analysis were generated:

1. Questions asked
   a. for clarification
   b. for support
   c. for a solution
2. Statements made
   a. supposing or imagining
   b. agreeing
   c. affirming
   d. suggesting
   e. offering a solution
   f. commiserating
   g. presenting a problem
   h. providing additional information (explaining)
      i. in the form of a story
      ii. in the form of metaphor or analogy
   i. correcting
   j. expressing an aha or a breakthrough
   k. expressing empathy
   l. expressing value or appreciation
   m. expressing resistance
   n. expressing a negative reaction
3. Exclamations
   a. of excitement
   b. of pleasure
   c. of value or appreciation
   d. expressing resistance
   e. expressing strongly negative reaction
   f. of encouragement

In addition, e-mail to the instructors in the form of student self-assessments for weeks three, seven and eleven are being analyzed for references of the elements of scaffolding or expressions of negativity or frustration which may connote non-scaffolding.

One month following the semester, each author will conduct three online interviews to ascertain the elements of scaffolding or examples of non-scaffolding perceived by the students within the reader response discussions in the course.

1. Has my experience with online reader response discussions influenced the way I think about learning? If so, how?
2. Does my experience with this online course contain any examples of scaffolding in reader response discussion? How did I scaffold my peers' learning? How did my peers scaffold my learning?
3. Has my experience with using reader response in an online environment influenced how I think about education and learning in general?

Data Analysis and Discussion

Four different kinds of data will be analyzed (document review, threaded message boards, e-mails, and interviews). The analysis will be triangulated in terms of methodologies, people, and time (Silverman, 1996; Stake, 1995). Furthermore, the informants will validate each interview transcript and interpretation. The three author/researchers will analyze data independently and debrief to analyze their results and draw implications and conclusions.

Document Review is the first kind of data analyzed. To invite students into the text in week three, I at first used guided questioning to help them tap into their existing schema and relate personal experiences to the concepts in the text. The following is an example of those instructions:

Questions to reflect on and respond to while reading.

Please note that this is challenging reading in that the language is complex and many times specific to the field of research. Try not to let this dampen your spirit, but read for general understanding and reflect on the main ideas. It is important that you read some of the discussion of the primary research in our field of literacy instruction and that you are familiar with the major researchers, their claims, and the research upon which they base their claims. Think of this as Popeye did his "spinach." It makes you strong in the field of literacy education. The discussion questions are designed to help guide you through this labyrinth of conceptually dense text. Please answer them in complete sentences in well-constructed paragraphs that have a topic sentence, supporting
points and a closing sentence. As a reminder, each WebBoard™ response plus follow-ups to two of your colleagues’ postings and responses acknowledgements to all who respond to you are worth 5 pts per WebBoard™ session.

While the instructions did not open much space for reader response, but rather supported the reader through the text, the follow-up responses to colleague’s postings did open that space and students began to question each other’s experiences and ask for opinions.

The second kind of data analyzed was student responses to each other’s postings. In Week Three, there were 16 original posts from 16 different students for a total of 58 student responses. There were 3.6 average responses per original posting.

The responses showed that the students were involved in the reading and communicated with their peers. Some students, 17%, asked questions such as, “How is it that the writing of the actual researchers has not called attention to policy makers that phonemic instruction is not proven to be the best reading instructor?” They synthesized the information gained from the articles and communicated their concerns with other students. For example, these were some responses to Chall, J., “Some Thoughts on Reading Research: Revisiting the First-Grade Studies” (1999).

Hi AG, Do you think that phonics is the great and wonderful phenomena that the First Grade Studies depicted it as being? ER

Do you think we are likely to see the same correlation of phonics to reading achievement as students move into later grades?

And students began to form opinions and take a stance.

I think they attacked the design to discredit the results as you stated in your question. If the design is flawed how can we believe in the results. I think people did not like the results of the research because it did suggest change. Change is always hard to do and some are not willing to do it. It differently takes effort and commitment. KP

This showed trust was being formed, and respect was beginning to develop. Approximately 50% of the questions requested clarification. For example LW writes:

P, Chall points out the decrease in reading achievement due to whole language but doesn’t examine it anymore than saying it was because of the lack of phonemic awareness. She also leaves out some elements about her own research as you mention. Why do you think that is? LW

An additional 32% requested support. PW asks:

ER, I thought they really ignored the “other factors” that played a role in students’ success, did you get that feeling too? PW

The rest, 18%, solicited a solution from their peers. For example KP asks:

I am a product of the 80’s group that resulted in lower reading scores. I did not have formal phonics instruction in the classroom and I did learn to read and comprehend. But, I must say I still have a difficult time with phonics. I can not blame this all on the lack of teaching because I did have to attended speech as a child as a result of many ear infections and not picking up our language as an infant/ toddler. Do you think phonics instruction is vital to teaching a child to read? KP

Online statements made were analyzed. Of the statements, 23% were statements agreeing with their peers, and 14% affirmed what their peers had to share. In some students’ responses, 13% proposed suggestions to their classmates.

In all honesty, I don’t know why there has been this great debate raging for so many years. After all, if we want to achieve balance in our lives, why would we not want anything other than balance when it comes to educating our children? The balanced approach, as indicated by Berninger, is the goal. ER

An additional 5% of the responses offered solutions.

I think part of the problem with all of this research is that we are researching readers. Readers are human, specifically, children, it is impossible to have a true control group. Furthermore, as we have all stated again and again, readers are individuals and in order for them to get the best instruction it must be individualized to meet their particular needs. LA

The same percentage of responses, 5%, commiserated with their peers online. Four percent of the responses presented additional problems in their posting. Twenty-six percent of the responses provided additional information by explaining or clarifying their position. An additional 5% told this in the form of a story, while 1% gave information in the form of a metaphor or analogy.

Corrections were offered in 3% of the postings, and 3% expressed an “aha” or a breakthrough.

While most of the postings were positive, 3% expressed resistance either to the reading or to the procedures they find in their schools.

Some exclamations, 8% of all responses, were made. Of those exclamations, half expressed excitement, 25% showed value or appreciation. For example KP writes:

That does make a lot of sense and I do agree with what you said about every student being a factor. This does help me understand Chall better. Thank you. KP

12% expressed resistance, and 12% expressed a strongly negative reaction. For example:

In retrospect (after reading the articles by Graves and Dykstra and Pearson) it is quite clear to me that Chall is just another example of someone misusing research. These studies never came up with any direct correlation between phonics instruction and improved reading. These studies do not really take into account any changes in demographics or populations. Even at the time the researchers were unable to completely, scientifically control all of the variables.

Data from Week Seven

During the seventh week of class, document review revealed that the instructions for reader response became more open to student interpretation. For example:
The following table 1.0 summarizes and compares the responses by category.

</tbody>
</table>

For the seventh week of online class, there were 12 original postings of the assignments and 12 different discussions occurring after reading two articles. There were a total of 134 responses from peers (this data does not include responses from the course instructor and class TA). There was an average of 11.2 responses for each original post of the articles read. While some of these were one-line questions, most involved participation and contributed additional information.

The responses showed that the students were involved in the reading and communicated with their peers. There were more responses the 7th week; this shows that more "conversation" is occurring online. Twenty percent of the responses involved the students asking each other questions. Of these, 42% inquired into clarification, 21% asked for support, and 37% sought a solution. Students were asking more questions, but less were asking clarifying questions. Students seemed to get to know each other better, so they asked less clarification was required. Students were beginning to need less technical or interpretive textual support from their peers, and started to ask for their help in solving their classroom dilemmas. In other words, they were beginning to apply some of the theory they were studying to the context of their classroom experiences. They were assimilating or accommodating (Piaget) this expository information into their existing schema. As a result, the scaffolding, which occurred from reader response in week seven, was scaffolding of a practical application nature.

Most of the comments, 77%, were statements. Most of these statements, 58%, were either agreeing or affirming statements made toward their fellow peers. This is an increase from Week 3 when 37% of the statements either agreed or affirmed. It appeared that students were appreciating their students more as they got to know them better. Also, 39% of the students provided suggestions or offered a solution.

For example LP wrote:

E: You asked how we respond to children who have the ability to read, but have no interest in doing so. I firmly believe that you should never FORCE a child to read for pleasure because then you are actually punishing a child with books. What I do is read aloud every day. Some days I read from a chapter book that we read throughout the year, some days I choose a trade book about something my kids like, like trains or birds, some days I read some funny poems and some days I read something by Jon Sciezka (sp?), who can motivate any boy in the world to pick up a book because of his funny almost inappropriate humor. What I have found is that even though the book has already been read to my students there is always a run on whatever book I have read aloud, they all want to read it again! Through the course of the year everybody finds some kind of book that they do like reading. I try to keep a large variety of books on my bookshelf, some easy, some difficult so that all students have something that holds their interest. Luckily Barnes and Noble gives teachers a 20% discount on books they buy for their classroom! LP

It appears that students feel more comfortable in offering their services and sharing information.

Discussions were enhanced by 45% of the responses, in which additional information or explanations were supplied to peers through the WebBoard. This is an increase from Week 3 of 19%. Thirteen percent of the students shared information in the form of a story, up from 5% in Week 3. Students seemed to feel more at ease and more able to share personal and relevant information. Students were beginning to open up and honestly share with their online peers. Also the stories were often of the students' actual experiences as a learner, or from her experiences in the classroom. This fits with the need to scaffold with practical application. The more open format of reader response gave students the opportunity to bring forward their personal experiences in response to the readings.

No corrections were made in Week 7, down from 3% in Week 3. It appeared that students appreciated and respected their peers more and felt they did not need correcting; students understood each other better.

While no students expressed empathy in Week 3, 2% of the responses did so in Week 7. Since students were beginning to know each other, they appeared to feel closer and express that relationship. No students expressed resistance or a negative reaction, compared to 3% in Week 3.

Fewer exclamations were found in Week 7 when compared to Week 3; 5% of all responses made in Week 7 were exclamations. All of these responses were positive, though. Forty two percent of all exclamations shared value or appreciation, 29% expressed excitement, and 29% expressed pleasure. Negative responses were absent from postings.

The following table 1.0 summarizes and compares the responses by category.

Using Rosenblatt’s theory of reader response with the expository text used in two teacher certification courses, coupled with opportunities for social interaction which connected students thought and language in an online environment, I wanted to see:

1. If scaffolding of learning would occur as a natural outgrowth of this process
2. And if it did, what forms of learning support would it provide.

The work of Piaget and related theorists is based on the premise that when individuals cooperate on the environment, socio-cognitive conflict occurs that creates cognitive disequilibrium, which in turn stimulates perspective taking ability and cognitive development. When students respond to text incorporating their own unique schema, through their statements, questions, and explanations and share this response in online discussion then knowledge can be social, constructed from cooperative efforts to learn, understand, and solve problems. Current cooperative learning theorists and practitioners David Johnson and Roger Johnson create cooperative learning environments based, in part, on positive interdependence. In this environment:

Positive interdependence exists when students perceive that they are linked with group mates in such a way that they cannot succeed unless their group mates do (and vice versa) and/or that they must coordinate their efforts with the efforts of their group mates to complete a task.

This environment does exist in this online learning community. At first, it was imposed by the guidelines of the assignment that required that students respond to each other’s posting. This led to positive interdependence (Johnson and Johnson). Positive interdependence promotes a situation in which students can achieve promotive interaction. Promotive interaction occurs as individuals encourage and facilitate each other’s efforts to reach the group’s goals (such as maximizing each member’s learning). Group members promote each other’s success in part by (Johnson & Johnson, 1989):

1. Giving and receiving help and assistance (both task-related and personal).
2. Exchanging resources and information. Group members seek information and other resources from each other, comprehend information accurately and without bias, and make optimal use of the information provided. There are a number of beneficial results from (a) orally explaining, elaborating, and summarizing information and (b) teaching one’s knowledge to others. Explaining and teaching increase the degree to which group members cognitively process and organize information, engage in higher-level reasoning, attain insights, and become personally committed to achieving. Listening critically to the explanations of group mates provides the opportunity to utilize other’s resources.

The authors believe that the positive interdependence that exists within the framework of cooperative learning is, in actuality, an explanation of the scaffolding which occurs within this online learning community as a result of students’ reader response to expository text.

Intermediate Conclusions and Implications
Bridging Craft and Academic: A Demonstration of Web-Based, Problem Based Learning Training Materials

Sarah Hough, University of California, Santa Barbara, CA 93101, US
Stacey Kyle, University of California, Santa Barbara, CA, 931010, US
Michael Gerber, University of California, Santa Barbara, CA 93101, US
Jill Leafstedt, University of California, Santa Barbara, US

Come and learn about a multi-media web based learning tool—built on a constructivist (problem based learning) approach—designed for use in teacher development.

Objectives and Overview

The purpose of this proposed poster/technology session is to present and discuss interactive, web-based learning tools that are the end-product of CASELINK. During this session participants will (1) become familiar with problem-based learning and its uses in teacher development; (2) have the opportunity to explore one of the PBL web-based modules in action; and (3) gain an understanding of the power of using online environments to facilitate PBL.

CASELINK and its successor School Link are development projects whose impetus was a question: How can traditional academic knowledge and the highly specific and contextualized “knowledge-in-practice” be integrated in a meaningful context for use in professional training? Utilizing a problem-based learning pedagogy, the CASELINK team designed, developed and field-tested four interactive multimedia web modules for use in existing courses for the development of prospective teachers' understanding of special education. When "knowledge of practice" and "knowledge in practice" are linked together in professional development programs, due to the way in which traditional learning is structured, the gap between the two can ordinarily be wide. Traditional "knowledge-of-practice" is packaged and typically resides in textbooks and lectures in central locations because these formats permit a satisfactory balance of per trainee cost and overall instructional benefit (i.e., the knowledge obtained by each learner). On the other hand, supervised teaching in the field is distributed over a geographical area defined by cooperating institutions and without much control of the nature or content of experiences. Creative solutions to this problem are important in order to improve the overall quality of professional preparation. The CASELINK modules attempt to address this issue using problem-based learning pedagogy along with multi-media web technologies.

CASELINK has developed a new pedagogical strategy for allowing access to professional knowledge by using a case/problem based learning program supported by interactive, multi-media, website case studies and associated data and documents. The CASE materials that have been developed bring together information from school professionals (including regular and special educators, administrators, counselors and psychologists) in school site-oriented, co-operative teams as these professionals collaborate on real-life messy problems, in an attempt to capture knowledge-in-practice.

The use of hypertext and QuickTime video was chosen as the appropriate forum for presenting the CASELINK materials to student users subsequently all of the CASELINK materials are mounted in a systematic way on CDs and the web. These multimedia materials include photos and video segments of different children, their parents, peers, teachers and other school professionals, along with IEP’s, and professional publications such as journal articles and book chapters.

Outline of the Session

During the session participants will have the opportunity to:
1. Interact with the a full PBL "CASE" that is designed for training teachers how to work with EL students.
Each Module can be viewed as having three main components: The problem framing component; the solution development component; and the reflective component.

A. Frame the problem
The process begins with a description of a core problem. Core problems will center around real school situations involving one or two disabled students. From the core problem, users will have several optional hypertext links to choose from, including links to role-specific individuals involved in the core problem. Examples of role-specific individuals include parents, special education teacher, school psychologist, pupil, school administrator, general education teacher, etc.

Meeting. Groups of students then meet (either in real time or online), in order to develop comfortable as well as efficient operating procedures (e.g., roles, responsibilities, notetaking/keeping). Student users then submit their understanding of the problem as a group, online through an interactive form on the module.

Stakeholders' perspectives. The submission of the interactive form then opens a gateway to a video presentation of the stakeholders' view of how they see the problem. Often these views are in conflict from each other as in a real life situation.

Reframing/reflection. Student users now are allowed an opportunity to reflect on differences between how they saw the problem and how the stakeholders saw it--with an opportunity to resubmit their problem statement if they so choose.

B. Constructing a solution to the problem
Role Strands. At this stage student users either choose or are assigned a role. Roles in most cases include parent, general education teacher, special education teacher, school psychologist, administrator, principal, and when appropriate the child with a disability. After determining which role they will adopt, the student researches all information within that stakeholders strand. This information can be obtained through video clips, reading assessments given, and accessing outside links on related topics on the world wide web.

Team Meeting. After obtaining all information they deem relevant to represent their role, student users bring their new knowledge to their team meeting at which point an agreement on a plan for the student in question must be reached.

C. Reflect on and discuss solutions. The final stage in the PBL module is the reflection and discussion regarding the submitted solution. In this stage student users are given a chance to compare their problem solution to that which was developed by the professional team in the case. As a team, the students sift, weigh, and integrate what information has been gathered. They discuss what differences exist between the professionals' solution and their own. They also reflect on the possibilities for these differences and the knowledge that they have gained from this unique process.

II: Explore some of the tools that are currently being developed to enhance the users experience with the CASE modules.
A. Chat rooms for team meeting and discussion
B. Video interviews with "experts" from the field.
C. Stand alone "information" modules that allow users to explore relevant topics in depth. (Such as IDEA, the Individuals with Disabilities Education Act).
D. Interactive pages that allow users to share (upload) resources and view and search through digital archives of previous solutions.

E.
Closing the gap between "knowledge in practice" and "knowledge of practice" requires education professionals-in-training to be brought as close to the reality of authentic school practice as possible. Knowledge-in-use is messy and is based upon the interactions of teams of school professionals; it exists in on-the-fly decisions in classrooms--decisions that are grounded in years of experience; and it is always shaped by the context in which the specific problem-to-be-solved is situated. CASELINK attempts not to bring these aspects of knowledge to the traditional learning environment, but to use technology to recreate the learning space to more closely resemble an authentic school decision-making environment.
New Internet Tools for Facilitating Scientific Inquiry

Richard A. Huber, Curricular Studies Dept., UNCW, USA huberr@uncwil.edu
Louis Lanunziata, Curricular Studies Dept., UNCW, USA lanunziatal@uncwil.edu

Abstract

This paper presents a case for using interactive Internet resources as tools for facilitating inquiry-based science instruction, as called for in the National Science Education Standards, with a focus on grades 4-14 application. Two categories of interactive inquiry sites will be demonstrated: (1) sites that provide simulation of scientific equipment and resources and (2) sites that allow students to interact with large educationally relevant databases.

Contrary to a common misconception, effective use of the Internet in science education has little or nothing to do with surfing the web. This is not to imply, however, that the Internet does not contain outstanding resources for supporting inquiry science. Experts are urging teachers to move away from activities that invite students to surf the web in favor of Internet activities that direct students to access and utilize pre-selected sites in order to accomplish pre-determined objectives (Huber & Harriott, 1998; Huber & Moore, 2001, Moore & Huber, 2001, Watson, 1999). For high school and middle school science teachers, interactive sites that use Java applets designed to facilitate students in accessing and interacting with large authentic data sets represent one of the currently most promising Internet applications. This paper examines two such sites; one site permits active inquiry about principles of physics the other site supports inquiry learning about river ecology. In addition this paper will examine the use of these Internet resources for special needs students.

In evaluating the suitability of Internet resources for supporting inquiry-based instruction, it is necessary to first define what is meant by the term, "inquiry-based instruction." While no single universally agreed upon definition of inquiry-based learning exists, it is generally accepted that inquiry-based classrooms are student centered and emphasize cooperative "hands-on and minds-on" learning activities in which problem solving and creative thinking are strongly emphasized. Through these experiences, curriculum goals are met as students construct meaningful, broadly applicable, well-structured, information-rich knowledge, skills, and affective domain attributes. The nature of inquiry-based instruction is perhaps most clearly described in the "vision" of the National Science Education Standards. As envisioned in the Standards, inquiry-based teachers function as facilitators and supporters of student learning rather than as disseminators of knowledge. The vision of the Standards is one of dynamic learning communities working within enriched learning environments supported by an educational system that has been overhauled to provide the support those communities will need. Within this setting, the Standards recognized the central and interactive roles of mathematics and technology in both scientific work and science instruction. According to the National Science Education Standards, in the inquiry-based classroom, students are actively engaged in cooperative, "hands-on and minds-on" learning activities that emphasize problem solving and creative thinking. Teaching problem solving and thinking skills to students with special needs, such as students with learning disabilities, mental disabilities, behavioral disorders and attention deficits, is also considered critical by many educators. Mildly handicapped students often are unsuccessful with tasks requiring inquiry and problem solving approaches (Mastropieri, Scruggs, & Butcher, 1997).

However, when appropriately prompted to reason through new information, studies have indicated that students with special needs can understand better and comprehend more than when directly taught the same information (Scruggs, Mastropieri, & Sullivan, 1994; Sullivan, Mastropieri, & Scruggs, 1995). Scruggs & Mastropieri (1995) also reported that inquiry-oriented instructional practices could effectively promote the understanding of science concepts for students with mental disabilities. In their text, the inclusive classroom: Strategies for effective instruction (2000), Mastropieri and Scruggs note that; "Inquiry-oriented approaches to science and social studies, found in both textbook and activity approaches can also be adapted for students with special needs.

These adaptations include use of hands-on materials, carefully structured questioning, redirecting attention, and reinforcing divergent, independent thinking." (p.545).

With instructional technology, in particular, multimedia applications, students with special needs can actively engage in scientific experiments requiring inquiry and problem solving and thought appropriate prompting, more successfully reason through new information. "In addition to providing an opportunity to obtain and observe unique aspects of the content, these instructional delivery systems can motivate students and stimulate their curiosity" (Salend, 2001). Through these experiences, curriculum goals are met as students construct meaningful, broadly applicable, well-structured, information-rich knowledge, skills, and affective domain attributes.

While there is an abundance of Internet sites that disseminate useful content information, sites that support productive exploration of interesting academically valid questions, as discussed above, are more rare. However, some sites do make use of very effective computerized displays of quantitative information that do make data analysis more productive and intuitive. Among the most effective of these displays are animated interactive line and color gradient graphs, such as those incorporating within the River Run site. Thus, the utilities provide simple and engaging mediums for open exploration and powerful effective tools for hypothesis testing. As an example of a graph sequence that invites hypothesis testing, consider the graph shown in Figure 1.
Figure 1. Data visualization from River Run indicating highly turbid water with a high fecal coliform bacteria count at the upper sampling sites on March 9, 1998.

After developing a basic understanding of the cause-and-effect relationships underlying the displayed information, students could form hypotheses of how other variables might behave within this scenario and change system settings, and "run" animations to test their hypotheses. One of the strengths of the River Run Data Visualization Tool is that it provides numerous opportunities for students to discover and explore extremely interesting ecological events, which tend to stand out when the data is graphically displayed (Huber & Moore, 2001). These provocative anomalies are abundant because the river systems from which the data are drawn have experienced numerous highly noteworthy events during the years over which the data are collected. Specifically, the River Run resource provides data and utilities for exploring data on the water quality of the Cape Fear River and the Northeast Cape Fear River from 1995 to 2000. During these years these river systems experienced a major poultry farm spill, several ruptures of hog waste lagoons, five hurricanes, and a 500-year flood. Consequently, when water quality data on the rivers are explored using the data visualization tool, conspicuous spikes in line graphs and flashes of color on the color mapper pop up frequently. These anomalies invite students to stop the animations, form hypotheses, reset parameters, and rerun the animations to test their hypotheses.

The explorescience.com web site facilitates inquiry by allowing a student to repeatedly conduct an experiment designed to illustrate important physical science concepts. For example in the density lab students can repeatedly conduct density experiments to reinforce the concept that density is the mass per unit of volume. This is a difficult concept for students to comprehend unless they can conduct the experiment repeatedly.

References

On-line offerings of courses have increased exponentially (Hall, Watkins, & Ercal, 2000). Efforts to meet the needs of diverse, non-traditional students have created a market for instruction that can be delivered in flexible formats. While the movement to increase the use of on-line instruction is rapidly moving forward, there is a lack of empirical data to identify the effects of this technology (Maki, Maki, Patterson, & Whittaker, 2000; Shelton, 2000).

There is also a corresponding scarcity of research to identify the characteristics that might influence a student to enroll in on-line instruction over traditional instruction (Robyler, 1999; Wang & Newlin, 2000). Previous research on student characteristics has focused primarily on demographics of students participating in on-line courses. Robyler (1999) found no differences in age, gender, GPA, or experience with technology when comparing students who chose distance learning over traditional courses. Wany and Newlin (2000) found students' geographical location from campus, hours at work, and number of children at home were not related to course format choice. Gender, age, and employment status had no relation to students' perception of on-line courses (Jiang & Ting, 1998).

The highly unique features of on-line instruction (e.g., lack of physical presence of instructor, flexible timing, dependence on technology) suggest corresponding personality and attitude differences between students who elect to take on-line courses and student who choose traditional courses. Few studies have examined this possibility. Robyler (1999) found that community college students who enrolled in on-line courses valued control over pace and timing of learning in the course. Wang and Newlin (2000) found that students in a distance-learning course had a higher external locus of control than students participating in a conventional course. Field-dependent students are just as successful as field-independent students in taking an on-line course (Shih, Ingebritsen, Pleasants, Flickinger, & Brown, 1998.)

Research on the personal characteristics of students who enroll in on-line courses compared to students who enroll in live format courses is highly limited and far from definitive. This inquiry addresses this informational void by examining the personality, attitude, and demographic characteristics of students who enroll in on-line classes and students who enroll in live, traditional courses.

Method and Instruments

Participants were Master's degree students enrolled Summer and Fall semesters, 2001 at a medium-sized Southern university. Students registered for one or more of three core courses required for the M.Ed. degree. Each of the three courses had both an on-line and live section. On-line courses were completely on-line as the student and instructor never met physically. Course objectives and content were identical for on-line and live sections. Of the 76 students who registered for on-line courses, 51 (67%) agreed to participate in the study. Of the 80 students who registered for live sections, 69 (86%) agreed to participate in the study. Only two students who elected to take more than one course chose to take one course on-line and the other live. These students were classified as on-line students. Data were solicited the first week of each course. The sample (N=120) was 78% female and the average age was 31.45.

Students voluntarily completed the Sixteen Personality Factor Questionnaire (16PF) Fifth Edition (Cattell, Cattell, & Cattell, 1993) and a brief demographic and attitude questionnaire constructed by the authors. The 16PF is a 185-item, widely used instrument designed to measure personality characteristics of normal functioning adults. The instrument has 16 primary scales (e.g., Warmth, Perfectionism, Privateness, Self-Reliance) and five global scales (i.e., Extraversion, Anxiety, Tough-Mindedness, Independence, and Self-Control). Favorable validity and reliability evaluations are reported by McLellan (1995) and Watt (2000).

The author-designed questionnaire assessed student demographics and attitudes about on-line and traditional courses. Student demographics consisted of gender, age, number of graduate courses completed, employment, and number of miles residence was from campus. Students were also asked an open-ended question as to their reasons for enrolling in either an on-line course or a live course. Ten attitude items were measured on a 1-5 Likert-type scale, where 1 = strongly disagree, 3 = unsure, and 5 = strongly agree. Two-week test-retest reliability of the items averaged .65 and ranged from .51 to .79. Item numbers three ("I am very interested in learning the content of this course") and eight ("I think that the content of this course will be difficult") were excluded from the reliability analysis, as these items were not expected to remain stable, especially within the context of a five-week Summer course schedule.

Results

A multivariate analysis of variance (MANOVA) was conducted to test for 16PF scale score differences between student enrolled in on-line courses and students enrolled in live sections of courses. An overall, multivariate F (21,98)=
1.02, p = .45 was obtained, indicating no between-group 16PF differences. Thus, personality differences were not found between the two groups of students.

Means, standard deviations, and t-test results for the attitude items by group are reported in Table 1. It is apparent from Table 1 that several attitude items differed significantly by group. Students enrolled in on-line courses indicate a higher level of agreement (M = 3.50, SD = 1.01) than live format students (M = 2.39, SD = .84) on the equivalency of on-line instruction compared to traditional instruction. On-line students have a more positive view of on-line courses (M = 4.25, SD = .74) than live section students (M = 3.16, SD = .88). Students in on-line sections indicate that face-to-face interaction is not as necessary for them (M = 3.90, SD = .82) compared to students in live sections (M = 2.34, SD = .92). Finally, the meaningfulness of traditional, live instruction was rated considerably higher by students in live courses (M = 4.16, SD = .85) compared to on-line students (M = 2.70, SD = 1.02). No other attitude items differed significantly by group.

Between-group analysis of demographic items did not reveal any statistically significant differences. That is, students in on-line courses did not differ from students in live courses on gender, age, number of prior graduate courses completed, employment, or number of miles residence was from campus. Analysis of the open-ended question assessing reasons for selecting either an on-line course or a live course revealed that convenience was the reason cited most by on-line students and personal interaction was the reason cited most often by the live section students.

Discussion and Educational Importance of the Study

A result of this study is that the personality characteristics of students enrolling in on-line courses do not differ from students enrolling in live, traditional courses. The two groups of students did not differ on such 16PF scales as Independence, Openness to Change, Self-Control, Extraversion, and Self-Reliance. Higher scores on these particular scales would be congruent with the unique demands of the on-line instructional format. In mirroring the acceleration of on-line courses observed nationally (Hall, Watkins, & Ercal, 2000), this university has been offering on-line courses for three years. Thus, we may be at a point in time where on-line students are personally and demographically heterogeneous.

There were however, significant attitude differences between the two groups of students. Students in on-line courses perceived that format as more equivalent to traditional instruction and had more positive views of on-line instruction than students enrolled in live sections of courses. Also, the latter group indicated that traditional instruction is more meaningful to them and that personal interactions are important in their learning as compared to on-line students.

Essentially, on-line students' perceptions of on-line instruction were more positive than the perceptions of traditional students who viewed on-line instruction with ambivalence. This was true even though traditional students did not differ from on-line students in computer savvy and course expectations. It would seem prudent for institutions to be responsive to the ambivalent views of many students and not adopt a "one size fits all" mentality in planning instructional formats. This seems particularly advisable in postsecondary institutions in which a business model atmosphere could inappropriately define technology as a goal, not a means to an end (Katz, 2001).

A relevant observation in this study was that on-line students did not reside significantly farther away from campus than traditional students. Equally important was the finding that the majority of on-line students reported that the major reason for selecting the on-line format was convenience, not driving distance. These two findings refute the popular notion that on-line courses are a form of distance education and suggest that vigilance be used to avoid over-commitment to students' desire for convenience.

The Learning to Teach with Technology Studio: Demonstration of a state-of-the-art Web-based Professional Development system for teaching K-12 technology integration

Jamie Kirkley, LTTS, Indiana University, US
Carolyn Scholten, LTTS, Indiana University, US

Abstract

In this demonstration and follow-up discussion, participants will examine an existing online professional development system for preK-12 technology integration and explore key issues related to designing this type of a system. One such Web-based system, the Learning to Teach with Technology Studio, will be presented. Following a demonstration of the tool, presenters and participants will examine the following key issues: (1) designing learner guidance and assessment systems; (2) balancing educational theory and practice; (3) building long-term partnerships with teachers; and (4) supporting online peer collaboration and community.

Background

In recent years, Web based professional development has expanded rapidly throughout higher education, corporate training, and the preK-12 arena. Organizations and institutions are increasingly offering Web based professional development opportunities to preK-12 educators. "Increasingly, the Internet makes it possible for educators to choose from a tantalizing array of professional development offerings - at a time and location of their own choosing" (Mather, 2000).

In the past several years, there has been an increasing body of research that highlights how technology can help to improve teaching and learning. (Barab, Hay, & Duffy, 1998; find other references). This has caused increasing demands for technology integration in schools. Recent reports have indicated that eighty percent of teachers report they do not feel prepared to integrate technology with their teaching (National Center for Education Statistics, 1999). Since finding time and resources for professional development in technology integration can be challenging, web based instruction offers a convenient, accessible, and often inexpensive method for updating technological and pedagogical expertise. It also provides opportunities to build a long-term plan for development of technology integration skills in an educational environment that, unlike short-term workshops, provides ongoing learning, mentoring and networking opportunities.

Yet Web-based learning environments are new, and principles for the design of this environment are just emerging (Duffy, Dueber, and Hawley, 1999; Kirkley, in preparation). In particular, supporting practicing professionals in a "learning anytime, anywhere" environment can be quite challenging. Yet it is the design of these types of environments that hold unique opportunities for enabling preK-12 teachers to seek convenient but high quality professional development opportunities to help them meet personal and professional goals.

Examining Issues of Developing an Online Professional Development System

The Learning to Teach with Technology Studio (LTTS) is one example of a Web based professional development system offering quality instruction in preK-12 technology integration. Funded through a five-year grant from the Department of Education's Funding for Improvement in Post Secondary Education (FIPSE), the LTTS is being developed at Indiana University to provide high quality Web-based learning modules emphasizing preK-12 technology integration. Teachers can work towards gaining professional credit units, certification, or graduate credits through partner institutions. Using an e-commerce model, teachers pay for taking modules, and module developers receive royalties.

Modules are designed by exemplary teachers who have experience integrating technology into their own K-12 classrooms. All modules use an inquiry based learning approach. Students are first presented with scenario where a problem or project is posed, and then they produce a product, such as an instructional plan, to address the problem. Problems are ill-structured because there are many ways students may develop and present a solution. Modules are centered on meeting learners' needs, which is critical for an online professional development system for inservice teachers. The LTTS also has a set of personalized tools that support the learner in reaching his or her professional goals.

There are four main issues related to designing a high quality web-based professional development environment. The first issue is developing strategies to provide learners with just-in-time guidance and assessment feedback. Currently most of the instructional design for Web based learning environments uses the information transmission-based model of learning where instruction occurs through written lectures, papers, and online tests. Yet new types of distance learning environments are being called for that promote student engagement using inquiry and
problem solving (Institute for Higher Education, 1999). Inquiry based learning is one example of a learning methodology that creates opportunities for online collaboration and problem solving (Duffy et. al., 1999). Yet supporting learners in an inquiry based, learning anytime environment can be challenging and requires new methods of instruction, scaffolding, and guidance as well as tools to support them.

The second issue relates to how to balance educational theory and practice. From a situated learning theory perspective, the learner is enculturated into a community of practice (Brown, Collins, and Duguid, 1991) where cultural norms, values, communication, and knowledge are part of the interwoven process of learning. Skills, strategies, and learning processes are closely connected to their context of practice (Naidu and Oliver, 1996). Building on the notion of situated practice, LTTS offers educational experiences that help teachers examine issues and develop materials based on their own students, classroom, and teaching context. LTTS is using inquiry based learning to enable teachers to examine questions, problems, and issues from their own context and produce a final product they can use in their own classroom. Modules are designed to help teachers apply theory to their own teaching practices. Yet depending on the educational outcome, there is not always agreement to how to balance theory and practice. This is an important issue to address in order to make professional development meet the needs of learners as well as institutions granting credit.

The third issue deals with understanding how to build long term partnerships with preK-12 educators. For an online professional development system to be successful, there must be strong partnerships established with key preK-12 educational organizations. The challenge is not only in developing these linkages but designing a system that can be tailored to support those needs of these partners.

The fourth and final issue is developing tools and strategies that support online peer collaboration and online community. Peer interaction and collaboration has been found to have a valuable impact on learning. The joint application of the individual efforts of two or more persons to a learning-related task provides students with the opportunity to develop critical thinking skills (Webb, 1989). Also, it can help students develop conceptual change and new understandings (Roschelle, 1992). Although we value collaborative learning, understanding how to support it in an online learning environment is critical to the success of any online learning system. The online learning community that LTTS will attempt to foster is influenced by the environment of instruction, peer and instructor interactions, and tools to support the learning process.

In conclusion, this demonstration will offer participants the opportunity to not only explore an innovative web-based professional development system but examine the key issues related to helping systems such as this one scale up to meet the needs of preK-12 educators as well as other audiences.

European Computer Driving License Online Course for In-Service Teachers and Public Administrators

Karel Kveton
UNESCO International Centre for Scientific Computing at the Czech Technical University - Prague
Czech Republic
kveton@vc.cvut.cz

Abstract: The European Computer Driving License (ECDL) is the European-wide qualification, which enables people to demonstrate their competence in computer skills. The UNESCO International Centre for Scientific Computing (ICSC) and the Czech Technical University specialists developed a first version of an ECDL Online Course in WebCT. This online course is used on a graduate level as well as for lifelong learning of teachers and public administrators.

Introduction

In the next years the Czech Republic is going to be affected by globalization and European regionalization. It will also be exposed to further global scientific and technological development of hardly predictable speed and intensity, which however indicates a number of significant surprises unprecedented in the past. The remarkably intensive internationalization will also affect the field of education. It is necessary to assume a realistic attitude to the future behavior of investors. The investors, big as well as small, expect to find in any country employees and managers who master the newest technologies and highest standards of ICT, who can run operations in branches and lead subordinates, manage the demands of new methods of work organization and who are able to communicate in an international and multi-ethnic environment.

Each of the generations will need a specific conception of lifelong learning with differentiated content, methods and approach. Such education must involve orientation towards long-term individual life planning and support active attitudes to individual employability. The Czech education system will have to change fundamentally to be fully comparable with the successful international systems, their formal aspects, but above all their content and methods.

Example of an ECDL Online Course

UNESCO International Centre for Scientific Computing (ICSC) at the Czech Technical University - Prague and the Czech Technical University specialists developed a first version of a European Computer Driving License (ECDL) Online Course. See http://www.cvut.cz/online, Demo - English version. The ECDL Online Course was developed in WebCT, which is a tool that facilitates the creation of sophisticated World Wide Web-based educational environments. For more information see http://www.webct.com/

ECDL is the European-wide qualification, which enables people to demonstrate their competence in computer skills. Key benefits for you as an individual are that it:

- raises your level of competency in IT & computer skills
- improves your productivity at home & work
- requires no prior knowledge of IT or computer skills
- provides you with an industry recognized qualification
Conclusions

The domestic and international indicators of lifelong learning show that especially our adult education develops too slowly and with poor results. Only one fourth of Czech businesses hold education and training to be the prior component of their personnel policy and the human resources development to be an integral part of their development strategy. Most sectors lack consistent education and training of the staff. The expenditures on education in Czech businesses and other organizations are less than half, compared to the same expenses in the Western European countries. Only every twentieth job applicant participates in retraining. Despite the increasing proportion of older generation in population, there has been no considerable development in their further education.

The above-mentioned reasons indicate an urgent need for a resolute turn. The following measures will be necessary:

- To specify the unclear responsibilities in various fields of adult education and to acknowledge lifelong learning as a key aspect of the national, regional, business and individual development.
- To establish support of lifelong learning using the experience of the successful countries.
- To motivate secondary schools, higher professional schools and universities to a larger use of their educational capacities for further education.
- To devise and implement accreditation mechanisms for educational programs and institutions.
- To encourage building of compatible and accessible databases listing providers of various lifelong learning forms and programs.

UNESCO International Centre for Scientific Computing (ICSC) at the Czech Technical University - Prague and the Czech Technical University specialists developed a first version of a European Computer Driving License (ECDL) Online Course. This online course is used on a graduate level as well as for lifelong learning of teachers and public administrators. See http://www.cvut.cz/online, Demo - English version, User Name "guest", Password "guest".

Diversified Instructional Modality System for Learning Transfer

Doo Hun Lim
University of Tennessee
dhlim@utk.edu

Abstract: Transfer of learning in online learning environment has become an emerging issue in colleges and universities as more institutions try to develop and deliver instructions online. In an effort to develop effective instructional development system to promote transfer of learning in online learning environment, the Department of Human Resource Development at the University of Tennessee has initiated a project called DIMS (Diversified Instructional Modality System) and developed online courses for undergraduate students. This paper will discuss the instructional design, technical, and development issues applied to the system for meaningful and transferable learning experience.

Introduction

Many researchers have conducted studies on instructional factors affecting student's learning, but seldom are found in instructional design factors affecting learning application. Attaining high degree of learning during and after a course is important, but students value such learning experiences that can be applicable and transferable to their personal situations and future careers. In order to satisfy students' needs for learning transfer, instructional designers of online instruction are required to identify appropriate instructional strategies and events that support students' learning and application of learning. The DIMS team was created in 1997 to develop an effective instructional development system to deliver undergraduate courses online. After the startup years to develop the system and four online courses, the DIMS team members recognized that the next step to upgrade the system was adopting instructional strategies increasing students' transfer of learning as well as learning itself. As a result of the speculation, a more diversified instructional modality system was developed and applied to create transferable online instruction.

Theoretical foundation

To identify learning transfer variables in organizations, many researchers studied instructional principles and strategies supporting learning transfer. Some example factors affecting learning transfer found include the principle of identical elements (Baldwin & Ford, 1988), the relevance of the content to the learners' jobs (Bates, et al. 1997), and the teaching of general rules and principles that underlie the instructional content (McGehee, 1961). As an instructional process to promote learning transfer, Gagne introduces nine events of instruction: gain attention, inform learner of objectives, recall prerequisite knowledge, present stimulus, provide learning guidance, elicit performance, provide feedback, assess performance, enhance retention and transfer. Evaluation was another factor to assess and improve instructional quality for better learning transfer through formative and summative evaluation. All these principles and guidelines were considered to develop a comprehensive course development system by the DIMS team.

Instructional Design and Technical Consideration

When the DIMS team was initiated, direct conversion from the classroom instruction to online format was utilized for course development. This method adopted presentation based delivery format (posting slide presentations on the web) because it helped develop online instructions from exiting classroom courses in a speedy and economic way. In 2000, the DIMS Wave II, which was the next generation of the development system, was created. In this system many advanced instructional design considerations and technologies were applied.

To make students' learning experiences meaningful and transferable four major learning principles were applied in the new system. First, self-directed active learning asked the learner to engage in learning content through web interaction. The learner, therefore, was mainly responsible for getting information and knowledge for specific subject area. Instructor guided the learners with carefully planned interventions.
whenever they are needed and considered to be appropriate to enhance students' learning experiences. Second, networked collaborative learning was adopted to promote learners' direct and/or indirect involvement in group activities to augment their learning. Third, to make the networked learning experience successful, the learners were asked to contribute shared knowledge building by active interaction with other peer learners through question/answer sessions, group discussions, and other team based reflective learning processes conducted online. The cyclical knowledge building processes made by all students in each semester eventually have turned into a master course knowledge database that was utilized by learners, instructors, and tutors to enhance instruction later. Finally, to ensure mastery and transfer of core competencies required by each course, learners were asked to develop a plan to apply learning to their works, current studies, and daily lives at the early stage of the semester. The application plan was then evaluated and modified throughout the semester for maximum transfer of learning to occur. By applying these learning principles, the following learning framework was developed.

![Figure 1: Learning framework for DIMS](https://example.com/fig1)

To effectively manage course development and delivery diverse web technologies were utilized. First, Java-based quiz generator was used to develop online tests and quizzes. CGI scripting enabled the use of forms for interactive activities and discussion sessions. Class assignments were also submitted through web forms using the CGI scripts. A database enabled interface system was adopted to present content of group case study and elicit group decision making through group communication and consensus. Streaming and multimedia plug-ins were required to view diverse multimedia learning contents developed for online delivery.

**Outcomes and Future Needs**

As a result of applying valid instructional principles and evaluation standards, the students learning experiences could have been increased to a successful degree. For example, the overall learning increase resulted from the new system was significant when it was measured and compared between the beginning and end of a course. Evidences of a high degree of learning application Trade by the students during the learning were also found. Many students commented their learning experiences were enhanced due to the interactive and supportive features of the delivery system.

As a future need enhance the system and quality of online instruction, the DIMS team is planning to embed a reflective mentoring system in the online instruction delivery. The major benefits of the system include stimulating the processes of analysis, synthesis and evaluation of learning content into students' learning experiences through reflective thinking and mentoring processes. Another issue is improving instructor quality for online instruction. Since those competencies required to teach online classes are different from classroom instruction, instructor development through training sessions is necessary.

**References**

Determining the effectiveness of distance-delivered courses and programs is important not only from an instructor’s perspective, but a necessary function for many stakeholders involved in the support of distance education (DE) efforts. This session will address the various aspects of DE that should be assessed in order to ensure a comprehensive evaluation strategy for distributed learning experiences.

**Problem Statement**

The outcomes of distance education initiatives can provide valuable insights to program effectiveness, as well as justification for program continuance. Unfortunately, the questions that are often asked about DE are either too few or inaccurately focused. For example, one of the common inquiries about distance learning is how it compares to face-to-face instruction. Although prevalent, this question is a poor one, as it is based on the premise that the delivery medium is the only factor that affects learning. The field of instructional technology discourages the use of such “media comparison studies” and offers a variety of solutions for determining the instructional efficacy of DE events.

Besides the effectiveness of the instruction, many other factors contribute to the success (or failure) of distributed learning initiatives. Student support services, technology functionality and accessibility, and participant completion rates are all indicators of the quality of a distance course or program. Cost effectiveness is yet another factor that draws great attention in terms of program justification and continuance. Some institutions expend tremendous monetary resources to create technological infrastructure and student support systems, and as such, must determine if the resources invested produced the desired outcomes. As anyone involved in the implementation of DE is well aware, the complexity of DE systems can make the assessment of such efforts quite challenging.

**Description of solution**

All of the aforementioned issues can be addressed by a comprehensive evaluation program. Such an assessment will require the involvement of various stakeholders in the DE delivery process. This presentation will offer strategies to create a thorough and informative approach to answering the question of quality for distributed learning experiences. Recommendations will be made regarding effective questions and techniques for distance education initiatives so that attendees can implement such solutions at their own institution.

**Outcome**

This presentation will be conducted by a group of faculty who have both subject knowledge of evaluation design, as well as three years of experience in the delivery of an on-line Master’s program in Instructional Technology. The presenters will draw from their experiences in determining their own program’s effectiveness and translate that to a set of generalized evaluation practices. Having to analyze the program that they offer has been informative in terms of defining what is meant by program “success” and what factors affect successful outcomes.

**Relevance to other institutions**

This session will be of interest to many conference attendees, who are likely stakeholders in the success of distance education programs at their own institution. Being able to demonstrate that the heavy resource requirements of distributed learning environments produce effective returns and meet the goals of the institution will likely attract a variety of participants across the spectrum of SITE attendees.
Accessibility for Distance Education

Lisa Katherine Lundy
College of Agricultural and Life Sciences
University of Florida
USA
lkj@ufl.edu

Abstract: As cutting-edge technology enable universities to offer distance education courses to a diverse population, it becomes increasingly important that efforts are made to help students break potential technology barriers to learning. One of these potential barriers is the issue of accessibility, referring to the degree to which a person with a disability can access technology. Students taking distance education courses are required to interact with technology, often engaging in sophisticated use of technology. This also extends to research they might be required to do at a distance, once again requiring the use of technology. For students with disabilities, it is important that instructors and instructional designers consider their special needs and try to adapt the technology in their course so the students will not be at a disadvantage. This project involves the development of a web site to help instructors evaluate the accessibility of their courses and make necessary changes to increase accessibility.

Preparing Teachers for Active Online Learning Environments

Doug MacLachlan, Online Instructional Support
Chinook College, Canada
dmaclachlan@email.cbe.ab.ca

Building a Vision

At Chinook College, we work with both classroom teachers and online teachers, preparing them to create meaningful and interesting online activities and programs for their students. The establishment of an effective professional development path is critical in creating a climate of confidence in which teachers feel supported and competent for the task. Our right on time professional support gives teachers the courage to be innovative, implementing new technologies in their work with students.

As educators create active online learning experiences, best practices from traditional face-to-face interaction must be adapted to the virtual setting. But more than this, students must be enabled to interact with content and community in different ways. Emerging technology tools invite us, demand of us, to consider new strategies for working with our learners.

Online teaching requires a significant cultural shift on the part of teachers and curriculum designers in order to optimize the interactive and collaborative potential of networked activities. (Kearsley, 2000). It may, in fact, require a lengthy process in terms of changing well-developed teaching methods. Teachers often have to adapt to a world unfamiliar to them yet very familiar to their students. Helping educators to make this shift will be a critical factor in the effectiveness of any virtual learning program. Staff development for teachers must prepare them for a role of both coach and resource facilitator whereby they nurture active learners toward participation in their own learning processes. (Kearsley & Lynch, 1994)

Who creates the staff development opportunities when the environment is so young, compared to traditional classrooms? How does a rapidly evolving technological system allow for effective vision-building and skill development? Philip Schlechty (1997) uses the term trailblazers to describe those who take the first steps in systemic change. These paradigm-breakers are the very few who have strong enough beliefs in themselves to pursue their novel ideas, in the face of a lack of belief displayed by the current system.

While there may be a number of trailblazers in a large institution, there is an art to finding and empowering them. The desired systemic change calls for at least a minimum of support and recognition along with the freedom to make and learn from mistakes. Gathering and mentoring those with a love for learning and a pioneer spirit must be done in a manner that is sustainable and purpose-driven. Our experience is that the desired outcome is best realized through a planned staff development initiative. Teachers require a timely support environment in addition to entry points commensurate with their skill level. This is in contrast to drive-by staff development (Senge, 2000) where training is viewed as a one-shot event, disconnected from the essential work of schooling.

In Chinook College's professional development program, educators start at a common point, and then choose their route based on the context of their teaching. Classroom teachers are given support as they create activities designed to enhance the learning experience of their students. Teachers who facilitate courses in our online program are mentored in a different way through participation in a virtual hub, a source of ideas, information, intervention, solutions, tutorial help and modeling. The themes of designing and facilitating online learning are explored in our PD courses, all of which are offered online, within a framework of understandings validated by the most current research. These themes will be developed in the remainder of this paper and illustrated through sample activities from our professional development courses.

Illustrating Themes of Online Learning
Participants in Chinook College's PD courses become online students for several weeks in courses facilitated by one or more trained instructors. By identifying strategies for building an online learning community, teacher-students come to see the range of learning options that support interaction, collaboration, and social presence.

Creating a Community of Inquiry

When teaching and learning migrate from the classroom to cyberspace, there are significant changes in the way that learners interact with the instructor and with each other. Palloff and Pratt (1999) make a case for a new paradigm of education arising out of cyberspace communities. "Key to the learning process are the interactions among students themselves, the interactions between faculty and students, and the collaboration in learning that results from these interactions" (p. 5).

Social interaction in a virtual learning environment has the potential to create a "community of inquiry" in which socially shared cognition takes place and critical thinking skills are practiced (Garrison, Anderson & Archer, 2000). A community of inquiry allows for the critical analysis of subject matter, questioning, and the challenging of assumptions. Such a community consists of three interacting components: cognitive presence, social presence and teacher presence. Cognitive presence describes the relative ability of the learner to construct meaning through sustained communication. Social presence is an emotionally and intellectually attractive telepresence, the degree to which a learner is perceived as a real person in the online learning community. Teacher presence includes both the design and management of the learning sequences, the provision of subject matter expertise, and the facilitation of active learning.

In our professional development courses, a variety of threaded discussions allow teachers to engage one another in meaningful inquiry. Following is a sample exchange over the issue of "cheating" in the online environment. The purpose of the activity is to allow teachers to experience an asynchronous discussion and determine in their own minds the value this form of critical discourse might bring to their work with students. The topic chosen is one that invariably brings out strong feelings from educators and results in some interesting exchanges.

|-----------------------------|--------------------------------|
| A major concern about online learning revolves around the authenticity of student work. What responses would you provide if you were asked "How do we know that the student we are communicating with online really did the work?" |

|-----------------------------|--------------------------------|
| I think that over a variety of assignments including the discussion forums, chat and writing assignments, the student's "voice" emerges. Inconsistencies would certainly show. Bottom line, even with passwords, user names and established processes, the element of trust and the importance of knowing the student are critical. I guess that the same question could be asked about the completion of courses for students who meet face to face- and many of the answers would be the same. |

| I think that after spending time with the student, and getting to know their level of commitment to completing their course, you develop a "sense" of that student, their comfort level and abilities. Hence, you would know their work and be able to recognize any discrepancies. |

|-----------------------------|--------------------------------|
| I agree with Ellie's first statement however, another question emerges. What if a friend or a parent has been doing the course work (chats, discussions, quizzes...) from the beginning. It would be very difficult to distinguish the students "voice". I believe that trusting the students is very important, but establishing a social presence among the students of the online class is just as important as the students' abilities. |

Figure 1: Transcript of Asynchronous Discussion

The postings by teachers in Figure 1 illustrate how conferencing contributed to the growth of a community of inquiry in an introductory online PD course. Garrison, Anderson and Archer (2001) have concluded from their research that computer conferencing lends itself well to critical, practical inquiry. A computer conference will serve as a true...
educational environment if it moves beyond "undirected, unreflective, random exchanges and dumps of opinion." (p. 21). Accordingly, our conferences are directed, focused and mediated if necessary by the facilitator.

Promoting Collaborative Learning

Far too much current training is aimed at short-term knowledge or skills acquisition—dealing with immediate needs (Drucker, 1995). "Learning how to learn" and project-based collaborative learning skills are rarely part of this training, yet these are the kinds of skills that employers say they want and that a knowledge-based economy demands. If individuals do not want to be left behind in the "turbulent, white water systems" of the new economy, they will require constant learning of new information and new skills (Vaill, 1996).

Many educators have discovered the role that technology can play in building collaborative learning group environments (Harasim et al., 1997). One of our professional development activities gives teachers the opportunity to experience the challenges and rewards of collaborating with colleagues electronically. The assignment requires group members to allocate responsibilities, choose a group leader and establish benchmarks for work completion. Each group is allocated a private discussion forum for planning and web space within the course, to which they post their final project as a presentation to the class. Following is a screen capture of one page from one presentation:

![Weird and Wired Online Learning Presentation](image)

Fig. 2 Slide from a group presentation on successful online learning

As we prepare our learners to be knowledge workers, a major focus must be on their ability to work with others in completing a project. Teacher-students not only extend this critical competency to the online world, but are also invited to reflect on their experience, frustrations and all.

Offering Interactivity and Visualization

What is interactivity in the context of an online course? Gilbert and Moore (1998) focus on the reciprocal exchange between the technology and the learner. Using this definition, one might conclude that any assignment is interactive if it involves human or computer-generated response to learner input. Gilbert and Moore do take the argument further, though, citing the factor of "influence" as critical. Interaction, or interactivity (they use the terms interchangeably), occurs when there is an interplay and exchange in which learners are influenced by technology, groups or other individuals.

While the first level of Chinook's PD courses focus on facilitating student learning, the second level provides opportunities for in-depth examination of designing for active online learning. A question we always ask is "what difference would it make if we printed the course and handed it to the student to complete offline?". This speaks to the issue of optimizing the incredible potential of the Internet for interaction and visualization. The fact that our K-12 students are described as the Net Generation creates a whole new pressure and impetus to be creative in our use of technology (Tapscott, 1998). These young people engage with information sources on the net, as well as with other people, then construct higher-level structures and mental images.

One activity in our eDesign course requires teacher-students to collaboratively create a learning activity that will require learner interaction with a micrometer, a device used to measure small objects. An interactive java applet is embedded in a page of the PD course, as it would be in a mathematics course. Teachers are put in virtual groups and
asked to dialogue with each other and come up with an activity that would guide students in their manipulation and exploration of the micrometer. The groups then post their activity for others in the class to critique.

![Micrometer Applet](image)

**Fig. 3 Screen capture of interactive Micrometer Applet**

One of the ideas generated involves: 1) holding up a few different objects (such as coins) to the monitor, then measuring by manipulating the java applet; 2) changing the resolution of the monitor and measuring each object again; 3) finding the ratio of the two measurements for each object and looking for a constant. The process involves both individual and group construction of knowledge, though no physical measuring device is ever utilized. Similar activities are included to address outcomes of other curricular areas.

**Providing for Active Assessment**

Teachers are designers as well as teaching and learning experts. We design learning experiences to lead our students to the achievement of learning outcomes. We modify those learning experiences so that we can be sure that all our learners understand. In addition, we design assessments that enable us to determine whether students have achieved those outcomes.

In creating an activity that integrates ICT (Information and Communication Technology) into curriculum, thoughtful planning is crucial. There are a variety of instructional design models that can help us in planning learning experiences. e-Valuator, a Professional Development course on assessment, invites teachers to design an assessment based on a model called "backward design", described more fully by McTighe and Wiggins in their book, *Understanding by Design* (1998). There are three stages in the process of backward design: identify desired results, determine acceptable evidence, then plan teaching and learning experiences.

The course helps teachers to examine the many issues related to effectively assessing students in online programs and activities. Additionally, they are provided with training in using the assessment tools available in the course management software. One of the directed activities in this course requires the teacher-learners to write a one-page proposal for an ICT activity they would like to design, using the backward design model. In doing so, they must come up with an "essential question" around which the activity is based and decide what will be accepted as evidence that the student has achieved curriculum and ICT outcomes. In other words, how will learning be assessed? Finally, they must write a rationale for the activity, describing where they would use it in their course.

![ICT Assignment](image)

**Fig. 4 ICT Assignment Introduction**

**Conclusion**
Four themes of active learning have been discussed and illustrated in this paper. Several other themes must also be addressed by training initiatives for online educators. Some of these include reflection and feedback, thought-provoking entry points, clear outcomes and criteria for success, choice in process and product, focus on real-world applications and fostering emotional intelligence.

An exploration of changing instructor roles must accompany the hands-on investigation of each theme. Through semi-structured interviews of 20 university professors, Coppola, Hiltz and Rotter (2001) determined that instructors experience role changes in three domains as they move into e-learning environments: cognitive, affective, and managerial. Both online instructors and teachers who choose to include a distributed learning component in their classroom work must recognize and prepare for this crucial transformation.

No medium, in and of itself, will likely improve learning in a significant way when it is used to deliver instruction (Owston, 1997). The important professional development will focus on curriculum opportunities and teaching strategies that will improve learning by bringing the power of new technologies into the daily life of the classroom, virtual or face-to-face (McKenzie, 2000).

Abstract: This paper describes a professional development path designed to support teachers as they shift from the traditional teaching environment to one that incorporates a virtual component. Several key themes of designing and facilitating online learning activities are discussed, in the context of preparing teachers to take on these roles. Each theme will be illustrated through sample activities from online PD courses and will also be discussed within a framework of understandings validated by current research.

Remote Assessment Methods for Deaf and Hard-of-Hearing, On-Line Learners

James R. Mallory, MS, Associate Professor
Applied Computer Technology Department
National Technical Institute for the Deaf
Rochester Institute of Technology
United States of America
jrmnet@rit.edu

Abstract: One challenge with online, remote teaching is properly evaluating the learner's knowledge in a fair, secure and efficient manner. Many teachers are apprehensive about online testing for a variety of reasons. One cannot touch upon the issue of remote assessment without also getting into the issue of ethics on the part of the student audience.

When implementing a testing method, factors such as security, ease and timeliness for data collection, ease of use by the students, turn around time and feedback to the students, flexibility of how the testing is done and administration/implementation are but a few of the issues that one should consider when implementing remote testing, whether the audience be deaf, hard-of-hearing, or hearing.

Introduction

Asynchronous, remote, online learning (also referred to as distance learning, e-learning, virtual learning, etc.) has evolved over the past 20 years in secondary education and is now rapidly growing. Much of this growth is due to increased Internet access speeds and new demographics of remote students who are enrolling in these types of courses. This same evolution is also occurring with the deaf and hard-of-hearing population. RIT, one of the largest providers of online learning classes in the U.S., enrolls 30 to 50 deaf and hard-of-hearing students each quarter into their online courses.

The growth of this online type of instruction brings with it a host of other issues, among them being the assessment of the learner's knowledge and the ethical practices of students taking these assessments. Although online assessment is available, traditional on-campus teachers do not readily embrace it like online learning teachers do for a variety of reasons. There are various commonly shared concerns by faculty using remote assessment methods. Some of these issues are covered in this paper, along with three proven methods of remote assessment used at RIT.

The Study

The findings reported in this paper were based on assessments used during RIT academic quarters and on surveys given to students at the end of the quarter in actual classes taught by either the author or by other RIT faculty. Data includes feedback from traditional, on-campus as well as distance learning deaf, hard-of-hearing and hearing students. Opinions, experiences and statements from various RIT faculty and distance learning technical administrators are also considered in the findings described in this paper. These assessment methods were used to not only evaluate the students' knowledge in the traditional or virtual classroom, but also to conduct preliminary research in an attempt to enhance distance learning specifically for the deaf and hard-of-hearing population. The “findings” are thus tentative and provide suggestions for more formal research in this area.

Three assessment methods used at RIT/NTID are remote proctoring, web-based testing through multiple choice and fill-in questions, and downloading and uploading answers using electronic conferencing software.
1. Remote Proctoring Testing Method

With this method, a remote proctor, (usually the student's supervisor, manager of an office area, library or other establishment) administers the exam and then collects it and submits this to the online learning office via FAX or US Mail. The exam is usually a traditional paper format where the student fills in the appropriate answers. The tests can be open book or closed book, and a time limit can be established if appropriate. Upon receiving the test from the instructor, the online learning office then forwards the test to the proctor. The proctor has signed a contract with the online learning office agreeing to certain terms. This testing method provides as much flexibility as the traditional paper tests handed out in a traditional class.

2. Web-Based Testing Through Multiple Choice and Fill in Questions

This is the method the author prefers to use after six years of delivering online instruction to deaf, hard-of-hearing and hearing students and experimenting with the three methods described in this paper. In this online testing method, the instructor develops a number of questions, usually in a multiple-choice type of format, and posts this on a virtual system or web site with protected access. The students log in to the site with their own unique username and password and take the test. The student has to select the correct answer from a list of potential solutions.

There is a way to also incorporate essay types of questions into these tests with systems such as Ideatools® if this feature is needed. Ideatools is a turnkey, Web-based course development system developed by Simon Ting, an instructional developer at NTID. Ideatools is currently a local application that has some unique features lacking in commercial products. The trademark for Ideatools is currently pending. For more information about this system, contact Simon at his email address: SKTNMP@rit.edu.

When the student finishes answering all of the questions to his/her satisfaction, he/she then presses the submit button and the test is automatically posted in the administrator section of the site and the multiple-choice questions are automatically graded. Open-ended questions need to be graded individually by the instructor by accessing each student’s test individually.

This Web-Based testing could also be combined with a lab assistant or other proctor to add another layer of security if the teacher felt it was needed as described in method 1 above.

3. Downloading and Uploading Answers Using Electronic Conferencing Software

In this method, a test template is developed using a common software format such as Microsoft Word. This template is designed so that the students can download the test from a folder in the electronic conference, type the answers to the questions directly into the template and then upload the exam to the secure conference drop box during the allotted time period. FirstClass® conferencing software was used by the author and a number of his RIT colleagues to evaluate this method of assessment.

Findings

The most prevalent teacher concerns with any remote type of assessment seem to be: the integrity issue of whether a student is actually taking the test himself/herself and is not getting help or is not really someone else; the teacher's discomfort with the technology; conceptual limitations of the assessment; ease of use of the technology by students; how easy and how timely data collection will be; how difficult administering the testing will be. These issues will be discussed as they relate to each type of remote testing method below.

1. Remote Proctoring Testing Method

Remote proctoring seems to be the most secure of the three methods and allows the maximum flexibility for asking questions in a format that does not limit the teacher in a conceptual way. Instructors can design the tests in the manner they have been accustomed to with no limitations. The only thing to keep in mind is that students cannot ask for clarifications. Mistakes in the test cannot readily be clarified for the students, so tests should be as clear and as error free as possible.
One pitfall of this type of assessment could be the lack of integrity of a proctor, which from the author's experience is rarely an issue. Normally a professional person with visibility and accountability within a company or a public service sector normally sings the proctor contract and actually proctor's the test. Another downside could be if remote students knew each other, took the test at different times and clued each other in on the content of the test. This could happen since this testing is asynchronous (students take it at their convenience as arranged by the proctor). Several years experience with thousands of students and faculty at RIT has shown that these issues are rarely a problem.

Another pitfall from an instructor/student perspective is turnaround time. There is usually at least a one-week window between the time the instructor submits the test to the online learning office for dissemination to the time it is graded and returned to the student. Tests seem to trickle into the instructor's traditional paper mailbox using this method. Grading has to be done manually one test at a time similar to traditional classroom exams. This slow turnaround time is often annoying to the remote student who is anxious for prompt feedback.

2. Web-Based Testing Through Multiple Choice and Fill in Question Method

This is the most time efficient way of distributing, grading and providing feedback to the students, but it is also the most limiting conceptually. Most of the work for this kind of testing is done up front developing the exam to fit the online format. An exam has to be designed in a format that fits properly on the computer monitor when viewed through a web browser. The author chose NTID's IDEA Tools designed by NTID developer Simon Ting to implement this, although there are many other products on the market that would work fine for this task.

Multiple-choice types of questions are ideal for this type of system. There are also ways to incorporate fill-in types of essay questions, but they are much harder to grade and immediate student feedback for fill-in questions is not possible due to the way in which these are graded and the automated nature of reporting the results. There are usually automatic grading instruments that will provide timely feedback to a student on how they did as soon as they complete the test or at a time designated by the instructor. Different weighting of questions is often difficult to achieve with these systems, so it is easiest to design an exam where each question is worth the same number of points.

Students enjoy the prompt feedback from this kind of assessment system, but this feedback may not incorporate a curve or a slight change that the instructor may have added after the test was posted. Again it is advisable to have the test as error free as possible once it is posted.

Another logistical item to pay attention to is that spacing sometimes changes once it is viewed on the web through a browser. The instructor could design a perfect, error free test in Microsoft Word, but once it is posted on the Web and viewed from a browser, it may look slightly different. The author has experienced several situations where one space or a shifted character could determine whether the output to a computer programming question is correct or incorrect, and this has become an issue.

Each question must also be limited in size so that the sample code and the output choices all fit on the monitor screen. If there are several multiple-choice answers for a particular section of programming code for example, the students need to be able to see the original code for each answer that is provided. If the questions were not designed correctly, the user would have to scroll up and down to view the entire question and all of the corresponding answers.

The online method is a great way to test students who are not able to take advantage of the proctor system, such as technicians who are out in the field, people who work swing shifts, or independent consultants who travel frequently or are stuck in remote geographical areas. It is also a great way to combine and compare the results of on-campus students to remote students. During one quarter, the author was able to test traditional, on-campus, college aged deaf students along with a group of 15 hearing Pittsburgh Telephone company technicians using the same online testing method and compare their results. The deaf students took the test in their department's lab while being proctored by a lab assistant and the remote students took the test independently on their own. The results of the two groups were similar.

3. Downloading and Uploading Answers Using Electronic Conferencing Software
This method is fairly secure for remote testing, because the electronic conference can detect which student downloaded the test, at exactly what time the test was downloaded and what time the test was submitted back to the conference. Tests uploaded to a drop box are very secure, because only the teacher can read each of the tests. The advantage to the student is that they can view their submission details to assure that the test was received by the instructor and see the time and date at which it was received as well as when the teacher viewed and downloaded their test to grade it. FirstClass™ was used for the electronic conference of choice for the author’s study.

Teacher Opinions and Issues with All Types of Remote Assessment

Whether talking to a teacher or doing a literature search, the issue of audience integrity frequently arises when the topic of remote assessment comes up. For this reason, many online teachers also choose to include authentic assessments such as student projects, group projects, term papers, portfolios of student work, and so on to determine the overall grade of a student for a given course.

One NTID faculty member, Dr. Greg Emerton, summarized what the author has found to be typical faculty concerns using online testing in a traditional classroom. Greg opted not to use computer testing for some of the following reasons: "I do my exams in class to maximize control of the testing situation." G. R. Emerton (personal communication, May 22nd, 2001) This security issue is probably the most prominent concern in online testing when talking to most teachers. Another faculty member, Dr. Marc Marschark, states his opinion of online testing. "I was concerned that if I had students answer essay questions online, they might be getting assistance (my tests are 'open book' -- not 'open friend'). Of course, that's no different than would be the case for take-home exams...but I never use those." M. E. Marschark (personal communication, May 22nd, 2001) Emerton also was concerned about the conceptual limitations of online testing. "My exams typically consist of a mixture of true/false and multiple choice questions and a number of short answer essays will allow the individual student to express what he or she knows about the topic. Reading across all of the answers for a given question also gives me a better sense of how the class is responding than scoring individual tests." This particular concern could easily be addressed by any one of the three remote assessment models previously described.

The responses of professors Emerton and Marschark are not uncommon. They are both master teachers and have many years experience teaching deaf and hard-of-hearing students at the post-secondary level. Their mindset is common among secondary and post-secondary instructors that the author has had a chance to interview.

Authors Findings on Remote Student Testing Integrity

The author has periodically allowed selected groups of on-campus students to take online tests both remotely on their own as well as in a controlled lab environment with a proctor present in his C++ and Visual Basic (VB) programming courses. Overall there was virtually no difference in the selected students' test scores, whether they take the test in a class or remotely on their own. Plenty of students have done poorly in their remote testing, when they could have easily booted up their computer and copied and pasted the program into a VB or C++ compiler to get the correct answers.

Distance Learning (DL) students' responses on remote tests also indicate that they did not cheat, as they could have easily uncovered the answers using the same computer that they were using to take the test. As a whole, DL students tend to do better, but according to the author's survey findings, this was because of the students’ age and work ethic rather than due to the fact that they are using remote testing.

Authors Findings from Student Surveys

For the past two years, the author has collected data from deaf and hard-of-hearing students who participated in both on-campus and DL classes in an effort to better understand the advantages and disadvantages of the DL format and delivery and assessment methods for deaf learners. There is very little data or information currently available about deaf, online learners themselves and how useful online assessment is to their overall learning. The presence of the National Technical Institute for the Deaf (NTID) on Rochester Institute of Technology’s (RIT) campus with 30 - 50 deaf and hard-of-hearing students
enrolled in Distance Learning (DL) courses each quarter provides an opportunity for examining these DL learners.

Because of the author's interest in the topic and the lack of information available, two questionnaires, with overlapping items, were developed to obtain deaf students’ perceptions of the DL experience and to gather data on the work ethic and other characteristics of these students. (Mallory & Long, 2001). One questionnaire was general to all RIT DL students (of which 20 out of 33 responded) and a second was specific to computer programming courses taught in the Applied Computer Technology Department on campus (of which 19 out of 26 responded). This paper focuses on the work ethic and assessment parts of these questionnaires for the fall, 2001 quarter. This questionnaire consisted of 35 items, (12 demographic, 6 open ended, and 17 Likert items) which asked students to rate the importance of various instructional components for their overall learning. Students were asked to rate course components on a five-point scale from “not important at all” to “very important”. They were also asked demographic and other types of questions, such as how old they were, what their communication preferences were and how many hours per week they spent working on this course. (Mallory & Long, 2001)

Within the ACT department, DL students put substantially more time each week into course preparation. For the ACT programming courses, 100% of the DL students put in at least 11-15 hours per week or more into the course each week, with 33% putting in 11-15 hours, 33% putting in 16-20 hours and 33% putting in 21 hours or more each week into course preparation. Their on-campus peers did not even come close to the same work ethic, with 35% putting in 1-4 hours, 59% putting in 5-10 hours, 6% putting in 11-15 hours and nobody putting in 16 hours or more per week.

Conclusions

Online assessment has become the model of choice for most remote teaching faculty at RIT and elsewhere throughout the country. This method of assessment is slowly gaining acceptance into the traditional classrooms for the deaf and hard-of-hearing in a variety of NTID classes as a viable alternative to traditional paper test taking. There are always trade offs, of course, and there are still things that traditional campus test taking can do that remote testing cannot. The application of these remote models depends to a large extent on the student population that it is serving and the comfort level of the instructor using this technology. A less mature audience or students with certain learning disabilities may not be a good fit for this type of assessment.

The evolution of traditional classroom teachers to online testing is growing slowly. It is often more work and not worth it pedagogically for teachers in traditional classrooms to change their method to a more automated way of assessing students. Online or distance learning instructors are more enthusiastically adapting these models.

Most teacher concerns are due to a lack of knowledge and experience of what remote assessment can actually do. These teachers do not have or are unwilling to spend the time to convert and debug their testing methods to an online format.

Abstract: Electronic Conferencing (also referred to as groupware) has become a frequently used tool in both on-campus and remote online learning classrooms. NTID faculty members have gained valuable experience with several electronic conferencing software products. The wide variety of class demographics covered in this paper included all deaf, all hearing and deaf/hearing mainstreamed student audiences in both traditional and on-campus, Distance Learning, and hybrid types of courses, with both traditional-aged college students and adult learners.

Introduction

College students today are constantly on the World Wide Web and regularly checking their email on the Internet. In fact, the United States as a whole is headed this way. The number of Americans with online access has more than doubled from 45 million users in 1998 to 105 million users in 2001. Of Americans with Internet access, the percentage of online users with home broadband access has grown from 6 percent in December 1999 to 19 percent as of September 2001. (Mount, 2001, pp. 44-45) In education and industry, email usage has increased also, as has the use of electronic conferencing. The number of email messages sent by America Online users on the busiest day of the year jumped from under 50 million in 1998 to just under 300 million in 2001 (Mount, 2001, pp. 44-45). Although the authors were unable to find minimal usage statistics in electronic conferencing, it is increasing in the same proportions.

This paper focuses on the use of electronic conferencing in the education arena. One author, Kathryn Schmitz, teaches English. The other author, James Mallory, teaches computer programming. Both authors have experience using Blackboard Conferencing, and one author has extensive experience with First Class and the other author is a relatively new user with Prometheus in the classroom. This paper is intended to give the reader a balanced perspective from both a new and experienced teacher/user perspective as well as using electronic conferencing to deliver technical and non-technical courses both in the traditional on-campus manner and in an online format.

The Study

The author's combined anecdotal experience derived in this paper comes from teaching deaf students in a traditional classroom setting and hearing, deaf and hard-of-hearing students in remote online learning classrooms. Data in this paper will come from students directly taught by each of the authors as well as information that was derived from a survey of deaf and hard-of-hearing online learners. The experiences reported in this paper were conducted in search of ways to enhance on-campus and distance learning courses for deaf and hard-of-hearing students. The "findings" are thus merely suggestions for more formal research in this area.
Collectively, the two authors teach 80 to 100 deaf and hard-of-hearing on-campus students each quarter. One author teaches computer programming and the other teaches English to this similar population.

Each quarter RIT averages 30-50 online learners who are deaf or hard of hearing and enrolled in a variety of technical and non-technical classes. One hundred percent of the on-campus students and 85 percent of the deaf and hard-of-hearing DL students described in this paper had access to high-speed Internet connections. Of the online students, 60 percent were deaf and 40 percent were hard of hearing. In this group, 45 percent of these students stated that English was their first language, 45 percent reported that ASL was their first language, and 10 percent stated that a language other than English or ASL was their first language. For the on-campus population, 63 percent of the students reported that English was their first language, 26 percent stated that ASL was their first language, and 11 percent of these students stated that a language other than English or ASL was their first language.

Findings

Integrating Electronic Conferencing into Remote Online Classrooms

Conferencing is crucial in a remote classroom because this contact is the forum where students get to know their instructor and one another. Students reveal their personalities, helping to form an online community, which then helps to make challenging technical courses more palatable and improves retention. Conferencing is crucial when information needs to be shared in an asynchronous, "anytime, anyplace" manner. The drop box feature of conferences lends itself easily to secure submissions of homework assignments.

Integrating Electronic Conferencing into Traditional Classrooms

Conferencing has improved many on-campus courses as well. The online community interaction helped to remove communication barriers between deaf and hearing students and faculty. Passive students who are often dominated by their more aggressive peers in traditional classrooms frequently blossom in an online environment. Different course sections that share common course content have been successfully blended by combining remote hearing and deaf professionals with on-campus traditional college-aged deaf students through electronic conferencing. Students enjoy the luxury of access to course materials and information on a 24-hour/7-day-a-week basis.

Types and Categories of Electronic Conferencing

Of the two categories of groupware used in online learning, one uses Web browsers and the other uses a separate client program. The web browser approach to groupware, such as Blackboard™ and Prometheus™, is often referred to as a "thin client" product. The groupware product that uses separate client programs, such as FirstClass™ are referred to as a "fat client" type of product. Web browsers are ubiquitous, and for most students who are new to online learning, the thin client approach has the advantage of employing a familiar tool with generally familiar navigation. Fat clients on the other hand offer more features and may be faster in some aspects.

Among the most popular fat client products used today are FirstClass™ and Lotus Notes™. Among the most popular thin client products are Prometheus™, Blackboard™, and Web CT. This paper focuses on the experience of the author with three products, Blackboard, FirstClass, and Prometheus. These three products will be compared via survey results from students, faculty, and administrators.

Blackboard

Blackboard 5™, the version of this e-Learning software currently in use at RIT, is easy for students to learn and use. Students use their RIT username and password to log on to the system to access any and all Blackboard-enabled courses for which they are registered. From this common "Courses" page, they can link to a catalog of all Blackboard courses on the campus, to a web search engine, or to the main page of a specific course.

The main page of the course presents them with announcements and a teacher customizable menu of buttons that link them to course documents, assignments, online assessments, a synchronous virtual
classroom, and a variety of communication and support tools. A course map button gives students access to a schematic of the entire contents of the course web site that can be expanded to whatever level of specificity the student requires. Special areas can be created for study groups which are accessible only to group members and the instructor. These include a discussion board, group virtual classroom, file exchange capabilities, and email. Students can also easily create their own web pages, which allows them to express their individuality and share their interests with others in the course. One of the features that students seem to especially like is access to the grade book.

In addition to the “Courses” page, Blackboard offers students two other pages, a “Community” page with a calendar and open discussion board for use by the larger campus Blackboard community, and an “Academic Web Resources” page where students and faculty can access current news, information, and full text articles in a variety of disciplines.

Blackboard is also quite easy for the instructor to use and customize by accessing a variety of functions from the instructor’s control panel. Course materials in almost any format can be uploaded with the click of a button. Several textbook publishers provide course cartridges that integrate their materials into the Blackboard program. Email can be sent to selected students or to all students with a mouse click. File exchange between student and teacher using a drop box is another useful feature. A pool of test questions can be created, and unique online assessments constructed from the question pool with only a series of point and click maneuvers. The instructor has complete control over the accessibility of online assessments, including whether or not they are timed, can be taken more than once, and if the students are allowed to view their errors and the correct answers after completing the assessment. The program scores the test and enters the scores automatically into the grade book, a feature that makes online testing attractive to both faculty and students.

Blackboard Negatives

The speed and robustness of a student’s Internet connection is a potential constraint on use of an interactive browser-based program like Blackboard. Students with slow dial-up modem connections may have problems viewing or downloading graphics intensive material or even navigating through the course. Students may lose their connection for a variety of reasons, including problems with the dial-up service, and be blocked from accessing a “one attempt” test. Although an indicator appears in the grade book alerting the instructor to an aborted test, there is no way to know if the disconnect was an accident or if the student was trying to get a peek at the test before actually taking it. Students who do not own a personal computer will need to access course materials from a campus lab computer. This may put them at a slight disadvantage to students who have 24/7 access. Finally, while Blackboard is relatively easy to learn, there are a few features that can be confusing. The drop box has two buttons - “Add file” which saves the file to the students own drop box, and “Send file” which sends the file to the instructor. A common error is for students to think they sent their instructor a file when they in fact have only saved it.

Prometheus

Prometheus™ is relatively new and has been available at RIT for about one year. The last time the authors checked, there are more than 30 colleges and universities using Prometheus, compared to more than 1,400 using Blackboard™. Prometheus includes almost all of the same features as Blackboard, noted above, with a few differences.

Prometheus is developed with Cold Fusion, an open-source code, which makes it attractive if the student user needs a customized solution. The product’s open-source code allows the subscribers to modify their installation, and the community of Prometheus developers can then share enhancements they have made to their installation. The user community associated with Prometheus will have a lot to do with how successful the open-source code concept will be. Time will tell if the developer community can be effective in developing, testing, and delivering coherent improvements quickly and safely.

One of the most important features of Prometheus are course modules that allows the instructor to teach multiple sections of a course while managing only one set of course materials. The ability to provide direct URLs and link to files within and without the system enhances the provision of information resources. Prometheus also has a mathematics editor so the teacher can enter equations and symbols directly into the system. In addition, the text editor includes various colors and fonts.
Prometheus Negatives

Among the product features, the “Discussion” tool has been heavily criticized for being difficult to navigate. RIT has made a few changes to their installation to improve these difficulties, and more changes are expected to come. Uploading files to the instructor from within the drop box function can be confusing to new users, but that too is being improved. A significant negative to this system is how new material is flagged as unread. The system indicates which section the new material is posted in by showing a small blue circle with a letter in it, such as F for Files or O for Outline, in the user’s main page, but upon clicking on the circle, the user is only taken to that section of the system, not right to the new material. In the case of the course Outline section, the user is shown the entire list of sessions with no indication of which one has new material.

Compared with Blackboard, Prometheus’ visual appearance is busy and crowded. Course announcements are presented on the login page, not the main page, which students frequently miss in the process of getting right into the course materials. At this time, the text editor in Prometheus does not include a Track Changes feature such as MS Word offers, which would be useful in editing student essays online. In addition, the system has difficulty running movies smoothly at times, even with broadband access.

FirstClass

FirstClass™ has an online chat feature similar to the previously two mentioned software products, which works well for occasional synchronous chats. If a student is not able to participate in the chat, then the discussion can be posted within the conference for later usage.

This system’s folders and sub folders are great for organizing and storing items that don’t need to be discussed, such as submitted homework and exams. Conferences and sub conferences are ideal for interacting on a topic or for dividing up topics that need to be discussed or shared. It is easy to change permissions in FirstClass so that only a certain student group can access the information in a certain sub folder.

The authors found the permission feature useful when combining both remote online courses with traditional on-campus courses into a common conference. As an example, in a C++ programming class at NTID, the on-campus students had a weekly quiz, whereas the remote students only had three tests per quarter. One sub folder was accessible for remote online students only, and another was limited to only the on-campus students. When demo instructional programs were posted, these were posted in a folder that was readable by both of these populations.

FirstClass Negatives

The fact that FirstClass is a fat client type of product requires the user to load the software on each computer that he/she wishes to use. Some students find this to be inconvenient, especially if they are required on their job to work on a variety of computers or if it is an on-campus student and the particular lab they are using does not have FirstClass loaded. The web version of FirstClass is not as functional as the client version.

One must maintain relatively flat folder architecture due to the way in which FirstClass flags messages. A red flag attached to the message indicates a message has not been read. This flag only propagates up one level, so if a folder is several levels down, a newly posted message would not be readily evident. If a folder structure is deep, the red flag would not be seen when a student or instructor first logs into the conference. Another negative using this software is if a message is already marked as read and the instructor wishes to move this message to a sub folder, the message will be moved and pop up as being unread again.
Conclusions

Electronic conferencing is a useful tool in both the on-campus and online classroom. When combined with the other strategies and tools in the classroom, the authors found electronic conferencing a wonderful communication enhancement which leveled the communication playing field and opened up the classroom. It also promoted personal responsibility on the part of the students, who could not so easily claim that the course resources were not available to them since they all were already online 24/7.

In general, the authors found First Class to be a bit more challenging in the beginning to get everything set up and get students rolling, but easier to use and manage once it was set up. Prometheus was easier for students to learn upon startup, but the inadequate flagging of new material made it difficult for the instructor to be sure that students saw new homework assignments or revisions to the course syllabus or outline.

Evaluating the Effectiveness of Online Instructional and Delivery Technologies for Deaf and Hard-of-Hearing Students

James R. Mallory, MS, Associate Professor
Applied Computer Technology Department
jmtnet@rit.edu

Gary L. Long, PhD, Associate Professor
Research Department
glIerd@rit.edu

National Technical Institute for the Deaf
Rochester Institute of Technology
United States of America

Abstract: This paper summarizes the authors’ findings for student ratings of the variety of instructional technologies used for RIT’s online learning courses and discusses implications for deaf and hard-of-hearing learners. The authors have been using varied technologies for delivering instruction and interacting with both on-campus and Distance Learning (DL) classes for many years with deaf, hearing and hard-of-hearing students. Some of the technologies used include electronic conferencing, VHS tape and web-streamed videos, web based instruction with text and graphics, digital video conferencing, multimedia desktop capturing simulation, sample source code and executable programming examples and Windows Media Player.

Introduction

For the past two years, the authors have collected data from deaf and hard-of-hearing students who participated in both on-campus and DL classes in an effort to better understand the advantages and disadvantages of the DL format and delivery methods for deaf learners. There is very little data or information currently available about deaf, online learners regarding which components of online learning are important for their mastery of course material. The presence of the National Technical Institute for the Deaf (NTID) on Rochester Institute of Technology’s (RIT) campus with 30 - 50 deaf and hard-of-hearing students enrolled in Distance Learning (DL) courses each quarter provides an opportunity for examining these DL learners.

Because of the authors’ interest in the topic and the lack of information available, two questionnaires, with overlapping items, were developed to obtain deaf students’ perceptions of the DL experience. One questionnaire was general to all RIT DL students and a second was specific to computer programming courses taught in the Applied Computer Technology Department on campus. This paper focuses on the questionnaire for all of the deaf DL learners at RIT for the fall, 2001 quarter. This questionnaire consisted of 35 items, (12 demographic, 6 open ended, and 17 Likert items) which asked students to rate the importance of various instructional components for their overall learning. Students were asked to rate on a five-point scale from “not important at all” to “very important” the following course components:

1. Testing and Interactions
2. Groupware Conferences
3. Web, Textbook and Instruction, Videotape
4. Homework and Interactions

A sample of the online survey can be seen in (Fig. 1) below.
Please indicate how important each of the following course parts was for your overall learning in this course. Please read the entire list before rating items.

Figure 1: Likert Question Samples from the RIT Online Survey

The Study

Procedure
Thirty-three students with a declared hearing loss enrolled in online learning courses taught at Rochester Institute of Technology (RIT) during the fall, 2001 academic quarter. Twenty of these students responded to a 35-item questionnaire that was administered online at the end of the quarter. Respondents were entered into a lottery and two individuals were randomly selected and received a $25.00 gift certificate for their participation.

Subjects
Participants were volunteers who were enrolled in graduate (30%) and undergraduate (70%) courses at RIT during Fall Quarter 2001. Approximately 35% of the students were enrolled in applied science/computer science courses, while the remainder of the students, (65%), were enrolled in liberal arts or business courses.

Sixty percent of the respondents considered themselves deaf while (40%) considered themselves as hard-of-hearing. An equal percent of respondents indicated that their first language was English (45%) said that their first language was American Sign Language (ASL) (45%). Ten percent of the sample was deaf students who indicated that a language other than English or ASL was their first language.

Findings
As a group, the respondents were not new to online learning and expected to do well in the present class. Seventy-five percent of the students had participated in a DL course prior to this one and 65% of the students indicated that they had used electronic conferencing before. Eight percent of the students expected to receive either an A or B in the course they were evaluating.
Communication

Instructor and student comments posed on an electronic conferences were seen as important or very important for students' overall learning by (80%) and (70%) respectively. The following comments from students further clarify how the electronic conference was important for their learning.

"Everyone has a different insight of quality management. The students that I am in class with has different background in their job, when they share their experience, you can see overall that not all management is the same or effective."

"I like this course because it is easy to communication with teacher and student at anytime, I mean 24 hours a day to contact him instead of sign up on the door to see him in person."

"Very effective and simple. I have a problem, immediately contact the teacher and will hear from them asap!~ I love it!" (Mallory & Long, 2001)

Sixty-five percent of the students indicated that the textbook or materials developed by the instructor were important or very important for their overall learning. Similarly, (60%) of the respondents indicated that a reference book was important or very important for their overall learning. Less traditional approaches for delivery of instruction web text, and graphic-based explanations, were rated as important or very important for overall learning by (40%) of the students. Lastly, feedback on the class tests was rated as important or very important for learning by (50%) of the respondents. These ratings take on more meaning when the following student comments are added to the total picture:

"It's a wonderful textbook."

"Online quiz can be taken over till you get 100%." (Mallory & Long, 2001)

Homework

A real strength of online learning seems to be the availability of feedback/comments related to homework assignments. Eighty-five percent of students felt that teacher's written explanation of homework was important or very important for their overall learning. Seventy-five percent of the students perceived online interaction/comments by the instructor and fellow classmates as important or very important for their learning from homework.

Deafness and Distance Learning

When asked, "What did you like about distance learning," 35% of the students indicated that the flexibility and pact of the learning were attractive features. Examples of these comments are:

"The flexibility of doing things on my own pace, with a time frame."

"I can do this on my own time, it frees me from having to go to boring classes."

"...going at my own pace is excellent about distance learning, and it makes my schedule more flexible not requiring class attendance." (Mallory & Long, 2001)

Thirty percent of the respondents indicated that one of the advantages of distance learning for a deaf or hard-of-hearing learner is the ease of communication. These student comments are illustrative:

"ability to communicate freely without barriers."

"Everything is text based and hearing isn't a problem."
"freedom of participation" (Mallory & Long, 2001)

The following statement by graduate student presents a direct comparison of the traditional classroom and the distance learning format for a deaf learner:

"I think I am a natural distance learning student! For my bachelor's I was in terrible shape since I couldn't really follow what was going on in the classroom. I didn't know enough sign to really understand the interpreters, the material moved too fast for me to get it from the instructor, so I felt I was a bad student and so on, so my GPA was horrible even though I honestly worked hard. I was lucky to have graduated with a 2.5 GPA. Now through distance learning I get the exact same material presented in the exact same way as everyone else in the class, hearing or deaf. It makes no difference, and I am able to make a positive contribution. I'm much more confident because I don't have the doubt that I'm missing something just said. For my Master's I have a 3.9 GPA, my sole B was, ironically, not a distance learning class but in a classroom, and on top of that without an interpreter available, and with a lot of classroom discussion. So I doubt I'll take an in-class course if I can ever help it." (Mallory & Long, 2001)

Finally, when students were asked, "What did you not like about distance learning?" thirty-five percent of the students said "nothing." The remaining comments focused on feeling more isolated in the distance learning format:

"No class discussion."

"I missed the interaction with teacher and peers on RIT campus."

"Students in telecourses sometimes feel isolated ... sometimes miss the real-timing face-to-face interaction." (Mallory & Long, 2001)

A couple of students mentioned that a distance-learning student needs to be disciplined:

"I do not have the discipline for it."

"Having to check FC on more than a daily basis. Too many things were done last minute and I couldn't keep up." (Mallory & Long, 2001)

Conclusions

This paper verified the preference that deaf students have for most aspects of a virtual, asynchronous type of classroom over a traditional on-campus classroom. Many RIT students saw the "flexibility" of the DL format as its most positive aspect. This perspective was reflected by one student who said "I like being able to do the homework and tests when I can." Other deaf students pointed to increased ease of communication allowed by online learning, "I like to sit by my computer and discuss with the teacher as much as I can, compared to the classroom where I will have to listen to the professor and have a limited time to discuss." (Mallory & Long, 2001) Frequently the asynchronous aspect of DL learning is mentioned as a preferred means of gathering knowledge and communicating.

The results from this paper with deaf and hard-of-hearing online learners in many ways is consistent with findings by Long and Richardson in a study at the Open University, London, England with approximately 200 deaf and hard-of-hearing adult respondents. (Long & Richardson, 2000) The English deaf and hard-of-hearing students were older, average age of 50, compared to this paper’s study where 45% of the students were 23 years old or less, 35% were 24 – 30 years old, 20% were 31 – 40 years old and 0% were over 40. In the Long and Richardson study, deaf learners were positive about the flexibility and pace of the online learning environment. Deaf learners also pointed to the ease of communication in this environment as compared to a more traditional classroom setting. In some ways, it appears that this instructional format helps "level the playing field" for deaf learners.
One of the potential side effects discovered in the England study which was not found to be true with the RIT population with this new mode of interacting with teachers and peers was a reported sense of isolation. One deaf respondent in the Long and Richardson study said "I often feel isolated from others when taking a DL course, but as a deaf learner I am used to that" The feeling of isolation would represent a small percentage of the population from the author’s perspective and data described in this paper. The authors’ felt that this was due to the lack of proper considerations and accommodations for the delivery and conferencing systems used in England. This situation did not seem to exist at the RIT classes, as all the video types of instruction were captioned or developed with the deaf audience in mind. Online communities were actually developed while students regularly interacted with each other asynchronously within the electronic conferences. In fact, Mallory used electronic conferencing to successfully combine remote, online hearing and deaf students with traditional on-campus college aged deaf students taking programming classes into one large online community. (Mallory, 2001) This diverse population of young, college aged deaf and hard-of-hearing students regularly interacted with deaf and hard-of-hearing adults who were out working full time in the corporate world. One remote class of hearing adult Pittsburgh Telephone company technicians were also integrated with deaf on-campus and corporate programmers in a C++ programming class.

Integrating Multimedia and Video Streamed Instruction into a Deaf and Hard-of-Hearing Classroom

James R. Mallory, MS, Associate Professor
Applied Computer Technology Department
jrmnet@rit.edu

Harry G. Lang, Ed.D., Professor
Research Department
hg19008@rit.edu
National Technical Institute for the Deaf
Rochester Institute of Technology
United States of America

Abstract: Multimedia and video streamed instruction delivered remotely via the web is becoming more prevalent for both the deaf and hearing Distance Learning (DL) population. Video streaming is becoming more popular because more students are connected to the Web at higher access speeds at home, work or school. Multimedia instruction is becoming more viable due to computers with faster CPU speeds, more RAM memory and larger hard disk storage.

There are various factors to consider when an instructor incorporates video streaming or multimedia instruction into their remote or on-campus lesson plans. Some methods are cost effective and simple to implement, while others are more expensive and complex, with longer learning curves. Some of the multimedia concepts discussed in this paper include the use of screen capturing software, screen graphic tools, video streaming from small desktop cameras and the use of camcorders for recording streamed videos.

Introduction

Today there are many cost efficient ways to deliver instruction to a remote audience, regardless of whether they are deaf, hard-of-hearing or hearing. The tools used and discussed by the authors in a "Multimedia Toolbox" include:

1. HiLighter™ - a screen visual tool, which turns a computer monitor into a flexible, artistic means of displaying and emphasizing information. Screen enhancement tools such as HiLighter cause computer generated presentations to become more lively and clear.
2. Snagit™ - A monitor sequence capture program which captures a computer screen and saves and stores it in a variety of different formats (*.bmp, *.jpg, *.tiff, etc.).
3. Camtasia Recorder™ - A monitor sequence capture software program which captures a computer monitor's sequence of events, allowing the instructor to deliver step-by-step animated instructions. This can be stand-alone instruction or used in conjunction with text and graphic based explanations.
4. Video Streamed Instruction, using sign language, recorded by: a digital camcorder; a small Logitech Camera mounted to a laptop computer; a studio grade production camera (and also streamed simultaneously with computer monitor captures, captioning and audio.

The Study

Multimedia tools
Multimedia screen tools were studied and initially tested in order to discover the best way to deliver technology instruction to a remote deaf and hard-of-hearing audiences. These tools proved to be extremely useful for delivering instruction to traditional classroom students and in other presentations as well. Streaming was studied as a way to incorporate sign language with other aspects of remote instruction. This paper will describe the authors’ successes and failure in these areas. The authors hope that the findings in this paper will provide suggestions for more formal research in the future.

The authors at the National Technical Institute for the Deaf (NTID) at Rochester Institute of Technology (RIT) investigated the use of “smart” white boards for delivering online Visual Basic (VB) instruction. This was found to be awkward, due to the need for the teacher to move around and also be able to use the computer. Shadows resulting from using sign language and front projections caused interference in the visual communication, the primary means of communication for most of the deaf and hard-of-hearing students. Rear projection may have been a feasible alternative, but was cost prohibitive. A more acceptable solution was to turn the computer monitor itself into a usable white board.

There are two software products that allowed use of the monitor as an online classroom white board – Altiris HiLighter and TechSmith’s Camtasia. HiLighter allowed graphics and text to be drawn on the monitor while Camtasia captured any movements or action which occurred on the monitor.

**HiLighter™** is a unique, desktop enhancement software which is easy to learn and will allow the remote instructor to use his/her monitor as a whiteboard for instructional purposes. Some of the HiLighter features include:

- Draw on-screen with transparent or solid color pen (similar to a television sportscaster)
- Zoom in on a user-defined area of the screen
- Shine a spotlight of any size or contrast around the screen
- Point arrows or other icons of any size to any screen location

HiLighter is produced by Altiris™ and can be found at: [http://www.altiris.com/](http://www.altiris.com/).

**Snagit™** is a tool that can produce customized screen captures with the press of a hotkey. Snagit allows capture of images, text, and video from a Windows desktop. Snagit allows the instructor to capture text or graphics from all applications, even those that don’t offer Cut and Paste. Images from Web sites, scanners, digital cameras or anything that can be seen on the computer screen can be captured. Captures can be sent to a file, the clipboard, the Web, as an e-mail attachment or posted on an electronic conference for the benefit of the remote audience. Snagit is a Techsmith™ product. ([www.techsmith.com](http://www.techsmith.com))

The use of moving pictures or animation to supplement text-based instruction is invaluable for explaining complicated course content to a deaf or hard-of-hearing remote audience. Camtasia™ captures the action and sound, (this is irrelevant for our deaf but not our hard-of-hearing audience) from any part of the Windows desktop and saves it to a standard AVI movie file or streaming video. The Camtasia screen recordings can then be posted on the remote course's electronic conference, shared on a Web site, or distributed via e-mail, an Intranet or CD. Camtasia is also a Techsmith™ product.

The first author successfully explained to a remote deaf audience how to construct computer programming designs in Visual Basic (VB) software code. The VB graphical user interface design and properties as well as the coding of each object could be exactly described within one instructional unit using this type of software.

**Video Streaming**

Video streaming can be thought of as a progressive downloading of a video file. Instead of waiting a long time for a movie to be downloaded to one's desktop all at once and then viewing it, the video is fed or “streamed” in small units of information at a time and is viewed as it is being downloaded. Streamed video is much more conducive to viewing large video files that may last from many minutes up to an hour or more. The video could be live or prerecorded and stored on digital media.

The three most popular video file types are Quicktime™, an “.mov” type of file, Microsoft Media Player™, an “.avi” type of file, and RealPlayer™, a “.rm” type of file. RealPlayer became the streaming software of choice for most of the NTID projects. RealPlayer works on both Macs and PCs. It has a proven track record in the streaming video arena. It was found to be complicated when embedded into HTML, however. When a RealPlayer streaming presentation contains multiple clips, such as sign language videos, computer screen images, captioning, etc., it needs to use the Synchronized Multimedia Integration Language (SMIL) to coordinate all of the parts. SMIL is a simple but powerful markup language for specifying how and when clips play. A SMIL file is not required to stream just one clip, so if an
An instructor wanted to simply send a streamed video clip with sign language, dealing with the SMIL file would not be necessary and this would greatly simplify the implementation of streaming. When multiple clips exist such as in the project described by the authors below, the process becomes much more complex because more than one stream is involved and a SMIL file needs to be used. After writing the SMIL file, the video is then ready to put on the RealServer and link to the Web page.

NTID has experiences with a large variety of streaming video projects and pilots—several conducted by the authors are described in this paper.

**Visual Basic Programming**

A pilot study implemented by the first author involved delivering Visual Basic Programming instruction remotely to students enrolled in either on-campus or distance learning programming courses offered by the Applied Computer Technology Department. Each video streamed unit was linked from the teacher's instructional web site, which can be viewed at: http://idea3.rit.edu/mallory2/vb/. RealPlayer and SMIL were used to simultaneously stream four events at the same time, including the computer monitor, sign language, audio and captioning. These multiple streams captured the Visual Basic (VB) programming demonstrations and were stored on a server and accessed asynchronously. These streamed files can be accessed in the "Visual Basic" folder located at the URL: http://nisvideoserver.rit.edu/OnlineWhole.htm. If the user needs to download a free version of Realplayer, it can be found at: http://www.real.com/. These video streams are best viewed using a recent version of Internet Explorer.

A hand held Panasonic camcorder was also used to record student responses during a national, week-long Visual Basic Programming workshop that he offered on campus to alumni who came from across the country. The participants' comments were recorded with the camcorder and posted on the server after the addition of captioning. These can be found in the "DHIT VB Workshop" folder located at the URL: http://nisvideoserver.rit.edu/OnlineWhole.htm.

**Technical Signs**

The authors also developed some pilot modules illustrating technical sign language for a forthcoming in-depth study of signs used for science instruction of deaf students. Using desktop Logitech cameras at several locations and in two different formats available from Logitech (*.exe file and *.rm file), several streaming videos were produced to evaluate the quality of reception on different platforms. These can be seen in the "Pilot Modules" folder at the URL: http://nisvideoserver.rit.edu/OnlineWhole.htm.

Streaming videos in *.mov format were easily produced with a digital camera and embedded in html as part of a National Science Foundation grant titled *Clearinghouse On Mathematics, Engineering, Technology and Science* (COMETS). Several “Video Examples” are shown at http://www.rit.edu/~comets/pages/cos/signguidelines.html.

**Classroom of the Sea**

The third video streaming pilot study involved the Classroom of the Sea (COS), also a National Science Foundation sponsored grant project. COS involves a collaborative team from the National Undersea Research Center for the North Atlantic and Great Lakes, University of Connecticut, American School for the Deaf in Hartford, and the second author of the present paper at Rochester Institute of Technology. To develop a means for communicating in sign language with high quality transmissions over the Internet, VBrick™ from VBrick Systems (www.vbrick.com) was used to set up a "vbx server". Ivar Babb and Peter Scheifele worked with their technical staff in using a digital video camera with the deaf students on a boat, the RV Connecticut, on the Atlantic during a water sampling activity. This signal was fed into the RV Connecticut’s network and then transmitted from the vessel to the antenna on the Marine Sciences building into the building’s LAN. From there it was picked up/split to 1 or 2 Vbricks to test the high quality imagery coming to the shore. One of these signals was sent to the vbx server which will trans code the signal to Windows Media™. This was the streaming format for viewing the web video with Streamplayer2™. The transmissions could also be viewed on the project’s web page. Both a static video camera and a mobile camera were used to transmit the messages in American Sign Language describing the at-sea research.
Findings

Multimedia Tools

All of the multimedia tools, HiLighter, Snagit and Camtasia, worked well when creating instruction to be directly delivered or when embedding instruction into streamed videos for use with deaf and hard-of-hearing students in remote locations. HiLighter was also found to be useful for working with visually impaired students in the computer labs on-campus.

Video Streaming

Technical Signs

The video stream modules produced with a Logitech QuickCam™ were successfully sent back and forth via email and posted them on the web using both a PC and an iMac. Logitech’s software allows the user to create and save the video as either a *.exe or *.rm file. These streaming files are very easy to create and email to people. Storing them on a server proved to be a bit more challenging due to software requirements and conflicts. In addition, only PC’s can read the *exe type of Logitech file, whereas both PC’s and Mac’s can read the *rm type of file. These two formats can be viewed at seen in the “Pilot Modules” folder at the URL: http://nisvideoserver.rit.edu/OnlineWhole.htm, and also at: http://www.rit.edu/hrmnet/Streaming/Index.htm. The sign language was of fairly high resolution when a video was sent via email or stored on the server. Live video, depending on the connection, can be choppy, as found in the pilot study with the Classroom of the Sea project. The authors’ felt that this was due to the connection topology as found in the study done by Mallory and Laury (2001) at NTID. In this study, desktop cameras and various network topologies and connections were studied as part of Laury's Master thesis. (Laury, 2001; Mallory & Laury, 2001). One challenge reading the *rm files produced by Logitech was not due to the Logitech software itself, but rather due to bugs in browser software. At first, the authors could view the files from a PC but they did not work with a Mac G4. The use of Netscape™ appeared to be the problem. Microsoft’s Internet Explorer™ proved to be far easier to read files that were posted on a server. Conflicts arose depending on which was loaded first, the browser software or RealPlayer. Browsers often contain their own version of RealPlayer, so conflicts can occur if RealPlayer is loaded separately. The browsers in this pilot had to be reloaded so that there would not be a conflict when running the streamed videos. More systematic study is needed under the four conditions (Mac/Netscape, Mac/IE, PC/Netscape, PC/IE).

Visual Basic Project

Assistance was obtained from NTID’s Instructional Television and Technical Services departments in an attempt to develop high-end, multiple streamed instruction which could be remotely and asynchronously accessed by students. Capturing a video and digitizing it is relatively easy. Converting the video-to-video stream into Real Player format is the difficult part if multiple streams are being combined; otherwise it also a fairly simple process. The easiest way to record a video is to have a camcorder that is digital and a connecting Fire Wire. This will allow the user to directly port the movie into the computer in a digital format. This movie can then easily be edited with a product such as Adobe Premier or other similar product. This would produce a high quality video. An analog camcorder could be used with the standard Audio Visual (AV) ports and a video capture card on a computer. Using this method requires more steps, because the movie has to be converted from analog to digital by going through the AV port and back. This method would work, but the video quality would degrade.

Streaming of the video is the most difficult part of this process if the developer is synchronizing multiple streams. If only a recorded video of sign language is being posted, the procedure is quite simple. The goal is to code the streamed video onto a web page for asynchronous viewing. The clearer the movie file is to view, the larger its file size will have to be. There is a trade-off between what file size is adequate to be able to understand sign language and the instruction when it is streamed to the user's desktop and what is a practical file size to store and stream video over a broadband connection. For video by itself, 15 frames per second throughput is normally fine to adequately view on the web. When combining multiple streams as mentioned above in the Visual Basic Programming instruction, however, throughput of 30 frames per second is recommended for the best clarity. The signal speed and clarity will tend to degrade as the various streams are combined and posted on the web. There are various PC Video editing software available. One product, Adobe™ Premier™ runs on either platform and was chosen for this project. There is also another Mac based video editing software, named iMovie, which is very popular. A large capacity server needs to be used for video stream hosting. A good “rule of thumb” to use is video typically consumes one megabit per minute for an average video.
Conclusions

Multimedia tools such as HiLighter, SnagIt and Camtasia can be used very successfully in delivering instruction to remote deaf and hard-of-hearing students. Video streaming is also ready to use for this same instructional purpose, but it is still not perfected yet due to a variety of evolving technology factors related to browsers, various streaming formats and connection speeds of the end users.

The authors found the streaming implemented for the Visual Basic Programming Course to be satisfactory. Primary concerns in this pilot project were related to the synchronizing of four different streams into a single instructional video, which demanded higher bandwidth. The streamed VB instruction worked fine, as long as the audience was connected at a high-speed Internet connection and used a recent version of Internet Explorer and RealPlayer. Using a Netscape browser, a low speed connection or a loaded system rendered the multiple streamed videos unacceptable.

During the initial tests of live video streaming, the streams were found to be very good quality for understanding sign language and seeing the science students working, although the signals were choppy at times, and at other times frozen for a while. Much was also learned about how to place the camera and, especially, use proper lighting for the primarily visual communication among deaf people.

Continued study of these technologies will assure enhanced streaming video quality in the future instruction of deaf and hard-of-hearing students, who will certainly benefit from the highly visual nature of these products.

Abstract: This paper focuses on the authors' experiences with interactive, synchronous internet video conferencing with deaf and hard-of-hearing students in two different settings. One setting involved teaching computer programming to remote deaf and hard-of-hearing students. Within the realm of this remote teaching, synchronous, remote tutoring was set up using Desktop Video Conferencing (DVC) using Logitech cameras and Microsoft's NetMeeting software. Another setting involves a science project that used one static and one mobile camera with Vbrick™ software to transmit sign language communication from a boat at sea to computers located at the university.

Introduction

In the past, distance learning with two-way video was out of reach for many remote students and institutions. Recent innovations in telecommunications have lowered equipment and transmission cost, making two-way desktop video feasible for businesses, classrooms, libraries, and even homes. In the education of deaf students, video conferencing is also becoming more prevalent due to the inexpensive pricing of desktop cameras and hand-held camcorders as well as the increased access speed at which the deaf and hard-of-hearing audience is accessing the Web.

The horrendous events of September 11th have also discouraged travel and encouraged the use of remote interactions. For example, one of the authors, who himself is deaf, was supposed to travel to England to present at a conference in mid September but "due to the disruption caused to flights from America following the terrorist attacks Dr. Lang was unable to attend" (Evening Telegraph, 2001, p. 2). An mm225 ISDN dual mode videophone was used in Derby, England, to project the speaker on a large screen. The presenter transmitted his lecture on the topic of video telephony from the Rochester Institute of Technology in Rochester, New York, to the conference in Derby, England. Remote interactions as demonstrated by this example are becoming more prevalent with the advance of technology.

In this paper, the authors share their experience in two different arenas. One area is teaching computer programming courses to deaf and hard of hearing students in remote locations. In these courses Desktop Video Conferencing (DVC) was used in remote, synchronous tutoring sessions. Initial experiments in delivering science concepts and sign language from a boat with deaf students and their teachers out at sea will also be briefly summarized.

Affordable broadband connections and technologies at home, work and school are rapidly growing. These high-speed connections are changing the capability of carrying large amounts of text, voice and video data over existing telephone and cable lines. Microsoft summarized the technology in a very concise manner: "For years now, computer networks such as the Internet have been carrying text-based
messages around the world. Most often, these messages take the form of electronic mail, though real-time chat programs are also used. As the quality and speed of computer networks increase, so do demands for higher levels of interaction that include voice, graphics, and video exchange in real-time. This growing trend toward richer communications via computer is known as Internet Conferencing.” (Microsoft, 2001, USA-L_News@yahoogroups.com)

Various researchers have investigated the transmission of sign language, which features significant motion of the arms and hands, and requires a frame rate high enough for smooth motion perception (Schumeyer, Heredia, & Barner, 1997). Science teachers such as Mary Ellsworth at the Model Secondary School for the Deaf in Washington, DC (http://csc.gallaudet.edu/soarhigh/SHMAHOM.HTM), have also previously experimented with computer-based videoconferencing over ISDN lines. Such research and instructional efforts are pioneering. Educators of deaf students eagerly await progress with the new technologies.

The Study

The experiments reported in this paper were action research projects conducted in search of ways to enhance distance learning. The “findings” are thus tentative and provide suggestions for more formal research.

Most of the Distance Learning (DL) courses at Rochester Institute of Technology (RIT) and the National Technical Institute for the Deaf (NTID), one of RIT’s colleges, have focused on asynchronous (any time, any place) delivery of instruction. After teaching multiple remote, DL computer programming courses to a deaf and hard-of-hearing audience, however, it was found that both synchronous and asynchronous types of online instruction are necessary for some students to have a successful distance learning experience.

One author tutored remote deaf and hard-of-hearing students via a QuickCam Desktop Camera in conjunction with Microsoft’s NetMeeting as an asynchronous tool for clarifying concepts with one deaf student and one teacher. This is often referred to as point-to-point video conferencing, where only two people can talk and see each other at a time. Although this hardware and software can easily incorporate group conferencing of remote students by the instructor, the project reported on in this paper involved only point-to-point video conferencing. The students selected were tutored on an individual basis in a credit-bearing DL course in Visual Basic Programming.

Desktop Video Conferencing (DVC) is one of many different types of conferencing tools. The DVC components include a video conferencing camera, such as the QuickCam camera used for this project, an Internet telephony application, a microphone, and speakers mounted to the local computer (the microphone and speaker built into a laptop computer were found to be adequate). DVC links two or more participants at different sites by using computer network(s) to transmit data. DVC is based on Codec (compressor-decompressor) technology. A Codec works via a mathematic computer algorithm to compress and decompress digital data. The data can be video, audio, or text based. A Codec is an important part of any Internet telephony application such as Microsoft’s Netmeeting.

To use Desktop video conferencing, the student and instructor both need to have a computer, a camera, and an Internet connection to send and receive the video. From the authors’ experience, the computer should be a Pentium-based PC running on Windows 95, 98, NT or Windows 2000. The authors have no experience with the new XP, Linux or other operating systems yet. The faster the processor speed the better the video will run. All the Pentium based processors are more than adequate to handle DVC. The user should have at least 32 MB RAM, although more memory will be better, especially if the user plans to have other applications open when using DVC. The PC should have enough hard disk space for file swapping; at least 20 MB would be a minimal requirement. A video capture card is also necessary.

The Internet connection for conferencing should be as fast as possible. It is recommended that both users be connected at speeds much faster than the Plain Old Telephone System’s (POTS) 28.8 kb per

The camera chosen should be a desktop type of camera that easily interfaces with the computer. Although the QuickCam had many features for storing photographs, it was the video feature of the DVC and the low price that was the most appealing for the project discussed in this paper. The QuickCam camera is capable of recording video at up to 30 frames a second.

Classroom of the Sea Experiments

The Classroom of the Sea is a National Science Foundation sponsored grant project with a collaborative team from the National Undersea Research Center for the North Atlantic and Great Lakes, University of Connecticut, American School for the Deaf in Hartford, and the second author at Rochester Institute of Technology. To develop a means for communicating in sign language with high quality transmissions over the Internet, VBrick from VBrick Systems (www.vbrick.com) was used to set up a "vbx server". A digital video camera was used with the deaf students on a boat, the RV Connecticut, on the Atlantic during a water sampling activity. This signal was fed into the RV Connecticut's network and then transmitted from the vessel to the antenna on the Marine Sciences building into the buildings LAN. From there it was picked up/split to one or two Vbricks to test the high quality imagery coming to the shore. One of these signals was sent to the vbx server which transcoded the signal to Windows Media. This was the streaming format for viewing the web video with Streamplayer2. The transmissions could also be viewed on the project's web page.

Both a static video camera and a mobile camera were used to transmit the messages in American Sign Language describing the at-sea research. Initial experiments proved successful. The ability to read sign language over the Internet was of sufficient quality to continue planning for two-way transmissions on an ongoing basis. Experiments with classroom lectures, including the use of Power Point slides, using this system were also successful. This will allow the team of scientists and educators in four different locations to interact during various science learning excursions with deaf students.

Conclusions

DVC is both inexpensive and easy for instructors and students to implement. The technology significantly enhanced remote tutoring sessions by making remote interactions more personal. Communication with the deaf and hard-of-hearing relies heavily on facial expressions, body language and gestures. DVC, when combined with the other tools mentioned in this paper, provided an adequate environment for successful remote tutoring sessions.

In distance learning tutoring for the deaf and hard-of-hearing, DVC is often too slow and choppy for fluid, extended sign language conversations, but it does allow the sharing of some limited sign language, gestures, facial expressions and body language. This real-time interaction significantly enhances chat sessions and white board viewing of instructional material such as text explanations or computer program source code. Netmeeting also allows the use of highlighting and drawing on top of instructional materials, which can easily be posted on the online white board or even saved later in an electronic conference.

Video conferencing is becoming more affordable as use of broadband connections and technologies such as ISDN, DSL and Road Runner at home, work and school increase. These high-speed connections will change the capability of carrying large amounts of text, voice and video data over existing telephone and cable lines. Videoconferencing systems also incorporate compressed digital video.
compression technology makes the transmission of video less costly by reducing the size of the video needed to be transmitted.

Broadband access has also impacted DVC and other types of video conferencing. A survey taken last year of 2000 online RIT students, of which 50 were deaf, gathered a 10% response rate and found that 70% of these students had access to broadband Internet access at home, work or school. (Fasse, 2000) Of the 20 respondents to a fall, 2001 academic quarter survey of exclusively 33 RIT deaf and hard-of-hearing online students, 85% of these learners had access to high-speed internet access while 100% of all on-campus students have capability to this access. (Mallory, Long, 2001) According to AOL, Americans with online access has increased from 45 million users in 1998 to 105 million users in 2001. Of these online users, those with home broadband access has grown from 6% in December, 1999 to 19% as of September, 2001. (Mount, 2001, pp. 44-45) This shift in the access speed of the student population makes video streaming an increasingly viable option for delivering synchronous communication and instruction.

Desktop Video Conferencing (DVC) is a widely available, low cost, practical technology that can be used in synchronous, online tutoring/teaching sessions. Although the limited throughput on the Web makes it challenging to observe sign language in a fluid and practical manner as a primary instructional or conversational tool in online courses, it has been useful as one means of tutoring remote deaf students when used in conjunction with a complete DVC package. A DVC package with a desktop camera allows the sharing of some sign language, gestures, facial expressions and body language. This real-time interaction significantly enhances chat sessions and white board viewing of instructional material such as programming code. Netmeeting also allows the use of highlighting and drawing on top of instructional materials, which can easily be posted on the online white board along with a chat session interaction. When the DVC video was combined with Microsoft NetMeeting’s other features, the total package was found to be an excellent communication and instructional tool.

The hardware, software, and Internet connections are now available to provide a complete Internet conferencing solution such as DVC at a very reasonable price. DVC incorporates the use of desktop cameras and software that can provide an adequate environment to perform remote, synchronous tutoring for deaf and hard-of-hearing students. With the increase in digital compression technology and students increased connectivity at high-speed, broadband access speeds, use of digital video conferencing will continue to grow.

Preliminary experiments with the VBrick software also show promise. In order to keep the education of deaf and hard-of-hearing students abreast with the rapidly growing distance learning opportunities, these and other emerging technologies need to be continually explored for successful synchronous instructional efforts -hearing learners over the Internet.

Model of a Planning Strategy for Online Courses

Yahya Matsom
Department of Adult and Career Education
Valdosta State University
United States
ymatsom@valdosta.edu

Abstract: This paper is a report on the findings of a study that utilized a modified Delphi method. Forty four faculty from eleven universities participated in this study and developed a planning strategy for the development of distance/online courses. Along with the model there were 42 factors and 135 sub-factors generated from the analysis of the data. Also included in this report are the model and the steps of utilizing the planning strategy.

Introduction

Advanced digital and electronic technologies are influencing instructional activities and redefining the meaning of formal education realities. Using these technologies education can no longer confined to a walled classroom and is accessible at any time, place and context. This transformation poses new challenges to educators, especially when effectiveness and efficiency of teaching and learning is concerned (Simonson, 2000).

A few years ago various digital and electronic technologies were used individually for different forms of distance education (Rosenberg, 1998). However, in the contemporary distance education settings most of these technologies are integrated to meet the demand of the dynamic and sophisticated teaching and learning activities (Dede, 1997). As a result, technologies that are used in distance/online courses are no longer selected based on the suitability and logistical reasons but are driven by how effective and efficient these technologies can be used to promote optimal learning.

Challenges in Distance Education

There are many attempts made by scholars to define distance education. They claim that distance education could be an effective form of education if it is properly planned, developed and implemented (Holmberg, 1995). However, there are disagreements among these scholars on what should constitute distance education. Based on this argument, therefore, it is critically important for educators to consider various teaching and learning factors before designing and developing distance/online courses.

Planning and developing instruction are always major issues in distance education (Moore & Kearsey, 1996). Distance educators who advocate the use of the systematic approach of planning instruction see its usefulness (Seels & Glasgow, 1998). Those who oppose to this approach argue about its ability to promote "reflection" and "real-world context" during its implementation. However, both groups agree that the utilization of the systematic approach for planning instruction have many advantages to promote effective instruction.

There are many incidents where distance educators are unable to effectively implement their distance courses (Ndahi, 1998). This problem is related to the misuse or misunderstanding about data to be used and lack of a desired planning approach to properly design and develop their distance courses. The problem becomes even more alarming when these educators have limited understanding of the interaction of the many factors that are involved in the planning for the development of distance/online courses.
Model of Planning Strategy

This model (Figure 1) is developed using a modified Delphi method that involves forty-four faculty from eleven universities. Unlike models of Instructional Design, the primary purpose of the model is to help educators in the planning phase of the development of distance/online courses. Major emphasis is given to assure that the right decision can be made before designing and developing distance/online courses.

The model constitutes of eight elements that are important to be considered before converting a traditional course into a distance/online course. In each element there are several factors and sub-factors (Table 1) that need to be addressed in order to make a sound decision. Although the elements of the model are presented in a sequence, however, the planning process for the development of distance/online courses can be started from any of the elements.

</tr>
</tbody>
</table>

### Step Seven: Students' Evaluation

<table>
<thead>
<tr>
<th>Factor</th>
<th>Sub-factors</th>
<th>Question</th>
</tr>
</thead>
<tbody>
<tr>
<td>F - Quality of assessment</td>
<td>Level/ assignments/ types/ accuracy/ validity/ reliability</td>
<td>What are needed, how and when to administer, and where should it be implemented to ensure the assessment address the sub-factors.</td>
</tr>
<tr>
<td>F - Types/ Methods of feedback</td>
<td>Test/ presentation/ interviews/ papers/etc.</td>
<td>Who, what, when and where the sub-factors are relevant. How to administer effectively.</td>
</tr>
</tbody>
</table>
Table 1: Steps of Utilizing the Planning Strategy

| F - Accountability of assessment | How, where and what should be done to ensure accountability |
| F - Interactivity of assignment   | To what extent the assignment should address the sub-factors, and how it can be done. |
| F - Format of assessment         | Should address the issue of relevancy of assessment based on context, content & time. How to do and what should be emphasized? |
| F - Ease of management           | How user-friendly the interface layout and to what extent this would help faculty/students management |
| F - Faculty teaching             | Address the issue of effectiveness and capability of faculty to transfer teaching skills. What, when, where, why and how to adjust? |
| F - Faculty/course management    | Address the issue of transferring/transforming knowledge, skills and course content in traditional class into online environment |
| F - Cost-effectiveness           | Address the issue of effectiveness and benefits of the course content and management to diverse group of students. |

Step Eight: Course/Faculty Evaluation

Conclusion

It is obvious from the literature that online education is still at its infancy and a sound planning is vital to the success of an online course. The current approaches of developing online courses are implemented without considering the transitional aspects that "connect" the institutional or system planning to the instructional planning. The author presented a new model for planning online courses by identifying the “missing link” through a study conducted using a Delphi technique.

Fostering Inquiry-Based Learning Online

Gail Matthews-DeNatale, TERC/Lesley University, US

Presentation Overview
Because the Web is a relatively new environment for teaching and learning, the first wave of research on distance learning has centered on the larger lessons to be learned about creating successful online courses. This paper narrows its analytical focus to a specific pedagogical approach, learning through inquiry. Using examples from three web-based distance learning courses that are part of an online Masters in Science Education program, this presentation will explore instructional design features that foster inquiry-based learning online.

What is involved in capturing the inquiry experience online?
The successful inquiry learning experience is carefully planned and focused on a clear goal, yet the process by which the lesson unfolds is collaborative, fluid, and open-ended. For this reason, each academic topic presents a unique set of challenges for course developers, faculty, and educational technologists who strive for inquiry.

These challenges have both technical and pedagogical dimensions. The process of fostering inquiry online requires re-examining old questions even while grappling with new issues:
- What does it mean to learn through inquiry? What are the central characteristics of inquiry-based learning?
- To what extent do online environments support or detract from a learner's inquiry experience? What can educators do to craft the online environment and facilitate the learning experience in such a way that course participants experience inquiry?
- How will faculty be able to tell if course participants are genuinely engaged in inquiry?

In the proposed presentation, the author will compare the design decisions made during the development of three graduate-level online courses (the introductory Try Science program course, Investigating Physics, and Biological Explorations). The author will identify common concerns and patterns of difference, present examples of original session plans, provide excerpts from formative assessment done with a pilot group of course participants, and discuss how the plans were revised in response to course participant feedback.

Project Research Sources and Methods
The paper grows out of a multi-year project to develop an online Masters in Science Education program (http://scienceonline.terc.edu). The program is a collaborative venture developed by TERC, a Cambridge-based educational non-profit organization, in conjunction with Lesley University. The project, funded by NSF and FIPSE, includes a research study of online learning conducted under the advisement of science educator Wynne Harlen.

Indicators of inquiry learning in program-sponsored courses are obtained from the following sources:
- weekly formative assessment questionnaires completed by a pilot group of course participants and submitted through an email list;
- participants' messages to colleagues and faculty in course discussion fora;
- participant course work, including investigation reports, write-ups of clinical interviews with children, and investigations developed by participants;
- course participant email correspondence with faculty; and
- post-course face-to-face interviews with course participants.

Preliminary Conclusions
While the process of fostering inquiry in an online learning environment bears some resemblance to the inquiry process in face-to-face settings, there are notable differences that must be considered if the course is to achieve its pedagogical goals. Because verbal cues and opportunities for on-the-spot clarification are largely absent in online learning, educators need to ensure that all communication and assignments are congruent with the inquiry approach.
To craft online experiences that set the stage for successful inquiry, developers and educational technologists also need to identify the inquiry challenges and opportunities that are unique to the subject matter. For example, a challenge in investigating the physics of motion is to gather data and discern patterns in motions that last only a few seconds. In contrast, a challenge inherent to biological investigation is tracking growth and making meaning of processes that unfold over the course of days or weeks.

The learning context also needs to be situated in inquiry -- it must be a place where participants experience the power of prediction, firsthand observation, and generating theories out of evidence. This requires an attention to detail, writing tone, timing of messages, and assignment structure that is unfamiliar to most classroom educators.

Abstract: As schools continue to invest heavily in technology, more trained technology leaders are needed to manage the use of it and prepare teachers to integrate technology in the classroom. To address this, the State of Louisiana has created a new certification for technology facilitators. Three universities collaborated to develop seven courses for online delivery that assist teachers seeking certification as building-level or district-level technology managers. This study attempts to present a case study on a collaborative effort to design and evaluate online courses that apply to state technology certification.

Introduction
The need in K-12 schools for technology leaders, planners, trainers, and managers continues to grow across the country. To address the need, state certification offices are changing procedures for certification of educational technology personnel to accommodate changes in certification requirements but driven by pressures to redo certification requirements that are out of date or inappropriate for 21st-century schools. Louisiana is no different. As a result of changes in technology certification by the Board of Elementary and Secondary Education in Louisiana, a variety of new courses were needed to prepare teachers to become building level technology facilitators or key educational technology leadership coordinators, directors, or specialists. Taking into account the large and continued investment in technology K-12 education, adding to the mix initiatives from the Governor’s Blue Ribbon Commission’s Technology Consortium for Teacher Education in collaboration with the State Department of Education’s Louisiana Center for Educational Technology, and recommendations from the Board of Regents for new certification guidelines to encourage emergence of new leaders in technology, certification guidelines were changed. To accomplish such an imposing task, institutions must collaborate with others to develop curriculum appropriate for new certification guidelines and train faculty to serve as online developers for classes that support certification. Furthermore, limited resources at colleges and universities mandate collaboration...
between institutions not only because it demonstrates sound practice but, out of necessity, is influenced by dwindling budgets. Courses offered online toward technology certification require a substantial investment in resources and faculty. Yet they offer a solution that is practical and accommodating to those who seek certification as building-level or district-level technology managers.

The Need For Certification

School districts across the country continue to spend additional funds and dedicate resources for educational technology. The State of Louisiana is doing the same in a concerted effort to reduce the ratio of computers in the classroom to at least 5:1 by the year 2004 (Louisiana Center for Educational Technology, 2001). The State Department of Education in Louisiana has a number of programs that support the use and training of teachers for technology integration. The Louisiana Center for Educational Technology assumes the leadership role in overseeing these technology programs which include InTech, InTech2 Science, LEADTech, FIRSTTech, regional technology centers, and Teach Louisiana (State Department of Education). “Taking into account the huge investment in technology for K-12 and higher education and the urgent need for leaders who are prepared to address the myriad of issues surrounding integration of technology in our educational system, it is critical that we take steps to expand the pool of qualified technology leaders” (Technology Consortium for Teacher Education, 2001, p.1). The certification of technology facilitators at the school and district levels addresses a primary goal in the state technology plan; all teachers will receive technology support from a certified technology facilitator. Certified facilitators will also assist teachers in achieving technology competency (Louisiana Technology Plan).

The Certification Program

The design of the certification process was a result of a study by educators to determine what was needed to improve the skills of technology facilitators and to address standards developed by ISTE (International Society for Technology in Education) called ECT (Educational Computing and Technology) Standards. This new certification process satisfies not only ISTE but also NCATE (National Council for Accreditation of Teacher Education) standards that are at the core of teacher education reform. Louisiana’s two new certifications for building and district level facilitators are based upon two ISTE ECT standards, Educational Computing and Technology Facilitation Standards (ISTE, 2001a) and Educational Computing and Technology Leadership Standards (ISTE, 2001b).

Certification for technology coordinators includes two areas, building-level and district level. The certification in Educational Technology Facilitation prepares building-level technology facilitators to provide professional development and resource materials for technology integration, and solve routine technical problems for teachers at their schools (Technology Consortium for Teacher Education, 2001). The second certification, Educational Technology Leadership, addresses the need for leaders to serve as technology coordinators at the district, state or regional levels. “These professionals focus on the overall planning acquisition, administration, management, and professional development for their district, regional, or state responsibilities” (Technology Consortium for Teacher Education, p. 3).

Design and Implementation of the Online Certification Program

Technology certification is typically offered at colleges and universities either as an “add-on” option or folded into a degree plan such as an M.Ed. These certification procedures take years to complete especially when those seeking certification cannot attend classes regularly on campuses that offer certification courses or degrees. An online solution is available in Louisiana as a result of collaboration between three institutions in Louisiana who designed and built courses that comply with Louisiana technology certification requirements. The Board of Regents in Louisiana proffers a program to support the development of online courses and initiatives, the Louisiana Educational Technology Facilitation and Leadership Program. This program is a grant source to provide funding for initiatives that promote online instruction in higher education.

In the wake of the online certification initiative, new courses were needed to comply with the updated certification requirements rendering old technology courses useless for application to technology certification. Recognizing that a mechanism was needed to build courses appropriate for the new

certification requirements, a group of three institutions—Northwestern State University, the University of Louisiana at Lafayette and Nicholls State University—collaborated on a project to redesign, field test and model new classes to be taught online that equal or exceed all State Department of Education certification requirements for certification as a building level technology facilitator or staff designee in Educational
Technology Leadership. A grant was written to the Board of Regents Distance Education Initiative, Louisiana Educational Technology Facilitation as the primary funding source with the impetus to include three institutions in a collaborative effort to create courses that apply to educational technology certification through the Department of Education. In addition, Northwestern State University would use these classes for the core of a Masters in Education with an Emphasis in Educational Technology online. This degree was already available but did not align itself with new state certification guidelines. The design of the project proposed that seven online courses be developed, fulfilling the new requirements for certification in Educational Technology Facilitation and Educational Technology Leadership recently approved by the Board of Elementary and Secondary Education. A survey revealed that over 300 people would be interested in pursuing the proposed certifications. Furthermore, superintendents, technology supervisors, school site administrators, and teachers had been interviewed to assess potential need for certified technology personnel.

The project was divided into three phases: design including faculty training, course development and evaluation of online courses. Moreover it was a model of collaboration between three universities that demonstrated the need to share resources between and within institutions. Seven courses were proposed for development for online distribution at Northwestern State University, University of Louisiana at Lafayette, and Nicholls State University—all institutions under the University of Louisiana System. The original grant was designed as a two-year process to include training of College of Education faculty who were new to electronic learning in the design and delivery of online courses. It also included development of a shared M.Ed. with a technology emphasis that meets state certification requirements. Other components of the grant called for designing and evaluating seven online courses; defining, developing and institutionalizing faculty support for distance delivery; and developing a model for online student support for courses taught at a distance. These included the obvious such as financial aid, advising, administration, student services, business affairs, library and bookstore.

The operating system and web-based software is Blackboard which is used for creating online classes, collaboration and evaluation. Northwestern State University was the host institution for the project. Most online classes included a development team of three to four faculty per course. The development team used Blackboard as a forum for course developers. Course descriptions, objectives and criteria were posted by faculty for discussion with each team. One participating team member served as the lead developer. An instructional designer coordinated the project and established the parameters for collaboration in course development. Several electronic forums, created on Blackboard, accommodated the planning and development of online courses for certification. First, a forum was created to introduce the course developers on a team to each other and to other members of the project. Second, a course Description/Outcomes forum was established for faculty to post course descriptions and elaborate their vision of the online course. Standards-based course descriptions from the Technology Consortium for Teacher Education and ISTE were posted. They were provided for faculty to review as they developed their course descriptions and objectives. A third forum was posted for Assignments/Activities. To support this a "Lecture" forum was created to allow developers to post and share pieces of content relevant to the courses. Fifth, a Links/Resources forum was created to post Internet references for the online class. A syllabus forum was posted for faculty to discuss the components of an appropriate syllabus for online certification courses. To address questions and comments from team members regarding other forums, a discussion forum for Questions/Comments was created. The target date to complete course development was Spring 2001 with implementation, RE: teaching courses already developed to follow in the summer and fall. Three (Technology Leadership in Schools, Technology Planning and Administration, and Advanced Telecommunications and Distance Learning) of the seven were completed and piloted during the summer at Northwestern State University. The remaining courses were completed in the summer of 2001 and offered in the fall by respective campuses. Nicholls State University offered Educational Telecommunications Networks and the Internet, Technology Leaderships in Schools and Professional Development for K-12 Technology Integration. The University of Louisiana at Lafayette added Design and Development of Multimedia Instructional Units and Technology Leadership in Schools.

Evaluation of Online Classes

There was a two-stage process for evaluation. The first was an internal evaluation performed at each campus by each primary investigator as designated from the grant. The PIs provided reports about student participation in the online classes including the number of logins. An external evaluator will provide the second stage of evaluation. This evaluator will provide and analyze data from student surveys.
to determine student satisfaction in the online course and other affective data. The external evaluator will also review components of the courses such as the syllabus, activities and assignments to insure they correspond to standards established by ISTE. The evaluator will also examine the instructional design of the course to see if it is appropriate for online delivery.

Inherent Problems With Online Classes Developed For Technology Certification

The development of these courses was a collaborative effort, which proved challenging to say the least. Communication between participants was limited as evidenced from postings and exchange on Blackboard. While some faculty were less than comfortable with this procedure, especially those that had never taught online before, they benefited greatly from the exchange and opportunity to use software for online instruction. Some course developers took liberty with their course objectives and how they compared to ISTE standards. Some teams represented from different campuses had an array of opinions as to course content for certain courses. Some wanted to take a theoretical approach to satisfy course objectives; others promoted a practical approach. Under the category of “lessons learned,” a longer timeline was needed to design and produce online classes; at least from one to two semesters. Regular progress reports from participants would have better served the grant. In addition, the faculty who had never taught online had a larger learning curve to overcome, as they were uncomfortable communicating with team members online and could not “envision” what differences are inherent between online and face-to-face instruction. Finally, the faculty had too many “irons in the fire” to dedicate adequate time to online course development not uncommon with faculty who volunteer for projects like this.

Conclusion

In an attempt to provide an online solution to deliver technology certification in Educational Facilitation and Leadership a grant was secured by three institutions for development, implementation and evaluation of seven online courses. In retrospect the project was not without problems and delays. But, the work was completed and the classes tested by the toughest critics of all, online students. What resulted is a cadre of courses for technology certification that are now offered into at participating universities. A byproduct of this project was a model of collaboration between three institutions with a common goal: design, implement and evaluate online courses that apply toward state technology certification. Furthermore, the effort provides credence to the notion that successful online classes must be properly designed, defined, evaluated, institutionalized to garner support for faculty to deliver courses at a distance, and modeled to include online student support, issues that continue to challenge distance learning initiatives.

Abstract: As schools continue to invest heavily in technology, more trained technology leaders are needed to manage the use of it and prepare teachers to integrate technology in the classroom. To address this, the State of Louisiana has created a new certification for technology facilitators. Three universities collaborated to develop seven courses for online delivery that assist teachers seeking certification as building-level or district-level technology managers. This study attempts to present a case study on a collaborative effort to design and evaluate online courses that apply to state technology certification.

Introduction

The need in K-12 schools for technology leaders, planners, trainers and managers continues to grow across the country. To address the need, state certification offices are changing procedures for certification of educational technology personnel to accommodate changes in certification requirements but driven by pressures to redo certification requirements that are out of date or inappropriate for 21-century schools. Louisiana is no different. As a result of changes in technology certification by the Board of Elementary and Secondary Education in Louisiana, a variety of new courses were needed to prepare teachers to become building level technology facilitators or key educational technology leadership coordinators, directors, or specialists. Taking into account the large and continued investment in technology K-12 education, adding to the mix initiatives from the Governor’s Blue Ribbon Commission’s Technology Consortium for Teacher Education in collaboration with the State Department of Education’s Louisiana Center for Educational Technology, and recommendations from the Board of Regent for new certification guidelines to encourage emergence of new leaders in technology, certification guidelines were changed. To accomplish such an imposing task institutions must collaborate with others to develop curriculum appropriate for new certification guidelines and train faculty to serve as online developers for classes that support certification. Furthermore, limited resources at colleges and universities mandate collaboration.
between institutions not only because it demonstrates sound practice but, out of necessity, is influenced by dwindling budgets. Courses offered online toward technology certification require a substantial investment in resources and faculty. Yet they offer a solution that is practical and accommodating to those who seek certification as building-level or district-level technology managers.

The Need For Certification

School districts across the country continue to spend additional funds and dedicate resources for educational technology. The State of Louisiana is doing the same in a concerted effort to reduce the ratio of computers in the classroom to at least 5:1 by the year 2004 (Louisiana Center for Educational Technology, 2001). The State Department of Education in Louisiana has a number of programs that support the use and training of teachers for technology integration. The Louisiana Center for Educational Technology assumes the leadership role in overseeing these technology programs which include InTech, InTech2 Science, LEADTech, FIRSTTech, regional technology centers, and Teach Louisiana (State Department of Education). "Taking into account the huge investment in technology for K-12 and higher education and the urgent need for leaders who are prepared to address the myriad of issues surrounding integration of technology in our educational system, it is critical that we take steps to expand the pool of qualified technology leaders" (Technology Consortium for Teacher Education, 2001, p.1). The certification of technology facilitators at the school and district levels addresses a primary goal in the state technology plan; all teachers will receive technology support from a certified technology facilitator. Certified facilitators will also assist teachers in achieving technology competency (Louisiana Technology Plan).

The Certification Program

The design of the certification process was a result of a study by educators to determine what was needed to improve the skills of technology facilitators and to address standards developed by ISTE (International Society for Technology in Education) called ECT (Educational Computing and Technology) Standards. This new certification process satisfies not only ISTE but also NCATE (National Council for Accreditation of Teacher Education) standards that are at the core of teacher education reform. Louisiana's two new certifications for building and district level facilitators are based upon two ISTE ECT standards, Educational Computing and Technology Facilitation Standards (ISTE, 2001a) and Educational Computing and Technology Leadership Standards (ISTE, 2001b).

Certification for technology coordinators includes two areas, building-level and district level. The certification in Educational Technology Facilitation prepares building-level technology facilitators to provide professional development and resource materials for technology integration, and solve routine technical problems for teachers at their schools (Technology Consortium for Teacher Education, 2001). The second certification, Educational Technology Leadership, addresses the need for leaders to serve as technology coordinators at the district, state or regional levels. "These professionals focus on the overall planning acquisition, administration, management, and professional development for their district, regional, or state responsibilities" (Technology Consortium for Teacher Education, p. 3).

Design and Implementation of the Online Certification Program

Technology certification is typically offered at colleges and universities either as an "add-on" option or folded into a degree plan such as an M.Ed. These certification procedures take years to complete especially when those seeking certification cannot attend classes regularly on campuses that offer certification courses or degrees. An online solution is available in Louisiana as a result of collaboration between three institutions in Louisiana who designed and built courses that comply with Louisiana technology certification requirements. The Board of Regents in Louisiana proffers a program to support the development of online courses and initiatives, the Louisiana Educational Technology Facilitation and Leadership Program. This program is a grant source to provide funding for initiatives that promote online instruction in higher education.

In the wake of the online certification initiative, new courses were needed to comply with the updated certification requirements rendering old technology courses useless for application to technology certification. Recognizing that a mechanism was needed to build courses appropriate for the new
certification requirements, a group of three institutions—Northwestern State University, the University of Louisiana at Lafayette and Nicholls State University—collaborated on a project to redesign, field test and model new classes to be taught online that equal or exceed all State Department of Education certification requirements for certification as a building level technology facilitator or staff designee in Educational

The development team used Blackboard as a forum for course developers. Course descriptions, objectives and criteria were posted by faculty for discussion with each team. One participating team member served as the lead developer. An instructional designer coordinated the project and established the parameters for collaboration in course development. Several electronic forums, created on Blackboard, accommodated the planning and development of online courses for certification. First, a forum was created to introduce the course developers on a team to each other and to other members of the project. Second, a course Description/Outcomes forum was established for faculty to post course descriptions and elaborate their vision of the online course. Standards-based course descriptions from the Technology Consortium for Teacher Education and ISTE were posted. They were provided for faculty to review as they developed their course descriptions and objectives. A third forum was posted for Assignments/Activities. To support this a “Lecture” forum was created to allow developers to post and share pieces of content relevant to the courses. Fifth, a Links/Resources forum was created to post Internet references for the online class. A syllabus forum was posted for faculty to discuss the components of an appropriate syllabus for online certification courses. To address questions and comments from team members regarding other forums, a discussion forum for Questions/Comments was created. The target date to complete course development was Spring 2001 with implementation, RE: teaching courses already developed to follow in the summer and fall. Three (Technology Leadership in Schools, Technology Planning and Administration, and Advanced Telecommunications and Distance Learning) of the seven were completed and piloted during the summer at Northwestern State University. The remaining courses were completed in the summer of 2001 and offered in the fall by respective campuses. Nicholls State University offered Educational Telecommunications Networks and the Internet, Technology Leadership in Schools and Professional Development for K-12 Technology Integration. The University of Louisiana at Lafayette added Design and Development of Multimedia Instructional Units and Technology Leadership in Schools.

**Evaluation of Online Classes**

There was a two-stage process for evaluation. The first was an internal evaluation performed at each campus by each primary investigator as designated from the grant. The PIs provided reports about student participation in the online classes including the number of logins. An external evaluator will provide the second stage of evaluation. This evaluator will provide and analyze data from student surveys.
to determine student satisfaction in the online course and other affective data. The external evaluator will also review components of the courses such as the syllabus, activities and assignments to insure they correspond to standards established by ISTE. The evaluator will also examine the instructional design of the course to see if it is appropriate for online delivery.

Inherent Problems With Online Classes Developed For Technology Certification

The development of these courses was a collaborative effort, which proved challenging to say the least. Communication between participants was limited as evidenced from postings and exchange on Blackboard. While some faculty were less than comfortable with this procedure, especially those that had never taught online before, they benefited greatly from the exchange and opportunity to use software for online instruction. Some course developers took liberty with their course objectives and how they compared to ISTE standards. Some teams represented from different campuses had an array of opinions as to course content for certain courses. Some wanted to take a theoretical approach to satisfy course objectives; others promoted a practical approach. Under the category of “lessons learned,” a longer timeline was needed to design and produce online classes; at least from one to two semesters. Regular progress reports from participants would have better served the grant. In addition, the faculty who had never taught online had a larger learning curve to overcome, as they were uncomfortable communicating with team members online and could not “envision” what differences are inherent between online and face-to-face instruction. Finally, the faculty had too many “irons in the fire” to dedicate adequate time to online course development not uncommon with faculty who volunteer for projects like this.

Conclusion

In an attempt to provide an online solution to deliver technology certification in Educational Facilitation and Leadership a grant was secured by three institutions for development, implementation and evaluation of seven online courses. In retrospect the project was not without problems and delays. But, the work was completed and the classes tested by the toughest critics of all, online students. What resulted is a cadre of courses for technology certification that are now offered into at participating universities. A by-product of this project was a model of collaboration between three institutions with a common goal: design, implement and evaluate online courses that apply toward state technology certification. Furthermore, the effort provides credence to the notion that successful online classes must be properly designed, defined, evaluated, institutionalized to garner support for faculty to deliver courses at a distance, and modeled to include online student support, issues that continue to challenge distance learning initiatives.

Abstract: According to research conducted in two studies examining incidental learning activity within a complex of asynchronous online courses and compressed desktop video courses at a mid-sized university, incidental learning outcomes not identified as part of the formal curriculum are evident. Learning to use technology and individual and group attitudes and behavioral patterns are two particular outcomes. The results of both studies illustrate the importance of incidental learning and of developing a learning environment that fosters positive outcomes. Theory and application concerning teaching and learning in online distance education courses and desktop video conferencing courses may differ. This paper compares and contrasts current online and DVC learning theory with observations and reflections of the researchers that show what may actually be happening with some students in today's distance education classrooms.

Introduction

A dichotomy may exist between theory and application concerning teaching and learning in online distance education courses and desktop video conferencing courses. According to research conducted in two studies examining incidental learning activity within a complex of asynchronous online courses and desktop video conferencing courses (DVC) at a mid-sized university (Furr 2000, McFerrin 1998), incidental learning outcomes not identified as part of the formal curriculum are evident. Learning to use technology and individual and group attitudes and behavioral patterns are two particular outcomes. The results of both studies illustrate the importance of incidental learning and of developing a learning environment that fosters positive outcomes.

Actual student observations uncovered specific student behaviors that produced a less than desirable classroom environment. Technology problems and lack of sufficient class interaction and participation cause students to become distracted from focusing on course content. While frustration levels in students in the DVC courses are higher than those in the online courses, elements of frustration exist in both. A comparison and contrast of current online and DVC learning theory with observations and reflections of the researchers show what may actually be happening with some students in today's distance education classrooms (Furr 2000, Hara & Kling 2000, Johnston 2000, Robertson 2000, Collins 1999, McFerrin 1998).

Asynchronous Online

The first study, titled "Incidental Learning in a Higher Education Asynchronous Online Distance Education Course" (McFerrin 1998), was designed to examine and describe the incidental learning activity of students in an asynchronous online course in a higher education setting. While literature concerning student performance and experiences in higher education online courses is available (Everett 1999, Neal 1997, Hites & Ewing 1996, Thomerson & Smith 1996, Jegede & Kirkwood 1994), little has been researched concerning incidental, or collateral, learning at the higher education...
level (Ragsdale 1997, Mealman 1993). McFerrin's research was conducted with data collected from interviews, journals, observations, email messages, and online conferencing software postings of 22 members of three sections of a graduate-level asynchronous online distance education course at a mid-sized four-year university in the spring of 1998. Each graduate student was interviewed at the beginning of the semester and at the end of the semester. A late-semester questionnaire was sent to all participants. All email and conference postings were analyzed. Each was asked to keep a journal throughout the semester.

Two types of incidental learning outcomes occurred. The first developed from the students' learning to use the technology itself. Accessing the Internet, developing search skills, working within an online course, and using conferencing software were teamed with an increase in researching, writing, and word processing skills. The second type of incidental learning outcome centered on an improvement in certain areas of the students' personal development. An increase in time management ability, self-directive behavior, self-confidence, and self-discipline occurred. Students in the online course exhibited an increase in self-knowledge and a belief that more new goals can be set and successfully accomplished. All students obtained unplanned and unanticipated learning outcomes not identified as part of the formal curriculum.

The results of the study illustrated the importance of incidental learning in an asynchronous online course. When developing coursework for graduate students in a life-long learning field such as education, faculty and administrators must seek to develop a climate in which incidental learning is likely to occur. Both students and instructors must see the value of incidental learning to the student and must foster its development.

**Desktop Video Conferencing**

The second study, "The Occurrence of Incidental Learning in Higher Education Desktop Video Conferencing Classes: An Ethnographic Study" (Furr 2000), addressed learning in desktop video conferencing (DVC) courses, a relatively new delivery medium for college courses. This study examined the incidental learning within a complex of compressed desktop video courses at a mid-sized university. Although ample literature covers incorporating technology into the classroom (Russell 2000, Saba 1998, Moore & Kearsley 1996, Cuban 1986), little documents the experiences and perceptions of students and faculty in distance education courses (Johnston 2000, Jegede et al. 1999, McKee 1999, Biner & Dean 1997). Because DVC is a new technology, even less literature targets its effects on teaching and learning environments (Cifuentes et al. 1999, Merisotis & Phipps 1999, Thorpe 1998, Mize 1996).

The DVC study was structured to replicate McFerrin's 1998 examination of incidental learning in asynchronous, on-line college instruction. The researcher employed grounded theory to examine the experiences and perceptions of participants--faculty, students, and staff--in five desktop video conferencing courses offered spring 2000 through a synchronous audio and video delivery system that allowed students in eight rural sites to complete education courses. The researcher triangulated data from field observations, interviews, surveys, participants' journals, and course materials. Quantitative measures of participant satisfaction and content analysis of journals and course documents also were used.

Consistent with McFerrin's findings, the researcher discovered two types of incidental learning outcomes not identified as part of the formal curriculum: learning to use technology and individual and group attitudes and behavioral patterns. Factors that afforded positive experiences and perceptions were convenience and reduced driving time, informal class atmosphere, small classes, prior computer skills, access to a computer and the Internet, internal student traits, and instructor facility with technology and distance education pedagogy. Factors that diminished a positive experience were technical problems, insufficient administrative support, inadequate training, weak proctor system, and negative student behaviors.

Unlike McFerrin's study, Furr (2000) found a higher level of frustration among participants in the DVC courses. Of the 52 students polled at the semester's end, 48% said they would take another DVC course, 17% said "no," and 21% said the type of course offered would determine their decision. The remaining percentage of students either did not answer the question or said they were graduating. Of those willing to take another DVC course, convenience was the top-cited reason. They were also willing to forgive technical problems, believing "bugs would be fixed." Nonetheless, a sizable number of students reported either a negative or neutral stance regarding DVC.

One graduate student commented: Today's class was very frustrating - just like all the other times. We could hardly hear [instructor x] and were having the usual technical difficulties. We only covered [one topic], and I was still confused after we finished it. I had typed a question in the chat box, but [instructor x] never saw it so it never got answered. And it takes forever to just get the class started. It seems like by the time we get everybody logged in and settled, the class is almost half over.
An undergraduate student said: Once they work the kinks out, it will be a great program, but I think the program is better suited for rural sites and better for nontraditional students. It's not so great for your typical undergraduate. I don't have any interaction with the teacher. Normally, you could see the teacher before or after class.

Faculty, students, and proctors shared with the researcher their frustration at the negative student behaviors that festered during the semester. One proctor, also a DVC student, said she had learned adults do not always behave like adults and that once instructors lost control of their classes, “they’ve lost it all.” She said many students were frustrated with initial and ongoing technology problems and never got past the frustration, which they vented aloud in class. “It became ongoing and public and diminished a professor’s authority and respect,” one proctor said.

The researcher observed many students coming to and leaving classes at will, napping, surfing the Internet, playing games on the computer, sending and receiving e-mail, completing homework for other courses, calling on cell phones, inserting music CD’s to listen to during class, badmouthing instructors, carrying on conversations totally unrelated to the course, and generally being completely off-track. One instructor noted that the array of technology available to students during class and the added focus and concentration needed for instructors to deliver a course and for students to process the content prompted students to go "mentally off-line."

The DVC study's results illustrated the importance of incidental learning in a desktop video conferencing course and of developing a learning environment that fosters positive outcomes. If a positive outcome is to occur, then DVC requires substantial technical training and support, administrative support for faculty, and a strong proctor system. Importantly, educators must continue to refine the pedagogy of effective teaching and learning with DVC. It is not an intuitively easy system to operate while simultaneously delivering course content, promoting student participation, managing student behavior, and troubleshooting technical problems.

As with any program, ongoing local evaluative studies that monitor participants' experiences and perceptions are critical if a DVC's program is to succeed, improve, and be sustained. Erhmann (1998) defined the technology of a program as its "hardware, software, and social technology" (p. 2). He emphasized the importance of knowing "what is happening right here, right now, this year, with these people" (p. 3). Fulk, Schmitz, and Steinfield (1990) constructed a Social Influence Model of technology use that considered influences such as work group norms and co-worker and supervisor attitudes and behaviors that positively or negatively influence attitudes, media use, and choices. Fulk (1993) proposed that an organization’s members could be expected to develop coordinated patterns of behavior based on observations of each other’s behaviors, the consequences of behaviors, and emotional reactions. Detecting those patterns, whether faculty, student, or staff, is crucial to avoid falling into the trap of the "rapture of technology" and failing to assess how different learners use technology differently with different and sometimes unexpected results (Ehrmann 1998).

**Similarities and Differences**

The two studies highlighted similarities that existed between these particular asynchronous online and synchronous DVC courses, including the:

1. Need for students to be self-disciplined, self-motivated, and patient
2. Variance in computer skills and technology accessibility that existed among the students
3. Use of email for communication between student and instructor
4. Compulsiveness of students
5. Unrealistic expectations of students
6. Lingering technology frustration
7. Vulnerability of at risk students
8. Lack of driving time and expense devoted to travel
9. Newness and niftiness of the technology
10. Expense to operate courses successfully
11. Smaller size of the classes
12. Lack of University-wide system for student evaluation

Key differences noted between asynchronous online and synchronous DVC courses included the following:

1. In a text-based online course, students tend to be more careful in their comments about other students, the course, and the instructor. In a DVC course students at remote sites can informally converse among themselves, with negative behaviors and comments often going unchecked. A strong proctor system, particularly with younger or more immature students, is key for DVC.
2. In a DVC course, negative individual attitudes and behaviors can affect an entire group, with an instructor unable to monitor individual and group behaviors simultaneously. Classroom management issues and strategies become accentuated in DVC courses.

3. In an asynchronous course, students understand the "transactional distance" between themselves and the instructor and do not expect immediate, real-time feedback. A DVC course gives students the illusion of one-to-one contact with the instructor and active participation. When a student's electronic raised hand or comment in the chat box goes unnoticed or unacknowledged for even a brief time, students tend more easily to disengage from class.

4. Students in online classes are accustomed to and expect a primarily text-based system, whereas the camera and monitor in a DVC class prompt in students a "TV" attitude. However, current DVC technology with its small video window and jerky transmission often relegates faculty and other students to tiny, out-of-focus talking heads. Boredom and disengagement again can result if students are not themselves focused, motivated, and disciplined.

5. A DVC system requires more technical support during class for both the instructor and students at remote sites. While an online class can weather downtime, a DVC course cannot. A DVC course requires more faculty technical training and preparation for technical contingencies.

6. In an online course, students can choose the time, pace, and duration of their course interaction. In a DVC course, the hours are set just as in a traditional course. Being tethered to a computer for two to three hours and staring at a computer screen can be physically tiring and boring, conditions ripe for frustration and disengagement. For DVC courses, changing activities and frequent breaks are key.

Conclusion

The two studies highlighted the differences and similarities in learning and teaching environments fostered by the two different delivery systems. Both researchers have years of experience as students, educators, developers, and researchers of distance education courses. Although "good teaching" has many universal tenets, the notion that faculty or students can seamlessly transfer from the traditional classroom to varied electronic formats should be dispelled. These findings underscore the importance of specific faculty development, curriculum planning, and administrative support for distinct electronic venues.

Tennessee Board of Regents - Regents Online Degree Programs

Robbie Melton, Tennessee Board of Regents, US
Carol Puryear, Tennessee Board of Regents, US
Bettie Phillips, Tennessee Board of Regents, US

Tennessee Board of Regents' colleges, universities, and technology centers joined in Fall 2001, to offer the Regents Online Degree Programs (RODP). All the institutions are fully accredited. All thirteen TBR two-year colleges deliver and award the noted associate degrees, while all six TBR universities deliver and award the noted bachelor degrees. Courses completed in the Regents Online Degree Programs are entirely online and transferable among all the participating institutions. Students are able to choose the college or university (home school) for their admission, registration, and the award of their degree.

**The degrees offered are:**

- Associate of Applied Science in Professional Studies:
  - Concentration in Information Technology
- Associate of Arts in General Studies (University Parallel)
- Associate of Science in General Studies (University Parallel)
- Bachelor of Professional Studies with concentrations in
  - Information Technology
  - Organizational Leadership
- Bachelor of Interdisciplinary Studies
  - General Studies/Liberal Studies/University Studies
- Masters in Education (in development for Fall 2002)
- Certificate in Computers Operations Technology
  - (TN. Technology Centers Fall 2002)

The Regents Online Faculty and Staff have been highly trained in teaching, learning, and assessing the needs of online students. The Regents Online Courses are designed for a 12 week semester--in an interactive, asynchronous (accessing courses at your convenience) format. These courses contain the same content and rigor as courses on campus. Student Services such as advising, library services, student support, and other forms of student assistance are offered for online delivery. Technical support for accessing course lessons and assignments are available 24 hours 7 days per week.

**Vision:** "A better life for Tennesseans through education"

**Mission:** "The Regents Online Degree Programs, using technology, will improve access to high quality, affordable, student-centered learning opportunities through cooperation among TBR institutions."

**Goals:**

To increase access to higher education for adult Tennesseans, especially those with some college experience. Census data document that Tennesseans lag behind both the national and regional averages of educational attainment. Further, attainment is uneven across the state, with rural areas lagging far behind urban areas. Economic development of the state depends on increasing the skill levels of the population.

To maximize the effective use of technology for delivery of college-level instruction. Distance delivery through the use of technology will increase access to higher education, especially in remote areas of the state and for adult learners for whom time flexibility is a critical resource.

To provide student access to web-based courses and degree programs. Web-based courses will reach populations not currently enrolled in higher education, and will also permit students who are currently enrolled in on-campus courses to take additional courses, thus completing their programs sooner.

**Partnership with Eduprise E-learning Corporation**

Eduprise, the leading provider of enterprise e-Learning services for education institutions and businesses, partnered with Eduprise to provide strategic planning, infrastructure hosting support and instructional development services. Eduprise established a major role in TBR's bold initiative by providing the infrastructure support services to underpin the strategic plan for the Regents' web-based degrees. These services include a hosted WebCT course management system, 24x7 technical help desk for students and instructors, WebCT software training for instructors, instructional design assistance.

**Current Success**
It was projected that the Fall 2001 enrollment would total to 300. However, the final enrollment number was 1,954 with a withdrawal rate of less than 12% and a dropout rate of less than 20% compared to the national average of 42%.
The student and faculty surveys indicated an overall satisfaction rate of 79%.
The early Spring 2002 registration (conducted in Nov. 2001) ended at 2,732 enrollments, far exceeding, the Fall 2001 numbers.
(This proposal is being submitted before Spring Final Registration)
Final registration will convene on January 7th, 2002. It is predicted that all courses will be closed due to full enrollment. If this proposal is accepted, the participants will receive data regarding the program, student, and faculty evaluations, Spring registration figures, average retention rate, and new degree programs.
Sexual Harassment Training Online: 
Incorporating Layout, Design, and Pedagogy

Robert L. Miller
Office of Civil Rights
Eastern Illinois University
csrml2@eiu.edu

Link to site: www.eiu.edu/~civil/sh
Password: eiu37

(This version is online for testing purposes and future modifications will include using streaming as opposed to embedded audio.)

Abstract: In order to provide a better working and learning environment, and to comply with state and federal law, Eastern Illinois University requires new employees to complete a sexual harassment training session within their first six months of employment. Because of scheduling conflicts or demands, this seminar is now being offered online. There are many challenges in developing this type of online course and special care must be taken to create the most interactive, informative, and user-friendly version possible. An effective course design will encourage and facilitate active user participation and will incorporate animation, audio, and other multimedia elements that enrich the learning process.

The focus of this paper describes how this course was developed and details design and pedagogical techniques educators can use to enhance their online seminar materials.

Introduction

The decision to offer sexual harassment training online should not be arrived at lightly. Face to face seminars still have the advantage when it comes to audience participation and interaction. Question and answer sessions provide valuable opportunities for members to get immediate answers to their questions. Advocates of online learning point out that while the technology itself is important, effective learning methodologies are crucial for a site to be successful (Turoff, 1999). Additionally, authors of online sexual harassment courses must be able to draw from experience and expertise in order to come as close as possible to recreating the live seminar in an online format. There is a wealth of information available on the net regarding sexual harassment. Therefore, users of your online seminar must feel that there is some type of extra value, or ease of use associated with your site in order for them to “buy in” to the concept and ultimately absorb the information. It is also important to remember that at least some users will not be at the site by choice, which will make them even more prone to distraction.

Site Design

Designing this site was the author’s first attempt at Web design. Macromedia Dreamweaver 4 was used along with Macromedia Fireworks 4 and Coursebuilder. Dreamweaver permits the user to design a site without knowing a single line of code and Fireworks (www.macromedia.com/software/fireworks/) makes it possible to animate and customize text and images. Coursebuilder, which can be downloaded for free from the Macromedia site, was extremely useful in making the site interactive.

Dreamweaver (www.macromedia.com/software/dreamweaver/) is a very user-friendly software package that comes with a how-to reference book along with movie tutorials and links to helpful websites. However, designing the first page still took approximately 10 hours. Successive pages were added more quickly. The use of templates is advised as this will streamline the design of the site and will provide uniformity. Integrating substantive content into the site was started two weeks after the project began.

Coursebuilder was used extensively in the site in order to get the user involved. This application makes it very easy to incorporate questions and answers throughout the course. Formats range from multiple choice and true/false questions to drag and drop interactions. Additionally, the software will track and record test answers and send them to a central location. Inserting a Coursebuilder interaction is easy and can be done with just a few clicks. Typing the question and answer choices can be done either in the Coursebuilder folder or on the Dreamweaver work page.

Site Layout
Appropriate color schemes, graphics, and animations are essential in creating a successful site. However, artistic design is not the primary purpose of a Web page. The substantive content should not be overwhelmed by excessive graphics and colors. Additionally, buttons and other navigation devices should allow the user to move easily from one area to another (Bohannon, 2001). Animating text can also make the site come alive which serves to keep the attention of the user. However, excessive use can be distracting.

The use of audio is another consideration when designing this type of site. Audio files can be distributed by either streaming audio or file downloading (Gerth, 2001). For longer audio files, streaming audio works better because it allows small portions of the file to be delivered and then play while the rest of the file is downloaded just ahead of the playback portion. For smaller audio files, it may be easier to just download the file to the user’s hard disk before playback begins. Because people retain only 20% of what they hear, and 30% of what they see, but 50% of what they see and hear, integrating audio to enhance learning is very useful (Gerth, 2001).

Pedagogy

As stated earlier, the substance of the site is of primary importance and must not be obscured by too many graphics, animations, etc. Additionally, the user must be involved in the course which is accomplished by making the site interactive. It is recommended that the user become involved as soon as possible. For example, in the instant course, after the user completes the registration materials and reads the course objectives, he or she is asked to complete a short quiz. Several general questions are asked regarding sexual harassment in the multiple choice and true/false format. Special care should be taken in selecting these questions because, in addition to providing interaction, the questions should be intriguing and create interest in the content.

For this particular subject matter, hypothetical scenarios are very useful and can be easily presented online. After providing the basic substantive information to the user, they should be asked to read a scenario and answer a short series of questions so that they can apply what they have learned. In Coursebuilder and Dreamweaver, the user can be taught many different concepts in the context of just a few scenarios by utilizing pop-up text boxes and links to other pages. For example, a user can be guided to the correct answer by pop-up messages that ask the user to consider additional information if they have trouble.

Conclusion

This paper has explored some of the basic technical and pedagogical concepts regarding the delivery on online sexual harassment training. A successful site takes time to create and requires the incorporation of appropriate colors, graphics, animation, and audio along with proper teaching techniques. The result is a very useful tool that provides much needed flexibility in the quest to educate faculty and staff members about sexual harassment.

Old Ideas, New Approaches to Online Distance Learning

Charles Mize, West Texas A&M University, US
Keri Rogers, West Texas A&M University, US

Introduction

As the world moves steadily into the twenty-first century, schools are faced with a variety of challenges. The use of technology for the delivery of instruction is one challenge that is increasingly gaining notoriety in this new century. With increases in funding for instructional projects and the use of the Internet as a tool to enhance connectivity, schools have not only changed the way that technology is planned for, but also have changed the process of education which is adding new opportunities for educators, students, and the school community. One opportunity that is foremost in many technology based discussions is online distance learning.

Distance learning in itself is not new. Even the use of computer networks for the distribution of instruction can easily be traced back to the 1960s. However, with the development and expansion of the Internet, access to computer networks have become more readily available to the general public. Therefore the use of the Internet to deliver instruction at a distance is perhaps at best, a new approach to an older method of instruction. The situation in which many schools and institutions of higher education find themselves, is how to effectively design online programs that successfully facilitate the needs of both faculty and students.

An Innovative Approach

One university in the southwestern part of the United States has developed an innovative approach to online, web-based distance learning. The program is innovative in both its philosophy and its approach to web-based course delivery.

The innovative philosophy followed is one of seamless technology integration that sees all students simply as students of the university with no distinction being made in anyway between students who receive course delivery online or through traditional means. Through the application of this philosophy, online students are never left hanging without the support needed to help them succeed. Each student is placed with a faculty advisor who guides the student through the academic portion of his or her online studies. Further, student services are provided to assist students with the successful completion of their programs. Student services, ranging from admission, registration, financial aid, personal counseling, career counseling, and even student activities, are provided through the online environment. Additionally, a technical support facility is staffed with individuals trained in helping students with their technical questions or to help facilitate communication between the student and university or faculty members. At any point, a student can call, email, fax, or chat online with someone that can help with questions.

The program also follows an innovative approach to course development and delivery. All faculty who teach online must go through a 25 hour training program prior to delivering their first course. No distinction is made between faculty who teach online and those who do not. Faculty who teach for the distance learning program and those who teach traditionally delivered courses are the same with the exception of the additional training for teaching online. Most faculty go through the training program while developing their first course for online delivery. The training covers topic such as instructional design, methods of building strong communication and interaction, pacing the course, developing multiple methods of evaluation as well as the various technology tools available to the faculty member for use in a course. As a result of the online training program, most faculty have a major portion of their first course completed by the end of training. After training, faculty receive continued support through the Instruction Innovation and Technology Lab, which is the faculty development facility at the University.

The technical portion of the program is innovative with the in-house development of the course delivery software. Many course management packages are commercially available, but are often restricted to a single instructional design model for course delivery. It was determined that in order to provide the greatest amount of flexibility to faculty for the design of their courses while at the same time providing an easy to use consistent environment for students, a new course delivery system would have to be developed.

The software package has a strong theoretical basis and moves the theory into strong practice. Many commercial course management packages follow a content – container model for course delivery. This model sees the course content and the delivery container as being independent of one another. Faculty simply type up their content and copy it into the pre-defined container for delivery (Figure 1).
However, the model used for this program sees the relationship between the content and the container as being reciprocal (Figure 2). In this model, faculty may choose many different instructional methods and designs to structure their content. Then the content and design is matched to the most appropriate technology for course delivery.

By providing faculty with the ability to develop a “best-fit” between the instructional task (content) and the delivery technology, instructional innovation can be achieved for the benefit of the student. The uniqueness of this distance learning program is the development of an environment that allows the flexible design of instructional task and content while maintaining a consistent interface for students and faculty to interact within.

Outcomes

The program began in 1997 with one course serving 24 students. For the Fall 2001 semester, the program offered 79 courses that served 1574 students with 2333 course enrollments. This number not only represents student access to a quality institution of higher education, but it translates into a student savings benefit of over 5,587,231 miles of driving, 94,787 hours of driving time, and over $1,834,424 in driving costs. Students who would have to spend many hours driving are now able to spend that same time engaged in their studies, increasing their opportunity for learning success.

Degree requirements for campus-based and distance students are the same. Currently, the program has 141 total courses in its course inventory with over 120 trained faculty ready to deliver their courses through this delivery method. However, the number of courses is not nearly as interesting as the number of complete degree programs offered. The university offers its Master’s degree in Business Administration and its Master’s degree in Education, Instructional Technology totally online. At no point is it necessary for students to physically come to campus to complete either of these two programs. At the undergraduate level, the university offers a Bachelor’s of General Studies, Emergency Management Administration and in Nursing (RN Completion). The number of programs and courses are constantly expanding to assist students in their desire for educational opportunity.

Quality
Survey research is conducted every semester to determine the demographic patterns represented by students who participate in the program. Further, student attrition, satisfaction, and benefits are monitored in order to inform faculty training, technological improvements and program development. Current research projects at both the graduate and faculty level covers such topics as online course quality assessment, mediated online communication, improved online instructional strategies, and improved interface design.

A Southern Association of Colleges and Schools (SACS) review committee made a physical visit to the university on May 8-9, 2000. After the review committee made its recommendation to the SACS board, a commendation and full accreditation of the university’s Internet based program was awarded in January of 2001.

Conclusion

As will distance learning as a whole, the ideas utilized in the development of this online program are not necessarily new. However, this program has been highly successful in pulling many concepts together into a successful enterprise. Individuals attending this session will have the opportunity to see at least one method for delivering degree programs online. Attendees will be given an overview of how this program used the principles of seamless technology integration to build a program that represents and includes all areas of the campus community. Attendees will also see both the positives and negatives of building such a program. As has been seen with many failures with online education in recent history, the pitfalls that can doom this type of program are great. However, with strong vision of what the outcomes for a program should be, good planning based on sound theoretical principles, and a bit of luck, an online distance learning program can be a good choice for many schools.
Abstract: A pervasive issue in online learning is the effective use of communications tools. In many instances, the creative uses of discussions, chats, and e-mail makes for a positive experience for learners and are critical factors in the level of student involvement in the course. This is especially true when conducting in-service courses or other adult learning situations where learners bring a rich array of experience that require a vehicle by which these experiences can be shared and passed along to their peers. In the design and delivery of numerous online courses implementing various technologies, we have experimented with and established a variety of best practices that are designed to promote high interactivity among learners. In effect, the use of these tools can develop better communications in instructor/student and student/student interactions and provide for more active student involvement. This paper ventures to present a series of useful strategies and best practices for online communication.

Introduction: One of the most common complaints by students after taking their first online course has been the lack of personal interaction that is commonly associated with the traditional classroom setting. Facilitating in-depth rich discussions as part of online class activities is one of the most critical elements contributing to a student's success or failure in an online course. Interaction with students has been found to be the most critical factor in student perception of successful learning experiences online. (Palloff, R.M., Pratt, K., 1999) This is especially true when conducting in-service courses or other adult learning situations where learners bring a rich array of experiences that require a vehicle by which these experiences can be shared and passed along to their peers (Knowles, 1978).

The level of involvement between students and content is seen as a critical factor in the retention of college students (Astin, 1992). Students can be encouraged and compelled to become actively involved with course content through creative and interactive online conferencing strategies. While only a few teaching methods are typically used in higher education, instructors have at their disposal a variety of instructional strategies that could be used to elicit the various types of
learning (Davis & Davis, 1998). In the design and delivery of numerous on-line courses implementing various technologies, we have experimented with and established a variety of best practices that are designed to promote high interactivity among learners.

**Background:** In early attempts at teaching on-line courses, many comments voiced ran along these lines: “I will never take an on-line course again!”, “There were times when we forgot we had a professor.”, and “I really miss the face-to-face contact with my fellow students.” Students often hold preconceived notions of on-line education as impersonal, instructor-less courses. However, through experimentation and review we have developed a list of several practices to instill in students effective use of communication tools online. In effect, the use of these tools can develop better communications in instructor/student and student/student interactions and get students more actively involved in the course content.

**Implementation:** Through trial and error, several techniques have been tested over the last few years. Some of the techniques listed below did not always work well at first. But, through refinement and practice, the following methods have proven to work the best most consistently in promoting better interaction among students.

Use an icebreaker - This is a simple process. The first step is to ask students to introduce themselves briefly and then to follow up with an assignment to post photos and autobiographies to all class members. It is also important to create a practice area for students to feel free to practice interacting with each other between classes. It is important to lead with a question or assignment that encourages and requires each student to participate. Another warm up exercise is to devote the first 10-15 minutes of each class session communicating with each student about their work, their life events, etc. In effect, this begins to create a sense of community that is necessary to developing a successful teaching experience.

Student moderated discussions – This technique was designed to give the student control of the interaction and participate in the teaching process. Allowing learners to participate in the direction of the class has been proven to be an effective method of not only creating learner ownership but also to raise learner satisfaction. The process used is to have a student or group of students develop the discussion topic in which they would present or pose multiple concepts and controversial topics, which could be debated or discussed on-line. The individuals presenting are responsible to research a topic for the discussion board, and provide reading materials for the other class members. These materials are then disseminated either through e-mail or by posting to a designated website. During the class period, the assigned student(s) moderate the discussion through the use of an online chat. It usually works best to breakout the class into groups. Each group is then responsible to post their
responses to their respective areas on the discussion board as well as report a summary when going back into the total class chat.

Role-play – One way to involve students more thoroughly with the class content is to turn the conferencing area into a dramatic scenario or role-play environment. For instance, political science students can each represent country’s involved in a summit meeting such as the G-8, and through the discussions, role-play a summit meeting on one issue, each student arguing for the concerns of their respective country. Separate conferencing areas should be used, one for the discussion and preparation of the upcoming role-play, and one for the role-play itself where individuals will ‘speak’ with the voice of their assigned role. This strategy could be useful to dramatize interviews of group project proposals, argue two sides of a legal issue, or conduct debates among philosophers.

Alter egos – The creation of alter-ego characters who represent extreme viewpoints about a content area could be useful in forcing students to recognize and react to various perspectives. In a course on negotiation, a professor can intermittently interject the opinions of extreme views using characters and encourage students to write responses appealing to these viewpoints. Some course delivery platforms allow instructors to alter the name of the submitter to further augment the presence of various ‘voices’ within the class discussion.

Various forms of groups – Online groups can take many forms. The class structure and logistics will often play as strong a role in how to create groups as the group project itself. For example, allowing students to self-select into groups may be desirable for a group project, but may require two weeks for the formation of groups alone due to the asynchronous nature of online collaboration. Online groups are also typically much smaller than groups in the traditional classroom. Success in a classroom-based team often hinges on the level of facilitation by the instructor. “Too much involvement and the team has no chance to develop its own cohesion, but too little facilitation and the team struggles and may lack a sense of purpose” (Arend, 2000) Also, strategies for including self-reported and peer-reported group grading sheets greatly assist the instructors’ task of ensuring an equal share of workload within groups.

Team presentations – Team presentations, while often a logistical challenge online, remain an important component of online collaboration and should not be overlooked. Teams need the opportunity to showcase their achievements and gain constructive feedback on their many decisions and conclusions. Online presentations can take the form of live chat-based ‘question and answer’, PowerPoint, web page or other multimedia, asynchronous feedback, or any combination of technologies and methods. One of the most successful approaches is to have teams submit their presentation in a convenient format, such as pdf files, to the instructor who then posts the presentation on a class web site prior to the class session. In this manner, other members can view the
presentation during the class session.

Faculty responsibility – As the instructor in an online course, there is an explicit responsibility to engage as a member of the discussions. Students are reluctant to participate actively in an area where the instructor has no presence. However, too much interaction can prove equally detrimental. An instructor who responds to each student posting immediately may unwittingly create an environment of over-cautiousness and reluctance on the part of students to participate and to explore new ideas. Students will need a level of freedom to learn that online conferencing is a safe place to test out new thoughts. But, the instructor must balance this freedom with an obvious concern for the direction of the discussions, and input of expertise.

Finally, the Instructor must serve as a model and interact with the students throughout the course. If an instructor expects certain levels of thinking, formality, and even grammar and style, this should be modeled in all instructor comments. Students should be directed early on regarding the desired format so they may become familiar with essential communicating skills. They can more quickly focus on the quality of their comments. Some instructors choose to divide conference areas into informal, free exchange of idea forums, and more formal, graded discussion forums.

Conclusion: Ultimately, using these processes to encourage and develop confidence and skill with online interactions have had a number of highly positive implications for both the students and the instructor. There is greater ownership and cohesion among the students. Participation throughout the length of the course evolves as student investment in the course continues to grow. And, at the end, students are much more positive about their experience in the course.

Beyond the Talking Head: Active Instruction in Online Instruction

Kathryn Morgan, Bemidji State University, US

What are the strategies for working effectively with students in online learning environments? What can educators do to stimulate meaningful student discussion? This presentation will provide examples of both written responses and online chat environments that reflect creativity, quality questioning strategies and online options that will increase the ability for the faculty to interact with students on a timely basis. Cartoons, case examples, and a collaborative response strategy will be used to illustrate the active concept.
Abstract

The QIICC Analysis feature of the Telequiz Assessment Protocol is a revolutionary method for analyzing student learning. The Telequiz Protocol has been used in Dr. Dwight W. Allen's Educational Curriculum and Instruction courses at Old Dominion University since 1997. The protocol allows students to take quizzes over the Internet at their convenience. These quizzes are comprised of randomly assigned multiple-choice questions based on the content of the course.

The QIICC Analysis feature allows for students to rate individual questions on several variables: Quality, Interest, Importance, Confidence and Challenge. The first three of these are fairly straightforward, however, the last two need some explanation. The purpose of this protocol is to attempt to discern how accurate students are in their understanding of their own knowledge, and to train them on how important it is to "know what you know."

Project Summary

Students are asked to provide a confidence level for each question comprised of three levels (high, medium and low). This data is meant to show how confident a student is in his/her answer. This data is then used, along with the answer accuracy, in order to calculate the score for individual questions. The scoring rubric is shown in Chart A:

<table>
<thead>
<tr>
<th>Confidence Level</th>
<th>Question Accuracy</th>
<th>Credit Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>HIGH</td>
<td>Correct</td>
<td>5 points</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Correct</td>
<td>4 points</td>
</tr>
<tr>
<td>LOW</td>
<td>Correct</td>
<td>3 points</td>
</tr>
<tr>
<td>LOW</td>
<td>Incorrect</td>
<td>2 points</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Incorrect</td>
<td>1 point</td>
</tr>
<tr>
<td>HIGH</td>
<td>Incorrect</td>
<td>0 points</td>
</tr>
</tbody>
</table>

As can be seen, the maximum credit that can be received for any one question is 5 points, however, during the implementation phase of this grant, several scoring alternatives have been utilized. Initially, each question was scored out of 5 points, thus making the theoretical maximum the goal for each quiz. During the initial testing of this protocol, it was found that this was in essence detracting for students who were not absolutely confident in their answers, and so the grading rubric was changed to grade out of 4 points. This grading scheme rewarded the students for high confidence levels. It was found that this grading process worked best in the k-12 educational setting, however, the students at the university level demonstrated much more confidence in their answers, and the bonus point for each question lead to extremely lopsided scoring – in some cases as many as 30 bonus points were awarded per test. Due to this, the scoring rubric at the university level was adjusted back to being scored out of 5 points.

The final variable, challenge, allows students to challenge any question on a quiz. A challenged question does not count toward a quiz grade. Each student is provided with 5 challenges at the beginning of the semester, and can be allocated more for any reason found appropriate by the instructional staff. If a student uses more challenges than they have left an email message is sent to them indicating this has occurred, and the challenges (over the number they have been allocated) are turned to non-challenged questions.

Results & Implications:

The data analysis for the implementation of the QIICC protocol shows that there are substantial benefits to using the process. Average confidence levels have consistently been above 4.0 (4 being MEDIUM confidence and 5 being HIGH confidence) – regardless of test site. In fact, the only instance where the average confidence dipped below this 4.0 plateau occurred at the university level, and even then only by hundredths of a percentage point (3.98 during the initial summer testing). The highest confidence levels, by far, were seen at the 3rd grade in Brunswick County (4.84), which demonstrates an important point that was learned during this testing of the protocol; students in the elementary grade levels have difficulty making the confidence judgments requires by the QIICC analysis. When asked directly if a student knew the answer to a question, often the student would admit that they did not, however, once a
choice was made — regardless of whether the choice was correct or not — the student would show high levels of confidence in the chosen answer. The testing of students in the 5th and 6th grade in St. Louis showed a much more realistic understanding of their confidence levels — approximately the same, on average, as those students in the 11th grade that were tested (4.31 and 4.33 respectively).

More important than simply looking at the confidence levels, is looking at the difference that the QIICC scoring rubric makes in grades. Throughout the testing, analysis has been done to compare the QIICC grading rubric with the more traditional rubric involving 1 point for every correct answer. The results showed some startling trends. Every administration of the QIICC protocol showed that students performed much better, in terms of the scoring percentages, using the QIICC scoring rubric. Using the same tests, and running the two separate scoring schemes, the students scored as many as 22 additional points (on a 100 point scale) through the QIICC scoring. The process in the K-12 testing, where each question was graded out of 4, showed that the average score ranged between 78.4% (3rd & 5th Grade samples) and 88.9% (11th grade sample) on the assessments using QIICC. In comparison, these same tests, when scored using the traditional one point per correct answer showed the average score ranged between 61.1% (5th grade sample) and 66.6% (11th grade sample) depending on test site. The QIICC scoring rubric resulted in grading difference between 17.3 additional points and 22.3 additional points.

The results at the university level, where each question was graded out of 5 points, show similar differences. Depending on the quiz that was taken (each of the six quizzes was used as a distinct administration of the process), the QIICC scores ranged on average between 65.9% (6th Quiz during the summer) and 92.6% (2nd quiz during the fall), while the traditional scoring ranged between 49.8% (6th quiz during the summer) and 74.1% (2nd quiz during the fall). The comparison of the two grading rubrics shows a gain of between 16.1 and 21.1 additional points using the QIICC scoring rubric. Complete results are shown in Chart B.

Conclusions

Although further research is warranted, this initial study has allowed for a more complete understanding of how QIICC Analysis, in conjunction with the Telequiz Protocol, can influence the assessment of students at all different levels of schooling: elementary, secondary and post secondary. This research shows that there is tremendous potential for including students in the assessment process, and for making assessment a more meaningful process.
ELEARNING IN EDUCATION: AN OVERVIEW

Raymond S. Pastore, Ph.D.
Department of Educational Foundations & Secondary Studies
Bloomsburg University
United States
raypastore@hotmail.com

Abstract: Elearning, as used in this presentation refers to the use of Internet technologies to deliver instruction. This objective of this presentation will be to examine the development of distance education from interactive video and computer-based courses to web-based instruction. The primary level of Elearning that this presentation will address is the use of web-based courses where 50% or more of the classes are online. This presentation will also address issues and problems associated with the implementation of Elearning.

Definition of Elearning

In a true sense, Elearning can be thought of as the delivery of information via all electronic media, including the Internet, intranets, extranets, satellite broadcast, audio/video tape, interactive TV, and CD-ROM. Although each delivery system has specific advantages and disadvantages, the power of the Internet has resulted in the rapid growth and expansion of Elearning in the form of web-based instruction. The most popular view today refers to Elearning as the use of web technologies to deliver instruction. Rosenberg (2001) has defined 3 criteria for Elearning:

- E Learning is networked, which makes it capable of instant updating, storage/retrieval, distribution and sharing of instruction or information.
- It is delivered to the end user via a computer using standard Internet technology.
- It focuses on the broadest view of learning – learning solutions that go beyond the traditional paradigms of training.

Types of Delivery

Elearning can be based on a dichotomous “blended learning” model (Selix, 2001) that views learning delivery modalities as synchronous/asynchronous and online/onsite. Synchronous learning is learning in real time. The instructors or a group of instructors may lead the class through a series of meetings to deliver course content. The advantage of synchronous learning is the “live” student/teacher interaction. The disadvantage of synchronous learning is the limitation to learning at a specific time. Asynchronous learning is learning on learner’s time as decided by the student. The obvious advantage of asynchronous learning is the flexibility of the student to decide when the lesson will take place.

The advantage of online learning compared with on-site learning is the savings in money and time for travel. The obvious disadvantage that is given most often by critics of Elearning is the loss of personal interaction with the instructor, although this may be somewhat disputed through the use of interactive web technologies.
Advantages & Disadvantages of Elearning

Proponents of online learning claim that Elearning delivered via the Internet is both efficient and effective in terms of learning and costs. Although Elearning is generally thought of as cost-effective, the degree of instructional quality in Elearning can vary as much as instruction led by traditional methodologies. Course completion can also become a major issue. Elearners who enroll in asynchronous learning courses must have motivation, independent learning skills, and determination to insure completion of their work.

Elearning resource providers such as Click2 Learn claim that online learning has many advantages over traditional classroom learning such as high memory retention and consistency in quality of instruction. As teaching models shift from teacher-centered, "one size fits all" learning to student-centered, individualized life-long learning, web-based Elearning supports new pedagogies. Techniques such as self-paced learning, collaboration, simulation, and exploration may become central to the concept of online instruction.

Elearning in Schools

As is the case with many institutions of higher educations, the number of high school offering online courses is increasing. Elearning in the public schools provides increased access to learning and more learning opportunities for students of all ages in any location; however, educators are facing challenges including economic, networking, and access issues. The integration of Elearning into the curriculum will require careful technology planning so growing needs do not rapidly exceed resources.

Future Trends

Elearning had become a new form of knowledge transfer and a unique and exciting delivery system. Future Elearning trends are expected in the following areas:

- Continued Elearning growth and expansion in Education and Business and Industry
- A greater Elearning role in the public schools (Office of Educational Technology, 2001)
- Improved web technologies to disseminate Elearning over the web
- The development of new Elearning and evaluation standards.

As John Chambers, CEO of Cisco Systems has said, "Education over the Internet is going to be so big, it is going to make e-mail look like a rounding error." (Internet Time Group)

Abstract: This paper is a report on the findings of a study conducted on a dually listed undergraduate and graduate TESOL distance learning course. Data were collected on the students' interactions with the course content and instructor to investigate differences in how graduate and undergraduate teacher preparation students interacted and responded to the distance learning delivery mode. Findings indicate that the graduate level students were more autonomous and confident using the new methods of course delivery than were their undergraduate counterparts. The implication of these findings is that the design of distance learning dually listed teacher preparation courses must provide for adequate support for the less experienced (undergraduate) learners. Suggestions for providing such support are included.

Introduction

Barry University in Miami Shores, Florida is committed to serving the needs of diverse populations. The teacher education programs at Barry University work with the community to provide relevant and accessible preservice and inservice teacher preparation courses. Teachers in the state of Florida are required to be ESOL endorsed; consequently, the teacher education programs at Barry University infuse TESOL courses in their preservice programs and offer TESOL courses at the graduate level enabling practicing teachers who are not yet endorsed to fulfill the state requirements. Large numbers of pre- and in-service teachers across the state enroll in the TESOL courses. To better meet the demands for such courses, Barry University designed one of the required courses, TSL 406/506 – Applied Linguistics, as a distance learning course.

The School of Education instructor who took on the challenge of redesigning TSL 406/506 as a web-based course had taught the course in a traditional manner many times and was, therefore, very comfortable with the content as well as the challenges that may arise from the course and strategies to effectively deliver the course. The instructor worked with the School of Education's distance learning design team to prepare the course for the distance learning format. Several elements had to be considered as the team began the design and development processes: 1) since the course was part of a state certification program, it must adhere to the standards and form that were in place for the traditionally delivered course; 2) the course is dually listed as both undergraduate and graduate courses, and, therefore, any given section of the course may have both novice and veteran teachers enrolled; 3) the course is a methods course and must balance theory and practice. The design team, with content, design, and technology expertise, collaborated to create a course that would serve the intended population.

Technological Implementation

Critical course elements for successful distance learning experiences were built into the course design. These were derived from the American Association for Higher Education's (AAHE) “Seven Principles for Good Practice in Undergraduate Education,” principles of adult learning (Knowles, 1998) and various research, studies, and literature reporting on effective distance learning design (e.g., Moore and Kearsley, 1996; Driscoll, 1998; and Horton, 2000). Elements incorporated into the course are listed in Table 1 with their corresponding strategies.

Table 1: Critical course elements included and strategies used in their implementation

The Study

The distance learning professional development course was piloted in the fall of 2001 and involved 14 students. The course was dually listed as an undergraduate and graduate course. Six of the enrolled students were graduate students, and the other eight were undergraduate. None of these students had previously taken a web-based course.

This study addresses the following research questions:
1. Is there a difference in how a pre-service (typically undergraduate) teacher embraces and applies the technologies in a web-based distance-learning course to the manner in which an in-service (typically graduate) teacher does?
2. What implications might differences in the approaches have for teacher educators who design and deliver distance learning teacher preparation courses at the pre- and in-service levels?

This study is informed by the research and literature base on teacher competence and experienced and expert teachers (Berliner, 1988; Sternberg and Horvath, 1995). Teachers, at various stages in their professional development, exhibit different behaviors in their teaching practices and in how they approach and plan for the teaching and learning experience. Generally, these stages of development are depicted on a continuum from beginning or novice teacher (which includes the pre-service teacher) to the experienced and accomplished (in-service) practitioner. Sternberg and Horvath (1995) propose an Expert Teaching Prototype, using three primary categorizations to distinguish the novice teacher from the expert: Knowledge, Efficiency, and Insight. Berliner (1988) describes Pedagogical Developmental Stages that portray and characterize the teacher in five developmental stages of professional development. These stages of development are not new to understanding how the novice and apprentice level teachers become expert and accomplished with typical classroom practice. This study, however,
seeks to determine whether or not the same or similar stages are evident in terms of novice and experienced teachers interacting with distance learning technologies in a professional development course.

The data derived from this study are in the following forms:
1. Assignments submitted by students
2. Frequency of student access to various course resources
3. Student messages to the instructor

Results

Data regarding the submission of assignments in four categories were collected. These data are listed below under the heading "Assignments Submitted."

With regard to the frequency of interaction with course content, the following data were collected. The graduate students recorded a total of 5141 hits to the course, which translates to approximately 857 hits for each of the six students. The undergraduate students recorded a total of 4619 hits, which translates to an average of approximately 577 hits for each of the eight students. The average of 857 hits for the graduate students is significantly different than the mean of 577 hits for the undergraduate students ($p = .05, df = 12$).

For the purposes of this study, the course was divided into three categories of pages: the Homepage that hosts various icons to access components of the course, the Organizer pages that open into other pages, and the Content pages. The Content pages list various components of the instructional modules of the course. Items Read are pages within the other structures. The averages for each group for these categories are reported below under "Average Hits Per Person." The following statistical observations result from an analysis of the data in the "Average Hits Per Person" section of Table 2. In terms of the Homepage, the average figure of 243 hits for the graduate students is not significantly different from the figure of 177 hits for the undergraduate students ($p = .05, df = 12$). Regarding the Organizer pages, the mean of 172 hits for the graduate students is not significantly different from the average of 129 hits for the undergraduates ($p = .05, df = 12$). In the area of Content pages, the average figure of 303 hits for the graduate students is significantly different from the figure of 144 hits for the undergraduate students ($p = .05, df = 12$). With regard to the average number of items read, the figure of 119 for the graduate students is not significantly different from the figure of 113 for the undergraduates ($p = .05, df = 12$).

The third category of data regards messages to the instructor, generally in the form of questions regarding various aspects of the course.

Table 2: Quantitative data collected regarding student interaction in web-based course

Interpretation and Implications

Overall, it is clear that the graduate students interacted more frequently with the course content than did the undergraduate students. Further, it appears that the graduate students expressed less concern about technology
challenges and course content than did the undergraduate students. However, since all six of the graduate students were also preservice teachers in this pilot, it is impossible to identify any correlation between the graduate students’ interactions in the course and pedagogical stages of development of teachers. One might look, however, to Sternberg and Horvath’s (1995) Expert Teaching Prototype to generalize and draw parallels between the graduate students’ experiences and “expert teachers.” Sternberg and Horvath (1995) suggest an Expert Teaching Prototype that draws on psychological research on expert performance in a variety of domains. The three primary features distinguishing the expert from the novice are: Knowledge, Efficiency, and Insight. Briefly, the prototype suggests that experts bring more knowledge to bear in solving problems and do so more effectively and efficiently than do novices. Further, experts are more likely to arrive at creative solutions to problems than their novice counterparts. The expert, then, is knowledgeable and has extensive accessible knowledge that is organized for use in performance. Finally, the expert is planful and self-aware in approaching problems and is able to derive solutions to problems through selective analysis of information (Sternberg and Horvath, 1995).

Applying this concept to the current study, one could say that graduate students are more “expert students” and therefore perform at higher levels of accomplishment than do their undergraduate counterparts, despite the fact that the content is equally new to both groups. In the present study, the distance learning format was novel to all participants; but the more experienced students, the “adult” learners, appeared to be more capable of adapting to the new situation of adult learning experiences than were the less experienced students.

The implications of this for the design of distance learning (or traditional) courses that are dually listed as both graduate and undergraduate is clear: to make the playing field more level and to nurture the less experienced student, instructional designers must scaffold learning to provide opportunities for learners to better master the knowledge, to become more efficient in the processes of learning the content, and to develop insights that apply to the current learning situation and that are transferable to other learning experiences. The nature of the distance learning course is ideal for such an approach. Since much of the interaction of the course is done asynchronously, the distance learning student may choose which scaffolds to use. Some suggestions for revisions to TSL 406/506 are suggested:

1. **Embed learning/study skills into the course content.** Elements such as highlighted text to focus students’ attention on essential concepts; hyper-linked text to examples of the concept in practice or to in-depth explanations; color-coded text to “arrange” course themes; and online tutorials in the use of basic technologies used in the course may assist the learner in developing a schema for learning in a distance learning format.

2. **Expand the course orientation.** A series of streaming video clips that address specific skills or knowledge required in the course, success factors for distance learning, and/or an explanation of the style of the course and its content may help “set the stage” after the initial face-to-face meeting. Including a brief course manual that addresses certain challenging issues or provides additional resources may provide a degree of comfort.

3. **Provide recommendations for time on certain tasks.** Offer suggestions for the amount of time that the learner should spend on certain tasks, helping the student budget his/her time. These suggestions might be written into the module with the assignment. Additionally, provide learners with suggested weekly time demands at the initial orientation session so they might build these into their calendars immediately.

4. **Engage students in more interactions with one another.** Establishing the social climate of the virtual classroom may provide learners with a degree of comfort to communicate and to work with one another. A virtual icebreaker at the start of the course that not only introduces students to one another but also employs some of the technologies that will be used in the course may help to establish a climate for success. Required virtual meetings scheduled one-third and two-thirds of the way through the semester to follow-up to the initial orientation meeting may help students stay on track. Authentic collaboration could be accomplished through group projects, jigsaws (groups of undergraduate and graduate students becoming experts on a topic from the course), and team projects.

5. **Highlight the relevance of the course to its practical application.** Include, at the beginning of each module, the purpose for the module content and its application to practice. Have students publish to the class web their field experience summaries and analyses and invite students to comment on or inquire about one another’s remarks.

**Conclusion**
Although these suggestions may sound like a great deal of hand-holding, indeed, that is what we must do as we introduce the student to a foreign learning approach. As Dewey (1933) suggests, as teachers we must balance the old and the new; “The best thinking occurs when the easy and the difficult are duly proportioned to each other” (p. 290). Assuming the purpose of the course is to teach its content, the delivery system and approach must be made simple. The cognitive dissonance that occurs when the student is confronted with a completely unfamiliar approach to learning is, at first, challenging and stimulating; but if the delivery model continues to be the focus of the learning experience, we cannot expect students to meet our learning expectations with the curricular content.

Teaming: A Catalyst for Transforming Distance Education Teacher Preparation Programs

Pam Petty
Western Kentucky University
Bowling Green, KY, USA
pam@pam petty.com

Abstract: This paper explains the concept of teaming as a literacy professor, a social studies professor, a teaching and learning strategies professor and distance instructors worked together to provide sound instruction and student support through the semester. Deliberate attempts were made to empower and include all students through the use of telecommunications technologies. A rationale for the field-based model, implementation procedures, and the program’s overall impact will be discussed.

Introduction

This paper explores how a “team” approach was used to build community and to establish collaborative relationships in Interactive Television distance learning classes at Western Kentucky University. Distance learning continues to grow in popularity and application in post-secondary education around the world. While providing opportunities for many students, traditional and non-traditional, to achieve their educational goals, distance learning also presents institutions of higher learning, instructors, and students alike with many challenges. The antiquated mode of “transmitting” information via lectures and then holding students responsible for that information is further exacerbated by the lack of face-to-face interactions in most distance learning situations. Feelings of isolation, lack of participation, passive learning, and feelings of anonymity are sometimes characteristic of distance learners. Many times instructors leave the learning situation completely unsure of whether or not they provided effective instruction or if they were able to “reach” students on any level.

Recognizing that these obstacles often add to frustration for students and those providing instruction, an attempt was made by three professors and three instructors at distance sites to follow Vygotsky’s tenets as they relate to the social aspects of learning, and to the role of teachers as facilitators of learning (Dixon-Krauss 1996). Much of the theoretical foundation that served to guide our decisions was based on Vygotsky’s theories of the social nature of learning. This was modeled in the way we approached our collaborative meetings with the instructors, in the way we structured the types of learning activities we included in our syllabi, and in the way we interacted via the different modes of communication we employed throughout the semester. We also considered Vygotsky’s Zone of Proximal Development as we planned for success – for professors, for instructors, and for students. We considered students active participants in the learning and employed a constructivist model of instruction. We defined the professors’ and instructors’ positions as mediators of the learning process. Technology served as the bridge between the different teachers and learners.

Structure

Western uses a “block” method for methods courses in its teacher education program. In that block method, three courses are taught as an integrated 9-hour course sequence. Block I includes social studies methods, reading methods, and a course in teaching and learning strategies. In the spring of each year, Block I is taught via Interactive Television to students on the main campus in Bowling Green and at three distance sites, namely Gasgow, Owensboro, and Fort Knox, Kentucky. The concept of teaming was incorporated as the university professors and the distance instructors worked together to provide sound instruction and student support through the semester.

Since these courses are “field-based,” students meet in traditional lecture classes with professors for a portion of the day and then are in area schools performing practicum experiences for approximately four hours per day, two days a week. Instructors are in place at each distance site to facilitate students, make
arrangements at area schools for placements, and to share in the responsibility for student learning of core content.

During the spring of 2001, approximately 85 students were involved in Block I and were located at four different campuses, Bowling Green, Glasgow, Owensboro, and Fort Knox. In preparation for the semester, the three distance Instructors met with the three university professors in four face-to-face meetings and in multiple meeting via Interactive Television to set goals, define responsibilities, and to plan the calendar for the spring semester.

Methods

To accomplish our goals of building community we focused on how this collaborative relationship would “affect student satisfaction, retention, and learning” (Brown 2001). Both in-class and out-of-class tasks focused on students developing learning relationships with the university professors, the distance site instructors, and with other students in all four locations. A kick-off day at the beginning of the semester allowed us to meet, exchange email addresses with students from other sites, and to lay the foundation of what it means to be part of community of learners. Students left the session with four email addresses of students from other sites and instructions on how to begin to make “connections” with others in our Block. All university professors had “interactive” webpages in place to support each of the three courses and one Block webpage provided students a central point of information. Students were asked to complete a template-based webpage in CourseInfo within the first week of class. The information page in CourseInfo had to include items of special interest, favorite websites, hobbies, and other items that would allow students to get to know each other through this medium.

In consideration of the social nature of learning, we targeted communication as a component that would be paramount to our success in actively building a team with the instructors and a community of learners with the students. The use of technology in the form of multi-modal telecommunications provided for communication between professors and instructors, professors and students, and student-to-student interactions. Discussion boards, on-line conferencing, and asynchronous chatting capabilities formed the nucleus of our “beyond the classroom” communications. The following is a list of the types of communication modes we employed:

- Interactive Television laboratory – each student has a speaker
- Electronic Mail – all students were required to have an email address
- Telephones
- Fax Machines – in every Interactive classroom
- Face-to-Face Meetings with students at distance sites
- Web Pages – Professors maintained course web pages, each distance site had its own web page, each student developed a seven page web presence
- CourseInfo (Blackboard) – Discussion Boards, Personal Information Pages, Virtual Classroom Chats, Electronic Gradebook
- America On-Line Instant Messenger – Students could have synchronous conversations with professors during days, evenings, weekends, holidays

Results

Our teaming design served to make this an invigorating experience in teaching and learning. We constantly made notes about changes, improvements, and goals for future semesters. We collected valuable feedback from instructors and from students at both the main campus and from the distance sites. Discussion of findings and future challenges provide a basis for sharing our discoveries with others.

Establishing a Learning Community of Media Design and Art Schools

The European North-South Axis

Abstract: The objective of EDULA (European Design Schools and Universities Learning Alliance) is to develop and apply a novel, integrated solution for distributed joint lectures and student e-teamwork by combining technology, methodology and skill development. This approach, based on new innovative learning methods and fostering joint practical e-teamwork in combination with face-to-face and lectures that are common in most educational institutions, presents a new organisational form in education.

The EDULA solution will support the paradigm shift from classical lectures to ICT (Information and Communication Technology) supported collaborative knowledge acquisition. EDULA will provide a collection of solutions, best practices and necessary education for the lecturers.

Preamble

In one of the literature depictions of the synergy of people and computers, the author (Pickover 1992) integrates people into the electronic environments. People began to see with "the eyes of the computer", they began to hear "with the ears of the computer" and they applied computer letters to write. At that point the above described was still a science fiction. Nowadays, in the era of ICT this science fiction vision transformed into the social fiction, as (Fassler, 1999) calls this phenomenon. The ICT makes it possible to communicate and exchange ideas without the physical boundaries. The application of the ICT also spread rapidly. At the beginning the ICT was available only to the smaller group of privileged people working at the governmental research institutions and universities. Nowadays ICT can be found in primary and secondary schools and in the majority of the average households. There is no night and day period in the virtual world, the communication and data exchange is intense and lasts 24 hours / day, seven days per week. One should only moderate and structure the information flows. Therefore we came to the conclusion to extend our teaching / learning process into the virtual world and to build a learning community. At this point we found the theoretical background in the work of Vygotski, who claims that a knowledge building community is a learning environment that supports the continuous social construction of knowledge (Vygotski 1978).

EDULA - The Project

The general idea of the international co-operation of the Media Design and Art Schools is to increase the level of expertise exchange and to foster the skill development. The technology applied will be one of the available web-based learning platforms like (Hyperwave eLS) or (WebCT).
The Project Goals

Within the EDULA project three goals have been defined as follows:

G1: EDULA provides a European resource of ICT lecturing and student e-teamwork, available to all the interested parties, that fosters the introduction and application of ICT for knowledge acquisition. The “knowledge pool” has to be considered as a resource of guidelines and practical examples that can be taken over as a form (model). Based on the model different topics e.g. practical projects and lectures could be carried out.

G2: EDULA will develop and apply an integrated solution for joint lectures and e-teamwork in distributed learning institutions. The solution will be applied and adapted in a series of trials in different learning domains. Joint lectures will be formally acknowledged by several partners.

G3: Workshops will be organised and carried out to educate the educators in the terms of application of the ICT technology for lecturing and student e-teamwork.

Enabling the knowledge exchange without the boundaries makes it possible that the knowledge flows without limitations and that students have the possibility to make decisions about their studies i.e. what, why and how do they prefer to learn. Students can decide to enrol in a course based on their estimation that the knowledge acquired within the chosen course will have the best value for their further professional development.

The experience offered within a knowledge-building community is the experience of the international e-teamwork. Within a chosen course, international student e-teams will be formed to work on a project. Elaborating the project solution, students will be actively involved in cross-cultural communication. This situation is much like the situation in professional life where an international experts team spread worldwide cooperates within a common project. Being part of such an international e-team enables the students to acquire also a certain spectrum of social skills. Students get involved into the active collaborative knowledge acquisition. By means of discussion and opinion exchange among the team members the process of collaborative knowledge building takes place. At the same time the students will gain rich experience in applying ICT at the e-teamwork. Based on these experiences, they will learn how to organise appropriately the work and collaboration supported by the ICT.

The Model of Work

The reported project was designed to apply the ICT to make a pedagogy shift from 'classroom-based-lecture' mode to a 'problem-based-learning', similar as stated in (Ferry and Kiggins 1999).

The pilot project is divided into two major steps.

(I) step: a small pilot project that will be carried out. In the stage of the pilot project only two groups of limited number of students (3-4 per group) from two sites will participate. Other partners will be active observers, meaning their input will be in form of their experiences, suggestions to which ICT to apply, etc.

The pilot project will be concluded with a workshop where all the participants will meet in one place to exchange their experiences and to evaluate as follows: (a) the project product i.e. the problem solution and (b) the methodology of work. Based on the evaluated workshop results a 'best practice' model for an on-line lecture will be made.

(II) step: in the following semester the 'best practice' model based on the pilot project will be translated into various on-line lectures to produce effective student learning. Based on the model defined different contents will be added. There won't be any limitation of student groups.

As shown in the Figure 1, in this phase of the project the 'best practice' model will be verified within various contexts and the evaluation will be again carried out. The proposed model will be refined and extended if and where necessary. Additional list of possible applications of the model in the practice i.e. various contents will be defined and described.
The first project the students will work on will be to define a specification of a content management system (with the functionality of a communication and information distribution platform) and to make the appropriate information pages. The students have different expertise. One group of team members has the expertise from the information design and the other group of team members has the expertise from databases and web programming. The hypothesis is that different expertise background will contribute tremendously to the collaborative knowledge building process and will make it possible to break the project into sub-tasks that has to be solved.

A content management system has to meet various requirements. The system should be a web-based tool and it should support structured communication among team members and among various teams. However, the platform will be used also by the international partners to share the 'best practice' models defined and to exchange the experiences.

Based on a specification a decision will be made if an available platform e.g. eLS or WebCT or similar offers adequate support. In case that additional functionality is required the tools will be extended in the required manner or a hybrid solution will be applied.

The information pages will be designed for the information distribution on various levels. First level (I) is considered to be a general information level, where basic project information and international partner data will be provided with the intention to inform the public about the project and the partner pool. Some information on on-going project in form of a summary could also be posted. Second (II) information level is to be considered as a cover communication and information for the pool partners and should be password protected. On this level the meeting announcements as well as the meeting presentations and minutes will be published. A separate area should be defined on the same level that will contain a list of 'best practice' models along with detailed description, case and evaluation data. On the third (III) information level the communication for the on-going projects should be enabled. The third level should also be password protected and it should make it possible to define exclusive project specific space to simplify the navigation and avoid the possible distraction and confusion.

Figure 1: The EDULA model of the work
Evaluation

Evaluation will be carried out sequentially after each joint project is finished i.e. once per semester. Evaluation results will have a direct impact on the best practice model. Based on the results the model defined will be adjusted and extended.

A model, that encourages us to critically question any form of new technology adoption consists of four elements as follows: (I) new pedagogical opportunities, (II) changed work practices, (III) technology (non)neutral and (IV) unintended consequences of new technology adoption. [Fox R: Digital Environments: Monitoring Changes to Teaching]

Various factors will be evaluated. Some evaluation aspects are as follows: does an interdisciplinary and cross-cultural project contribute to the motivation of students, does it raise the involvement of the students, is there an improvement of the knowledge acquisition and knowledge utilisation. The other point of view is the perspective of teacher, how they were able to provide support to the international group, if they sensed any difficulties by coaching the team, explaining the project topic.

Conclusions

The results expected from the EDULA are as follows:

1. To make a collection of best practice models of ICT application for joint lecturing (enclosing the entire project documentation: detailed project specification along with learning objectives, problem description, lecture model applied, technology specification, project results and evaluation results)
2. To provide workshops on the use of the ICT for lecturing with the presentation of practical applications, that will be carried out at least twice per year and organised at various partner locations
3. To organise a knowledge management platform that will be a major source of information related to the innovative application of the ICT for lecturing
4. To define several joint courses / lectures, acknowledged by all partners, that will be carried out by lecturers coming from various educational institutions, based on intensive application of the ICT fore-teamwork

All partners are making active efforts in the direction of international exchange of students. Based on the EDULA, the exchange students could have more options to choose the courses of their personal interest and to participate at the joint courses offered together with other partners within the EDULA.

Students with rich experience and high competence level in applying the ICT for co-operation and team work will project the application models into business environments. The collection of verified "best practice models" and paradigm shifts can be applied for various situations and will therefore be supportive for a wide range of the population.

The whole EDULA concept, including ongoing projects, evaluation results and best practice models of the ICT application for lecturing will be published and presented at the international conferences. Another form of presentation is participation at the exhibitions, where the e-teamwork projects along with the project results can be displayed for the public. Based on the EDULA concept workshops will be organised twice a year by various partners to educate the lecturers and mediate the experiences gained.

Semi-automated evaluation services in a distance education program

Ken Potter, Virginia Tech, US
David Halpin, Virginia Tech, US

Effective evaluation of student work is an important and time-consuming component of distance learning programs. The authors describe the design and development of a scalable, computer-based approach that permits personal review of student work while automating much of the evaluation process, including the recording, storage and distribution of grades.

Statement of the problem:

As distance education programs expand their course offerings and numbers of students, the impact of the expansion on faculty support issues must be considered. Although the use of online course tools has made possible the actual delivery of instruction to growing numbers of students without significantly increasing demands on faculty, the same cannot be said of associated support issues such as viewing student work, assessment of student performance, providing relevant feedback, and recording and distributing grades. Systems are needed to automate as much of the support process as possible while relieving faculty of some responsibilities for student evaluation and preserving the benefits of interaction with students.

Description of project:

Virginia Polytechnic Institute and State University has offered a distance education Master’s Degree in Instructional Technology (ITMA) for the past three years. The first iteration of the program was offered to three distinct cohorts; members of these cohorts graduated in May 2001. A second iteration of the program began in the fall of 2000 and a third iteration began in the fall of 2001. The number of students in the additional iterations was more than double the students in the first iteration while the number of faculty members has remained constant. During this same period, the on-campus course loads for Instructional Technology faculty have remained constant.

Without changes in faculty support services, a substantial increase in online students without a corresponding decrease in on-campus course load would have been unworkable. As more students were added to the distance education program, additional time was needed to respond to student questions regarding grades, evaluate and provide feedback on student work, and record grades. Without additional faculty or faculty support, the current faculty would have been overwhelmed and the program could not have grown.

Recognizing the need for additional support, program funds were provided for faculty support in the form of two part-time graders for the ITMA program. To achieve optimum utilization of the graders, provide ongoing feedback to the learners, and maintain the quality of the program, a system was required to minimize unnecessary efforts in grading and feedback. The system had to permit graders to easily access student work, provide comments based upon faculty-generated rubrics, assign grades to the work, and record, store and distribute the grades.

Two faculty and three graduate students from the Instructional Technology program explored the means by which the above responsibilities could be shifted from faculty to support personnel without sacrificing quality feedback. The process began with a series of sessions aimed at systematically describing the features and outputs of the ideal support system without reference to any specific technology. After the characteristics and capabilities of the ideal solution were fully specified, they were converted to technology-related terms. Finally, technologies whose outputs matched the requirements were examined and eventually a combination of technologies selected.
The design and development team collaborated to produce a web-based student/grader interface. Using off-the-shelf software (Cold Fusion and Microsoft Access), a semi-automated system was developed and implemented that allowed students to enter assignments, review grading criteria, and examine scores. Assignment information entered by students was made available to graders who, with the click of a button, could automatically retrieve grading rubrics, assign points, and post grades. The system also allowed graders to enter comments that were stored, along with the other grading information, for future reference and analysis. Numerous other options to eliminate unnecessary steps by graders were included as part of the system. For quality control purposes and to identify student problems, additional information was collected automatically by the system. For example, data dealing with elapsed times between submittal and grading were recorded, as was information concerning numbers of failed attempts to submit assignments.

The web-based system was designed and developed to be scalable. Additional courses and cohorts can be added to the system. The system also was created to function for a variety of purposes. For example, the same approach that was used for submittal of course assignments can be used later for submittal, review, and assessment of student portfolios.

Outcome:

The semi-automated, asynchronous, web-based system was implemented in January 2001. Early problems with the system were relatively minor and typically related to inadequate grader training, failure of users to follow instructions or, in a limited number of cases, the absence of error-trapping safeguards in the system. The system allowed two part-time graders to evaluate and record relevant information for over 1000 assignments from a total of 80 students during a 10-week period. Rubrics for additional courses have been developed and added to the system. The system is being reviewed for possible use by other distance learning and on-campus courses. Efforts are currently underway to integrate the grading information with the software used for the delivery of instruction.

Relevance to other institutions:

The faculty support system described in this presentation provides an effective and efficient means to deal with evaluation services resulting from increased numbers of distance education participants and courses. The system is applicable to any discipline and can be adapted to both large and small audiences. The system retains the benefits of personal interactions while automating numerous steps in the evaluation process.

The system may be used in any distance education and on-campus program where evaluation of student work is based on clearly defined rubrics. The system collects and stores faculty-defined data that can be used for evaluation and research purposes. The fact that data are stored in a standard database format simplifies future retrieval and analysis.

Suggested Audience

The audience most likely to benefit from the presentation would include any person involved with designing or developing faculty support systems for distance education programs, including administrators, faculty members, trainers, and instructional designers.
Parents have chosen to home-school their students for many years. Home-schooled students have long been isolated from the school environment. A growing number of students are being removed from the school environment for a myriad of reasons, and many more parents are electing to home-school their children, especially in the wake of school violence. While these students may be outside of the school building, the school is not absolved in their responsibility to educate them, particularly those that are excluded from the classroom environment. In the past, teachers were hired to work extra-duty hours to educate these students separately. However, with the increasing availability of technology, teachers are able to remotely access student’s records and teach and communicate with students. An online curriculum is needed to address the already alarming shortage of teachers, the overwhelming cost involved in having an at-home teacher that the district must support, and the often-prohibitive distances involved, particularly in rural areas. In many states, a need for a comprehensive online curriculum arises when both home-schooled students and students who have been removed from the confines of the traditional classroom request or require by law access to the general education curriculum. A public school district is legally responsible for educating all students in that district, and in Colorado, a state of school choice, parents can elect to have their children attend any school in the state. Because of this, students should be able to access the curriculum of any school in the state, and an online curriculum is certainly a viable and exciting answer.

Englewood Public Schools in Englewood, CO, chose to make this leap into online curricula in April of 2001, when we contracted with NCSLearn, formerly the Computer Curriculum Corporation. Funds to pay for this project came directly from the state, as excluded, home-bound and home-schooled students receive a disk and user name and password free of charge. The primary focus for this project was to provide both our excluded students and home-schooled students both inside and outside of district boundaries with the general education curriculum that they needed and deserved to enrich their educational experience. In order to serve these students, two system administrators/curriculum specialists have been added part time to not only manage the system but also manipulate the curriculum to create an appropriate individualized instruction plan that meet the needs and address strengths of each student. The two curricula have a range from pre-K through 8th grade and 2nd grade through post secondary. Both curriculum focus on reading (mechanics, technical reading and reading within the content areas), writing, math, and civic responsibilities and citizenship. Because of technical issues and other barriers, and to achieve our overall goal of a cutting edge district in distance learning, research into other possible curriculum providers continues. In addition, the future holds promise that an online program for teacher inservice courses can be either contracted or created by district personnel. Such a program was part of the initial goal of the program and is becoming one of the next priorities.

Currently, there are 25 students enrolled in two different curricula. So far, the largest hurdle has been keeping students independently motivated to complete the required number of hours, 90 per semester. However, those that are motivated by working with the technology have been very happy with the program, and have been achieving at a much higher rate than is available to most students. This session will address the successes and pitfalls of this program, and give parental and student feedback on both the program as a whole and the curriculum. In addition, plans for the future will be addressed. A handout detailing the program with information about the curricula and web addresses for more information about the district will be provided.
A Rubric to Encourage and Assess Student Engagement in Online Course Conferences

M. D. Roblyer, Adjunct Professor of Educational Technology
University of Maryland University College, College of Education, U.S.A.
(mroblyer@polaris.umuc.edu)

Abstract: Although student interaction and engagement in online discussions or "conferences" is a required component of many online courses, instructors often find it difficult to assess whether or not students are adequately and meaningfully engaged in online discussion activities. Instructors in a web-based education degree program offered by the University of Maryland University College (UMUC) developed a conference participation rubric to serve two roles: (1) to encourage greater student participation in online course conferences and (2) to assess and grade performance in these activities. This paper reports on the instrument developed for this purpose and discusses faculty and student reactions on its usefulness in the program's online courses.

Introduction

As has been noted in many previous studies of distance courses, (Roblyer & Ekhaml, 2000; Zirkin & Sumler, 1995), interaction is considered one of the most important characteristics of successful distance learning environments. Although the distance instructor has the responsibility for incorporating most interactive qualities of an online course, at least one dimension of this interaction is incumbent on the students themselves: voluntary responses to online discussions or "conferences." However, it is difficult to impress on students the importance of their contributions and involvement to the success of a distance learning enterprise, let alone articulate what is required for them to interact adequately and effectively.

Many strategies have been suggested for how to foster engagement in online conferences (Klemm, 1998). Instructors in the UMUC online programs have been trained to incorporate these strategies in their online course designs, and UMUC students report high degrees of satisfaction with their online learning experiences. Graduate education faculty at UMUC decided that giving students a conference participation rubric might serve several important functions in online learning environments. First, it would act as a benchmark for behaviors expected of them in online discussions. Second, it would act as a strategy to encourage their appropriate interaction in online forums. Finally, since rubrics originally were designed to be assessment tools for complex, problem-based, environments (Jonassen, Peck, & Wilson, 1999), the conference rubric would serve to help online faculty evaluate student performance in an area of online learning that traditionally has been difficult to assess.

Methodology Used to Develop and Revise the Rubric

Initially, three elements of conference participation behavior were identified, and a rubric was developed by creating a $0 - 4$ scale ($0 =$ lowest) with descriptions of levels of performance for each element. The draft instrument was posted in an online faculty meeting and faculty members were asked to review it and suggest revisions. Also, it was posted in an online graduate course on web-based pedagogy to solicit
student comments. All were asked to evaluate the rubric using criterion measures for rubrics described by Jonassen, Peck, & Wilson (1999, p. 225). These criteria focus primarily on the identification of useful elements and include: comprehensiveness, clarity, and unidimensionality (elements could not be broken down into two or more behaviors). Faculty members also were asked to comment on the rubric's usefulness for their own purposes. Some 15 instructors and students responded with comments and suggestions, and the rubric was revised based on their feedback.

As a result of faculty and student feedback, several revisions were made. One element (Frequency of Posting) was divided into two elements (Frequency of Posting and Timeliness of Posting) and various revisions were made to the wording of the levels. The wording of several levels was revised to make them clearer and to sharpen the focus on desired behaviors. For example, in the original rubric draft, several students cited ambiguity in the wording about timeliness of interaction. Faculty noted that quality of contributions related to two different aspects (relationship to topic and quality of writing). The revised rubric elements are described here; a copy of the revised rubric itself is shown in Figure 1.

**Rubric Element #1: Frequency of Posting**

Although perhaps not the most important aspect of participation, the number of posted comments is one measure of engagement in the discussion. Also, most discussion conferences have a central theme, but more than one concept or topic is developed in the course of the conference. This element of student engagement focuses on a combination of how frequently the student interacts in the conference and on how many different concepts interaction occurs.

**Rubric Element #2: Timeliness of Posting**

Although most discussions are asynchronous, they are most useful and meaningful when students join discussions promptly. To encourage prompt participation, UMUC instructors usually set deadlines for joining the conference. This element focuses on joining by deadline, as well as responding in a timely way to concepts under discussion. If students respond very late in a thread, the discussion already may have developed to the point that their reactions are not as meaningful as they might have been if posted earlier.

**Rubric Element #3: Type of Posting**

Students have the tendency to think of interaction as communication required only between instructor and student (instructor-to-student and student-to-instructor). But, as Moore (1989) emphasized, there is an additional kind of interaction: student-to-student. This element communicates that all three types of interaction are important and expected. This element also addresses reacting to concepts raised in the conference as opposed to initiating new ones. Ideally, students should do both.

**Rubric Element #4: Quality of Posting**

The quality of student participation in an online conference seems at least as important as the quantity of postings. This element attempts to address three characteristics of meaningful participation. The first, most basic requirement is that comments relate to the discussion. Sometimes students inexplicably post comments that have nothing to do with what is being discussed. (This may illustrate lack of reading of required texts or simply lack of understanding of the concepts involved.) The next important aspect of quality is that comments reflect knowledge of the background reading. Students' opinions should be more than personal views; they should be analyses of the materials they have been reading. Finally, student writing is a measure of quality. Comments should be succinct and well-formulated. Sometimes student comments either are wordy and rambling or too terse; either can limit their contribution to the discussion.
RUBRIC DIRECTIONS: The rubric shown below has four (4) separate elements that reflect aspects of engagement in online discussions (conferences). For each of these four elements, circle a description below it that applies best to the student's participation. After reviewing all elements and circling the appropriate level, add up the points to determine the student's online engagement in the discussion (e.g., low, moderate, or high).

Figure 1. Rubric to Measure Student Engagement in Online Course Conferences

Perceptions on Usefulness and Uses of the Conference Rubric

In general, students' comments indicated enthusiastic support for the rubric. Faculty reviewing the instrument had some reservations about how much time it would take to assess each student properly. However, all comments indicated approval for posting such an instrument to set expectations and guide performance. In actual use for assessment purposes, faculty may choose to weight one or more of the elements to reflect their perceptions of the importance of each aspect of online participation. For example, one faculty member felt actual number of postings (Element #1) was a faster and more feasible measure for faculty to emphasize in grading. Other faculty members felt that the number of postings was not as important as the quality. To facilitate its use as a grading tool, faculty also may choose to ignore certain elements or levels of this instrument and focus on only a subset of them. However it is used, a rubric of this kind seems a useful tool to encourage and guide student participation in online conference activities.

abloom@njcu.edu

Abstract: The traditional way education programs provide an opportunity for preservice teachers to think about and apply pedagogy has been through onsite field experiences. In this paper we explore the use of distance education as a supplement to the current field experiences. We suggest that distance education is an excellent vehicle for delivering vicarious field experiences and structuring practice with reflection. The concept of virtual field experiences is explored. The impact such experiences can have on the development of essential habits and skills of reflection are considered. Benefits of using supplemental virtual field experiences and six guidelines for them are provided.

Teacher education programs continuously grapple with finding ways to provide instruction and experiences that develop students' teaching expertise. One way in-service teachers develop expertise is through reflecting on, critically thinking about, the instruction they provide. Classrooms provide teachers with opportunities to apply and reflect on the application of pedagogical principles. Currently, the student teaching field experience is the primary time when preservice teachers reflect on the application of pedagogical principles, rules, and terms to classroom settings. Many teacher educators, however, now question the use of field experiences as the primary vehicle for linking theory and practice. How successful the student teaching experience will be is greatly dependent on how effectively the student teachers can reflect, or make connections between their experiences and/or observations in the classroom and larger ideas. Many preservice teachers have not engaged in professional reflection and are unfamiliar with how to reflect on their professional practice. Logically, preservice teachers should develop the essential habits and skills of reflection prior to beginning their field experience.

Technology can be a powerful tool in helping preservice teachers understand and grasp educational concepts that may be difficult to explain in traditional formats (Hasselbring, et al. 2000). As described above, the traditional way to provide opportunities to think about and apply pedagogy to teaching has been during real life field experiences. We suggest that distance education is an excellent vehicle for delivering vicarious field experiences and structuring practice with reflection. During lessons, or virtual field experiences, transmitted via satellite or ISDN videoconferencing preservice teachers can gain access to real life classroom instruction. They can begin to ask questions of children and cooperating teachers. By providing this preparation early in a teacher education program, prior to the student teaching experience, preservice teachers will be better prepared to make the most of their student teaching experience.

In this paper we explore the use of distance education as a supplement to the current field experiences. Below is a discussion of benefits of using virtual field experiences. Six guidelines for structuring the videoconferences are provided.

1) Make the experience valuable. Videoconference sessions should provide something that cannot be achieved through other traditional means of education. It should support course content and student learning. Virtual field experiences have been especially beneficial to undergraduate and graduate nontraditional students who commute and work during the day and therefore attend evening classes making extensive real life field experiences difficult. For these students, distance education provides a viable alternative to some of the preservice field experiences and supports their acquisition of professional skills and knowledge. For example, videoconferencing with schools on the west coast of the USA can provide real time virtual field experiences to students who attend school at night in eastern states. An added benefit of virtual field experience is that it can provide exposure to diverse cultures and backgrounds of children living in the southwest, northwest and possibly other countries. Thus exposing preservice teachers to multicultural issues and environments not available to them through other means.

2) Follow a formula. Both the college students and the school children need to become accustomed to participating in the videoconference. As students participate in additional videoconferences they will become more comfortable with the technology. Setting up routines that can be counted on will facilitate higher comfort levels. We suggest that the videoconference consist of (1) a teaching segment, (2) time for the grade school children to ask question of the university students, (3) time for the university students to ask questions of the grade school children, (4) time for the university students to ask questions of the cooperating teacher, and (4) time for the cooperating teacher to ask questions of the university students.

3) Balance distance education with face-to-face discussion. As described above the discussion with the cooperating teacher and students done online. However, including supporting face-to-face discussion with peers and the university professor prior to and after the videoconference should improve the experience.

4) Use three key processes. The following three features are essential to the process of learning how to reflect: modeling, scaffolding, and fading. Modeling is when someone demonstrates an expected and/or appropriate behavior (Bandura, 1989).
Modeling of cognitive behaviors involves verbalizing or writing down the thinking behind the behavior (Eggen & Kauchak, 1997). Scaffolding refers to the instructional support that allows a student to perform a skill (Vygotsky, 1978). Scaffolding applied to teacher education means that the teacher educator initially provides a considerable amount of support through explanation and demonstration. As the teacher candidates demonstrate their ability to carry out more of a task independently, the scaffolding is withdrawn. This is referred to as fading. Fading is essential to individual and shared accountability. The videoconference sessions should include three features at varying intensities, dependent on the stage in the students' developmental process.

5) Practice makes perfect. There should be ample opportunity for group and individual reflection about observed instruction. This practice should be provided at earlier stages in the preservice teacher's career as guided and independent practice during methods classes. Preservice students may continue collaborative reflection with each other and the professor asynchronously during student teaching via e-mail and discussion groups instead of attending on-campus seminars.

6) Focus on three kinds of knowledge. The reflection should foster the establishment of connections between student teachers' experiences and pedagogical knowledge (Clark, 1995; Ross, 1989; Shulman, 1992; Siens & Ebmeier, 1996; Sparks-Langer & Colton, 1991), including declarative knowledge (knowledge of terms and facts), procedural knowledge (how to use declarative knowledge), and strategic knowledge (when to use declarative knowledge and procedural knowledge).

Virtual field experiences can prepare preservice teachers to make the most of their student teaching experience. It provides time for preservice teachers to practice asking questions—a skill essential for their continuous life-long professional development. Additional, this distance education project allowed faculty at the university to model exemplary pedagogy that integrated technology in meaningful ways.

Creating, Implementing and Sustaining Community in a Online Distance Education Course

William A. Sadera, Towson University; Paulette Robinson, Towson University; David Wizer, Towson University

Abstract:

In this presentation we will discuss some of the unique features of an online distance education course: 1) the online course design was created in such a way to manage the information overload that could occur with 45 students; 2) a team of three faculty from Towson University designed and taught the course; 3) students negotiated all but three of the course topics and selected the topic their small group would present to the class; and 4) the class used and modeled the use of distance technologies (we only physically met as a group three times).

Introduction

This course, Distance Education Theory and Practice, was taught to graduate students across the state of Maryland using constructivist teaching strategies and case-based modules designed to bridge theory with applied practice. The course was unique in several ways: 1) the online course design was created in such a way to manage the information overload that could occur with 45 students; 2) a team of three faculty from Towson University designed and taught the course; 3) students negotiated all but three of the course topics and selected the topic their small group would present to the class; and 4) the class used and modeled the use of distance technologies (we only physically met as a group three times).

As a result of completing this course, students were be able to:

- Demonstrate knowledge of the principles of distance education and related delivery technologies.
- Understand how to select, evaluate, and integrate distance education strategies into learning/training environments.
- Use distance education methods and technologies with confidence.
- Critically analyze and reflect on the nature and complexity of on-line learning environments.

Students attained these goals through research and the completion of two major projects. These projects included, the facilitation of class lessons and the evaluation of existing distance-based programs. More importantly each of these two projects were done by the students cooperatively, with peers, via on-line technologies.

Team Teaching

This course was team taught by three faculty members of the College of Education at Towson University. Originally, the course was to be offered on the Towson University campus and at two satellite sites, as three distinctly separate courses. Following some discussion, it was believed that we could make better use of our resources by offering the course on-line and teach the course as a team of three. This decision offered benefits for both the students and the faculty. This benefited the students by giving them a larger group of peers to work with and a resulted in richer and thicker discussions of subject matter, ideas, opinions, and reactions. In addition, it allowed them the opportunity to learn from the strengths and experiences of multiple faculty rather than a single faculty member. The team teaching benefited the instructors by allowing us the opportunity to share ideas and, similarly to the students, learn from each other. The faculty had varied backgrounds and experiences with distance education and teaching in an on-line environment. Teaching as a team gave us the opportunity to focus on teaching the topics we knew best and had the most experience. This provided the students with better instruction with each course topic covered.

Course Design and Structure

Distance education courses are often plagued with student disorientation and alienation which effects course retention and the quality of the experience for the students (Harasim, Hiltz, Teles, & Turoff, 1995; Schwitzer, Ancis, & Brown, 2001). In order to meet this challenge head on, the three faculty in the course purposefully designed a structure that grouped students in small, medium and large groups to build a greater sense of connection for the students.

Online Environment Courseware

The course was taught using WebCT internet-based learning technologies. WebCT is a learning management system that provides an overall structure to create an online learning environment. The instructor can choose from a variety of
tools and can customize the look and feel of the course. In order to develop a sense of community within the course communication tools (i.e., email and discussion groups) were critical. Students also made use of synchronous Chat and Whiteboard technologies offered within WebCT. The final component integrated to establish community within the class was the student project space. This area offered file-sharing options for groups while they worked on collaborative projects and a space for the other students to view their work when it was completed.

**Grouping Students**

In teaching the course, the students were divided amongst the instructors into three groups. A concerted effort was put forth to mix all of the students from the three geographical instruction sites so that they would not have a tendency to work with peers locally and avoid using the distance-based technologies. From these three sections of 15 students each, groups of three and then groups of five were formed with each student belonging to a small and then larger group. Individual learning journal spaces offered the smallest grouping between the instructor and each student. Each group was provided with a project space to share files and present information to the class as well as private group discussion spaces.

**Assignment Projects**

This grouping strategy offered a way to build social relationships at a variety of levels within the course. The groups were tasked with a project that with individual student roles where each student was assigned a role by the group. The group of three facilitated a two-week discussion in the bulletin board for their section (15 students) on a course topic they selected. Students were required to choose from a list of pedagogical techniques for their facilitation method and a classroom assessment technique (Angelo & Cross, 1994) to formatively evaluate their instruction. The larger group of five’s task was to evaluate a distance education program using the American Council on Education’s Distance Learning Evaluation Guide (1996).

**Developing Community Through Student Interactions**

We began the process of building a community with an all-day, face-to-face orientation. In the orientation, students participated in activities that allowed them to become comfortable with WebCT, creating Web pages, navigating Internet. They also participated in team building activities designed to help form create relationships that could withstand a distance.

Students completed learning journals at the end of each week. Within these learning journals the student reflected on their learning and the strategies they were applying within the on-line learning environment. Faculty not only supported them in their learning process on-line, but also posed critical questions for student to reflect upon. The learning journals established a close relationship between instructors and students. This allowed the student to build a stronger connection and sense of support in this foreign environment.

Participating in on-line discussions at multiple hierarchical levels within the projects produced reciprocal relationships and robust interaction (Roblyer & Ekhaml, 2000). These reciprocal relationships began at the small group level and were reinforced within and through the discussions in the larger groups. The design and implementation of the various group structures were integral to the successful interaction and community formation throughout the semester.

Distance Education: Can the Institute Affect Persistence?

Ellen R. Scalese
School of Computer and Information Science
Nova Southeastern University
scalese@nova.edu

Abstract: Distance Education (DE) is the perfect solution for today's non-traditional learning. However, the attrition rate in DE environments is much higher than in "traditional classrooms". The topic of increasing persistence continues to be a concern among distance institutions. This paper studies methods that administrators and instructors can institute to increase persistence.

Introduction

Many institutions are making substantial investments in new technologies for teaching. Colleges are evolving in response to the pressure of student diversity, technological change and economic restructuring. Pressures to change will continue, if not accelerate. This change will have significant impact on colleges. If colleges and universities are going to respond to the pressures and educational needs of the adult learner, they must offer distinct, comprehensive, and pedagogically meaningful learning environments. There have been innumerable studies done on improving the quality of distance education (DE). There is one exceedingly important area that continues to be a concern, the subject of student attrition. DE programs throughout the world are characterized by having higher attrition rates than their campus-based counterparts. It is imperative that colleges identify what leads DE students to drop out and then to take appropriate preventative measures (Morgan & Tam, 1999).

Persistence and Retention Strategies

Until now, much of the research has been limited to studying a single variable as it affects attrition. The combining of multiple variables as possible predictors of attrition has generally been overlooked. It is more appropriate to use an approach that can help to identify the interrelated facets of the experience. Recent research has regarded student persistence as a multivariate problem involving complex interactions over the period of the course (Kember, 2001). Primarily, most students will give reasons such as the “lack of time” as an easy explanation for drop out. It is not contested that time constraints are indeed a factor in student non-persistence, but the importance attributed to them may be misleading. The second is that both non-persisting and persisting students experienced situational, institutional, dispositional and epistemological problems that posed barriers to completion. Yet, some students persisted while others did not (Garland, 1993). It should be noted that of these four characteristics, situational and dispositional barriers to persistence are beyond the control of the college or university. However, research indicates students list at least one institutional or epistemological barrier during their participation in a distance-learning program. Since these indicators are within the control of the institution, it is both the challenge and the responsibility of the educational institution, instructional faculty and support staff to address the issues that are under the college’s control and thus strengthen the positive experience for the students. To improve retention in DE, institution retention strategies must address epistemological and institutional problems related to the improvement of the educational environment of the distance learner in the hope of tipping the balance toward retention (Morgan & Tam, 1999).

Distance Learning needs to have the best technology infrastructure. Hardware and software required for the course should be prominently listed on the site to ensure that a minimum of problems occurs. There should be a downloadable technology manual. The institute should require a one time face-to-face orientation that trains students in the needed technology skills and provides familiarity with the course delivery tool. Some institutions have been able to reduce attrition by assisting the student with a self-perception inventory. In order to provide the locus of control and just-in-time support necessary to DL, technical support should be provided via e-mail, phone and fax.

The creation and operation of a DE support infrastructure requires the collaboration of all departments whose activities deal with students and faculty. Distance students are often faced with the challenges of tracking down the appropriate contact person for questions. Staff specific to the DL program should be added to existing staff to ensure students have access to the range of students’ services appropriate to support their learning. The admissions process gives an early impression of the institution.
The web site should provide a page that clearly describes the admissions process and requirements, and should provide an online application form. Applications may be submitted online, faxed or mailed. There should be a staff person designated to process DL admissions. Financial aid information should be easily found, accurate and straightforward. Registration is an important online administrative service. An effective online registration system should be provided. Academic advising is a core student service. There should be a staff person designated to provide counseling to the DL students concerning course selection, concerns and requests. A distance library should be provided with remote access to databases, electronic resources and journals. A distance reference librarian can be contacted via e-mail, fax or phone (Dringus, 2000).

This ever-evolving landscape of distance education requires the distance educator to develop new skills. From an institutional perspective, as distance education programs are implemented, decisions must be made regarding hiring and training of instructors. There is currently no expert to answer the inevitable questions as to training DE teachers. What competencies or skill set will be needed? What competencies are more important, technical, interpersonal, instructional or management?

The teacher must view the instruction in an entirely different manner. The educator will need to change thinking and teaching styles into an effective educational environment that focuses on the needs of the learner. Many teachers are not adequately prepared to teach online. They are not ready for the difference between teaching and management of an online course and a face-to-face environment. They absolutely must not learn how to teach online as they proceed, but they should be trained and confident before they enter the online classroom. The instructor’s role in a Web-based environment demands newfound skills and pedagogical philosophies (Sims, 1998). Instructors must understand that teaching in an online environment is not just about delivering content it is about communicating. Students in DL are separated from the other learners and the instructor. Communication and interaction among the students and the instructor can help to decrease the feeling of isolation by forming a sense of community. Studying at a distance requires a high degree of motivation. A primary goal of communication in DL is to motivate students rather than just provide information to them (Abramson, 1998). Having teachers complete a self-assessment survey before teaching in a DE program helps to ensure that he realizes guided conversation must be understood as a fluid role, and one in which conversation is multi-directional and inharmonious.

As the instructor transitions from the classroom to DE vast changes occur in their functions. It is critical to provide skill training, and it needs to focus not just on the technology, but to focus on the learning environment. Faculty should partake in a training program to: 1) develop an understanding of issues associated with teaching and learning when instructors and students are separated by distance and/or time, 2) acquire the skills needed to design effective instruction, facilitate DL, and integrate DL resources, techniques and instruction, 3) stress the need for timely feedback and developing a sense of community, and 4) understand the differences in teaching adults who bring a wealth of experiences to the “virtual classroom” (Bond & Finney, 2000). Instructors also need to experience being students in a distance environment; one way to do this is to do part of their training through DE. It is also beneficial to institute a mentoring program where experienced instructors mentor new instructors.

Conclusions

By carefully identifying and dealing with the institutional and epistemological barriers that are within the distance-learning institute’s ability to improve, DL institutions may well find that more students are persisting. The more enlightened the administrators become in the study of attrition, the sooner the scales that measure and compare attrition rates in distance courses and traditional courses, may come to a balance.

The Significant Challenge
That Distance Learning Represents to Educators

Abstract

Distance education, e-learning, Web-based courses, etc. represent opportunities for educational institutions, faculty, and students. There is no doubt about that, assuming that these myriad initiatives are appropriately orchestrated.

What educators must realize is that conducting courses within these delivery modes is a tremendous amount of work, plain and simple. They will be challenged at every turn and in ways that they likely did not anticipate.

The success of their course(s) ultimately depends upon how they apply themselves as educators to the task before them or at hand. If they approach these efforts with anything less than the utmost in preparation, comprehensiveness, dedication, and positive attitude they will be risking failure and term-long struggles and disappointment. They and their students will likely have a negative learning experience. This is, of course, just the opposite of what we all want to achieve, every time we enter a classroom, regardless of what form today’s classroom might take.

They are dedicated to learning, determined to do an exemplary job of delivering and facilitating outstanding educational quality. They best be prepared for the associated amount of time, effort, and care that must go into both developing online courses and delivering them with the requisite amount of associated academic rigor.

This short paper and presentation will include but not necessarily be limited to the following:
1. developing the online course
2. producing a comprehensive syllabus
3. setting learner expectations
4. detailing educator expectations
5. taking advantage of all of the available features and resources in a given platform
6. synchronous course components
7. asynchronous course components
8. educator availability issues
9. what can go wrong will go wrong
10. framing the best possible course and learning experience.

This could also be done as an interactive discussion, enabling participants to share, respond to, and offer recommendations for the significant challenges that they face as educators conducting courses at a distance.

Short paper will follow.
Skills, Modifications, and Obstacles: Teaching Online Courses at the High School Level

Rachel Sellers Bordelon, Louisiana State University, US
Janice Hinson, Louisiana State University, US

The Internet is redesigning the way courses can be delivered to students, with the result that time and space no longer constrain teachers or students. Harrison and Bergen (2000) state that “internet access is becoming more widespread and its capabilities for delivering multimedia lessons are improving daily; the Internet is becoming the vehicle of choice for distributing learning across distances” (p. 57).

Delivering coursework online is a relatively new concept in education; however, it has become a valuable tool for increasing educational opportunities for high school students, especially those living in rural areas. For example, some rural high schools in Louisiana are not able to offer advanced courses because they lack qualified teachers. Because of this, capable students at these schools have not been able to meet the requirements to qualify for the Tuition Opportunity Program for Students (TOPS), Louisiana’s comprehensive college scholarship program. In order to provide equal opportunities for all high school students, the Louisiana Center for Educational Technology implemented the Louisiana Virtual Classroom Project during the 2000-2001 school year. Now, all students can participate in web-based classes taught by certified teachers while completing the requirements for a TOPS scholarship.

Purpose of study
The purpose of the study was to examine the implementation of the Louisiana Virtual Classroom Project to determine the skills that teachers needed to teach Internet-based courses, the modifications teachers made to their teaching practices as a result of teaching in virtual environments, and the obstacles they faced.

Methodology
Participants
Eleven teachers were chosen to teach the first online courses. Each had five to ten years of teaching experience in their field, and all had taught in the same subject areas in which they designed their web-based courses. They received a $6000 stipend to design and teach a course for one year. Five of the eleven teachers participated in an in-depth study. These five were chosen based upon subject area and their willingness to participate. Jeanne taught Algebra I; Claire, Fine Arts Survey; Edith, World History; Blanche, Exploration and Analysis of Environmental Issues, and Paul taught Survey of American Literature. The project began in August 2000, and approximately 140 high school public and private high school students enrolled.

Data Collection and Analysis
In-depth case studies of five teachers were developed. Data collection included observations, interviews, pre- and post-surveys, the Profiler instrument, and responses that had been posted on a discussion board. Because the purpose of this study was to examine the experiences of teachers, student data were not collected. Data were analyzed using the constant comparative method to examine emerging theme and patterns across cases.

Discussion
Essential Skills

Organizational skills. Teachers discovered that they needed to be more organized when teaching in an online environment and noted that students appeared to be more comfortable when course materials were organized systematically. The teachers also found that they needed good organizational skills to manage the curriculum. As a result, some of them had to eliminate a portion of their teaching materials, because the time lapse between the assignment distribution and assignment return was too lengthy. Often, several days passed before the assignments were returned from students. Edith, Paul, and Claire stated that they reduced the number of assignments due to the lack of time. Harrison and Bergen (2000) found that in reality, teaching in an online format requires teachers to be more organized than in a regular classroom environment. In turn, the students are then able to post their materials and assignments online in an orderly fashion.

Technical Skills. The teachers in this study also indicated that prior technical skills are extremely important when teaching a virtual course. Although the participants possessed technical skills as teachers, they felt they should not be responsible for any internal server problems and online glitches that intermittently prevented students and teachers from working on the course. Even though the teachers knew how to correct a locked-up computer, they could not configure a computer to connect with network or troubleshoot connection problems in actual practice. Wang (2000)
noted that before teachers can move on to the integration stage of technology, they must first possess basic computer skills.

Teaching modifications

Course format. To manage instructional materials in an online format, the teachers divided their courses into blocks, units, modules, or components. This method prevented the students from feeling overwhelmed. Within each section, a theme or a specific topic was addressed and online resources were included. Three of the teachers stated that they had revamped their traditional lessons to include online resources. In addition, the teachers found that in the beginning, students had problems adjusting to an online learning format. As a result, the students turned in assignments late or not at all. As the semester progressed, the majority of the students submitted their work on time.

Cooperative learning. All of the teachers integrated cooperative learning strategies into their online courses and used e-mail, live chat, and the discussion board to promote collaboration and interaction. Teachers explained that student participation in project-based learning enabled them to assess students' levels of participation and whether individual students were actually achieving the goals established for the course. Students also benefited from cooperative learning through peer feedback and review their work.

Obstacles

Technical problems. All of the participants had expected technical problems to be resolved before their courses began. However, in August, Edith and Blanche both remarked that e-mail was not working at the Blackboard site; in October the Blackboard e-mail still was not working, so the teachers decided to use the students' personal e-mail addresses to send information. Students also experienced frequent technical problems while taking online quizzes. To remedy this, Blanche and Claire taught the other teachers to reset the quizzes. Jeanne stated that the chat rooms tended to freeze most of the time; so Blanche suggested alternative forms of communication for students, such as NetMeeting or Tapped In. Teachers also reported that the Blackboard server malfunctioned frequently -- either at night when they were trying to post assignments or on weekends when the students were attempting to complete assigned activities. The teachers stated that they often were frustrated with the situation because they were unable to work on their own courses or assist students when the server was down. Teachers also noted that students needed procedures for getting help when they were unable to access their courses. There was no full-time technician available at the Louisiana Center for Educational Technology to provide technical assistance to the teachers and students in this project. Research conducted by Grenier-Winterh (1999) indicates that technical issues for an online course need to be addressed before the implementation stage begins.

Lack of support and a sense of isolation. Teachers felt that more communication would have been beneficial and recommended that an online discussion forum be established at the beginning of the school year so that teachers can share ideas and solve problems. Teachers also wanted additional support from their principals and thought it would be helpful to require principals and staff members who serve as contact personnel at the schools to attend an orientation explaining their roles. Teachers commented that students also needed additional support. Most of the students were unaware of the contact person at their particular schools, and the teachers thought that regular meetings with the contact teachers and students at each school through Compressed Video would be helpful.

Summary

The Louisiana Virtual Classroom teachers began the school year with little knowledge of how to develop or implement online courses. Although they had studied how to do it and attended an orientation, they had not participated in an online course themselves. Consequently, the teachers were basically on their own instructionally and technically as they organized their courses' content, adjusted the format, and reconsidered the amount of time for assignments. They also realized that they had to include more cooperative learning activities to promote interaction between students. The teachers felt that they needed more support from the state technology center and from their principals. Teachers also thought that students needed additional support at the school level. Finally, tech support is crucial if online course delivery is to be effective. The Louisiana Center for Educational Technology used the findings from this study to improve the Louisiana Virtual Classroom Project for the 2001-2002 school year. Because online delivery, especially at the high school level, is relatively new, the findings from these case studies should be helpful to high school teachers or college professors who are interested in developing and implementing online courses.
Collaborative University Teamwork in Designing a Distance Education Course for the Government
Submitted by Penelope Semrau, Ph.D. and Barbara A. Boyer, Ph.D.

This presentation describes a project to educate a team of college students in designing and developing an online course for the National Security Agency (NSA) utilizing constructivist methods of teaching.

This project involved converting a face-to-face National Security Agency (NSA) course to a multimedia web-based course. The conversion involved a team of undergraduate and graduate students from Instructional Technology, Art Education, Computer Science, Special Education, and Graphic Design. Representation of various cultures was taken into consideration when selecting the students. In addition, two students were already teachers in the public schools and had experience in curriculum development. Two professors directed the project—one from Instructional Technology and the other from Art Education. The focus of the team was on collaborative group work and a constructivist approach to learning. Constructivist approaches served as the basic foundation for organizing and developing the project “...where students develop their knowledge through team collaboration, discuss different interpretations of a problem, and negotiate and synthesize ideas drawing from various disciplines” (Boyer & Semrau, 1995, 14).

The students were trained in new skills and how to research and work collaboratively. Training was provided on html, Photoshop, Premiere, MediaCleaner, Pagemill and the designing of web pages. WebCT was used for managing the website, communication and collaboration, and uploading pages.

A major focus was to keep the web course interactive emphasizing learner control. Useful tools for designing constructivist approaches to learning are hypertext and hypermedia because they allow for a branched instructional design rather than a linear top-down approach. It was also important in the distance education course that there be a balance between the text and the use of graphics, diagrams, video and audio to reinforce the learning.

Through this project the students became constructively involved in their own learning and acquired in-depth experiences in collaborative learning and team approaches. The students became empowered as creators of their own curricular materials and web pages instead of being passive viewers of others’. All of Bloom’s higher level taxonomies were implemented: Students analyzed websites, synthesized criteria they had researched, applied their book readings, compared and contrasted criteria, designed and produced their own web pages, and focused on sound educational practices. As Gibson (1998) noted “...we, as distance educators, need to be learner-centered reflective practitioners” (p. 143).

This presentation identifies the five stages involved in creating a distance education course. With every stage, specific strategies are detailed and actual solutions are illustrated.

1. Planning and Development of the Content
2. Layout and Design of the Website
3. Implementation
4. Editing the Content
5. Assessing Learning and Evaluation
Establishment and Improvement of the Distance Learning Project at Inter American University of Puerto Rico, Bayamón Campus

Yolanda Serrano, Inter American University of Puerto Rico, PR
José Guillermo Santiago, Inter American University of Puerto Rico, PR

The Inter American University is the largest private university in Puerto Rico with nine campuses and two specialized schools, and a total of 46,000 students. The Distance Learning Project of the Bayamón Campus was developed during 1999 by faculty members, students, administrators and technicians. The project started on January 2000 with 11 courses, 13 faculty members and 250 students. During this academic year, 19 courses, 25 faculty members and 460 students are participating in this project.

Nevertheless, some difficulties have been observed: first year students don’t have the computer skills necessary to participate in online courses; the first group of online courses created didn’t have uniformity in design; the process of involving faculty members in the development and design of online courses has been slow; and some technical problems with the university net and the online course platform (“Learning Space”) has been observed.

However to improve this project, the following determinations have been adopted: a questionnaire was created to make students aware of their abilities, aptitudes and computer skills necessary to complete an online course. Also, a previous interview by the professors with the student is recommended. Guidelines have been created for the development of the new online courses, with emphasis on the use of a diversity of tools. Continuous workshops are given to faculty members interested in the creation of new online courses and technical support is provided to those who are already offering the courses. Technical problems of students and professors with online courses are channeled through the Faculty Support Center and the Coordinator of the Project.
Abstract: Motivation is generally defined as the magnitude and direction of behavior, the choices people make as to what experiences or goals they will approach or avoid, and the degree of effort they will exert in that respect (Keller, 1983). Web-based instruction offers various bonuses to promote and develop intrinsic motivation in learners. Intrinsically motivated learners are learners who are not only interested in completing the requirements for a course but who also have a personal awareness in grasping the content. There are several instructional motivation theories that provide helpful perspectives. In this paper, based on the ARCS (Attention, Relevance, Confidence, Satisfaction) model some instructional strategies will be presented for Web-based instruction.

Introduction

Motivation is generally defined as the magnitude and direction of behavior, the choices people make as to what experiences or goals they will approach or avoid, and the degree of effort they will exert in that respect (Keller, 1983). There have been several motivational theories and models in educational psychology such as Expectancy-Value theory (mainly represented by Atkinson's theory of achievement motivation and Rotter's social learning theory), Theory of Achievement Motivation, Social Learning Theory, Attribution Theory, etc. Most of these theories could be beneficial for instructional designers to be aware of motivation in various ways. However, they do not provide systematic guidelines for instructional design. On the other hand ARCS model provides integration of numerous strategies for increasing motivation. In addition, this model integrates motivation theory and motivational strategies with instructional design theory (Keller, 1983).

ARCS Model

The ARCS (Attention, Relevance, Confidence, Satisfaction) model is useful for instructional designers because it helps understand the construct of motivation in terms of four distinct categories, provides the systematic motivational design process, and motivational strategies (Song & Keller, 2001). The ARCS model gives a rich descriptive synthesis of concepts and theories of motivation combining systematic approach to motivational design. It also offers motivational strategies and tactics.

Components of ARCS Model

Attention generally refers to establishing and maintaining curiosity and learner arousal. Relevance is related to linking the learning situation to the needs and motives of the learner. Confidence refers to the learner attributing positive learning experiences to their individual behavior. Satisfaction deals with developing the desire to continue the pursuit of similar goals (Keller, 1992).

Web and Motivation

Web-based instruction offers various bonuses to promote and develop intrinsic motivation in learners. Intrinsically motivated learners are learners who are not only interested in completing the requirements for a course but who also have a personal interest in understanding the content. Web-based instruction offers many ways to develop intrinsic motivation in learners. With its information-rich environment in multimedia forms, the Web can help to generate curiosity and interest in students. This visually appealing and information-rich space can easily arouse and sustain attention in the content. The Web can also provide equal and non-judgmental environments, in which everyone can participate, each with an equal voice. These kinds of environments provide critical thinking; enhance confidence, and that lead to feelings of satisfaction that are intrinsically reinforcing.

Suggested Strategies for the Design of Motivating Web-based Instruction

Based on the ARCS model there are several strategies that can be offered. Some of the commonly used strategies for each components of the model as follows (Visser, 1998; Cote, 1998);

To gain and sustain Attention:

- Use novel, surprising, incongruous or uncertain events.
- Stimulate information seeking behavior inquiry.
- Maintain interest by varying elements of instruction.
- Provoke mental reasoning and problem solving by sending students to Web pages with differing opinions.
- Use good screen design to capture the interest and attention of the learner.
- Use relevant multimedia elements to help keep students on task.
- Build interactivity into the instruction.
- Do not send all of the materials at the same time; only send the next part of the course when the learner is about to finish the first delivery.
  - If this is not an option, an additional text or paper could be used to help the learner focus.
• Use a variety of media.
• Send occasional encouraging letters (e-mail) which focus on the material, or on the part already done (satisfaction).
• Send a challenging or provocative message to the student.
  o The mere arrival of an unexpected message will stimulate attention of the learner.
• Provide speedy feedback on assignments.
• Use frequent short questions.
• Include challenging statements that help the learner to reflect on the course content.
• Show real (and not fake) interest in how the learners progress through the course.

To provide relevance:
• Use concentrate language and use examples and concepts related to the learner’s experience and values
• Use strategies that match the motive profiles of learners
• Show how instruction relates to the student’s future goals.
• Try to apply instruction to real world scenarios.
• Demonstrate why the material is important to the student.
• Adapt course requirements to the learning style of the students.
• Inform learner of what is expected (state objectives).
• Give feedback to relate the course content to the learner’s goal.
• Help learners to understand on how the instruction they are doing can contribute to solving the (professional) problems they are facing or can enrich their performance.
• Help learners to define priorities and to manage time.
• Provide samples of assignments.
• Stress relevance by giving examples, especially in the feedback on assignments, that relate to the learners’ daily circumstances
• Explain in detail why a learner has to do certain things.

To built a confidence:
• Provide performance requirements and evaluative criteria
• Provide multiple achievement levels, personal standards, and opportunities for learners to experience success
• Build in frequent summaries and reviews.
• Provide opportunities for the students to interact with the instructor, other students, and the instructional materials.
• Inform learners in detail about what is expected of them, not only by describing the objectives of the course/lesson, but also by defining the standards of performance as to, among others, the organization of their assignments and the marking key.
• Clearly define standards for measuring performance and grading the learners’ work
• Help learners feel that they have control over the outcomes of their work
• Require learners to submit their first assignment early in the course. (Lack of confidence is often the reason for delays)
• Introduce feedback loops that allow students to catch up or to improve.
• Stress that learners will succeed if they work hard
• Give credit for even minor improvements and if possible give learners positive feedback.
• Provide variety of opportunities for students to be successful. Letting students know they themselves are, or have been, responsible for their success through their personal ability and effort also increases and builds confidence.

To develop a satisfaction:
• Provide opportunities to use newly acquired knowledge in real or simulated settings
• Provide feedback and reinforcement that will sustain the desired performance
• Share work done on the Web with others, especially at other institutions.
• Utilize fair rewards that are based on the quality of work produced.
• Encourage collaboration among students as they develop Web-based assignments.
• Provide frequent, timely and adequate, encouraging feedback
• Use remarks like “This is really an interesting piece of work.”
• Keep learners informed about their progress through the course

Conclusion

Teachers with a profusion of experience are designing classroom instruction. However, those teachers have limited experience in designing web-based learning. This paper presented an introductory instructional design model for incorporating motivation into course design. It is believed that specific strategies and ideas for using ARCS model to design motivating web based instruction can be beneficial to designers. A clear and understood goal of most education is mainly to motivate learners to desire to learn and to find satisfaction in learning rather than just completing the assignments to get a grade. It is not so easy to encourage this kind of motivation. But it is obvious that Web-based instruction may offer some advantages and extra help.

Camp Internet Distance Education Program

Timothy Tyndall, Camp Internet, US

Camp Internet is a K-12 distance education program currently providing daily classroom curriculum and programming for over 9,000 students in Southern California. Over the next year, through a new USDA RUS grant the program will include an additional 300 classrooms in Arizona, New Mexico, Colorado and Nevada. Sponsored by the California Department of Education and the USDA Rural Utilities Service as well as through private subscriptions by school districts such as Los Angeles Unified School District. The Camp Internet program, now in its 10th year, provides project-based learning as well as a strong mentorship component bringing students online daily for math, science, history and reading studies. Using advanced technologies such as GIS (we give GPS units along with a variety of other learning tools to each classroom at the beginning of each year), video chatrooms and personal electronic student portfolios Camp Internet provides an environment for both teachers and students to learn and develop technology skills essential for the 21st Century. Subject experts from universities, federal and state agencies as well as authors, musicians and artists come online weekly as "trail-guides" to give the students direct contact with the sources of their information. Chatrooms are used to teach students skills in "dialog", learning to listen, ask good questions and then report on the question and answers. Current programs include "Exploring the California Channel Islands", "Exploring the California BackCountry", "Exploring the Ancient Southwest" and "Exploring the Global-Garden". Camp Internet is also responsible for ongoing Teacher Technology training for all of our school districts, providing 4-day intensive training sessions during the summer at our Technology Center in Santa Barbara, California and ongoing teacher training at school district labs throughout the year. (we train around 400 teachers each summer). Our paper will review recent activities and results in teacher training and methods used as well as a review of current classroom activities and results from the past year. Camp Internet was just awarded its 5th USDA Rural Utilities Service distance learning grant to take the program into the southwest opening the program to schools in Arizona, New Mexico, Colorado and Nevada. Working with the California State University system Camp Internet also provides credit to teachers taking part for a full year as well as a $1,000 stipend. Participating classrooms receive CD-ROMs each month with new GIS, math and video units to encourage participation by schools which may have limited bandwidth. The Camp Program also works with the CYFAR program setting up programs for youth, family and children at risk projects and provides an excellent study in the application of new technologies to parts of our communities with limited literacy or limited English language skills. Our paper will provide current updates on both Teacher Technology Skills training methodologies and classroom programs.
The virtual library. A new approach to knowledge through Internet
Ricardo A. Viglianco, Graciela P. Rodriguez
Virtual Library, Faculty of Biochemical and Pharmaceutical Sciences, University of Rosario.
Institute of Experimental Physiology (IFISE) CONICET. Rosario Argentina Email:
rviglian@citynet.net.ar

Objective: Opening of a new space to pedagogical development in order to facilitate the interaction among teachers, students and knowledge.

Methods: The mentioned objective was accomplished by means of a new space which allows the access to Internet free without restriction by means of an optical fiber connection. Such a space is called a Virtual Library. In this space students and teacher from the Faculty of Biochemical and Pharmaceutical Sciences including future Biotechnology Licentiates, may use ten personal computers, which maintain a permanent connection to Internet. All users search for information regarding different topics which are in the field of their respective interest including for example the access to international databases related to specific topics as protein sequences, which were not possible to perform formerly in this Faculty. In addition, the users can establish contact with people from other World universities by mean of e-mail or chat; they can get access to web pages or archives as well as to other service which are offered through Internet. Advanced students from System Analyst career that belongs to J.J. de Urquiza Institute of Rosario supports and brings information to the users. Such a multidisciplinary interaction not only increases web use by people from the Faculty but also improves teaching experience and knowledge appliance of future System Analyst. A cooperation agreement was signed between the Faculty and the Institute to provide necessary lawful support. This project started in March 2000. Actually about 48 teachers and 682 students are registered as users of the Virtual Library. It was statistically calculated that users are web navigation during two thousands hours a month. This project is at present of regular use by teachers that provide also a Virtual Class to the students. Next November will start the first postgraduate course through distance by e-mail, which is offered through the Graduated School of the faculty of Biochemical and Pharmaceutical Sciences. Such a course has the purpose to provide an intelligent use of new technologies to new graduates in Biochemistry and Pharmacy.

Conclusions: This experience considerably increases fields of knowledge not only to students but also to teachers within an academic environment that allowing both professional and personal enrichment. This model should be adopted by other academic institutions as a regular offer.
Multiplicity & Flexibility as Web-Based Collaborative Learning Course
Design and Implementation Considerations – A Case Study

C. Y. Janey Wang
Learning Technology Center
The University of Texas at Austin, U.S.A.
janeywon@mail.utexas.edu

Abstract: This presentation examines how multiplicity and flexibility were essential considerations in the design and implementation of an award-winning Web-based collaborative learning course. Design features supportive of multiplicity and flexibility are examined, as are implementation and assessment processes employed in meeting these goals. Future online collaborative learning course design and research implications are discussed.

Introduction

The Internet has created opportunities for widespread electronic delivery of news, information, and curriculum that have altered the ways we communicate, share knowledge, deliver education, and conduct business. It also provides unique opportunities to prepare learners for “future responsibilities” and “success in life,” as well as tailoring instruction to meet individual learner’s needs and interests while drawing strengths from students’ diverse backgrounds (Dewey, 1938, p. 17).

A case study of a Web-based course that integrated computer-supported collaborative learning is used to illustrate the importance of multiplicity and flexibility as key elements in designing collaborative and interactive online learning environments. This study describes the course context, objectives, and structure of an award-winning Web-based collaborative-learning course, Instructional Technology Planning and Management (ITPM), offered in the spring of 2001 at the University of Texas at Austin. This course received the “National Distance Learning Course Award” from the University Continuing Education Association, and the instructor received the “2001 Excellence in Distance Learning Teaching Award for Higher Education” from the U.S. Distance Learning Association.

Multiplicity refers to the multiple ways of presenting and delivering course material and providing multiple channels of communication, interactive activities, and learning strategies. Flexibility refers to the provision of choices to learners in designing a learning environment more responsive to their needs and interests. Such an environment characteristically invites questions and suggestions, provides timely support and options for learning tasks, rich readings and interactive assignments, while providing ongoing individualized feedback.

This paper examined multiplicity and flexibility in the design, implementation, and assessment of an online course that emphasized collaborative learning. Essential features of multiplicity and flexibility discussed include: multiple course representations, tools, communication types and channels, support, interactions, flexible course structure, personalized communication and feedback system, and cultural-sensitivity to better meet the needs of learners from diverse backgrounds.

Study Summary

Based on the researcher’s experience in course design and implementation, multiplicity and flexibility emerged as important factors in meeting the needs of learners from diverse backgrounds. This study examined an online course, ITPM, offered to both on-campus and distance learning students. This course was situated in a virtual environment where students met through both asynchronous and synchronous online interactions. The major intellectual product developed by the students was a strategic technology plan collaboratively produced as students learned the basic concepts and tools of strategic planning. The course was comprised of eight modules, each representing a major component of the planning process. Modules progressed from simple to complex tasks.

Four aspects discussed in this paper include: course content and structure; course delivery; social interactions and support; and course evaluations. Multiplicity was represented in the course content and
structure by providing rich information, resource links, reading selections, activities, and assignments. The course emphasized cognitive, social, and technical aspects of learning. Most assignments and activities were group-oriented where interaction was essential. A dedicated group discussion site provided students a platform for social interactions. Although most communication occurred asynchronously, the planning teams also made significant use of synchronous communications. Collaborators chatted, asked support staff for assistance, discussed tasks, and socialized with peers in real-time.

Multiple tools were employed for various task purposes, while multiple media were employed for course presentations (text, graphics, streaming video, video-conference, audio-conference) and for group interactions (e-mail, phone, voice mail, synchronous chat line, audio and video-conference, and face-to-face interaction for on-campus students). In considering technical failures, the course content was available at multiple Web sites. In considering accessibility, a CD-ROM of streaming video segments was made available free of charge at the beginning of the semester. This enabled students with low-bandwidth connections to easily access all video and audio elements of the course. The multiple ways of presenting course material and the multiple platforms for providing course content not only increased learners' interest options but also provided flexibility in the event of technical glitches. The multiple channels available for learners to approach the instructor, support staff, and other students provided options and alternatives for flexible communication.

Course design was the result of a collaborative effort among a team of diverse backgrounds. Likewise, student support was organized around a collaborative group effort. Learners were able to obtain assistance from an array of sources, including the instructor, the teaching assistant, a technical staff, an administrative coordinator, a network administrator, and two subject-area consultants. Multiple sources of support were available via an online weekly newsletter, handbook, and announcements, technical support, and consultants' areas. The teaching assistant monitored group activities daily and provided timely instructional and technical feedback to learners.

Multiple types of assessment were employed to maintain student accountability in achieving individual and group learning goals. These included the instructor's evaluation, learners' self-evaluation, peer evaluations, and group product evaluations, as standardized by evaluation rubrics provided in the course content. Learners evaluated themselves and their teammates by two methods: rubric-based ratings and qualitative comments based on individual judgments.

Evaluation of individual student's progress was based on cumulative monitoring, analysis, and feedback of students' online participation (self, peer, and product evaluation results), as well as their frequency of communication and quality of their contributions. To keep learners abreast of their progress, descriptive written or voice feedback on learners' performance and future assignment deadline reminders were provided at the end of every module.

Conclusion and Future Implications

Multiplicity and flexibility were incorporated as design features in order to approximate the complexity of real world contexts where multiple solutions collaboratively arrived at are the norm. Incorporating multiplicity and flexibility into the design involved providing multiple ways of presenting and structuring content, providing multiple communication channels, providing choice of readings, learning resources, assignments and task, and providing flexibility for learners in working collaboratively to accomplish learning projects and solve problems. There were also constraints in the application of multiplicity and flexibility. For example, the course start and end dates were fixed by the university calendar while the intensive time constraints required fixed deadlines for completion of specific learning projects and tasks. Given the pressing need for online instruction that is responsive to the needs of individual learners, further research into the use of multiplicity and flexibility as design features of the distant-learning environment is warranted.

Abstract: The purpose of this paper is to share the lessons learned from facilitating a Web-based professional development course for K-12 educators. Offered in Spring 2001, Using the WWW in the K-12 Classroom was the pilot course of a newly developed Professional Development Series offered by a university located in the Appalachian region. The course facilitators were an assistant professor at the host university and a part-time faculty member who lives in California. The shared experience of facilitating a course at a distance brought up many issues about the role of the instructor and communication between instructor and student. The instructors intend to share their reflective study of these issues and other lessons learned to provide further insight into successful facilitation of Web-based distance education courses.

Overview of the Course

A total of 153 in-service teachers were enrolled in the 10-week, self-paced course titled Using the WWW in the K-12 Classroom. The four main objectives of the course were for teachers to improve their Web searching skills, collect Web resources relevant to their grade level and content area needs, explore methods for integrating Web resources into their planning and instruction, and develop a basic Web page.

The course was developed using WebCT and included email and bulletin board communication tools. Course content was presented in six modules, each with accompanying assignments such as participating in bulletin board discussions, responding to reading and reflection questions, and creating a Web page. The course was graded on a Satisfactory/Unsatisfactory basis, with 80% required on each assignment to receive a passing grade.

Lessons Learned

Instructors

One of the most notable aspects of teaching a Web-based distance education course is the communication between the instructors and course participants. The instructors noticed rather early in the course that their written responses to students were more formal than those they would typically make in a face-to-face course. For example, instructors noted that in providing feedback on assignments, they often began by writing “Thank you for submitting your assignment.” The instructors constantly reflected on the heightened sensitivity they used in communicating with participants. A concern about loss of inflection and tone in written communication meant that instructors spent a lot longer composing written messages than they would composing a verbal response to a student in a face-to-face course.

Instructors also faced the unique challenge of using the technology to teach about technology. To facilitate the nature of a self-paced course, the instructors were restricted to using asynchronous communication tools to help participants troubleshoot Internet-related problems. Because part of the course was focused on developing Web
design skills, instructors found that often communicating at a distance posed a challenge for effectively communicating how to use the technology.

Other lessons learned were related to course development and the role of the instructor in a Web-based distance education course. Some of the issues that arose during the course are discussed below.

Initially, the instructors planned to divide the teaching load by alternating weeks for which they would be responsible for facilitating class discussion, grading assignments and responding to questions. Recognizing that participation was slow in the early weeks of the course, the decision was made to divide responsibilities by module so that one instructor was responsible for monitoring discussion, assignments, and questions for some of the modules and the other instructor was responsible for the remaining modules. This also allowed for greater consistency in grading individual assignments and made things less confusing for students who needed to submit corrections.

Instructors found that including an orientation module that served as an overview of the course and an introduction to the WebCT environment facilitated participants' comfort level with communicating by bulletin board and private mail, both of which are skills required for successful participation in the course.

While all course participants received feedback on their work, the instructors noticed that participants who submitted assignments early in the semester were more likely to receive in-depth feedback.

Instructors were challenged to find ways to make essential components of assignments more prominent for learners who did not read assignments carefully.

Keeping track of participants' assignments and revised assignments was a challenge. Midway through the course instructors asked participants to send a private mail message indicating that they had completed an assignment or were submitting a revision. This facilitated the tracking of assignments.

**Participants**

The types of questions participants asked and the general quality of their assignments suggested that more specific guidelines and examples were needed to support them in completing assignments successfully.

Participants had a desire to be connected by grade level and/or content area. Some participants "found" each other by reading introductions posted to the bulletin board. Others wanted the instructors to make the connections for them.

Some participants required more personal interaction with the instructors and called the university to ask for specific help over the telephone. The number of calls increased toward the end of the semester.

It became apparent when reviewing assignments that all participants did not thoroughly read the course content and directions. Informing students that an assignment was incomplete or unsatisfactory accounted for a large number of the private mail messages instructors sent. Looking for a pro-active way to address this situation, the instructors developed eight tips for successful participation in an online course, which is now included with participants' registration packet.

When posting assignments to the bulletin board, participants tended to follow the pattern of the first posting. Subsequently, the first posting set the stage for the quality of the discussion. If the first posting was well constructed and thorough, those that followed tended to be of high quality as well. On the other hand if the first posting was incomplete or poorly constructed, subsequent responses tended to follow that pattern. In the first case, the instructor was less involved in facilitating the discussion, as it tended to be participant-led, in the latter case, the instructor was more involved in order to increase the quality of the discussion.

Although the course syllabus indicated that instructors would respond to private mail and bulletin board postings within 48 hours, participants had a need for immediate feedback. Self-grading components that were automatically scored by WebCT seemed to make participants impatient for feedback on other assignments.

**Conclusion**

Facilitating an online course is both challenging and rewarding. What the instructors of this course discovered is that the challenges have as much to do with the technology and course design as they do with the interaction between instructor and participant. This reflective study of two online course facilitators is important because the lessons learned are instructive to other online facilitators. It is also important because the lessons learned were used to make revisions to this and subsequent professional development course offerings.
COPYRIGHT AND FAIR USE:
BLIND MEN DESCRIBING THE ELEPHANT

Leo Wells
Barat Program for Learning With Technology
Barat College of DePaul University
Lake Forest, IL
gwells1@barat.edu

Abstract: The “fair use” of documents secured from the Internet for educational use has historical precedents dating back centuries. Indeed, the concepts of ownership of intellectual property have been sharply debated since the invention of movable print. Fair use can be defined based on the purpose, nature, and amount of material accessed, and on the economic impact of the use of the material. Various scholastic organizations have implemented policies to define fair use and to make the Internet useful to scholars, but fair to the authors of documents. New technologies are now available to ensure copyright compliance.

Much is written on the various laws and regulations concerning the educational “fair use” of copyrighted material from libraries, the Internet, and a host of other sources. From issues of historical precedents, to ownership of the source material, to recent statutes, to myth and innuendo, fair use is defused through different filters to be different things to different practitioners. Authors describing “fair use” will emphasize isolated aspects of this doctrine, similar to the poem of blind men describing different parts of an elephant (i.e., the tail is like a rope, the ear is like a fan, etc.). We notice what seems most obvious and visible from our limited perspectives.

The problem of copying the work of another author goes back a few hundred years. Goehner (1997) suggests that the very invention of the Gutenberg printing press created the opportunity to steal the written word, what with the newly-found ability to mass-produce documents.

McLaughlin (1999) suggests that recently enacted regulations are nothing new at all, but rather they are more in keeping with eighteenth century Germanic states that enacted laws to protect the author and publisher of a work. Apparently, the typical book or pamphlet would be copied again and again despite the author’s wishes. McLaughlin cites eighteenth century philosopher Immanuel Kant who said, “...The counterfeiter undertakes the author’s business, not only without any permission from the owner, but even contrary to it” (Kant, 1795).

The very act of accessing an Internet website causes a copy of the web page accessed to be placed on an end user’s system (Lipinski, 1999; McLaughlin, 1999). This aspect of “fair use” allows for “browsing” in the digital environment, even with a copy in the computer’s RAM (Lipinski, p. 13).

After describing the extent of the Copyright Act of 1976 and what constituted a copyrightable work, MacKnight (2000) defines four factors within the law which are “...not specific on what is or isn’t ‘fair use’” (p. 110). The purpose of the extracted work, e.g. research, teaching, scholarship, has to be considered. The nature of the copyrighted work, whether it is creative, or factual, or whether it has been previously published determines its fair use. Unpublished materials and creative works are more likely to be denied fair use. The amount of the work extracted varies with the work. The effect on the potential market must not harm the author’s opportunities for sale of the work.

A major state flagship university system has developed easily readable “rules of thumb” for not only determining the “fair use” of an Internet document, but also making “course packs,” images, music, multimedia, distance learning, research copies of articles, and holding materials on “reserve” status in the library (University of Texas System, 2001).

Templeton (1998) lists his “top ten” myths about copyright on the Internet. Templeton’s discussion about these “myths” indicates that even our e-mail is copyrightable. The inference is that although some works are copyrightable, the marketability of those works is virtually zero. What could we charge folks for reading our e-mail or Usenet postings? The “myth” of educators being immune from copyright is gone. The ideas that “they can’t sue ME,” and “I have rights” vanish when the reality is that litigation stemming from a copyright violation is CIVIL, rather than criminal, and the rules are startlingly different.
Financial issues dominate other authors’ concerns over copyright and ownership of Internet products. Smith, Eddy, Richards, and Dixon (2000) insist that copyright law and litigation over intellectual property rights will be arenas of significant risk as educational institutions become providers of Internet education. They suggest that anti-trust regulations could be construed to include educational institutions “if they acted with commercial motive” (p. 6). Smith, et al. suggest that universities might be somewhat behind in the establishment of policies to address possible anti-trust litigation. (p. 11)

Admitted Luddite David Noble decries the proliferation of Internet courses for profit by universities (Noble, 2000). Noble insists that the professors (authors) who create courses (works) have a right to own their course material and that the university has no right to profit from the creative work of professors. Simpson and Turner (2001) report on methods one university has implemented on assigning ownership of intellectual material based on a professor’s usage of university time, university resources, the professor’s job description, and the number of students involved (University of North Texas, 2000).

Lipinski (1999) argues that “fair use” is also a key factor in distance education. He maintains that current laws be augmented to allow for the various problems related to distance education, e.g. access to materials. Moreover, the current laws correctly indemnify libraries, etc. from liability if they have taken some array of safeguards to prevent document piracy. Lipinski suggests that new technologies, such as watermarking documents, printing denial, and tracking be employed for copyright management.

The motivation for this present research stems from discussions among peers on just what “fair use” is, how it works, how it is implemented, and how much we can demand from both faculty and students as to compliance. Hopefully, this present paper will be expanded for greater depth. How we as practitioners, and our students, who will in turn influence even more students, deal with this will make the difference as we implement technologies and delivery systems yet to be conceived.

Abstract
This paper outlines the role played by the New Opportunities Fund (NOF), 'ICT for Teachers' initiative in the UK. This Government scheme, which commenced in April 1999 (TTA 1998), provided a sum of money for every serving teacher in the UK, to 'buy' professional development training in ICT (Information and Communications Technology), from Government Approved Training Providers. SIfT (1999) as a provider to the scheme, has developed pedagogically sound learning materials (TTA 2001a), addressing the needs of individual teachers, delivered through a Virtual Learning Environment. We believe that the results, issues, experiences and questions arising from our research have implications for researchers all over the world. Indeed with the SIfT training in the main delivered via the Internet, the international aspects of delivering training for teachers by this medium is continuing. SIfT materials are currently being used by in excess of 1000 teachers, in England and Jersey, have been trialled in Norway and are being used in Germany.

Introduction
The Stevenson report, published in the UK in 1997, identified that "The Government must launch a long term strategy to increase the effective usage of ICT in schools". With respect to teacher support, it identified "The overall aim should be radically to improve and accelerate the skills, experience and confidence of teachers so that they can use ICT to facilitate learning" (Stevenson 1997).

In response to this report, the Government established one of the largest training schemes for 'serving' teachers in the UK - the New Opportunities Fund (NOF) ICT for Teachers initiative (TTA 1998), which it supported with £230 million from the national Lottery. The aim of this current scheme is to facilitate the national targets set by the Government, for all teachers to be ICT (Information and Communications Technology) confident and competent to teach using ICT, by the year 2002 (DfEE 1997). The focus of the training is to help teachers to use the technology within their subject area of the curriculum, rather than teaching purely how to use the technology.

Staffordshire ICT for Teachers (SIfT), a collaboration between Staffordshire University and Staffordshire Local Education Authority (LEA), in the U.K. became a Government Approved Training Provider in February 1999, following the competitive tendering process (Whitehouse et al. 1998). SIfT was approved as a national provider for England (one of fifty approved providers) to deliver ICT training to secondary teachers (of students aged 11-18), within the subjects of Geography and Design and Technology (SIfT 1999).

SIfT planned to deliver the majority of their training to teachers, using a web-based Virtual Learning Environment (VLE), in this instance Lotus Learning Space. A Virtual Learning Environment is defined as 'an integrated software system, which combines within a package facilities for the delivery of learning materials, communication (synchronous or asynchronous), assessment and student feedback' (LTSN/THES 2001).
The SIfT aim was to create a ‘virtual’ learning solution, which:

- utilised technology to support the strengths of human contact;
- made the technology available so that teachers had the opportunity to learn with interesting and lively experiences of ICT, in a subject context which was familiar to them;
- offered the opportunity to learn mainly within the teachers own physical environment, enabling the ‘learning on demand - any time, any place, at your own pace’ style of learning.

This paper gives a high level view of the SIfT model, covering: materials and delivery; the relevance of the tasks set; support given; the sharing nature of the resource base; and the networking and discussion opportunities. It explains the design of the SIfT 12 Unit grid and the issues of pedagogy that were addressed, reflecting on how timeframes drove the development and how feedback, both from teachers and the Teacher Training Agency quality assurance process, improved the model. Finally the paper evaluates the SIfT provision, drawing on evaluation evidence published on both the NOF ‘ICT for Teachers’ scheme and the SIfT training, commenting on the impact of SIfT and the current on-going research.

Development of the SIfT 12 Unit Grid

The design adopted by SIfT was to create a highly structured model, subject focused to the perceived needs of the users (Milligan 1999). The SIfT training was developed as a 12 Unit grid, consisting of four subject strands, each with three levels of ICT capability - beginner, intermediate and advanced. This grid was then implemented for teachers at secondary level (with students aged 11-18 years) for the subjects of Geography and for Design and Technology.

Figure 1: the SIfT model, illustrated for Geography © SIfT 1999
Figure 1 shows the implementation of the SIfT design for Geography. The four subject strands are: 'How ICT is changing the world we live in', 'Developing enquiries using digital resources', 'Using spreadsheets with geographical data' and 'Using ICT in fieldwork'. Each of these strands is offered at 'Beginner', 'Intermediate' and 'Advanced' level of ICT competence, resulting in twelve units in all, numbered from 1 to 12. The Unit is broken down into two or three Courseworks, identified as 'Coursework A', 'B' or 'C', each with a common framework of 'Stimulus', 'Assignment', 'Small steps to success', 'Assessment' and 'Learning Outcomes'. The 'Small steps to success' are the learning tutorials within the Coursework, which provide the materials for the learner to develop the knowledge and skills to be able to carry out the 'Assignment'.

Under the ICT for Teachers' scheme, funding is available for teachers to 'buy' four units from a possible twelve, thus providing flexibility for teachers to choose the SIfT units, which most closely reflect their ICT competence level and subject need. A teacher selecting Unit 4 and commencing on Coursework A 'Making an impact with presentations', would thus follow the 'Small steps to success' tutorials, identified consecutively as 4A1-4A6, to cover materials in the areas of 'Teaching and Learning' and 'ICT skills for presentations'.

The SIfT 12 Unit grid and framework were particularly suited to the 'Content Centred' Virtual Learning Environment (Milligan 1999), of Lotus Learning Space (LLS) Version 2.5, which was used for this development. LLS had been acquired by Staffordshire University in December 1997 and had been used by local students from September 1998. Within LLS, the student encounters four main areas - the 'Schedule', 'MediaCenter', 'CourseRoom' and 'Profiles'. The Schedule holds the outline of the virtual course, whilst the MediaCenter holds the course-related material. The SIfT Units and Coursework framework would thus be accommodated within the Schedule area of LLS (Stimulus, Assignment, hyperlink headings to the Small steps to success, Assessment and Learning Outcomes), whilst the SIfT Small steps to success tutorials would reside within the MediaCenter. Of the remaining LLS areas, the CourseRoom would permit on-line discussion, collaboration, assignment creation, submission and feedback, whilst the Profiles area would enable participants to submit their own personal information, relating to their education, experience and interests.

In creating the SIfT learning content within the VLE, the aim was not only to produce 'bite-sized' pieces of learning (taking no more than 30 minutes elapse time), but also to provide material which was pedagogically sound, incorporating qualities of the 'virtual tutor'. The objective was to create material, which was motivational and friendly, innovative, lively, interactive and dynamic, and to place special emphasis on understanding and accommodating the many requirements of the teachers' daily needs.

**SIfT Pedagogy**

Gagné (1985) identifies nine events of instruction for any desired learning, (see Table 1). These instructional events provide the external conditions that are necessary for learning to take place; the events usually occur in the order listed. Within the SIfT Coursework materials, Gagné’s nine events of instruction are developed within the Stimulus, Assignment, Small steps to success, Assessment and Learning Outcomes, and are explained here in the context of the SIfT Geography materials.

1. Gaining attention.
2. Informing the learner of the lesson objective.
3. Stimulating the recall of prior learning.
4. Presenting the stimulus material with distinctive features.
5. Providing learning guidance.
7. Providing information feedback.
9. Enhancing retention and learning transfer.

| Table 1: Gagné's nine events of instruction |
Stimulus
The aim of the Stimulus is to gain the teacher's attention (Gagné's instructional event 1). The SIfT Stimulus uses a goal-based scenario, to set the scene of the learning and to motivate the user. Within the subject of Geography, the stimulus may be delivered through a scenario, which could be surprising, emotional, a mystery, a conundrum or paradox, something confusing, fun, dramatic or moving. Geography, Unit 4, Coursework A - 'Making an impact with presentations', begins with the use of presentational slides containing images of the Colombian Earthquake, February 1999 and makes the statements “Imagine you lived here” and “Think about how these people feel”.

Assignment
The Assignment informs the teacher of the lesson objective (Gagné's instructional event 2) “Your task will be to follow the instructions carefully to create a presentation to start a lesson with a whole class or a small group....”

Small steps to success
The Small steps to success are the tutorials. In stimulating the recall of prior learning (Gagné's instructional event 3), the SIfT materials provide a selection of geography lesson scenarios and the question is asked “Which of these are genuinely enhanced by using a presentation?” The teacher may call on the tutor’s opinion or knowledge base (revealed through a hyperlink), to provide learning guidance (Gagné's instructional event 5). This guidance uses images to further illustrate the impact of slides to deliver the required message, thus presenting the stimulus material with distinctive features (Gagné's instructional event 4).

The SIfT Small step tutorials provide content which may be re-used, immediately by teachers themselves, within a classroom situation. The steps include humour and focus directly on the teachers' needs, their problems and environment. Step 4A2 'Setting up a computer with a big screen' commences with the words "This tutorial may be NO USE AT ALL". If the school does not have the projection facilities, it pre-empts any negative teacher response, which may have been directed at the SIfT materials, creating instead an empathy with the SIfT team who understands their circumstances. Whilst working through the tutorials, if the teacher experiences difficulty or requires clarification, access can be made to an on-line mentor through the LLS CourseRoom, for further learning guidance (Gagné's instructional event 5). In providing support, SIfT are responsive to teachers' questions, encouraging the teachers, sharing thoughts and returning a little more information than requested – using our own awareness of new ideas.

Assessment
Whilst the Assignment informs the learner of the lesson objective (Gagné's instructional event 2), the teacher implements their new ICT knowledge and ideas, in a way that is relevant to them within their school – usually in planning an appropriate piece of teaching and learning. This can be semi-negotiated with a SIFT tutor (Gagné's instructional event 5) if the teacher wishes, via the on-line CourseRoom. The opportunity for the teacher to 'Request for Review' work which is in progress, enables the tutor to elicit performance (Gagné's instructional event 6) and to provide information feedback (Gagné's instructional event 7) on how to improve their lesson assignment.

The assessment is further developed by the application, of the ICT materials created, within the teachers' own educational context and the completion of the Plan, Teach and Review pro-forma within the Assessment area. The teacher is asked to reflect upon the context of the teaching and learning in which the ICT was utilised, the actuality of their delivery, its success and opportunities for improvement. The teacher then 'Submits for Grading' their ICT materials and their Plan, Teach and Review pro-forma, via the CourseRoom of the Lotus Learning Space software, to receive further feedback (Gagné's instructional event 7), and to receive assessment of performance (Gagné's instructional event 8). This application of the teachers' learning within their working environment and their reflection upon it, serve to enhance retention and learning transfer (Gagné's instructional event 9).

Learning Outcomes
The Learning Outcomes provide the user with a clear identification of the stage that their learning has reached at the end of the current piece of Coursework. “On completion of Unit 4 Coursework A you will be able to: Critically appraise the potential uses of presentations in teaching geography....”

All of Gagné's nine instructional events are thus developed within the SIfT materials, providing a strong pedagogical design, implemented through the SIfT 'virtual tutor' model.
Evaluation of SIfT and the NOF 'ICT for Teachers' initiative

With the launch of the SIfT training in January 2000, the NOF initiative did not permit time for research of best materials. SIfT adopted an iterative practice to development, prototyping the materials and subsequently reacting to feedback from teachers, integrating suggestions and new ideas within the content. Further development occurred in 2001, following quality assurance by the Teacher Training Agency, of the SIfT model and materials.

A day of face to face training introduces teachers to the VLE and SIfT materials. The central focus of SIfT is then on classroom practice, the training materials illustrate a range of classroom approaches with critical evaluation, developed through various learning styles. The product of the teachers' work is created within the VLE CourseRoom, building the resource base for others, with individuals able to download and use other teachers' endeavours. SIfT believes that as the system grows and more and more teachers add assignments to the system – teachers will consolidate their experience by using the products of other people's work, further enhancing retention and learning transfer. It is the opinion of the SIfT team that a flexible delivery strategy for a Virtual Learning Environment has been created, developed, and tailored to individual needs and which is scaleable (Milligan 1999). Currently in excess of 1000 teachers are registered users of the SIfT secondary Geography and Design and Technology materials in England, Jersey, Germany and Norway.

The Teacher Training Agency (TTA 2001a) said of SIfT: “The model is actively chosen by schools, mainly because of its subject specific nature and networking potential. The programme is well constructed and connected, with all the required elements covered. ....The elements of each unit within the modules are well constructed to form a complete whole that provides for a diversity of initial ICT ability and teaching experience... This strong subject provision focus, adopted by SIfT, has not always been present in training offered by some providers (TTA 2001b) and as a result led the Office for Standards in Education (OFSTED 2001) to identify that such training was less effective in raising teachers' confidence to use ICT.

The training has increased teachers' use of ICT resources to enhance subject teaching, aid communication and share good practice (TTA 2001b). Whilst OFSTED (2001) also found that the NOF training programme had contributed to an increase in the use of computers, they said it had rarely contributed to the pedagogic expertise to help teachers make the most effective use of ICT in their lessons. This is in contrast to the SIfT delivery, where the TTA (2001a) found: “The delivery of the programme places emphasis on the development of pedagogical related issues. The material and structure of the training can facilitate the development of significantly advanced pedagogical thinking and extend the use of ICT within the school.”

Although the TTA acknowledges that the SIfT materials are broad and comprehensive, appropriately supportive and generally accessible, they identify that “there is evidence that teachers with minimal or no experience of the Internet will not make the maximum use of the materials ...it leaves a number of teachers feeling overwhelmed and disempowered in taking responsibility for their own learning.” The SIfT team are aware of the many difficulties that teachers face and through their research are endeavouring to create further support mechanisms.

Anchored Collaborative Inquiry

Susan M. Williams
Department of Curriculum and Instruction
University of Texas at Austin
United States
susan.williams@mail.utexas.edu

Abstract: This paper describes Anchored Collaborative Inquiry, a model for in-service professional development that combines a traditional face-to-face workshop with online discussions in which teachers compare simultaneous implementations of the same reform-oriented curriculum. Tests of the model indicate that although the shared context encouraged teachers to participate much more than was required for course credit, they often failed to engage in a sustained dialog or to provide descriptions of their classroom implementations that would allow facilitators and peers to respond to their reports.

Recent discussions of in-service teacher education call for ongoing experiences that take part in the context of teachers' own practice (Cochran-Smith & Lytle, 1999; Franke et al., 1998). These experiences are expected to take the place of the often-maligned in-service workshop and lead to learning that is flexible, self-sustaining, and generative (Franke et al., 1998). The call for situated teacher learning occurs at the same time that the Internet and World Wide Web are making possible numerous opportunities for online professional development (Goldman, 2001). Little is known about how teachers use these opportunities and the effects they have on teachers' practice. This paper presents an example of extending the impact of traditional professional development through the use of ongoing computer conferencing to promote teachers' reflection on their practice.

Our model for professional development is called Anchored Collaborative Inquiry (ACI). ACI is based on anchored instruction, an approach developed over the last decade by the Cognition and Technology Group at Vanderbilt (CTGV, 1997). The enduring idea behind anchored instruction is that sustained exploration of realistic, meaningful problems leads to learning that is highly valued and likely to be used when needed. In the ACI workshop teachers explore ways of teaching a reform-oriented curriculum (CTGV, 1997). Then each teacher implements the curriculum in his/her classroom simultaneously and discusses the results of the implementation online. As they engage in this dialog with peers, teachers attempt to make sense of what is occurring in their implementation and to enhance their understanding of how students learn to solve complex problems. In our model, professional development includes 1) Face-to-face meetings to learn about a reform and collaboratively plan for implementation, 2) individual implementation in each teacher's classroom, and 3) shared reflection via an online conferencing system during the implementation.

Previous research on professional development that takes place completely online indicates that a sense of community forms slowly and face-to-face meetings can be helpful in overcoming a sense of isolation (Goldman, 2001). Face-to-face meetings can also contribute to a sense of trust among participants essential for those engaging in challenging, long-term tasks. Participants without a sense of trust are more likely to be guarded in their responses and less likely to engage in a critical examination of their assumptions. On the other hand, participants who know other participants are more likely to be interested in what their colleagues have to say and to feel an obligation to continue the discussion.

While traditional face-to-face workshops may lead to development of a sense of community, they lack the ongoing interactions with colleagues and coaching in teachers' classrooms thought to be necessary for effective professional development (Putnam & Borko, 1997). This type of long-term support is time intensive and difficult to implement on a large scale; however, it may be facilitated by online interaction. The ACI model combines facilitated face-to-face and online discussions to enhance teachers' understanding of reform-oriented teaching. In the following paragraphs, we summarize the results of tests of the ACI model.

Findings
Teachers need personally relevant activities to encourage interaction in online learning communities. Tests of the ACI model suggest that teachers’ sustained and active participation in the online conference was related to the shared context established by the workshop experiences and the simultaneous implementation of the reform curriculum. Teachers were very goal-oriented in their use of the online conference. They did not use the forum to initiate social conversations or to engage in professional discussions that were unrelated to the implementation; however, the number of postings was over twice what was required for course credit. Likewise the number of replies to these posting was approximately twice the requirements. Thus in the ACI conference, it appears that teachers were responding to a specific learning goal rather than an opportunity to discuss general issues.

Access to descriptions of events in participating teachers’ classrooms are critical for facilitators and teachers to carry out collaborative inquiry online. Typically researchers and teacher educators regularly observe in the classrooms of collaborating teachers. In our project, all participants were completely dependent on the descriptions of the classrooms provided by the teachers themselves. Adequate information was difficult to obtain from our teachers for several reasons: First, they were unaccustomed to articulating how they knew students were learning and what they were learning. Second, they lacked experience in implementing the reform and may have failed to notice and report important events. Third, text descriptions of classrooms are difficult to create and time-consuming to type. Teachers may have lacked the time and writing skills necessary to create rich descriptions.

Participants in online collaborative inquiry need to be able to carry on a sustained dialogue in order to discuss ideas and integrate information from others into an understanding that grows and develops. Only one-third of teachers’ postings during the implementation phase of our conference were replies to a previous posted message. The others were disconnected reports of various aspects of the implementation. It is possible that teachers (and learners in general) are not accustomed to carrying out an extended dialog about a single idea, i.e., following an idea from its initial statement to some kind of conclusion (Wilson & Berne, 1998). This kind of interaction was more likely to occur during the face-to-face part of the ACI model than online. Developing this type of interaction is likely to be a difficult learning goal and is likely to significantly extend the amount of time required to establish a productive learning community.

Professional development that attempts to change teachers’ beliefs and practice requires a fundamentally different kind of interaction than researching resources, communicating with parents or colleagues, or other ways that teachers use online communication. Online discussion was successful in extending support to teachers separated by distance from professional development personnel and in encouraging teachers to reflect on their practice in the context of this reform. However, online professional development rooted in teachers’ own practice requires some means of sharing what is happening in the classroom with those online. Significant preparation and experience will be necessary to enable teachers or other participants in online learning communities to develop the skills to describe the settings in which they are learning and working and to develop a culture where this type of sharing is the norm.

THE GUIDING ASSUMPTIONS OF SUCCESSFUL DISTANCE EDUCATION PROGRAMS

Barry Willis, Professor
Associate Provost
University of Idaho
Moscow, Idaho USA
bwillis@uidaho.edu
(208) 885-6373

At its core, distance education is a change process, not a delivery system and historically higher education culture has proven resistance to change. Perhaps the greatest benefit of distance education is its potential role as a catalyst for adapting the way educational institutions do business. In a relatively short span of years, the proliferation of programs and services available at a distance have resulted in a heightened sense of competitiveness unheard of in higher education. For institutions that are up to the challenge, the current interest and growth in distance learning presents a new opportunity.

In a few short years, distance education and its off-spring (e.g., web-supported instruction, videoconferencing, etc.) have been transformed from a quaint irrelevancy to a lightening rod for change on many university campuses. Sherron and Boettcher (1997) suggest that the current rush to implement distance learning programs by colleges and universities is occurring for three major reasons:

- The convergence of communication and computing technologies,
- The need for information age workers to acquire new skills without interrupting their working lives for extended periods of time, and
- The need to reduce the cost of education.

These reasons and others have attracted hopeful politicians and others with minimal background and little previous interest to distance education. Others who view distance education as the “Trojan Horse” signaling “the commodification of higher education” have been equally moved by distance education for quite different reasons (see Noble, 1997, 1998, 1999). It is ironic that the politicians who trumpet the benefits of distance education the loudest know relatively little about it, while those who see a dark side to the use of educational technology feel quite comfortable using the Web and related media to espouse their views. Irony aside, the accompanying claims of what distance education can and can’t, should and shouldn’t do, have resulted in an ever-widening gap between the rhetoric and reality of distance education. Closing this gap can be accelerated by thoughtfully considering a number of key assumptions shared by many successful distance education programs:

1. **Distance education is about increasing access, not making money.** Those who look to distance education as a revenue-generating machine resulting in financial windfalls for their programs or departments are typically disappointed when they factor in the true costs of this endeavor (see Oppenheimer, 1997). These costs include hardware/software, system maintenance/upgrading, telecommunication/transmission charges, technical support, faculty/program development and evaluation, student support...and a myriad of personnel and infrastructure costs associated with these vital components and services. The importance of these critical and continuing costs and constant technological change usually necessitate the reinvestment of virtually all income generated by the enterprise. Those who take profits typically do so at the expense of needed upgrades with the potential risk of losing whatever market share they fought to win in the first place.

   This is not to say that distance education is without its financial benefits. Many Land Grant institutions, for example, provide statewide educational programs and services. A few years ago, this could entail chartering aircraft to fly faculty to remote outreach or extension centers in various locations served by the Land Grant Institution. Even today, it is not unusual for faculty to drive 200-300 miles a week to meet with students located far from campus. The costs of such enterprises in terms of time, energy, and faculty goodwill are excessive.

   In contrast, the appropriate use of distance education can be cost effective...even if the end result isn’t a financial windfall. What does result from the appropriate use of technology may be even more beneficial: the ability to maintain and even grow the market for institutional programs and services. Given the rural and cloistered nature of many of our best Land Grant institutions, the ability to reach out to students wherever they reside is a huge competitive advantage and a potential determining factor in enhancing or even maintaining institutional viability.
Without exceptional management skills and a thick skin, the implementation of technology is an impossible task that and on the road to obsolescence. Need to constantly plan ahead realizing that the technology that you are implementing today is likely already dated isn't. Keeping up with technology is a never ending battle filled with unmet expectations, too few resources, and the education enterprise.

Those creative and concerned faculty who are willing to take the leap of faith required to be successful in the distance overall instructional program, or the motivation to complete the course that originally offered so much promise. Without adequate course design, there may be little lasting enthusiasm for the based courses) with little apparent influence and day-to-day involvement by a thoughtful and skilled teacher, may play the preeminent role in successful academic encounters, regardless of the sophisticated technology being used.

The best that can be said about the management of technology is that someone has to do it...and do it right. There is no technological “silver bullet”...not even the Web. Every new technology is accompanied by its share of advocates proclaiming it to be the ultimate delivery tool promising to solve all instructional problems, even those that are yet to be fully understood. In reality, a poorly defined problem has an infinite number of solutions...we just never know which one is the most appropriate. Until instructional needs are understood in detail, any technology could be appropriate...or inappropriate.

Even those at the forefront of technological innovation, including Bill Gates of Microsoft and Andrew Grove of Intel, candidly admit they are unsure where the future of technology will lead their companies (Grove, 1999). As a result, they invest heavily in marketing, research, and development in efforts to maintain their technological preeminence wherever the future might lead them.

For institutions without the research and development funding to invest in every potentially beneficial instructional delivery innovation, the best advice is to avoid technological solutions in search of instructional problems. Instead, focus on the requirements of the content to be delivered, the needs of the learners being served, tangible instructional opportunities (e.g., the need to train a computer literate cadre of highly motivated professionals), and potential obstacles (e.g., limited bandwidth to the locations you serve). Attend to these requirements and the most appropriate technological solutions will make themselves apparent. In this context, the primary benefit of the Web is not as a delivery system in and of itself, but as a standardized platform from which various technological solutions can be launched.

Nevertheless, those who think the Web is the ultimate solution to all instructional problems should review the research literature of the 50s stating the same thing...about the overhead projector.

The only constant in the world of instructional technology is change. Anticipating change and technological directions is always challenging and filled with uncertainty. Move too fast and your technological upgrade will be obsolete before it is fully implemented. Move too slowly and your programmatic market share could slip before you can catch up. Just as damaging, failure to innovate will signal your competition and potential markets that your program is no longer viable.

In a world of technological change, timing is everything. Those who learn to embrace technological innovation when the timing is right will be the big winners. The rest will be left to fight over the crumbs.

Lasting technological change is typically the result of evolution rather than revolution...Over the past thirty years technological innovation has evolved in a fairly consistent manner. This process could be referred to as technological birth, death, and resurrection. In the “birth” stage, new technologies emerge, unrealistic expectations are set, and the potential impact of the new tool is over-hyped. In the “death” stage, the original outspoken advocates move on to the next innovation, general enthusiasm gradually fades, and interest wanes as the realities of what the new technology can and can’t do emerge. Finally, in the “resurrection” stage, thoughtful reflection occurs as the new technology is tested in various, often random, instructional settings. While the technological innovation is found inadequate in most applications, it proves beneficial in addressing a limited number of very specific needs.

Over time, the once proclaimed technological cure-all takes its place among other teaching tools and fades from the forefront of technological innovation...into the hands of those who can put the benefits of the technology to best use.

It is for this reason that few effective instructional experiences are anchored to a specific technology. More often than not, a variety of technologies, each filling a specific and well defined role, are woven together by a skilled educator into instructionally sound and technologically transparent academic experiences.

The emphasis of distance education should be in the quality of the academic program, not in the use of technology. Selecting technology is easy compared to the focused attention and subtle insights needed to design, develop, and implement a truly effective academic program. This is why the skilled teacher will continue to play the preeminent role in successful academic encounters, regardless of the sophisticated technology being used.

Similarly, instructional delivery experiences that rely almost solely on technology (e.g., first generation web-based courses) with little apparent influence and day-to-day involvement by a thoughtful and skilled teacher, may generate initial student interest. Without adequate course design, there may be little lasting enthusiasm for the overall instructional program, or the motivation to complete the course that originally offered so much promise.

Finally, successful program administrators will spend adequate time and resources to nurture and support those creative and concerned faculty who are willing to take the leap of faith required to be successful in the distance education enterprise.

There is no glory in managing instructional technology. You’d think there would be, but there isn’t. Keeping up with technology is a never ending battle filled with unmet expectations, too few resources, and the need to constantly plan ahead realizing that the technology that you are implementing today is likely already dated and on the road to obsolescence.

The best that can be said about the management of technology is that someone has to do it...and do it right. Without exceptional management skills and a thick skin, the implementation of technology is an impossible task that
gives those involved the illusion that they are in control, when in reality they are at the mercy of technological innovations that don't exist today, but will be demanded tomorrow.

7. **Learning is enhanced when technology is used to directly link students to other students.** The lack of effective and personalized student-student interaction and feedback is the potential "Achilles heel" of distance education. Conversely, the need for effective distant student-student interaction provides a great opportunity to creatively use technology. In fact, whether it is teacher-to-student or student-to-student interaction, learning is enhanced when technology is used to improve communication (see Flottemesch, 1999).

In my experience, effective instruction almost always requires that a fully engaged teacher establish the learning framework, even when the target audience consists of highly motivated adults. Also of critical importance is the learning that takes place when students are linked to other students...without any teacher present. Given the inherent separation that is evident in most distant learning environments, it is difficult for many students to maintain any continuing connection to the instructional context, let alone the content being presented in any given course. By creating learning spaces and technological linkages that bring distant students together as groups and as individuals, the gaps between what is being taught and what is being learned can often be bridged (see Wallace & Weiner, 1998).

8. **Face-to-face instruction is still a valid delivery method in support of distance delivered courses...when possible.** Many assume that there is no need for face-to-face instruction in distance delivered courses. After all, that is why many get involved with distance education in the first place...to avoid the "real time" constraints of face-to-face contact. In fact, some of the best distance delivered courses have well integrated components in which teachers meet directly with students, either individually, in small groups, or with the entire class. If personal interaction among the teacher and students is deemed an important course component, it is critical to meet as a group as early in the semester as possible. Experienced distance faculty report that the student comfort level in using technology increases significantly if the students and instructor meet early in the course and develop a personal working relationship.

The ideal scenario is to bring students from all sites together for an intensive day or two early in the course and incorporate group process techniques to foster cohesion and unity of purpose among participants. Ending the semester with another intensive face-to-face session at which time final projects are presented and course objectives are summarized is a beneficial capstone experience. If time and budget permit, meeting an additional time or two during the semester will likely prove both academically useful and personally rewarding.

Undoubtedly, incorporating "real time" interaction increases the logistical challenges of any distant course and requires faculty and student sacrifices as they struggle to match schedules. In some cases, however, the sacrifices are worthwhile and often essential. In the case of technical courses, for example, where laboratory experiences are critical to successful course completion, the question isn't "if" face-to-face communication can be incorporated, but "how" it will be accomplished. The challenge is then to maximize the time of faculty, facilitators, students, while scheduling the technical facilities needed to accomplish it.

Despite the potential benefits derived by focused personal contact, many educators (and even more administrators) feel that incorporating face-to-face communication in distant courses is expensive and defeats the inherent flexibility and perceived lower costs that initially attracted them to distance education.

Depending on where the course is being delivered, it may be physically impossible to bring the teacher and students together. Nevertheless, it is better to rule out personal contact as impractical or instructionally irrelevant than it is to fail considering it in the first place. When the logistics can be successfully navigated, teachers and students alike are rewarded by well-planned and highly interactive face-to-face contact.

9. **Many faculty are comfortable when distant students from other institutions take their classes, but don't like their students taking classes from faculty at other institutions.** This is a major stumbling block to cooperative distance education ventures and has limited the success of strategic partnerships relying on the sharing of faculty expertise. The best partnerships are forged when specific academic needs are identified and on-campus expertise is absent. In these cases, competition is not a factor and both sending and receiving institutions benefit. Despite being a major institutional and political motivator for the initial start-up of distance education efforts, true academic alliances have proven elusive and are the exception, not the rule.

Until the culture of course "ownership" moderates and the "not invented here" syndrome fades, wide scale institutional cooperation will be more a goal than a reality.

10. **At its core, distance education is a change process, not a delivery system.** Historically, higher education culture has proven resistant to change. Perhaps the greatest benefit of distance education is its potential role as a catalyst for change in the way educational institutions do business. In a relatively short span of years, the proliferation of programs and services available at a distance have resulted in a heightened sense of competitiveness unheard of in higher education. For institutions that are up to the challenge, the current interest and growth in distance learning presents a new opportunity. While the dangers of competing and failing in this new...
world of educational access may pose significant problems, the refusal to aggressively move forward may be the greatest risk of all.

By any standard, distance education has proven to be a useful tool for educators and administrators who have taken the time to adequately assess its strengths and weaknesses. Continued success will require the careful planning, implementation, and tracking of distance education successes and failures.

This discussion keeps leading back to one incontrovertible conclusion: Distance education is one piece of the educational delivery puzzle, but not the “answer” to all program delivery challenges facing educators today.

There is little doubt that distance education has the potential to positively impact higher education. The greatest gains will only occur, however, after the opportunities and limitations of technology-supported delivery are critically reviewed and realistically analyzed. The sooner this happens, the better...for teachers, administrators, and most of all, the students who stand to gain the most through innovative solutions to the myriad delivery issues educators and society face today.

Abstract: The Blackboard course management system is an example of the technological advancement being used by instructors at some higher institutions. Our research is an in-depth qualitative case study exploring the perception of six instructors' use of Blackboard for course instruction. Data was collected through observations, semi-structured interviews, and a review of relevant documents with participants at two Mid-western universities. Five major themes were found to emerge from this study. The themes were: a) accessibility and flexibility, b) challenges and problems, c) training and support, d) assessment and evaluation of students' work, and e) communication and student participation. The findings demonstrate that Blackboard makes education accessible to students who are unable to attend college, and it provides flexible learning for students who are on campus. The challenges and problems of using Blackboard include a large amount of time involvement and technical problems.

Introduction

Technology is progressing rapidly and is having a direct impact on educational instruction methods. The Blackboard software platform is an example of the technological advancement being used by some instructors at institutions of higher learning. This study was limited to six instructors who use Blackboard at two Mid-western universities for course instruction.

The purpose of this case study was to explore the perception of six instructors' use of blackboard for course instruction. Data was collected through observations, semi-structured interviews, and a review of relevant documents with participants at two Mid-western universities. Blackboard is defined as a server software platform that provides a powerful environment for online teaching and learning, internet-enabled communities, and advanced integration with multiple administrative systems.

The overarching quest was to discover how six instructors in two Mid-western Universities describe their experience of using Blackboard for course instruction. Four research questions guiding this inquiry were:

1. What is the instructor's perspective of Blackboard?
2. What are the amounts and types of technical problems?
3. To what extent does the instructor believe the learner is meeting the goals and objectives of the class?
4. What is the role of the instructor who uses Blackboard?

The significance of this study was to gain a deeper understanding of how Blackboard is being used as an instructional tool for distance courses, as a supplement to on-campus courses, and to better
understand how faculty use the program for course instruction. Gaining knowledge about instructors’ use of Blackboard could help determine its usefulness as an instructional tool.

Method

We used the qualitative case study tradition. A case study is an exploration of a “bounded system” or a case (or multiple cases) over time through detailed, in-depth data collection involving multiple sources of information rich in context (Creswell, 1998). Several features mark our project as a case study: We identify the “cases” for the study, the six instructors who are using the on-line instruction system, Blackboard; the cases are bounded by time (3-month data collection) and program (Blackboard); we situate the cases within two campuses in two Mid-western cities; and we use extensive, multiple sources of information in data collection such as direct observations, interviews, and online course documents.

The instructors participating in this study were purposefully chosen. Six instructors from two Mid-western universities were selected. A background information protocol was developed so that the participants would be able to describe their online teaching background. The participants should meet the following criteria in order to be included in our study: the participants should be from higher education institutes; the participants taught at least one course using Blackboard as an online teaching tool; and the participants used Blackboard as either a completely on-line course or as a supplementary tool.

The data were collected through six semi-structured interviews. “Interviews provide ideas filtered through the perceptions of interviewees” (Stake, 1995). All the interviews took place in the instructors’ offices and were approximately 30 – 90 minutes long. Each interview was audio taped and then transcribed. We also gathered field notes by conducting observations. “Observations provide the most complete natural setting for qualitative research and they also give the researchers a first-hand experience with the informants, and the researcher can record information as it occurs” (Lincoln & Guba, 1985). Two observations were conducted in instructors’ offices with the instructor and the observer as participants. One observation lasted 30 minutes; the second observation was 1 hour 45 minutes in length. The third observation was conducted in the “virtual classroom” with the instructor, two students and the observer as participants. We also collected data through a background pre-interview form that was sent to the participants by email a week prior to interviews. Furthermore, the documents about the features of Blackboard and the instructors’ course documents were downloaded and printed out for review and analysis.

Findings

Theme One: Accessibility and Flexibility

Can the online instruction make learning more accessible? Can online instruction provide for flexible learning? Listen to the participants as they describe their experiences.

When course content and activities are provided online, students no longer need to worry about accessing course materials. Busy students can choose to download readings or take practice exams whenever it is most convenient. Dr. Cat indicated, “With Blackboard I have all of the information for the course available in the electronic format, and available 24 hours a day, 7 days a week. That to me is an advantage.” Mr. Gorilla also pointed out, “Anywhere they can get online, whether it’s here on campus, downstairs in one of the computer center. I had students take the quizzes three quarter miles away across Nebraska. They have the ability to do the quizzes at midnight. Anytime they want, anywhere they want, and they can take that. That is a plus for them.” Mr. Lion suggested that one of the advantages of online instruction is “the anytime, anyplace aspect that allows you to teach students whom you ordinarily would not be connect with.”

On-line instruction also removes reliance on physical attendance. In traditional education, students must attend class at a predetermined time and place. Online instructions enable students to access learning without the constraints of attending class or meeting together at a certain date, time, and location. Dr. Cat posited, “What Blackboard does is to make possible for students who can’t come and take traditional classes to be able to get a degree.” Dr. Squirrel added, “It makes my class available to someone who would
not otherwise be able to take the class, like the student in Japan who could not take time to come to Lincoln for my class.” Dr. Panther concluded, “The Internet is a good way of reaching learners who would have great difficulty in connecting with our institution through the usual on-campus learning events.”

Theme Two: Challenges and Problems

Mr. Lion said, “I spend a lot of time in order to do what I want to do, trying to figure out ways to use Real Presenter and also figuring out ways to use the Internet directly into the Blackboard presentation.” Time was also a major factor for Dr. Panther: “I spent my Christmas putting the course on-line... The up-front investment is important.” In addition, he mentioned, “In working with eleven students, I spend a significant amount of time teaching them how to navigate on the site, how to get them logged on, talking with them on the phone, etc.”

Dr. Squirrel, who has taught the same course on-campus and on-line, points out that a task such as a class presentation requires “more preparation to do that on Blackboard” than in a classroom. Dr. Cat, who was instrumental in getting Blackboard at Love University makes a strong statement about time requirements for Blackboard: “I can tell you that it took tremendous amount of time to prepare all of the information that I now make available to the students that are taking the class at the distance. For example, in the class that I teach, the statistics classes, I had to prepare approximately 27 or 28 hours of video, then edited and put on CDs, and that’s a very time consuming task.”

Student problems discussed by the participants include: students not being able to access Blackboard, not being able to receive attachments, unable to sign on and navigate around or get synchronous chat, and not having the necessary computer requirements to obtain the information. Mr. Lion stated, “One of the main problems was signing on” and “there were several students who had trouble getting on synchronous chat.” Dr. Panther also experienced difficulty with synchronous chat and found the solution “was to go to e-mail.”

Dr. Cat discussed the difficulties of taking quizzes on-line in that “if they [students] took too long working on the problem, they will be disconnected by the Internet service provider.” The instructor would then have to log on and reset the quiz in order to allow the student to retake the quiz. This brought about another problem for the student: “All of the questions were lost, so they have to completely start over again. Which is real bad enough for the students and for the instructor too.”

Theme Three: Training and Support

Mr. Lion stated that his first experience with Blackboard was “by searching the Internet and then I attended continuing education workshops.” Mr. Lion believes his “chief challenge is to learn to use the program more effectively to make me a better instructor. We need to invest more money and time in learning to use the program by offering more workshops.”

Dr. Cat believes “Blackboard is user friendly, it doesn’t require a lot of support. If students have problems with Blackboard, they call the help desk. I have not really had any students that complain about the support that’s been available for Blackboard.” Overall, Dr. Cat finds the support for Blackboard as very good.

Mr. Gorilla has used Blackboard support when putting things on-line. When he faced problems, “the help desk has been very helpful to help me out.” He has solved most of his problems through the help desk where he has found “the people that I talked to had the knowledge able to solve the problem.” Although he has not gone to any meetings, Mr. Gorilla said, “I know they also have at least one once a month get together where people that have problems can go and talk and find solutions to their problems using the Blackboard.”

Theme Four: Assessment and Evaluation

Learner assessments are essential in education. Effective instructors use a variety of means, some formal and others informal, to determine how much and how well their students are learning (Ridley & Husband, 1998). I will let the six instructors describe how they assess their students’ performance in their own words.
Online quizzes and tests can increase motivation and provide concept reinforcement. Mr. Gorilla used quizzes as a motivation: "I use the quizzes as a motivation to have them read the chapter so that they participate." Dr. Cat used quizzes as reinforcement. He stated, "I have banks of questions which are related to the three units for the class. Students can generate a random sample of questions that were in the question bank and find out what their understanding happens to be for the content. They can do this as many times as they want. Get some practice and preparation for the exams... All these are supposed to work together so that it reinforces learning process, and it's all related to the content for the class."

The immediate feedback feature of the Blackboard assessment tools also impressed Mr. Gorilla. He remarked favorably, "Students take entire quiz online, The Blackboard grades it, and gives them a score immediately."

The two instructors who used online quizzes and exams also told us how they managed the assessment. Dr. Cat required a proctor for the exam. He stated, "They have to have a proctor who is acceptable to me and also to the division for continuing education. This person could be a school official, and not a family member. Uncles, aunts, spouses, brothers or sisters don't work." On the contrary, a proctor was not used in Mr. Gorilla's online tests. He declared, "They are not supervised. I do not use any proctor. It's not a concern of mine.... I guess I am not much concerned as long as they know the material."

The two instructors had the same style of online tests such as open-book, open-notes, and no time limit. Dr. Cat described, "The students take the exams that are open-book and open-notes. They are usually almost timed two and half-hours. They are not designed for that length of time, but I try not to have a time limit, or to speed. So they have a very comfortable amount of time to finish things." Similarly, Mr. Gorilla indicated that it was an open-book quiz and there was no time limit involved.

To evaluate performance informally, instructors also use a variety of techniques. For example, they pose questions on the Blackboard and encourage students to participate in the discussion. Dr. Panther described, "I assess student performance through the questions and discussion in the synchronous discussion... I use a lot of questions from the text that we use. I do not use tests." Mr. Lion suggested how he assessed the quality of the discussion: "I always observe the number of postings of students." Dr. Squirrel added, "I read their responses then I see how much in depth they are and I see how many times they participated.... I said to my students not only do you have to post your own idea or opinion you have to interact with other students via Blackboard."

Theme Five: Communication and Student Participation

The final theme in our research project was communication and student participation in Blackboard. The focus of this theme was to compare the quality of student communication between traditional classes and on-line classes.

Much research has been conducted to identify the benefits of the computer-assisted training and many researchers agree with the fact that "the main advantage of computer-based discussions is that all students can and usually do participate due to a low-anxiety atmosphere" (Hadley, 2001). Two of the participants, Mrs. Kangaroo and Dr. Cat indicated that Blackboard discussions help to facilitate students' participation because the system provided a low-anxiety and impersonal communication atmosphere. Mrs. Kangaroo, who used Blackboard as a supplementary device in her traditional class, said that she decided to start using it because she wanted to give shy students and students who are afraid to express their opinions in the classroom a chance to participate in classroom discussions.

According to Dr. Cat, "One of the strengths of Blackboard is the ability to be able to facilitate communication...it's somewhat impersonal because it's electronic." Dr. Panther pointed out that "on-line discussions are a fine tool to facilitate communication either in face-to-face or on-line courses."

The instructors mentioned a problem with effectively using Blackboard to communicate emotions between students and the instructor. Dr. Squirrel pointed out that she can only get "written cues from my students." She thinks that sometimes it's better to communicate emotions when you see a student face-to-face: "I can’t see them yawn or their facial expressions...I don't have those kinds of cues I use in my face-to-face teaching." She also noticed that she was more comfortable in person-to-person communication than in writing communication.

Dr. Cat in his interview gave advice on how to facilitate communication. He said that "one way to increase participation is to increase the amount of participation and make it part of the grade...and to grade the number of participations, or to grade the quality of way they participate."
Conclusions

We identified three groups of people that may benefit from the information provided in this study: university administrators, instructors of on-line courses, and students who take on-line courses.

University Administrators that choose to adopt a distance learning system such as Blackboard must be willing to go beyond the purchasing of the system. Financing an on-line course instruction system needs to include hiring or training qualified personnel who can provide a support network where instructors and students can call and get answers to their questions. Workshops should be offered frequently and range from basic levels of Blackboard instruction to advanced levels. Additional workshops should be provided in regard to changes and up-dates in the system.

Faculty who want to provide on-line instruction for a distance-learning course or add on-line instruction as a supplement to an on-campus course need to attend at minimum a basic workshop on Blackboard. Additional levels of Blackboard workshops are greatly encouraged, as well as attending workshops dealing with changes and up-dates in the Blackboard system. Faculty members desiring to use Blackboard must understand the time commitment involved, the up-front time of putting the materials online and the continuous time demand throughout the semester in working with the students. According to the majority of the participants interviewed here, the time commitment is greater for on-line courses than that of on-campus courses. Online instructors can evaluate student performance by providing assessment opportunities. You can add assessment activities to a course management system like Blackboard by incorporating practice tests, quizzes, and examinations. However, you should not rely only on online testing for grading purposes. You should have at least two other methods of evaluation, such as discussion participation and group projects.

Students who are interested in taking distance-learning courses need to find out the computer requirements, the software and hardware, as well as the desired Internet access they will need in order to participate successfully. Students should also be provided information by the university support system on how to access and maneuver throughout Blackboard courses. Online students should report to the instructor if the pace and material developed is satisfactory or indicate areas where course content needs revision or further explanation. Students’ feedback can help instructors identify which teaching methods are most effective and may help instructors improve the course.

Future research needs to include information gained from at least three areas not addressed in this study: a) the students who are using Blackboard for distance learning and as a supplement to on-campus instruction, b) the staff involved with teaching Blackboard workshops and providing support to instructors and students, and c) the administrators who are involved with making decisions in regard to the Blackboard platform for course instruction at the university. Additional research needs to be conducted to look deeper into the needs of the university instructors who are teaching on-line courses. In addition, future research is needed to assess the online instruction in terms of teacher effectiveness.

Asynchronous On-Line Discussions: Facilitating Critical Thinking Skills Within Traditional Classrooms

Ya-Ting Carolyn Yang
Department of Curriculum and Instruction
Purdue University
United States
yangyc@purdue.edu

Abstract: In a traditional classroom, discussions are often hindered due to limited class time and unequal access of interaction. It is difficult for instructors to monitor collaborative discussions and critical thinking. An asynchronous online forum is a promising tool to cope with this problem. This paper reports an ongoing project that examines the effects of asynchronous online forums on critical thinking and overall learning performance, and also probes students’ overall perspectives toward the effect and function of using asynchronous discussion forums in the context of university courses. The research design, participants, instruments, and data analysis of this project are described.

Problem Statement and Research Objective

A primary function of education is to teach and develop critical thinking skills. In many cases this occurs through class discussions (Bloom, 1956; Newmann & Wehlage, 1993). Yet, in a traditional classroom, critical thinking usually occurs through both instructor-student interaction and peer discussion (Klinger & Connet, 1992). However, discussions may become difficult to facilitate in the following situations: 1) in classes where students have no opportunity to express their opinions because of limited class time or class size; 2) when a small number of students, such as extroverted or more eloquent students, dominate the discussion; 3) when the classroom environment is not conductive for a discussion (e.g. if the chairs or desks in the room cannot be moved); 4) if the topic is one where the students are reluctant or uncomfortable to express their views face to face. Although instructors can assign collaborative inquiry tasks to be completed outside of class time (or even during class time), it is difficult in the classroom, and impossible outside of the classroom, to monitor collaborative discussion and critical thinking. As a result, instructors can neither coach nor assess the inquiry. It is only the final product of inquiry that can be reviewed (Duffy, Dueber, & Hawley, 1998).

Asynchronous online forums (i.e., text-based computer-mediated communication tools) are promising tools that offer an opportunity for interactive discussions outside the classroom and at the same time provide an opportunity for the instructor to moderate such discussions. Some studies have compared the effectiveness of online forums to face-to-face forums; however, verbally based face-to-face forums and textually based asynchronous forums make direct comparisons difficult (Anderson & Kanuka, 1997). In essence, the core issue should be whether asynchronous discussions supplement instruction to foster critical thinking, and/or enhance overall student learning performance. In addition, while a majority of the data used for comparisons between online forums and face-to-face forums has been based on learner attitude surveys or surveys used to gain descriptive information, little data has been gathered to ascertain the differences of effectiveness on critical thinking and overall learning between the experimental groups who utilize asynchronous online forums and the control groups who do not. The question, “Are asynchronous online forums effective in higher education?” still remains largely unanswered.

The purpose of this research project is to examine the effects of asynchronous online forums on critical thinking and overall learning performance and, in addition, to probe students’ overall reactions and perspectives toward the effect and function of using asynchronous discussion forums in the context of university courses.

Research Design

The research design is a pre- and post-test quasi-experimental design. The independent variable is the use of the structured asynchronous online forum. Students in the control group will only use in-class discussion
mode. In addition to in-class discussion, students in the experimental group will use a structured asynchronous online forum (threaded discussion bulletin board) as a supplement to their on-campus class where a series of discussion topics will be posted on the class Web site and facilitated by the instructor. The students taking BMS 241, an undergraduate course at Purdue University, in fall 2002 and spring 2003 will be the subjects in control group and experimental group, respectively. There are two dependent variables examined in the study: students’ learning achievement and student attitude. The first dependent variable is the learning achievement of the students that is measured at two levels—acquisition of declarative knowledge and critical thinking skills. Declarative knowledge refers to the concepts, principles, issues, and facts presented in a learning situation. It is measured as the scores on the four quizzes and two exams on course content. Learning in terms of critical thinking is measured via California Critical Thinking Skills Test, class discussions on asynchronous online forums, and essay questions that go beyond declarative knowledge acquisition and involve analysis, synthesis, reasoning, interpretation, and induction. The second dependent variable is student attitude with three categories: attitudes towards asynchronous online forums, class discussion, and the course in general. Student attitude has been defined as scores on the attitude pre- and post-course Likert-type surveys developed by the researcher. The interview questionnaire will also be administered to probe student’s attitude toward the study.

ANOVA will be performed to justify whether there is a difference among the subjects in terms of age, educational backgrounds, attitudes toward asynchronous forums and the course, and knowledge of content at the beginning of the class. The dependent variables, including students’ learning achievement and attitudes toward the course and the asynchronous online forum, will be analyzed by using a one-way ANOVA at the end of the class. In addition, the qualitatively analytic procedure that organizes the data, generates categories, themes, and patterns, and searches for alternative explanations for the data, is adopted to analyze the data from the interview questionnaire to generalize themes regarding students’ perspectives about the study. In order to pilot test the efficacy and reliability of the proposed research design, BMS 241 class in summer 2002 will be used as a pilot study for the experimental group.

Implications of Results

The importance of class discussion has been highlighted by a host of research studies; to move students beyond assimilating inert facts into generating better mental models, teachers must structure learning experiences that highlight how new ideas can provide insights in intriguing, challenging situations (Dede, 1996). This research speculates about how an increasing important tool—asynchronous online forum, can afford educators enormous pedagogical opportunities, opportunities that could not be realized in the classroom and that may reshape traditional face-to-face education. It is our anticipation that asynchronous online forums are the means that afford students the time for thoughtful analysis, reflection, and composition as their discussion of an issue evolves and that allow instructors to mentor and evaluate the critical thinking skills exhibited during out-of-class discussions. It is this potential of asynchronous online forums that we find so exciting. However, the actual impact and effectiveness of the asynchronous forums as a supplement to on-campus instruction is still insufficiently researched. Thus, this research project will identify and experimentally examine asynchronous online forums in a constructivist paradigm, and provide useful information as to the overall reactions and perspectives of students toward the effect and function of using asynchronous discussion forums in university course delivery.

The Evolution of Distance Learning: Distance Education, Virtual Classrooms, and Web-Based Instruction

Ya-Ting Carolyn Yang
Curriculum and Instruction
Purdue University
United States
yangyc@purdue.edu

Abstract: Distance learning is a great tool for educators to reach traditional and non-traditional learners. Yet, like any tool, it is only useful in the hands of someone who clearly knows what it is, and how to use it. Nowadays there is considerable confusion in the use of terminology for distance education, virtual classrooms, and Web-based instruction. Two questions are frequently raised: a) what exactly are these distance learning methods, and b) is there any difference among them? This paper aims at providing answers to these questions by describing the origins, growth, technology used, as well as definitions and characteristics of each of these three instructional methods. Additionally, the similarities and differences among these teaching methods are addressed by a thorough discussion. The discussion differentiates distance education and its varieties and comprehensively explains the meaning of the terminology that distance education technologies have conveyed.

Introduction

New technologies for distance education are the most rapidly changing of all technologies we deal with in our school settings. In the relatively short period of the past two decades, distance learning courses have been delivered via broadcast television, satellite distribution, and compressed video over telephone lines. Most recently, the resources and capabilities of the Internet and World Wide Web (WWW) have been utilized to support distance instruction. Accompanied with these new technologies, new terminology, such as virtual classrooms and Web-based instruction, regularly appears in the distance learning landscape. Today many educators use the same technologies, such as computers, the Internet and WWW, to deliver their distance learning courses, and interchangeably use the terms—distance education, virtual classrooms, and Web-based instruction. However, what actually are distance education, virtual classrooms, and Web-based instruction? Are the concepts of these instructional methods the same? Or are they distinctly different in some aspects? In order to answer these questions, the definitions of these three terms, as well as their origins, growth, and technology used were first examined at the outset of this paper.

Definitions of Distance Education, Virtual Classrooms and Web-Based Instruction

Distance education is now often defined as “institution-based, formal education where the learning group is separated geographically, and where interactive telecommunications systems are used to connect learners, resources, and instructors” (Simonson, Smaldino, Albright, & Zvacek, 2000, p. 20).

A virtual classroom is “a teaching and learning environment located within a mediated communication system” (Hiltz, 1994, p. 3). It is a classroom that does not exist as physical or concrete places, but exists virtually by way of the activity and the medium(a) used. For example, a virtual classroom is created when learners and instructors simultaneously see and hear each other and spontaneously interact by two-way interactive television (I-TV), a technology enabling simultaneous, two-way audio and video connections across multiple sites. However, a virtual classroom is not restricted to a synchronous learning environment. It is also created when two or more learners log into an on-line forum and discuss the course content asynchronously.

Web-based instruction is defined as “a hypermedia-based instructional program that utilizes the attributes and resources of the World Wide Web to create a meaningful learning environment where learning is fostered and supported” (Khan, 1997, p. 6).
Origins, Growth and Technology Used

Distance Education and Virtual Classrooms

From the above definitions, it is not hard to see that technology and distance education, virtual classrooms, as well as Web-based instruction are intrinsically linked. Within the field of distance education research, there have been a number of attempts in the literature (Bates, 1993, 1995; Garrison, 1985; Keegan, 1995) to classify the relationship of technology to distance education and an effort to divide the development into what are called “three generations”. According to Bates (1993, 1995), the first generation of distance education is characterized by the predominant use of a single technology, and lack of direct learner interaction with the instructor originating the instruction. Correspondence education is a typical form of first generation distance education. The second generation is characterized by a deliberate integrated multiple-media approach, with learning materials specifically designed for study at a distance, but with two-way communication still mediated by a third person (a tutor, rather than the originator of the teaching materials). Autonomous distance teaching universities are examples of second-generation distance education. The third generation of distance education is based on two-way communications media that allow for direct interaction between the instructor who originates the instruction and the remote student— and often between remote students, either individually or as groups. Third generation technologies result in a much more equal distribution of communication between student and teacher and also between students.

According to Garrison’s (1985) classification, the above three generations are labeled (a) correspondence, (b) teleconferencing, and (c) computer-based. However, Garrison’s attempts are not clear about why the “correspondence generation” and the “teleconferencing generation” are supposed to have ended before the “computer-based generation” begins. Keegan (1995) suggested that it be better to regard the developments in the use of technology in education as a cumulative process in which the benefits of distance education are added to conventional face-to-face provision to bring the enhancement that technology can provide. Keegan attempted to analyze educational provision from the point of view of distance education by identifying three differing structures:

Conventional education is the normal offering of education in schools, colleges and universities today. Its characteristic structures are the dialogue, the lecture developed by the medieval universities, the tutorial and seminar, the laboratory practical the field trip and the periods of study in the library or resource center. Its characteristic technologies today are the overhead projector and the white (or black) board. With the developments of technology of the Industrial Revolution, the conventional face-to-face interpersonal provision continues, grows more widespread with the growing involvement of almost the whole population in sequential schooling for a substantial number of years (Vertecchi, 1993) and is itself enhanced by technology.

Teaching at a distance can be tracked back to 150 years ago. In 1840, Sir Issac Pitman, the English inventor of shorthand, came up with an ingenious idea for delivering instruction to a potentially limitless audience: correspondence courses by mail (Matthews, 1999). However, it was not possible for instructor and learners to teach and learn in different places without the developments of technology, especially in transportation and communication, associated with the Industrial Revolution. Teaching at a distance is characterized by the separation of instructor and learner and of the learner from the learning group, with the interpersonal face-to-face communication of conventional education being replaced by an apersonal mode of communication mediated by technology. Teaching at a distance brings great benefits to the people who cannot or choose not to attend the schools, colleges or universities. However, an emotional dimension of the interaction, such as the eye-to-eye contact and interpersonal interaction, of the instructor and learners is lacking in traditional distance education.

Teaching face-to-face at a distance was achieved with the telecommunications revolution of the 1980s, which associated with the deregulation of the telecommunications, the increased speed of chips and the introduction of broadband technologies. The introduction of cable and satellite technologies that can be now linked to virtual classrooms brought undreamed of new dimensions to distance education. Within the virtual classroom, the lecturer can see and hear the learners present in the class
and also all the other learners at the other sites hundreds or thousands of kilometers away. The interaction of face-to-face education has been recreated electronically and complemented the limits of apersonal interaction that traditional distance education has.

In this present phase, conventional face-to-face education in schools, colleges and universities continues and is further enhanced by the influence of the new communications techniques. In addition, many researchers consider virtual systems based on (electronically) teaching face-to-face at a distance as a new and cognate field of study to distance education.

Web-Based Instruction

As the Internet emerged since 1969 and the Web was first released onto the Internet in 1991, extraordinary growth has taken place and WWW is becoming an increasingly powerful, global, interactive, and dynamic medium for delivering instruction. Thus, the nature of the relationship between the instructor and learners continues to change as developments in technology allow them not only to communicate in various ways, but also to access and generate a wide range of resources.

The WWW, a worldwide connection of computers which enables users to easily view text, graphics, sound, and video from any computer with Internet access, allows information to be distributed worldwide, using a generic interface that can be obtained by running programs that work on various computer platforms. These characteristics empower Web-based instruction, delivered in whole or in part on the Web, to be an additional valuable tool for distance education. Like correspondence and extension courses delivered at a distance, Web-based instruction allows learners to use self-directed techniques to learn new knowledge at their own rate, and at convenient times and places. Additionally, it provides learners and instructors previously inaccessible information resources at the fingertips of them.

Web-based instruction takes many forms, from environments where only text and supporting graphics are transmitted between educator and learner, to situations where live two-way, real-time text or video interaction can take place between the educator and learner or between learners. Questions and answers must freely flow between all participants. By using interactive TV, virtual classrooms achieved the dream of teaching face-to-face at a distance to allow learner interaction that traditional distance education, such as correspondence, can’t achieve. Furthermore, web-based instruction could fulfill the dream of a totally interactive virtual classroom, where questions and answers flow freely, yet the learners have immediate access to Web-based reference material to support their arguments. In addition, because WWW uses a generic interface that can be obtained by running programs that work on all learners’ computer platforms, Web-based instruction does not need to require learners to travel to virtual classrooms at fixed times on fixed days to join the learning group as the virtual classrooms might need.

Because of the development of the WWW and computer-mediated communication systems (CMCS) in the 1990s, many features of virtual classroom through interactive TVs in 1980s, such as face-to-face interaction of a instructor and learners, can be fulfilled by using WWW and CMCS in this new decade. Thus, a broader definition of virtual classrooms has been redefined in 1990s by many researchers as follows:

A virtual classroom is a computer accessible, on-line learning environment intended to fulfill many of the learning facilitation roles of a physical classroom (Clarke, 1997).

A virtual classroom is usually based on computer groupware, or can be operated over the Internet (Matthews, 1999, p. 58).

Due to the ubiquity and popularity of the Internet—particularly the WWW—most virtual classroom implementations are Web-based (Hsu, Marques, Hamza, & Alhalabi, 1999). The concept of virtual classrooms has been refocused on on-line learning environment created by computer-mediated communication systems rather than by interactive television. It does not emphasize the synchronous face-to-face interaction through I-TV; instead, it focuses more on the asynchronous on-line discussion and instruction for a instructor and learners to collaborate on the advancement of learning through technology. It seems that the new concept of virtual classroom in recent years refers to “a virtual classroom for Web-based learning” and does not have much difference from the concept of “Web-based instruction.” Thus, many people use these two terms interchangeable while addressing the issues of the on-line instruction or distance education.
Discussion

New terminology, such as correspondence education, virtual classrooms, computer-based instruction, and Web-based instruction, has been created along with the Industrial Revolution, the telecommunications revolution of the 1980s, and the creation of the WWW in the 1990s. It is clear that distance education would not have been possible without the developments of technology, especially in transportation and telecommunications. The technology is ever evolving and will continue this way into the future. As the technology evolves, new terminology of distance learning will also be created.

When reflecting on whether there is a difference among distance education, virtual classrooms and Web-based instruction, our response is “Yes, there is a difference among these three teaching methods in terms of the specific technology that creates these varieties of distance education.” For example, because of the telecommunications revolution in the 1980s, the instructor and learners at separate places can see and talk to each other face to face by interactive TV. The new term “virtual classroom” was thus created. Because of the creation of WWW in the 1990s that allows instructors and learners to access a wider range of resources, the term “Web-based instruction” was then created to explicate the meaning of this new instructional method for distance learning. Obviously, new terminology will continuously be coined to convey the meaning behind new teaching and learning methods that technologies have fostered. In addition, there is a strong possibility that the traditional definitions of instructional methods, such as the definition of virtual classrooms in the 1980s, will be continuously redefined to explicate the new technology. These redefined definitions might be somewhat confusing (or be used interchangeably) with the newly created ones, such as the revised definition of virtual classrooms in the 1990s vs. the definition of Web-based instruction (an example that will be explained in the discussion). However, most importantly, the purpose of these teaching methods—distance education, virtual classroom, and Web-based instruction—is undeniably the same: to improve teaching and learning at a distance by using technology.

Although new delivery technologies may provide more alternatives, greater cost savings, and increased flexibility in delivering instruction to distant learners, we should frequently remind ourselves to remain focused on instructional outcomes, not the technology of delivery. As Keegan (1995) recommended, it is better for us to regard the developments in the use of technology in education as a cumulative process in which the instructional media of distance education are continuously incorporated to the previous ones to bring the enhancement that technology can provide. With in-depth knowledge of what distance education and its varieties actually are—their characteristics, similarities and differences, we can now utilize these valuable teaching methods to provide more convenient, more accessible and better instruction for our distant learners.

Conclusion

The development of new technologies has continuously reinvigorated distance education that offers magnificent opportunities for the teaching and learning process beyond the physical limits of the traditional classroom’s walls. However, in today’s distance learning field there is substantial confusion in the use of terminology among distance education, virtual classrooms, and Web-based instruction. The reasons that cause this confusion are twofold: a) there is a great portion of overlapping among these teaching methods in terms of the educational technology and delivery methods used, and b) the concept of redefined traditional teaching methods, such as redefined virtual classrooms in the 1990s, might be similar to the concept of the newly created methods, such as Web-based instruction. However, it is very clear that these terms are all describing the same situation—teaching and learning at a distance using a mediated technology to facilitate the communications between the instructor, learners and resources. As distant educators, our goals are also clear—no matter which teaching methods and technologies we select, our purpose is to make improvements in both access to and the quality of distance education and to bridge the gaps between distance learning and traditional face-to-face learning environments.

A Strategy for Analyzing On-line Communication

Timothy Youngman
University of Houston
Houston, Texas, USA

Abstract: Creating equitable learning opportunities is a goal of many educators, but this is often confounded by preexisting power structures that favor some students over others. Computer-mediated communication has been hailed as a mechanism to improve education. It has been argued that participation in virtual communities can give students greater opportunities for expression of ideas. In order to fully understand this potential, on-line chat rooms can be analyzed for their capacity to create an ideal speech situation. This paper examines the theoretical basis for using virtual communication, discusses the requirements for ideal speech to occur, and examines the interactions from a virtual community.

Introduction

Technology can transform educational policy and practice, and ultimately society, when coupled with a pedagogy focusing on collaboration (Sernak & Wolfe, 1998). In recent years, the availability of technology has increased significantly, making on-line collaboration a viable option for many students. Through tools and strategies such as file exchange, electronic libraries, whiteboards, on-line debates, role-taking activities, and student dialogues, there is ample opportunity for learners to communicate with others on-line (Bonk & Cunningham, 1998). Technology, such as the chat room, offers students a level playing field where there is no immediate bias based on a person’s physical attributes or traditional power roles; the essence of their thought is allowed to come through.

Understanding Dialogue

According to Habermas (1984) when people enter into a dialogue they make statements based on their objective, subjective, and normative/evaluative ideas about reality. Objective statements are based on multiple points of access whereby more one than one person has the ability to make an observation. Subjective statements are made to indicate an internal state of affairs in which the only person who has access is the person making the statement. Normative/evaluative statements are those that reflect standards agreed upon by a group of people. When making a statement, a person tacitly understands that someone else may question the validity expressed in the speech act. Should this situation arise, the speaker may need to provide reasons to support the claim. This provides a context for argumentation to take place until both parties are satisfied. All forms of communication rely on this basic framework, but in order for it to succeed, several conditions must be satisfied.

In discussing the conditions for a meaning-making event to occur, Habermas (1984) proposed the ideal speech situation. This is a theoretical standard that can be used as a basis for judging the context for communication. Ideal speech, according to Habermas, occurs in a communicative setting in which reasons can be given, discussed, and argued without the use of force. Accordingly, four conditions must be met to achieve an ideal speech situation:

- The participants have equal social status.
- All participants are equal in their autonomy and responsibility.
- The participants are willing to discuss ideas openly and are willing to receive criticism.
- There is no force or coercion, allowing the reasons to stand on their own merit.

Although this is a theoretical standard that can never be fully achieved, some situations are closer to the ideal than others.
Ideal Speech and the Classroom

Research indicates there is inequality in the classroom favoring some students over others based on attributes such as gender, class, ethnic background, race, cultural background, and sexual orientation (Banks & Banks, 1993). Given this differentiation, it is apparent that many classrooms do not approach the ideal speech situation and will be unable to transform power relations within schools to achieve a more postmodern approach to education (Aronowitz & Giroux, 1991). However, technology offers some promise in helping to level the playing field.

The ability to communicate with people electronically in chat rooms may offer students some unique opportunities to more closely approximate the ideal speech situation. Students have the opportunity to expand their identity by exploring different aspects of the self and work through problems that could not be dealt with in the "real world," (Turkle, 1995) provided they have the opportunity to come forth as individuals rather a member of a particular group.

Ideal Speech and the Chat Room

In light of Habermas's articulation of the ideal speech situation, chat rooms can be analyzed for their ability to give everyone equal status, autonomy, and responsibility. With this in place, does the force of reason carry more weight than the coercion of a more powerful person? Is the chat room a better place to discuss ideas openly and receive feedback?

In addressing these questions, excerpts from chat sessions were analyzed. The sessions were conducted as part of on-line discussions in a graduate class at a large, urban university in the southern United States. All of the participants were given pseudonyms to hide their identity. No one had any knowledge of the other participants' gender, ethnicity, or social status. Based on the analysis of the text, key areas were identified where the setting changes or controversial statements were made. The researcher identified a range of possible meanings for each of the statements and identified the validity for each. A process of pragmatic horizon analysis was used to break the meanings into those that are foregrounded and backgrounded. Meanings in the foreground are those the speaker is attempting to consciously communicate to the audience, while those that are backgrounded are not intentionally communicated but may serve as a driving force for what a person actually says (Carspecken, 1996).

In many of examples the participants were able to openly express their ideas, and the weight of their respective arguments came from their internal perspectives of the situation. Because none of the participants was aware of anything about the person other than what was revealed through their dialogue, none of them had any power over the other in the traditional sense. Many of the exchanges demonstrated a willingness to discuss reasons and ideas, rather than simply assert dogmas.

Although technology is not a panacea for all issues facing educators, it offers a new approach. Computer mediated communication has the potential to provide learners with an opportunity to grow in a community where they are judged on their ideas rather than their physical characteristics.

Educating a diverse population for the future through technology is the major theme of this section. Technology is the tool used for increasing diversity in the teaching/learning experience. Proponents of multicultural education feel that mutual respect and harmony among ethnic and racial groups is essential for the future. Local school districts and teacher preparation programs have made strides in opening the world to diverse populations. Thoughtful and creative technology use in the classroom has brought the world into the classroom for many students and adults.

So many good articles grace this section that only a few are highlighted to demonstrate the theme of educating the future through successful school projects, the revamping of teacher preparation programs and accessibility laws and issues. Examples of successful school projects could be seen through the articles written by Litton and Beckett. Edmundo Litton in his article “Bridging the Digital Divide: A School’s Success Story” documents the progress of ethnic minority females from a low socioeconomic background. He describes what the school is doing correctly, to bridge the digital divide by interviewing and observing students and teachers in a technology setting. He presents the qualities that can make all high schools a success. In the article “Integration for ESL Success: TESOL Standards, Multiple Intelligences and Technology” Carol Beckett focuses on how a school can build upon the strengths of English language students by acknowledging their differences while developing their English language proficiency. She discusses how developing computer literacy and the information technology skills prepare these students for the increasing technological job market. She concludes with demonstrating how the integration of technology TESOL standards for Pre-K - 12 students and the theory of Multiple Intelligences can support learning differences and develop English language skills across the curriculum.

The progress of teacher preparation programs and technology is phenomenal. A sample of five articles among many shows the keen efforts being made in this area. In an article by CY Janey Wang “Bridging the Differences on the Web Through Effective Communication and Collaboration” explores how effective communication and collaboration among online learners of diverse backgrounds are encouraged by design. In addition, communication techniques utilized by members in the Web-based learning community in bridging differences, achieving goal, and optimizing individual learning are explored. The researcher suggests that the ideal curriculum bridges diversities by encouraging, inspiring, and inviting multiple perspectives within a highly flexible environment of multiple communication methods, learning styles and approaches. Shadow W.J. Armfield and Marilyn Durocher in “Modeling and Developing Technology Integration with Pre-Service Indigenous Teachers” discuss how a site-based traditional elementary and special education programs are taken to a reservation so that aides can continue their employment in schools while earning their degree and certificate. The authors discuss how the courses were interwoven to help students have a clear understanding of elementary education curriculum while simultaneously gaining an understanding and an ability to effectively integrate technology for learning and teaching. Also in “Gender and CS1: An Approach that Benefits Males and Females” by Thad Crews, Jeff Butterfield and Ray Blankenship, the project goal was to teach novice teachers to write computer programs through a series of short design activities focused on fundamental logic structures that transcend hardware and specific languages. Then “Integrating Diversity in Children’s Literature in the Elementary School Curriculum through the Use of the Internet Technology for Preservice Educators” by Joyce Armstrong focuses on assisting preservice teachers in learning about current diverse literature through the Internet. The Internet, what an invaluable tool!

On the other hand, as we celebrate the success, we also realize that we still need to continue stepping toward progress through Chloe Rose’s “Expertise and Access: Teachers Accounts of Technology Disuse.” She explores the pressing concerns of teachers who are faced with recent and ongoing demands made by provincial policy-makers, administrators, and parents to implement and integrate computer technology in k-12 schools in Canada. She focuses on the ways in which these concerns
are complicated and shaped by gender inequalities among teachers, within the school system, and in society, especially in relation to their competence with and usage of computers. In a diverse world her concerns become our concerns.

Finally, there are articles that teach us about web accessibility for diverse learners.

“Web Accessibility for Diverse Learners” by Laurie Ayre addresses educators’ concern for making Internet materials available to all students, including those who are physically challenged or hearing impaired. Standards for web design, and implementation strategies are discussed, and a list of Internet sources that provide support, information, and free testing of existing materials are presented. Also in the article “Distance Learning: Eliminating the Digital Divide” by Sheryl Burgstahler, access, legal and policy issues are presented. An overview of design considerations for assuring that a distance learning course is accessible to potential instructors and students with a wide range of abilities and disabilities are presented. She leaves readers with information that can be used to help develop policies, guidelines, and procedures for distance learning programs. A course accessible to everyone is what diversity means.

Diversity and technology are the future. The articles above are only a few of many interesting projects in this section that show progress in motion.
Modeling and Developing Technology Integration with Pre-Service Indigenous Teachers

Abstract: This paper discusses how two pre-service teacher education courses were interwoven to help students have a clear understanding of elementary education curriculum while simultaneously gaining an understanding and an ability to effectively integrate technology for learning and teaching. Furthermore, the paper will detail the successes and challenges of combining these courses for a site-based teacher-training program in a rural, indigenous community where various levels of expertise and access to technology were prevalent. The paper will also describe how the students constructed knowledge through the creation of meaningful and germane artifacts.

Introduction

"In a community of learners, teachers and students are role models, not ‘owners’ of some aspect of knowledge. They are acquirers, users, and extenders of knowledge in a sustained, ongoing process of understanding." (Norton and Wiburg, 1998).

Northern Arizona University (NAU) is located in Flagstaff, Arizona, only 50 miles from the Navajo Reservation and 75 miles from the Hopi Reservation. Because of its proximity to these two cultures, NAU has put great focus on working with the members of both tribes to help them attain college degrees regardless of their location. Through site-based programs, the Center for Excellence in Education has focused on providing face-to-face instruction to indigenous people who wish to become certified teachers. One such site-based program occurred in Tuba City, Arizona during the fall semester of 2001. The twenty-five students enrolled in this program represent the Navajo, Hopi, Anglo, Apache, and Acoma cultures. All of the students are non-traditional in the fact that they have returned to school as mature adults and three have already obtained bachelor's degrees in areas outside of education. Because of the diversity of the population, it was important to create a community of learners from which the students could take a sense of connection with other educators while at the same time maintain their individual cultural identities.

In accordance with Piaget’s theory of situated learning, "knowledge is not a commodity to be transmitted. Nor is it information to be delivered from one end, encoded, stored and reapplied at the other end. Instead, knowledge is experience in the sense that it is actively constructed and reconstructed through direct interaction with the environment" Ackerman (1996). This site-based program takes the traditional elementary and special education degree and certification program to the rural areas so that students can continue their employment in schools while earning their degrees and certificates. In this way, students are learning about teaching, while working in classrooms, actively constructing and reconstructing knowledge as they participate in the program.

The Dilemma
Rural communities throughout Arizona are at an educational disadvantage due to their distances from the three university campuses in the state. The program in which these students are involved provides face-to-face instruction, but has not provided on-site support resources such as the physical availability of instructors, peers, and reference materials usually found on university campuses. As a result of this inequity, it is paramount that students in these communities have technological access and skills in order to utilize the same resources as students on the university campuses. Upon examination of the program components, it was found that two courses could be combined in order to help the students acquire skills necessary to access resources for their learning, while transferring their new abilities into methods for curriculum implementation.

The two courses used in this project were Technology in the Classroom, and Elementary School Curriculum. The Technology in the Classroom curriculum is based on the idea that “When learners actively construct knowledge, it is more meaningful, applicable, and memorable.” (Jonassen, 1996); students in this class participate in and create technology-integrated activities, which they can use with their future students. Elementary Curriculum is a course in which students learn various methods of teaching and then create lesson plans to model what those methods would look like in the classroom. Traditionally these two courses have been taught independent of one another. The goals of the two courses lent themselves to a natural integration (See Table 1, Goals 1 through 3). In the fall of 2001 the traditional system was set aside and the two courses were combined so that students would have the opportunity to enhance their skills in technology for both teaching and learning through practice and modeling.

Table 1: Course goals.

The Process

The program was set up so that each course would be taught in a three-week period, four nights a week, and four hours a night. Elementary Curriculum was scheduled to be taught the first three weeks of the semester and Technology in the Classroom was scheduled for the final three weeks of the semester. As a combined course, the time allowed remained the same, but the content was interwoven and taught by both instructors.

The Foundation - the first three weeks

Because a strong sense of community was culturally appropriate and educationally desirable, the students and instructors participated in classroom experiences and assignments designed to connect students with one
another, the instructors, elementary curricular content, and the technology. Activities progressed from face-to-face sharing of beliefs, experiences, and values to creating an online community of learners and practitioners. During icebreaker activities, students and instructors shared elementary school experiences. Internet research was introduced and e-mail accounts were created to facilitate communication between and among students and instructors. Then students used a computer to create a metaphorical image of themselves. These images were shared on a class web page. At this stage, the students were ready to do further research about elementary learning and teaching, and to be able to share this information electronically with each other and the wider educational community. Assignments included finding and sharing information about characteristics of elementary schools, children, and teaching methodologies, including the integration of technology into both learning and teaching. They created PowerPoint presentations to share the information they had found in their Internet research. Students were then asked to incorporate the information into an electronically produced parent newsletter in which they described their educational philosophy, and classroom procedures and expectations.

At the end of the first three-week period, the students were prepared with the research, communication, and technological abilities they would need for the subsequent courses of the semester. Over the next twelve weeks the students completed four more of the required courses for the program. These courses covered assessment, special education, and educational psychology.

Putting It All Together - the final three weeks

When the students returned to the Elementary Curriculum and Technology in the Classroom combined courses, they had been exposed to the information they would need to complete the culminating assignments. The theory of Constructionism purports that learners are more likely to internalize and utilize information and skills gained through the construction of meaningful artifacts (Kafai and Resnick 1996). In alignment with this theory, the students were asked to create a web portfolio and an integrated thematic unit.

The web portfolio that the students were creating had a number of components including the integrated thematic unit (see figure 1). Below are the descriptions of each of these components.

- **Splash Page** - Serves as an introduction to the website and includes a graphic, contact information, and links to the other pages.
- **Address State Standards**
- **Address Diversity Issues**
- **Address Developmental Levels of Students**
- **Address Special Education Needs (including Assistive Technologies)**
- **Content Lessons**
- **Integrated Thematic Unit**
- **Web Portfolio**
- **Educational Philosophy**
- **Assistive Technology Page**
- **Resource Page**
- **Splash Page**

Figure 1: Graphic representation of the culminating assignments.

The web portfolio that the students were creating had a number of components including the integrated thematic unit (see figure 1). Below are the descriptions of each of these components.

* Splash Page - Serves as an introduction to the website and includes a graphic, contact information, and links to the other pages.
Integrated Thematic Unit — The students demonstrated their knowledge of developmental levels, diversity issues in the classroom, and use of state standards in lesson planning, and the ability to adapt and accommodate lessons for students with special needs.

Educational Philosophy — The students were to reflect upon the educational philosophy created in the first three weeks of class and use their new understandings to expand and clarify their educational values and beliefs.

Assistive Technology Page — This page is a summary of research about assistive technology and a description of specific assistive technologies used when creating the integrated thematic unit.

Resource Page — During the semester the students had gathered various Internet resources about educational topics. On this page, each student included at least five of the most useful resources they had found, along with a brief description of the contents of the site.

Conclusion

This paper has two conclusions, that of the students, and that of the instructors. At the end of the semester, students were asked to write to the instructors their perceptions of the things that worked and didn’t work for them individually. Quotes from these responses are included in the student section.

Students: what didn’t work

- “My suggestions are that if you plan to put two classes together, they need to be all at once, not spread out the way we did.”
- “The only change I would recommend is to allow more time for each class.”
- “The class was not very effective—very stressing especially for those of us who do not have computers.”
- “Saving the thematic unit plus others until the end.”
- “When classes are combined it’s very hard for us and the instructor. It should be separated. We could have learned more about technology.”

Students: what worked

- “I can honestly say I have learned and grown beyond my expectations. Although we started off slow, we ended pushing ourselves harder than we ever have before.”
- “In the integration we were allowed to make technology useful in our prospective teaching careers.”
- “Even though it seems like there were some parts untaught in the texts, it integrates and fits in with other courses taught in the semester. I do believe I learned quite a bit and increased my knowledge in an educational environment.”
- “I really enjoyed having the two classes together because it really showed me what integration of two subjects as one unit is really like.”
- “I thought this was tough, but it taught me how we as teachers intend to push our kids to do something new.”

Instructors: what didn’t work

One problem with the course design was communicating with students the interrelatedness of content for the two courses. The students came to the first class with expectations of a traditional separation of content matter. Their educational experiences had not prepared them for a course in which multiple subjects were being taught simultaneously. As the instructors, we failed to provide the students with the necessary scaffolding to be prepared for what lay ahead of them. This lead to frustration, and confusion about specific content expectations.

As many of the students responded, time was a stressor for both instructors and students. By dividing the courses between the first and final three weeks of the semester, the issue with time was magnified. Without this configuration, though, the students would have not have had the benefit of the instruction in technology at the first of the semester, and would not have been able to use all of the courses’ information in the culminating assignments. Along with the issue of time is the availability of technology to rural communities. A number of
students had to travel long distances on unimproved roads to use technology for creating assignments and communicating with instructors and peers. Not only did students have problems finding available technology, but also had to contend with the capricious nature of rural Internet service both inside and outside the classroom.

Instructors: what worked

Upon reflection, we realize that many of our initial goals have been achieved. The students were able to experience class activities both as learners and as educators; translating the things that they were feeling and doing into what their student would also feel and do. They immediately used new knowledge to create artifacts that can be used in their own classrooms. The students became a community of learners, sharing resources and ideas. As some students mastered ideas and skills, they shared their expertise by teaching their peers. In the culminating activities, they left the traditional isolationism of teaching to work together in creating units that integrated content material in a realistic, culturally specific manner.

All things considered, we feel that this is an effective model for helping pre-service teachers understand how content specific curriculum, individual student needs, technology, cultural diversity and a sense of community can be interwoven to construct dynamic classrooms of their own.

INTERGRATING DIVERSITY IN CHILDREN’S LITERATURE INTO THE ELEMENTARY SCHOOL CURRICULUM UTILIZING INTERNET TECHNOLOGY

Abstract: Teacher training in most colleges and universities include training in current genres of children’s literature. These courses typically allocate much time in demonstrating how to locate appropriate literature and in presenting teaching ideas to preservice teachers. However, diversity within the different genres is often overlooked. This paper presents pedagogy for the preservice teacher in the development of current diverse literature in the elementary curriculum utilizing numerous Internet sites.

Children’s Literature classes are very popular courses in elementary teacher training programs. Course descriptions include objectives such as reviewing relevant literature for preschool and elementary students, examination of different genres to compliment the elementary school curriculum, and the development of an appreciation of the literature created for children. Time is devoted not only to the evaluation of children’s literature but also to the teaching techniques employed to involve the elementary students in the literature. There are also numerous courses offered at colleges and universities on internet technology. However, future teachers need to incorporate their internet knowledge into their own teaching. (SITE, 1998) This integration should not be restricted to a single college course about technology but integrated into all methods courses in elementary education.

In the past, Children’s Literature courses focused on a canon of exemplary 20th century children’s books. (Goldstone, 2002). Hearne (1998) compiled a list of 35 books to act as examples of the historical pattern for quality children’s literature. This pattern details the relationship between text and art. Today’s authors do not always adhere to this pattern. There is not always a clear, traditional, linear story structure or a sugary happy ending to the story. Along with this newer type of story, diversity has become a theme in children’s literature. Moll and Greenberg (1990) infer that everyone lives in families and communities that draw on cultural diversity. If we view all children’s literature from this point of view then our task is to create a collection of children’s literature that is a balance of many different cultures.

Galda and Cullinan (2002) present the statistics that, “approximately one-third of the students entering schools are of African-American, Asian-American, or Latino backgrounds.” (pg.277). As educators we need to expose children to quality literature about many ethnic groups and the diverse cultures. Literature and the internet are the means that many people learn about the uniqueness of each group of persons and the universal experience of being human. (Huck, Hepler, Hickman, Kiefer, 2001) Preservice teachers need the skills to evaluate culturally diverse literature and to include this literature within the curriculum.

To assist preservice teachers in learning about current diverse literature, the internet becomes an invaluable tool. Search directories and engines that are useful include Yahoo, Looksmart, and AskJeeves.
for Kids. Utilizing Banks' (1998) four-step model of integrating diversity content into the curriculum a teaching pedagogy can be developed for the preservice teacher. Banks' lowest level for integrating diversity into the curriculum is the "contribution approach". At this level preservice teachers can explore the web sites of The Children's Literature Web Guide (www.acs.ucalgary.ca/~dkbrown/) or Vandergrift's Children's Literature Page (www.scils.rutgers.edu/special/kay/childlit.html). Preservice teachers should focus on literature that describes the contributions made by various ethnic groups to culture.

The second level of Banks hierarchy for integration of diversity is the "add on" approach. At this level content, concepts, and themes are added into the curriculum (Banks, 1998). Web sites to locate literature include New Years Around the World (www.coe.wayne.edu/~mpettap/lesson/newyr.htm) and Religious Holidays (www.adl.org/ctboh/old/holidayactivitiesguidelines.html). These sites describe ideas and children's literature that adds extra information to the elementary curriculum.

The third level of Banks' model is that of the "transformation approach". At this level the curriculum is actually changed, not more added. This third level enables students to develop an understanding of problems, concepts, and concerns of an entire culture, not just from the majority point of view. Web sites to explore for literature includes Connecting Students to the World (www.guilford.k12.nc.us/webquests/) and A Celebration of Diversity: Immigration and Citizenship (www.libsci.sc.edu/miller/diversity.htm).

The "social action approach" is the highest level of Banks' model. (Banks, 1998) At this level students identify problems and develop solutions to these problems. Web sites include Racial Profiling (www.horizonmag.org/6/racial-profiling.asp) or Yahooligans/Around the World/Activision and Volunteering/Peace Corps. (www.ourdays.com/old/tour).

The above mentioned sites are only a very small sample of the possibilities of the internet. When introducing the various genres to preservice teachers it is important that cultural diversity is not a separate unit. It should be include in all aspects of the curriculum and the internet is a tool to inform teachers of children's literature that can be used in all aspects of the curriculum. Lesson plans, award-winning books, pen-pal sites, sharing of children's writing, and reviews of new books are only a sampling of what is available for the preservice teacher.

References

Abstract: This paper addresses educators' concern for ensuring that Internet materials are available to all students, including those who are physically challenged or visually or hearing impaired. One salient example is the controversy that arose related to the inaccessibility of the Sydney Olympic Games Website for visually impaired persons (Carter, 2000). Teacher educators should not produce, distribute, or support Internet materials that are in violation of the 1990 Americans with Disabilities Act (Public Law 101-336). Only through making sure that online materials adhere to a set of standards for web development, such as those established by the World Wide Web Consortium (W3C), can educators ensure accessibility for students with disabilities.

Introduction

There are 20.9 million Americans aged 15 and over with work disabilities. Although over 2.1 million people with disabilities make use of the Internet either at home or in another environment, they are less than half as likely as non-disabled individuals to have access to a computer at home and three times less likely to have the ability to connect to the Internet at home (Kaye, 2000). The Americans with Disabilities Act (ADA), which celebrated its eleventh anniversary in 2001, has prompted an enormous amount of litigation in schools and the workplace. On November 4, 1999, the National Federation of the Blind filed suit against America Online in the Federal District Court under the ADA (Wingfield, 1999). The National Federation of the Blind, a nonprofit organization of 50,000 members nationwide, took the position that America Online and the Internet must provide public accommodation for persons with disabilities. This was the first legal action taken against an Internet company. The suit was settled on July 26, 2000, when the National Federation of the Blind and America Online reached an agreement to work closely together to ensure continued progress on accessibility for individuals with disabilities. In addition, America Online reinforced this commitment to accessibility by posting an accessibility policy on its Web site. This anecdote serves as a cautionary tale for Internet and Web site developers. Furthermore, teacher educators must become familiar with issues of accessibility, striving to support compliance with standards that promote universal access to online materials and to educating future teachers about them. This paper will describe standards for web design under Section 508—Web Accessibility of the Workforce Investment Act of 1998 (Public Law 105-220), and implementation strategies for computer accessibility and web content. It will also provide an annotated list of Internet sources offering support, information, and free testing of existing materials.

Legal Requirements for Internet Accessibility

Some of the important accessibility issues pertaining to Web page design relate to the way in which individuals interact with computer technology and to the accessibility of the information itself. For instance, certain individuals with disabilities might find it impossible to use a keyboard or mouse. Some users may require appliances that have a text-only screen, a small screen, an older browser, or a slow...
Internet connection. Others might have difficulty reading or comprehending text or may not be fluent in the language of the document.

Limitations to Internet accessibility have been addressed through two major pieces of legislation, The Americans with Disabilities Act (PL 101-336), and the Workforce Investment Act of 1998 (PL 105-220). The Americans with Disabilities Act (ADA) provides that institutions subject to the act must furnish appropriate aids and services to ensure effective communication with individuals with disabilities, unless doing so would result in a fundamental alteration to or in an undue burden on a program or service. Examples of aids include audiotapes of texts, Braille materials, large print materials, and captioning and text readers. Furthermore, on September 9, 1996, the U.S. Department of Justice issued a policy ruling extending ADA requirements to include communication through the Internet.

Two years later, the Workforce Investment Act of 1998 (Public Law 105-220), based on the ADA, significantly fortified the technology access requirements of Section 508 of the Rehabilitation Act of 1973. Effective August 7, 2000, Section 508 requires that when Federal agencies use electronic and information technology, they must ensure access to people with disabilities, unless it would pose an undue burden to do so. The level of access must be comparable to the same available to non-disabled Federal employees and members of the public. States receiving Federal funding under the Assistive Technology Act of 1998 are also subject to Section 508 provisions. [See Waddell and Urban (2000) for an in-depth discussion and links to government publications related to this legislation.]

Implementation Strategies for Computer Accessibility

Three major organizations provide extensive resources for ensuring computer accessibility to individuals with disabilities. These include IMS Global Learning Consortium, specifically Specifications for Accessible Learning Technologies (SALT) Project, Microsoft, and Apple Computers Worldwide Disability Solutions Groups (WDSG).

Specifications for Accessible Learning Technologies (SALT) Project, a joint venture among the IMS Global Learning Consortium members, has as its goal to make online learning resources accessible to people with disabilities. One half of the project's funding is provided by the U.S. Department of Education, with the other half coming from contributions from project partners, Blackboard, Educational Testing Service, and WebCT. These project goals are to:

- Promote awareness of accessibility issues, especially within the e-learning community
- Create development guidelines and best practices for inclusive design of software applications for learning, education, and training
- Advocate for the development of e-learning software applications that meet or exceed accessibility legislation requirements
- Contribute to IMA specification development, with a focus on accessibility extensions to existing IMS specifications. (SALT Detailed Overview, 2000, p. 1)

The IMS Accessibility Working Group published IMS Guidelines for Developing Accessible Learning Applications, Version 0.6 in October 2001. This white paper discusses current accessibility solutions that are available for implementation as well as unresolved access issues that affect educational technologies. This document will continue to be expanded, updated and revised.

Microsoft provides resource guides for ensuring computer accessibility based on the nature of specific disabilities, including vision, hearing, mobility, and cognitive and language impairments. These guides are made available to educators and the public at http://www.microsoft.com/enable/default.htm Microsoft lists assistive technology products for each impairment. Organizations should consider which of these products should be provided to its members or constituents. Furthermore, Microsoft supplies an impressive set of links to papers covering access issues, which are organized by impairment type. Another important feature of Microsoft's Web site are the step-by-step tutorials for enhancing the accessibility of each of its products. A designated member of an organization can use these tutorials to make certain that impairments will not bar users from having access to Microsoft products.

Apple Computer's Worldwide Disability Solutions Group (WDSG) supports the development and distribution of Apple's Macintosh Human Interface Guidelines, which is freely available at
Implementation Strategies For Web Content Accessibility

At the foundation of a strategy for assuring Web content accessibility, each organization must establish a set of priorities for which accessibility issues receive primary and immediate attention. In 1999, The World Wide Web Consortium (W3C) established a useful set of priorities for implementing accessibility standards for a Web site (see URL under Internet sites). Web design elements that enhance accessibility have been assigned to one of three priority levels. For each priority level, W3C has listed a number of checkpoints for individual design elements. These checkpoints can serve as a basis for evaluating the overall accessibility of Web content. For items given Priority 1 status, guidelines must be followed to ensure all disability groups will be able to access the information contained in a Web document. An example of a Priority 1 checkpoint is as follows:

Provide a text equivalent for every non-text element (e.g., via “alt,” “longdesc,” or in element content). This includes: images, graphical representations of text (including symbols), image map regions, animations (e.g., animated GIFs), applets and programmatic objects, ascii art, frames, scripts, images used as list bullets, spacers, graphical buttons, sounds (played with or without user interaction), stand-alone audio files, audio tracts of video, and video. (Checklist of Checkpoints for Web Content Accessibility Guidelines 1.0, 1999, p. 3)

A Web content developer should comply with Priority 2 guidelines to prevent disability groups from having difficulty accessing information in the document. For example, Priority 2 guidelines require that foreground and background color combinations provide sufficient contrast to be easily viewed by someone having color deficits and when displayed in black and white only. Further, the designer should clearly identify the target of each link.

Priority 3 guidelines may or may not be addressed, but still can cause access difficulties for one or more disability groups. To comply at a Priority 3 level, the content developer must specify the expansion of each abbreviation or acronym in a document where it first occurs, the primary natural language of a document, a logical tab order through links, form controls, and definitions of objects. Organizations are encouraged to adopt the W3C guidelines and checklists as a means of improving web content accessibility.

Internet Sites

The following list of Internet sources provides support, information, and free testing of existing materials:

1. Disability Information Links. The National Information Center for Children and Youth with Disabilities (NICHCY) is an information and referral center focusing on disabilities and disability-related issues of children from birth to age 22. Their information is targeted for families, educators, and other professionals. This site offers an extensive set of links to PDF-format publications. The NICHCY home page is located at http://www.nichcy.org/.

2. Web Content Accessibility Guidelines. The World Wide Web Consortium (W3C) provides a comprehensive set of Web design guidelines at http://www.w3.org/TR/WCAG/. W3C’s Web Accessibility Initiative is supported in part by the U.S. Department of Education’s National Institute on Disability and Rehabilitation Research, the European Commission’s Information Society Technologies Programme, Canada’s Assistive Devices Industry Office, Microsoft Corporation, IBM, and Verizon Foundation.

address specific HTML code requirements for images and image maps, multimedia, page organization, table and frame layouts, and hypertext links.

4. **Website Design.** The Trace Center of the College of Engineering at the University of Wisconsin provides a comprehensive set of links dedicated toward building more usable Web sites at http://trace.wisc.edu/world/web/. These links include valuable Web access tools for both users and authors.

5. **Page Checker.** Validate your pages with an ADA validation tool such as Bobby, sponsored by IBM and downloadable from http://www.cast.org/bobby/DownloadBobby316.cfm for a $99 charge. A second alternative is A-prompt Test Program available at http://aprompt.snow.utoronto.ca as a free download. W3C HTML Validation Service is freely available at http://validator.w3.org/. This service checks documents for compliance with W3C accessibility guidelines and makes recommendations for improvements.

6. **Model Programs.** The Family Center on Technology and Disability (Family Center) is a project funded by the Office of Special Education under the U.S. Department of Education. One of its goals was to identify exemplary programs that provide technology support and services to families of students with disabilities. The Family Center Web site at http://fctd.ucp.org/fctd.htm provides a brief description of six model technology support and service programs, including sources of funds, populations served, and services provided, as well as contact information. These can be used as templates that an organization can use in establishing its own program.

**Conclusion**

It is clear, given the resources now available, that educators can begin to address the issue of web accessibility for diverse learners. Any society will strengthen itself by recognizing and supporting universal access to instructional materials for all people. While facilitating the participation of individuals with disabilities, awareness of emerging accessibility issues and work towards full Internet access must increase to improve the participation of individuals with particular learning preferences as well (visual, auditory, kinesthetic). It is the hope of the authors that this article will encourage educators to become more aware of the issues and resources surrounding access to the Internet and promote a desire within them to ensure equal access for all learners.

Miami, Florida 33054 U.S.A
mbacalla@stu.edu

Abstract: This paper will focus on the efforts over the past two years of the South Florida PT3 group to Bridge the Digital Divide. Success stories with African American and Hispanic pre-service teachers will be shared. PT3 collaboration with an African-American elementary school will be discussed from the viewpoint of the teachers and administration of Golden Glades Elementary School in Opa Locka, Florida.

The St. Thomas University Plan to Bridge the Digital Divide in South Florida

A consortium of schools with St. Thomas University in Miami, Florida as the lead partner was awarded a PT3 Capacity Building grant during the first year of the PT3 program. The teacher education program at St. Thomas University serves students of many ethnic groups. It is located in an urban area with a large African American population along with immigrants from many Hispanic countries and the Caribbean.

The purpose of the initial grant was to work with area elementary schools, such as Welleby Elementary, to train the pre-service teachers at St. Thomas University and Trinity International University to use computers effectively in classroom instruction and thereby impact the diverse students in Miami-Dade County. The grant sought to train teachers who will not only teach in the inner city schools but stay in the inner city schools. By serving pre-service teachers who represent these underserved populations, the program sought to impact inner city classroom instruction.

What Do the Administrators and Teachers at Golden Glades Elementary Have to Say About Their Involvement with PT3 and Universities?

Golden Glades Elementary is a small PK-6 elementary school in Opa-Locka (Greater Miami), Florida. Its 520 students are predominately African-American and 90% of its students qualify for free or reduced school lunch.

The use of technology to increase student performance had been a high priority at Golden Glades since 1994. Through numerous grants and commitments from both the school's regular and Title I budgets, the school had been retrofitted and its infrastructure
expanded with both hardware and software acquisitions. Every classroom was equipped with 4-7 internet ready computers, a local area network equipped with diagnostic/prescriptive software, an instructional management system, and a media center with a fifteen station computer lab. Teachers were mandated to involve students with computer assistance instruction for a minimum of 140 minutes a week.

Yet student performance continued to wane. Technology was used by teachers as required but little integration occurred between the curriculum and that technology. There were few technology experts on staff, and their roles were so diversified that little innovation was in evidence.

Then PT3 occurred. Given the opportunity to partner with Saint Thomas University and Florida Gulf Coast University in a collaborative effort, seven members of the Golden Glades Elementary staff became technology experts. With this diversity of expertise came the beginnings of curricular change. WebQuests and “integrating computer software to match curriculum” became catch words. LCD panels and computer/television hook-ups became necessary. Teachers began asking for different software programs and they began using them in different ways. True curricular change had begun.

The effects of true curricular change cannot be measured in short blocks of time. Yet the test scores of Golden Glades Elementary showed great gains in 2001. Anticipation for further test gains in 2002 is great. PT3 hopes to improve public education by training future teachers for the technology of tomorrow. Yet, when organized properly, it can also influence the public sector today. Golden Glades is a living example.

On-Line Presence

Information about our project may be viewed at: http://garnet.fgcu.edu To view these discussions, one may register for the PT3 Fall and/or spring courses and create an identity. Once this is done, posting will be enabled for the viewer. Our website also contains information that documents our workshop activities with our partners. Our website is located at: http://coe.fgcu.edu/PT3/home.htm.

National Educational Technology Standard-Based Lesson Plans Are Written

The technology enhanced lesson plans for the Fall 2001 Semester are written and can be viewed on the BEACON database. The website for BEACON is www.beaconlc.org Selected lessons will be shown at this session.
Integrating Technology in the Pre-service College Classroom and Beyond by Developing Exit “e-portfolios”

Mary Kay Bacallao, Ed. D.
St. Thomas University
16400 NW 32nd Avenue
Miami, Florida 33054 U.S.A
mbacalla@stu.edu

William Halverson
Florida Gulf Coast University
Ft. Myers, Florida, U.S.A.
bhalvers@fgcu.edu

Abstract: The PT3 project, “Bridging the Digital Divide in South Florida” has proposed a module comparing outcomes of pre-service teachers that produce electronic portfolios to outcomes of pre-service teachers using traditional paper portfolios. Also, pre-service students will be evaluated on the degree and quality of technology integration into the field experience and internship experiences in the K-12 classroom. But first, the PT3 project will incorporate in one existing pre-service educational technology course; the creation and implementation of an e-portfolio project. This project will be implemented by using collaborative initiatives, online communities, and student initiated ideas incorporated within a pre-service Introduction to Computers in Education EME 2040 course.

History of the Project

In 1996, the Florida Department of Education introduced the Educator Accomplished Practices (EAP). These EAP standards “recognize the relationship between a strong foundation of content and pedagogical knowledge and the ability to apply this knowledge in practice while exhibiting professional behaviors.” To demonstrate these standards, many institutions now have pre-service students develop, and present, in a formal review, an exit portfolio. An exit portfolio helps these pre-service students organize and show accomplished practice evidence. At Florida Gulf Coast University, for the first time, in one course called Introduction to Computers in Education, EME 2040, during the Spring 2002 Semester, pre-service students will be developing and implementing an electronic portfolio. An “electronic” exit portfolio (e-portfolio) hopes to take the student learning process a step further by integrating appropriate technology throughout the pre-service experience and beyond.
Purpose

This presentation will be a collaborative session examining the challenges and successes of the several components in integrating an e-portfolio project in an existing pre-service college course.

On-Line Presence

Information about our project may be viewed at: http://garnet.fgcu.edu. To view these discussions, one may register for the PT3 Fall and/or spring courses and create an identity. Once this is done, posting will be enabled for the viewer. Our website also contains information that documents our workshop activities with our partners. Our website is located at: http://coe.fgcu.edu/PT3

Interdisciplinary Partnerships

We have fostered relationships among other departments by recruiting professors from other disciplines to be participants on the subject area teams. We began with professors from Communication, Guidance and Counseling, Math, Science, and English. Several of the professors we originally recruited have resigned due to the differences between their professional fields and teacher education at the elementary level. We have, however, retained a few professors from other departments.

Professors Collaborate with Pre-Service Teachers

We have addressed the need for collaboration with K-12 teachers by placing eighteen K-6 teachers from five elementary schools on the subject area teams. This has been an essential part of our project as professors and pre-service teachers relate with classroom teachers on a regular basis. Four of these K-12 teachers serve as team leaders.

The Foundation Standards in the Curriculum Guidelines for Teacher Preparation Programs in Computer/Technology Literacy developed by International Society for Technology in Education for NCATE will be included within the e-portfolio project.

The completed e-portfolios will be hosted on the student.fgcu.edu domain for the students to use during their studies and for one year or so after they graduate. It is the authors hope to host all of the students’ e-portfolios on the College of Education domain when it is feasible to do so. This would showcase our students Education Technology Proficiency. The domain for this database of student e-portfolios would be located at www.coe.fgcu.edu. Selected e-portfolios in progress hope to be shown at this session.
Community Mapping: Learning and Teaching in Context

Gina Barclay-McLaughlin
Theory and Practice in Teacher Education
College of Education
The University of Tennessee
Knoxville, TN
United States

Abstract: This paper is designed to share efforts used to prepare pre-service teachers and practicing teachers to work more effectively in urban schools with diverse populations. Pre-service and practicing teachers use community mapping methods and integrate technology skills to increase their understanding of the contexts within and beyond the classroom that influence their students' learning and development. Additionally, community mapping methods and technology skills support teachers to identify, examine and make maximum use of nontraditional learning opportunities.

Introduction
In every community there are opportunities and assets to support and improve instruction and learning (McKnight and Kretzman, 1993). Urban inner city communities often generate negative images and are perceived from the outside as contexts of crime, despair and hopeless (Mead, 1986). Little attention has been devoted to capturing the natural and available opportunities and assets that might support growth, learning and development. In these settings many untapped assets exist. They are reflected in individuals, formal and informal groups, organizations and institutions, traditions and customs, and the many artifacts within a given context. Too often, teachers focus narrowly on the learner or traditional resources of the classroom setting. Some lack a real sense of the full range of gifts and resources, even within their own classrooms, that can help to motivate students and support desired learning outcomes. Resources of the school are sometimes underutilized, forgotten, and in too many cases, unknown. Instead, substantial attention is centered on student deficiencies and the inadequacies of their families and neighborhoods/communities. This paper is an attempt to capture strategies used by pre-service and in-service teachers to increase their understanding the contexts, processes and mechanisms that contribute to desired behaviors and positive outcomes for students in their classrooms and schools.

Community Mapping
McKnight argues that far too much attention has been devoted to the negative aspects of declining communities. He (1993) popularized the notion of community mapping when he published with John Kretzman, Building Communities from the Inside Out. The authors demonstrated through their neighborhood work in Chicago that communities are filled with assets, which are substantially overlooked and underutilized. Similarly, the work of Dunst, Herter, Shields, and Bennis (2001) offers a focus on community-based mapping natural learning opportunities to support the inclusion of children with disabilities and other special needs. The authors describe community mapping as methods and procedures used by practitioners and parents to locate and compile
information about everyday learning opportunities. The focus is on opportunities for learning. Thus it is a shift from barriers to assets. Community mapping can serve as a viable process and method of identifying such opportunities and resources.

Community Mapping and Technology
Community mapping is now emerging as a powerful tool for teachers and technology can be used to facilitate and enhance this process. This integrated approach for identifying contextual assets and influences on children’s learning also enables teachers to capture and examine a range of ways to start from the familiar in order to facilitate and broaden student learning. Examining the various contexts in which children interact in daily life offers teachers greater depth in understanding their students and their needs. As a growing number of teachers in urban schools live outside of the communities of their students and have different cultural experiences and histories, it has become increasingly important to bridge the gap. This kind of understanding is essential for maximum use of natural learning opportunities. Technology is a useful tool for capturing the information and documenting its occurrence.

The Mapping Process
In this section we offer a brief description of the community mapping process and examples of the ways teachers explore and identify learning opportunities. Participating teachers are required to work in groups for a number of reasons. First, the notion of community suggests social interaction and engagement. Second, it is often helpful to explore new and unfamiliar territory with feedback from others. Third, it helps to have support in using equipment and making decisions about what to capture and how to best do so. Finally, group projects provides multiple perspectives and serves as a check and balance system.

Participants have available to them an array of tools to capture and present their work. They have access to still and video digital cameras, audio tape recorders, laptop computers, and projection machines. Additionally, they have the benefit of a variety of software materials to support their attempt to capture and present their work and experiences during and after the investigation. This includes, but is not limited to, power point, word, photo shop, hyper-studio, inspiration, media player, i-movie, and pinnacle.

The process officially begins with teachers forming groups. Participants of the group meet initially to plan the process; determine roles, tasks, and responsibilities; and to make plans for a final class presentation. Mapping begins with a focus on the classroom and available opportunities for learning in this context. Teachers sometime shadow a student to get a sense of social interactions in the setting. The physical setting and social and emotional climate of the classroom are also important features of the classroom to capture.

The next phase is center on the school context. This phase of the process is often a surprise to practicing teachers who find assets they have never used. Shadowing a teacher and a student in this context offers important insights. We have found that teachers use resources in different ways, even at the same school. Phase three provides a
focus on the family context. Capturing the home and family contexts requires trusting relationships. Nonetheless, teachers feel they have gained valuable insights to guide their practice.

The final phase of this process is the community. Participants create a map of the community and attempt to identify available services and resources. In each phase there is an attempt to shadow as least one individual to gain a sense of a typical day in the life of the individual.

Throughout the process teachers write reflections about their experiences and continuously document the role they each play within the group. Group members share with each other a description of each person's role in the group during the process. A group reflection is required at the end and is designed to capture and summarize their collective effort in the process.

In groups, participants collect and document artifacts to collectively construct their reflections of classroom, school, home, and community contexts. The tools allow individual and groups to capture evidence of the natural environment, maximize opportunities and resources to support instruction, and take advantage of a range of activities and experiences. Though a continuous process of reflection, participating teachers in training create slideshows to formally share their constructions. These constructions include relationships and experiences that are connected to their students' daily lives.

**Conclusion**

Group presentations and class evaluations demonstrate the value students place on this learning experience. It includes sights teachers feel they have gained about their students and the contexts that influence their behaviors and learning. More important, teachers share how new knowledge and insights inform or change the work they do with children, families, and the community. The work of participating pre-service and practicing teachers illustrates the stages of the process for preparing teachers to connect with the natural environment of children. This new or increased level of understanding guides their teaching practices and maximizes opportunities for learning and achievement. The use of technology throughout the process is a useful and objective source for capturing learning at each phase. It is also a source for continuous reflection and reference.
School District Websites: An Accessibility Study

Marty Bray
Claudia Flowers
The University of North Carolina at Charlotte

The Americans with Disabilities Act (ADA) of 1990 provides the same civil rights protection to individuals with disabilities that apply as a result of race, gender, national origin, and religion (Button & Wobschall, 1994). Title III of the ADA directs that public facilities make reasonable modifications to control discrimination and support accessibility in policies, practices, and procedures (Council for Exceptional Children, 1994). As a result of this landmark legislation, accessibility alterations such as providing ramps to elevated areas and providing accessible signage through height adjustments and raised lettering have become commonplace across the United States.

The Perkins Vocational Act of 1984 called attention to America's need to support individuals who were less fortunate by birth or economic circumstances. The Act underscored the need for improving vocational programs and serving special populations of students. The Act created an awareness of the population of people that had gone unnoticed with little or no training.

The World Wide Web (WWW) has become an invaluable resource for many people with disabilities. Accessibility across platforms and geographic distance makes the WWW an ideal universal tool for gathering and disseminating information (Heflich & Edyburn, 1998). Many school districts use the Internet to disseminate a wide variety of information to students and parents. Wong (1997) discussed using the Internet for increased self-advocacy by individuals with physical impairments. It is ironic, however, that while technological developments have enhanced and provided new exciting opportunities for the WWW, they have, at the same time, complicated and limited the accessibility of the content and resources for individuals with disabilities.

Physical barriers are obvious accessibility concerns. Web page developers need to be just as aware that on-line barriers can create significant problems for some users. The Americans with Disabilities Act requires that all organizations make reasonable accommodations for individuals with disabilities. Even though there has not been a judicial ruling on WWW accommodations for individuals with disabilities, home page developers should work towards designing and building Web sites that are accessible to all individuals. It is important that Web page developers use and follow standards that allow accessibility to all WWW users.

To examine the accessibility of school districts' home pages a descriptive study was conducted. The population Web sites for this study were school districts located in the United States and Canada. A list of 567 School District Web sites was randomly selected from an online school web directory. Each home page was analyzed using the software package Bobby 3.2 (Center for Applied Special Technology, 2000), which allows researchers and other professionals to evaluate Web pages in accordance with the W3C Web Accessibility Initiative's guidelines.

Approximately three-fourths (74.3%) of the home pages were not approved by Bobby 3.2. This indicates that at least one Priority 1 error (seriously affects accessibility) was detected on these pages. There was an average of .91 Priority 1 accessibility errors on the School District home pages. In addition, the average number of Priority Two and Priority Three errors was 2.33 and 1.64 respectively.

Web developers at school districts need to examine their Web sites for accessibility problems. It is strongly recommended that validation methods be used in the early stages of Web development, which will help make problems easier to correct and assist developers in avoiding many accessibility problems. In addition to evaluation tools such as Bobby 3.2 expert and novice users with disabilities should be invited to view home pages and provide feedback about accessibility or usability problems and their severity.

Distance Learning: Eliminating the Digital Divide

Sheryl Burgstahler, Ph. D.
Affiliate Associate Professor, Director of DO-IT (Disabilities, Opportunities, Internetworking and Technology),
Co-Director AccessIT (National Center on Accessible Information Technology in Education)
University of Washington, U.S.A.
sherylb@cac.washington.edu

Abstract Today, distance learning is the fastest growing mode for the delivery of instruction. Distance learning programs desire to bring learning to anyone, anywhere at anytime. However, some students, including those with disabilities, cannot fully participate unless design features are employed to make distance learning courses accessible to them. Designed well, distance learning options create learning opportunities for students with a broad range of abilities and disabilities. Designed poorly, they erect new barriers to equal participation in academics and careers. This paper summarizes strategies and lists resources for developing distance learning courses that do not create a digital divide.

New distance learning courses seem to be appearing everywhere. However, the idea of learning at a distance is not new. It has been around for a long time. Instructors have used printed materials and the postal system to deliver correspondence courses for hundreds of years. Televised courses were offered soon after televisions began to appear in homes. Today, in specially equipped facilities, instructors teach several classrooms full of students brought together through interactive television. Delivery of courses via the Internet is now common.

Many distance learning courses use multiple modes of delivery. For example, class discussions may take place using electronic mail; course content may be delivered via the World Wide Web, printed materials and television; and the class might occasionally meet in a televised instructional facility. Distance learning programs often have as a goal to reach as many students as possible. While they almost always consider people separated by distance and time, they rarely consider issues faced by potential students and instructors with disabilities. Many distance learning courses erect unintended access barriers for students and instructors with disabilities, creating a digital divide between those who can participate and those who cannot.

Ethical grounds can be used to argue that courses should be designed so that individuals with disabilities can fully participate. Many people simply consider it to be the right thing to do. Others are more responsive to legal mandates. The Americans with Disabilities Act (ADA) of 1990 requires that people with disabilities have equal access to public programs and services. According to this law, no otherwise qualified individuals shall, solely by reason of their disabilities, be excluded from the participation in, be denied the benefits of, or be subjected to discrimination in these programs. The United States Department of Justice clarified that the ADA applies to Internet-based programs and services by stating, "Covered entities that use the Internet for communications regarding their programs, goods, or services must be prepared to offer those communications through accessible means as well" (ADA Accessibility, 1996). It is clear that distance learning programs have a legal obligation to make their courses accessible to qualified students who have disabilities.

The following paragraphs give examples of access challenges faced by people with disabilities and present design considerations for assuring that a course is accessible to potential instructors and students with a wide range of disabilities. The field of universal design provides a framework for this discussion.

Barriers Encountered by Students with Disabilities

Specialized hardware and software products, often called assistive technology, allow individuals with a wide range of abilities and disabilities to fully operate information and networking technologies (Closing the Gap, 2001). However, assistive technology alone does not remove all access barriers. Listed below are examples of access challenges faced by students in typical distance learning courses.

Mobility Impairments: Some potential students may not be able to move their hands. They may use alternative keyboards, mice and/or speech input devices to gain access to Internet-based course content and communication. Sometimes people with mobility impairments do not have the fine motor skills to select small buttons on the
screen. If their input methods are slow, people with mobility impairments may not be able to effectively participate in fast-paced “chat” communications. Participants may face access challenges if place-bound meetings required in a distance learning course are not wheelchair-accessible.

Hearing Impairments: Most people who are deaf or hard of hearing face few challenges in accessing the Internet since most resources do not use sound output. However, when Web sites include audio output without providing text captioning or transcription, a student or instructor who is deaf cannot access the information. Course videotapes that are not captioned are also inaccessible to these students. They may also be unable to participate in telephone conferences or videoconferences unless sign language interpreters or other accommodations are provided.

Blindness: Individuals who are blind often use a computer equipped with screen reader software and a speech synthesizer. Basically, this system reads with a synthesized voice whatever text appears on the screen. They may also use a Braille refreshable display that presents screen text line by line in Braille with small plastic pins. To navigate the World Wide Web they may turn off the graphics-loading features of a standard Web browser. Students who are blind cannot interpret graphics (e.g., pictures, charts, drawings, image maps) unless text alternatives are provided for their speech output systems to use. Printed materials, videotapes, televised presentations, projected slides, and other visual materials also create access challenges for people who are blind. These barriers can be overcome with alternate formats such as audiotaped printed materials, Braille printouts, electronic text, tactile drawings, and audio descriptions or transcriptions for videotapes.

Low Vision and Other Visual Impairments: Students with limited vision can use special software to enlarge computer-generated screen images. Using this software, however, means that they may see only a small portion of Web pages at a time. Consequently, they can become confused when Web pages are cluttered and when page layouts change from page to page. Standard printed materials may also be inaccessible to them. They may require large print or electronic text that can be enlarged or accessed with a screen reader. When Web pages are designed in such a way that students must be able to distinguish between colors, individuals who are colorblind cannot successfully navigate the pages or understand the content.

Specific Learning Disabilities: Some specific learning disabilities impact the ability to read, write, and process information. Students with some types of learning disabilities may need to use audiotaped books. When accessing a computer, some use speech output and/or screen enlargement. They may have difficulty understanding Web sites when the information is cluttered, when confusing vocabulary or grammatical structure is used, and when the screen layout changes from one page to the next.

Speech Impairments: People with speech impairments may not be able to effectively participate in interactive telephone conferences or videoconferences. However, modes of participation, such as electronic mail and chat, that do not require the ability to speak, are fully accessible to them.

Seizure Disorders: Flickers at certain rates (often between 2 to 55 hertz) can induce seizures for people who are susceptible to them.

Principles of Universal Design

For some students, visual, hearing, mobility, speech, and learning disabilities can impact their participation in distance learning classes. If a course developer designs a course to maximize access as the course is being developed, fewer access challenges will arise when the course is offered. It is much easier to plan ahead than to create accommodation strategies once a person with a disability enrolls in the course. Simple steps can be taken to assure that the course is accessible to participants with a wide range of abilities and disabilities.

“Universal design” is defined by the Center for Universal Design at North Carolina State University as “the design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design.” (http://www.design.ncsu.edu/cud/univ_design/ud.htm) At this Center, a group of product developers, architects, environmental designers, and engineers established a set of principles to apply in the design of products, environments, and communication and other electronic systems. General
principles include: the design is useful to people with diverse abilities; the design accommodates a wide range of individual preferences and abilities; the design communicates necessary information effectively, regardless of ambient conditions or the sensory abilities of the user; the design can be used efficiently and comfortably, and with a minimum of fatigue; and appropriate size and space is provided for use by people with a wide variety of body sizes and physical skills. When designers apply these principles, participants can use their products and services with a wide variety of abilities and disabilities. The next sections provide examples of how employing universal design strategies can make distance learning courses accessible to everyone.

**Place-bound Instruction**

Some distance learning courses include interactive videoconferences, proctored examinations, and other on-site instructional sessions. In these cases, the facility should be wheelchair accessible and the furniture should be able to accommodate wheelchair-users. Accessible restrooms, telephones, and parking should be available nearby. Instructors should speak clearly; face students when speaking (to facilitate lip reading); and describe all visual materials (for those who cannot see them). Standard disability-related accommodations, such as sign language interpreters, should be provided when requested.

**Internet-based Communication**

In some distance learning courses students and instructors communicate via real-time chat systems, where, students and instructors communicate at the same time. Besides imposing scheduling challenges for everyone, this type of communication is not effective for people who type very slowly. This includes people with some types of learning disabilities and those using alternative input devices because of impaired hand use. Instructors who use such tools should be prepared to allow an alternate method of communication (e.g., e-mail) for students with disabilities. Text-based electronic mail, bulletin boards, and electronic distribution lists generally erect no special barriers for students with disabilities. E-mail communication between individual students, course administration staff, the instructor, guest speakers, and other students is accessible to all parties.

**Web-based Materials**

Applying universal design principles to the design of Web pages makes them accessible to individuals with a wide range of disabilities. In 1999, guidelines for making Web pages accessible were developed by the Web Accessibility Initiative (WAI) of the World Wide Web Consortium (W3C). Effective in 2001, the United States Architectural and Transportation Barriers Compliance Board (Access Board) developed standards for Web pages of Federal agencies as mandated by Section 508 of the Rehabilitation Act Amendments of 1986. Although the legislation is targeted at Federal agencies, the standards provide a model for other organizations working to make their Web pages accessible to the broadest audience. Both of these sets of guidelines can be found at Web sites listed at the end of this paper.

To make Web page content and navigation accessible, certain types of inaccessible data and features need to be avoided or alternative methods need to be provided for carrying out the function or accessing the content provided through an inaccessible feature or format. For example, a distance learning designer can avoid using a graphic that is inaccessible to individuals who are blind, or he can create a text alternative for the content that is accessible to the screen readers used by those who are blind. Web pages for a distance learning class should be tested with a variety of monitors, computer platforms, and Web browsers with the graphics- and sound-loading features turned off. Testing to see if all functions at a Web site can be accessed using a keyboard alone is also a good accessibility test. Special programs (e.g., A-Prompt, Bobby, WAVE) are available to test Web pages for accessibility.
Printed Materials

Braille, large print, audiotape, and/or electronic formats may be required by students who are blind or who have specific learning disabilities that affect their ability to read. Making the text of printed materials available on-line is a good solution for students who cannot read standard printed materials.

Video Presentations

It is best if videotapes or televised presentations are captioned for participants who have hearing impairments and audio described (that describes aurally the visual content) for those who are blind. If the publisher does not make these options available, the distance learning program should have a system in place to accommodate students who have sensory impairments. For example, the institution could hire someone local to the student to sign audio material for a student who is deaf. Real-time captioning (developed at the time of the presentation) or sign language interpreting should be provided when requested by participants in videoconferences.

Telephone Conferences

Standard telephone conferencing is inaccessible to students who are deaf. Instructors who use telephone conferencing for small group discussions could allow e-mail communication as an alternative. Students who are deaf may be able to participate in a telephone conference by using the Telecommunications Relay Service (TRS), where an operator types what the speakers say for deaf students to view on a text telephone (TTY) and translates printed input into speech, however this system might be too slow to allow participation in lively conversations. A similar videoconferencing system is available in some regions. Another accommodation involves setting up a private chat room on the Web. A transcriptionist types the conversation for the deaf students to view. Students can also type contributions into the chat room that can be voiced by someone monitoring the chat room.

Benefits for Everyone

Distance learning courses are designed to reach out to students no matter where they live and no matter what schedule they are on. If universal design principles are used in creating these courses, they will also be accessible to any students who enroll in them and any instructors who are hired to teach them, regardless of the abilities and disabilities. Applying universal design principles assists people with and without disabilities. For example, using clear language and navigational mechanisms on Web pages facilitates use by those whose native language is not the one in which the course is taught as well as people with visual and learning disabilities. People who have turned off support for images on their browsers in order to maximize access speed benefit when multimedia features provide text alternatives for the content, as do people who are blind. Similarly, people who cannot view the screen because they must attend to other tasks benefit from speech output systems that are often used by people who are blind. Captions provided on videotapes and video clips assist people who work in noisy or noiseless surroundings and people for whom English is a second language along with people who have hearing impairments. Making sure that information conveyed with color is also available without color benefits those using monochrome monitors in addition to those who are colorblind. When carefully designed, distance learning courses do not need to create a digital divide.

Abstract: This paper is a report on the findings from a study I conducted on the integration of multicultural education and computer-mediated communication (CMC). A qualitative approach was used to collect and analyze data. Analysis of the data allowed me to build logical connections of evidence in relation to the integration of multicultural education and CMC based on the recognition of a shared pedagogy. Parallelism in the pedagogies of the two areas—CMC and multicultural education—created a window of opportunity for unique practices and instruction. The outcomes are presented.

Introduction

Due to the features and innovative uses of computer-mediated communication (CMC), some educators (Appelbaum and Enomoto, 1995; Cummins and Sayers, 1996; McCormick, 1995; Riel, 1992; Roblyer, Dozier-Henry and Burnette, 1996) are exploring its significance to multicultural education. A popular perception is that because of its capabilities of linking, expanding, and interacting, CMC is an ideal technology for fostering some goals of multicultural education. Essentially, this ideal rests on a belief in the pedagogy that multicultural education and educational technology have in common. With a common pedagogy serving as the basis for the two, it is asserted that certain CMC practices can support certain practices in multicultural education while simultaneously, the principles of multicultural education can inform the educational use of CMC.

Damarin, in "Technology and Multicultural Education: The Question of Convergence," (1998) compares electronic pedagogies with emancipatory pedagogies, concluding that the two are parallel. Damarin ascribes the parallelism to two primary ideas:

1. the rejection of student accumulation of preselected facts as the driving mode of education and
2. the assertion that the social organization of the classroom must change in ways that not only displace the authority of the teacher as a dispenser of all valuable knowledge but also disrupt the traditional hierarchies (pre)determining who succeeds in school (p.17).

Damarin provides the following table to illustrate the parallelism of the two pedagogies which allow them to support each other.

<table>
<thead>
<tr>
<th>Emancipatory Pedagogies</th>
<th>Electronic Pedagogies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reject 'banking system' of education</td>
<td>Knowledge shared by student and computer-based resources</td>
</tr>
<tr>
<td>Decenter the teacher</td>
<td>'A guide on the side, not a sage on the stage'</td>
</tr>
<tr>
<td>'From margin to mainstream'</td>
<td>Recognized multiple ways of knowing</td>
</tr>
</tbody>
</table>
The parallelism portrayed in Damarin's table illustrates a "pattern of consistencies and sameness across areas of practice that do not share common elements" (p. 18). Damarin contends that these consistencies can create a window of opportunity for practitioners (including instructional developers, curriculum planners, and teachers) who focus on educational technology to join those who focus on equitable multicultural education in an effort to define and devise curricula and activities that serve their common purpose. (p. 18)

This window of opportunity created by the consistencies between the emancipatory pedagogy of multicultural education and the electronic pedagogy of CMC was the starting point for this study.

The Study

Through this particular window of opportunity, multicultural education and CMC were brought together to foster an on-line forum. The on-line forum, purposed to facilitate discourse construction on critical pedagogy, supplemented a graduate English course on U.S. multiculturalism and the composition curriculum. The nine graduate students enrolled in the course interacted, via web conferencing, with five experienced teachers. While the graduate students were located at a predominantly white university in the mid-west and had little experience teaching students of color, the experienced teachers were located in different cities throughout the U.S. and taught courses whose enrollment was predominantly that of students from underrepresented groups.

The objectives of this setup were to help students prepare to address the demands of educational reform, engage in collaborative critical inquiry, and make reflective decisions regarding multicultural education pedagogy in the composition curriculum. By helping to overcome time and space boundaries between students and teachers, CMC was employed to facilitate a democratic environment where

- the participatory construction of discourse could take place among the graduate students and experienced teachers;
- attention would be devoted to the practices of experienced teachers so that educational research could be linked with reflective practices;
- and students and experienced teachers would collaboratively develop materials and activities that promote a critical pedagogy for composition classes.

A qualitative approach was used to collect and analyze data. Data were collected through the transcripts of the on-line discourse, audio-taped interviews conducted at the end of the course, field notes, course artifacts, and user profile information (provided by the web conferencing system). Because CMC is a medium of medium of written discourse, the online activity was archived and then the written exchanges observed. Also, interviews were conducted using Anderson and Jack’s (1991) interview and analysis techniques which entail shedding greater agendas of convention and listening for meaning in the participants’ moral languages, meta-statements, and attending to the logic of the narrative. Analysis of the data allowed me to build logical connections of evidence in relation to the integration of multicultural education and CMC.

Findings

Patterns of interactions and exchanges relevant to the philosophy, purpose and objectives of the course emerged. They can be categorized into two types of interactivity and interactions: designed and unplanned.

Designed interactions corresponded with the objectives of the course and electronic forum. These exchanges were required of the students and experienced teachers and were mediated, usually prompted by a general question to everyone. For example, to prompt discourse among the participants concerning linguistics issues, the instructor posted the following questions: "Should students have the rights to their own languages? And what are the implications?" Such was done
to stimulate dialogue, critical thinking, and reflection on pedagogical practices concerning issues of linguistics. Designed interactions were further categorized into the following:

1. Establishing Presence, designed to unveil the backgrounds, experiences and perspectives of the participants, and which was essential to constructing discourse informed by multiple perspectives;

2. Linking Educational research and reflective practices, which allowed students to compare critical theory with the practices of the experienced teachers; and

3. Collaborating and Sharing, where participants asked questions, raised issues, and shared ideas about resources, materials and activities.

Unlike designed interactions, unplanned interactions and exchanges were not mediated, prompted, nor necessarily anticipated. However, when the transcripts were analyzed, unplanned interactions appeared to be just as significant to the relevance and application of the forum as the designed interactions. These interactions seemed more democratic because the students initiated them. There were three categories of unplanned interactions and exchanges:

1. Responding to Course Readings, in which students introduced, commented on, and asked questions about specific topics and issues from the course readings that were of specific interest to them;

2. Supplementing In-class Discussions, where students revisited and elaborated on in-class discussions; and

3. Lending Personal Testimonies, where participants went beyond sharing professional practices and academic thought and revealed personal narratives making potentially abstract participants become more personable and human.

Evident in unplanned interactions and exchanges is the participants' interest in and invested ownership of the forum.

In this particular window of opportunity, the consistencies between the emancipatory pedagogy of multicultural education and the electronic pedagogy of CMC provided a concrete foundation for determining the purposes, structure, and activities of the on-line forum and a unique environment for supporting them. Through interviews, the participants reported that their on-line experience stimulated thinking, provided models and ideas, and added legitimacy to the importance of gaining multicultural scholarship. Essentially, they welcomed this opportunity.

While the consistencies between the two pedagogies supported this unique window of opportunity for the participants, interpretations of their experiences shed light on issues and limitations that stem from the elements that multicultural education and CMC do not have in common. Three major issues emerged as participants described their experiences.

1. Equitable Access. CMC was used to access the perspectives of educators who are currently immersed in issues related to the course content, but because of time and distance were inaccessible. However, technological inequality permitted only those privileged with Internet access to participate. Equitable access research shows that Internet access is available less in schools with large numbers of students of color and of low-economic status than in schools whose students are predominantly white and who are of high economic status (Doctor, 1992; Leigh, 1999; Novak, 1998; Romiszowski and Mason, 1996). Therefore, the on-line discourse was shaped by the perspectives of those teaching in environments that are predominantly white while the perspectives of those teaching where there are large numbers of students of color did not have the opportunity to contribute.

2. Software Capability and Design. Also, interviews revealed that participants that did not possess the skills to overcome technical difficulties seemed to remain on the periphery of participation. Consequently, the central members of the forum were those who are technologically proficient. CMC is not for the "technically timid" (Ruberg and Sherman, 1992). One of the participants stated: "Why can't we use the software to reconstruct race relations...? Well, because the only software available for us to do that is too difficult..."
3. *Electronic Atmosphere.* Furthermore, because of its absence of nonverbal status cues, CMC is noted to render a democratizing effect on communication and discussions (Harasim, 1993). However, according to participants' interpretations of their experiences, the exclusion of nonverbal status cues seemed to contribute to a falsified, abstract, imperceptible community where they did not feel totally comfortable with making proclamations, rendering judgment and sharing beliefs and practices. Such a community can have an ostracizing effect on participants who don't feel they meet with the perceived conditions of the forum's environment.

**Conclusion**

Traditionally, the agendas of multicultural education and technology have been pursued separately. However, as evident in this study, parallelism in the pedagogies of the two areas creates a window of opportunity for unique practices and instruction. Integrating multicultural education and CMC allowed us to create an environment where unique learning opportunities were available. Graduate students were able to correspond with teachers who were immersed in the issues outlined in the course. Together the participants constructed discourse on critical pedagogy in composition, and shared and developed resources and materials.

While parallelism in the pedagogies of multicultural education and CMC provide opportunities, the elements that they do not have in common can leave a gap in activities and practices. As shown in this study, the limitations or shortcomings of this particular integration of multicultural education and CMC were related to the socially and culturally based assumptions of technology designers, developers, and implementers (Damarin, 1996). Future integrators should seriously consider issues of equitable access, software design and compatibility, and the abstractness of the electronic atmosphere as they influence participation.

Abstract: For several decades video technology has been used in teacher education for self-improvement, assessment, students feedback and various other purposes. Digital video technology allows teacher educators to videotape snapshots in urban schools that capture student and teacher demographics, teacher-student interactions, collaborative, flexible grouping of diverse student populations, best practices in teaching, and general characteristics of urban school settings. Selected digital video clips can be integrated into the course curriculum by teacher educators to explore urban culture as the dominant form of community life in contemporary schools. The edited video clips can be disseminated to all students via the Internet, CD-ROMs or videocassette formats. The students in the SOSE3306 Culture of Urban Schools course can view the video clips for discussion and reflection with the entire class. The paper will discuss how a collaborative relationship between an ISD and a University helped design and develop an online Multicultural Education course using a field-based approach and digital video technology. The topics of the paper include: the collaboration of the ISD and the University Teacher Education Program, planning and scheduling the use of digital video, video taping sessions, selecting of clips, matching the clips with the curriculum and schedule, and final dissemination of the clips via CD-ROMs.

Introduction

Many teacher education programs offer at least one course on multi-cultural education with a strong emphasis on authentic experiences and exposure to different school cultures and ways of thinking. However, delivering the multi-cultural education course over the Internet while maintaining the same degree of rigorous critical thinking is a considerable challenge.

Beginning from Spring 2002, students taking the online Web-based course SOSE 3306 at the University of Houston Downtown thus assemble a realistic snapshot of urban school settings in the greater Houston area. Typically students at UH-D come from diverse backgrounds: some are current school teachers while others are traditional undergraduate students; some grew up in another country and culture, while others graduated from high school some time ago and become teachers as second careers. It is important to provide a realistic perspective on current urban issues in public education for those entering the teaching profession.

In looking for a good model for online discussion when designing the WebCT online course, SOSE 3306 Cultures of Urban Schools, the authors incorporated the Critical Friends Group (CFG) principles into the various field-based technology activities of the course. One of the designers of this course has worked with CFG for over a year and is also teaching educational technology courses. The other designer of the course is the Director of Field Experiences for the Teacher Education Program at UHD. The online course is offered for the first time in Spring 2002 with maximum of 25 students. The purpose of the paper is to explain how technology is used to enrich students' early field-experiences and how CFG processes have been implemented into the interaction of the online course.

Early Field Experiences

Through field experiences, teacher candidates observe and work with real students, teachers, and curriculum in the natural settings of K-12 schools. Common sense alone dictates that pre-service teachers who participate in field experiences in school settings are better prepared to understand and deal with the complex realities of today's schools, classrooms, and students.
The rationale for field experiences in teacher preparation is grounded in the work of John Dewey (1904; 1938). He was a strong advocate for the experiential training of teachers. Dewey viewed the teacher as learner, and thus the need for that learner to be provided experiences for constructing his or her own learning.

A study conducted in Texas (Fleener, 1998) provided evidence that candidates who receive increased amounts of field experiences in their teacher preparation programs are retained in the profession at significantly higher rates than those prepared through traditional campus-based programs.

According to nationwide survey results, the vast majority of teacher candidates first engage in field experiences prior to their junior year in college. A total of 77% of elementary programs and 70% of secondary programs require candidates to first participate in field experiences in PK-12 settings during their first or second year of college (Huling, 1998).

Field experiences prior to the student teaching experience are commonly referred to as early field experiences. Teacher candidates participate in early field experiences in a variety of schools and classrooms. In elementary preparation programs, according to Huling (1998), 77% of the candidates work in more than one PK-12 setting while 73% of secondary candidates participate in early field experiences in more than one PK-12 setting.

The online course SOSE 3306 which is a prerequisite course to the field-based "blocks," attempts to provide students, who are typically juniors, with early field experiences. Instead of participating in lectures in a university classroom, the intention is for students to watch interviews, classroom snapshots via technology, and conduct investigations by physically visiting and conducting local school investigations. In designing the course, the CFG model has been integrated by the authors’ into the course activities.

The Professional Development Model of Critical Friends Groups

Critical Friends Groups, although practiced in K-12 for some years, has only recently been incorporated into higher education through coach training. For several years, the National Coalition of Essential Schools and The Annenberg Challenge Institute have devoted efforts into formalizing an approach to school staff “self-analysis,” through a program called “Critical Friends Groups,” or CFGs

CFGs are the product of a simple idea: providing deliberate time and structures to promote adult professional growth that is directly linked to student learning. A CFG consists of eight to twelve teachers and administrators who agree to work regularly together to define and produce improved student achievement. As a group, the members establish and publicly state student learning goals, help each other think about better teaching practices, look closely at curriculum and student work, and identify school culture issues that affect student achievement. Each CFG chooses a coach who is selected either from the school staff or from the ranks of trusted outsiders. The coach helps the group build the sense of trust that must exist if they are to work together in a direct, honest, and productive way. The coach also helps the members learn and master techniques that sharpen self-insight, promote creativity, and encourage candid, usable peer feedback.

(www.harmony.pvt.k12.in.us/www/CFG_Process.htm, accessed on Dec 15, 2001)

To summarize, a CFG is a group of six to twelve educators working with students everyday within a school or district who meet on a regular basis to explore and change their teaching practices in order to improve student learning. More and more schools and districts are using “CFG processes” in other settings as well, such as in staff meetings, in-service workshops, cross-school study group meetings, administrator’s meetings, and department and team meetings, etc. Most CFGs in the Houston area meet on a monthly basis to share teaching practices, collaboratively examine student work, and reflect on how teaching practices impact student learning. Participants also engage in regular peer classroom observation and occasionally discuss readings to inform their reflections and practice.

Administrative Aspects of the Online WebCT Course

The following WebCT features have been employed to facilitate Critical Friends Groups (see Figure 1):

Syllabus: A syllabus is used to inform students of the general course requirements.
Welcome Page: This page is sent out to the students' personal e-mail addresses prior to the semester to greet the students. It is also included in the course homepage for review purposes.

Classroom Norms: Students taking online courses have special challenges such as new classroom rules, due dates, correspondence, emergency contact methods, interaction with peers, etc. These pages attempt to explain the classroom norms so that students are more comfortable and confident and so that they can have a rewarding learning experience.

Calendar: Since the online students may not come to the University campus at all, they may not be familiar with the university routine. The calendar informs them of the scheduled readings, assignments, due dates of major project, etc. using a format for weekly work.

Bulletin Board: To encourage virtual interaction, the electronic bulletin board function is also used. All bulletin board topics are referred to by week number to assist students in locating the area and content for a specific week.

Course Module: The course module feature of WebCT has been modified as the Table of Contents. This starts with general instructions for the week and displays weekly activities below the weekly introduction as explained in the following section.

WebCT Mail: The WebCT Mail is used for instructor-student and student-student correspondence. Some projects are received as e-mail attachments.

The Content of Course Modules

The Table of Contents (or Course Module) serves as the major point of contact for students' work on projects (see Figure 2). Each week starts with an Introduction that informs the students what to work on and how to complete the assignments. This is unlike the lecture-type format and attempts to integrate the messages and lectures into the various projects. Under weekly titles, project descriptions together with handouts in digital format (HTML, MS Word, RTF) are posted. Since this is a projects-based course, each week the students have to complete 2-4 projects. Some projects are as easy as reading a short chapter and posting comments through the mail, while others are more complex, semester-long projects that require investigation of the topic by interviews, Web searches, observations, team collaboration, etc.

Technology Field-Based Activities: The school district requires that Internet use and image consent forms be signed by parents to release snapshots of students for instructional purposes in university classes. Through the University's collaboration on the Partnership for Quality Education (PQE) project, the Department of Urban has these parent consent forms for taking video snapshots of students on file. The classroom snapshots were taken in natural classroom settings (see Figure 3). The content of the activities was natural and was not pre-arrange for the videotaping. The teacher interviews were also taken in the teacher lounge, again, to provide a natural setting for student understanding (see Figure 4).

Critique of Classroom Activity Snapshots: At the beginning of the semester, students in the online course are provided with video clips in PowerPoint format on the course CD. The classroom snapshots range from two minutes to seven minutes. The video clips include classroom activities taken in a local urban elementary school. Students watch the video clips and evaluate the classroom activities by applying the five dimensions of multiculturalism discussed in the Banks' book. They post their critique on the electronic Bulletin Board. To encourage students to refer back to the textbook, the five dimensions of multiculturalism are used as a framework. The five dimensions of multiculturalism include 1) Equity Pedagogy, 2) Prejudice Reduction, 3) Empowering School Culture, 4) Content Integration, and 5) the Knowledge Construction Process. The text-based discussion principle of CFG, reminds students to refer back to the exact page or section in a text to enhance communications and understanding of the text. When critiquing the classroom activities, the students are required to give exact examples of what they have seen to support their argument or point. The online posting activity is a good model for critical thinking, interactive online discussion, and CFG. Other CFG discussion principles were built into the electronic Bulletin Board activities as well.

Developing Reflective Practitioners: Reflection is a strong emphasis of CDF. On the same course CD, there are interview clips of four teachers of different genders, years of teaching experience, teaching subject areas, and cultural backgrounds. The interviews range from two minutes to seven minutes. For each teacher interview, the students are to complete a rubric that asks them to gather information from the snapshots about the teachers' background, examples of teachers' cultural shock when they first started teaching in urban schools, and teaching
strategies for different learning styles. The rubric ends by asking the student to reflect on which are the most touching remarks and why, what they agree and disagree with, and other aspects of the teacher interviews.

Critical Friends Groups Implications: Strengths and Weakness

Nationally, CFG is one of the approaches used in providing professional development in schools learning communities (http://www.usm.maine.edu/smp/projects/cfg.html). The National Commission on Teaching & America's Future (1996) has recommended that future teachers have more rigorous preparation and more authentic field-based experiences to enable them to cope with the increasing complexity, challenges, and diversity of current schools and classrooms. What has been advocated is a more holistic conceptualization of the preservice teacher experience and increased collaboration between universities and public schools (Guyton & McIntyre, 1990). This class CD used for technology field-based is a exactly a product of increased collaboration between universities and public schools.

Given the technological scenario for the future that has just been painted, it is fair to ask whether such future systems are capable of delivering an appropriate level of quality of teacher preparation. Research on distance education by and large has shown that, when appropriately planned, distance education can be as effective as conventional classroom based education. While there are some exceptions in terms of certain types of content or certain groups of students, the move towards integrated multimedia networking may be expected to extend the range of effective distance education applications (Collis, 1991).

Abstract: The digital divide encompasses not only race and socioeconomic status, but gender as well. The gender gap in technology is a result, in part, due to biased software that has been made accessible to females. This paper will provide a brief history of the gender gap in technology, review the available literature on gender-biased software, and explore the ramifications inherent in its use. In addition, recommendations will be offered that are designed to assist teachers in selecting and implementing gender equitable software into their classrooms.

Although technology is playing an increasingly important and omnipresent role in our society and the world, inequities continue to exist in access and manner of use within various groups throughout society (Clark & Gorski, 2001). Race, ethnicity, age, socioeconomic status, education, disability, language, and gender are factors associated with what is called the Digital Divide. Initially, the Digital Divide was primarily related to a lack of access to technology, but more recently the Divide has been further deepened by disparities in technological usage (Clark & Gorski, 2001).

Since the early 1980s, much research has been conducted on the existence of the gender gap in technology, which continues to be a pervasive and persistent problem (AAUW, 2000; Fiore, 1999; Gehring, 2001; Koch, 1994; Mark, 1993; Sanders, 1993; Sanders & Stone, 1986). The gender gap is evidenced at home, in schools, throughout media and society, and in the workplace. A number of complex factors are attributed to the gender gap in technology. There are psychological, social, attitudinal and environmental components that work in concert that affect females’ attitudes, interest, and use of technology (Mark, 1993). Females receive inadvertent and implicit messages that the computer is not for them, and avoid it accordingly. As a result, females suffer from lower self-confidence about their technological abilities as well as a lack of self-esteem (Sanders, 1993). Furthermore, this lack of experience leads to negative attitudes toward and disinterest in technology-related endeavors, both of which have serious implications for females’ educational and professional opportunities. As the number of jobs in technology-related fields grows exponentially, the opportunities for women to participate in that field will be decreasing. The end result of the gender gap is that women will be ill prepared for a world that is becoming increasingly technological (Sanders, 1993). Because technology permeates society in numerous ways, it is imperative that issues of gender equity in technology be confronted and resolved.

Factors contributing to this gender difference are perhaps the most important part as well as the most difficult part of achieving technological competence. As stated earlier, studies have shown that computers are more attractive to boys than to girls and the literature reports several factors that might attribute to the gap in both access and usage. In many cases, both electronic games and home computers are the primarily vehicles of entertainment for children. Unfortunately, these vehicles reveal stereotypes and promote misrepresented conceptions of gender roles that can lead to a gender gap in technology.

While the video game business has grown to become a $10 billion industry in the United States, it remains an industry overwhelmingly geared to and supported by men and boys (DeBare, 1996a). Industry analysts estimate that no more than 30 percent of all video game players are female (DeBare, 1996a). The reason why these numbers are so low, is because video games are not being created to interests girls. Studies have shown the digital divide within gaming started in video arcade back in the early 1980s and has continued to exist today (Kiesler et al., 1985; DeBare, 1996a). These studies addressed issues and implications related to girls’ interest in electronic games, preferences of software and their opinions on using technology either as a source of education or as entertainment. Although there was evidence of girls’ genuine interest, there emerged themes of misrepresentations or misconceptions of the use of computers.

As there has been concern to games being a product to widening the gender gap in technology use, there also has been concern toward educational software. Over a decade ago, only a few educational software programs were being developed, but times have changed. Everybody is making software, which includes interactive storybooks, multimedia reference works, animated adventure games; and application type programs,
word processors and spreadsheet programs. Some educational software incorporates simulations or exploration and others are designed to teach and/or drill specific facts or academic skills. Whatever the technique, it is crucial that software designers understand the way children view gender and work to develop software that does not perpetuate gender stereotypes or bias. The literature shows supportive evidence that educational software, as do games, is presented in a format that adheres to violence and war and more traditional male sports (Lepper & Malone, 1987; Chappel, 1996).

In addition to games and educational software, gender bias exists in clipart programs. In the past, researchers have investigated media images harmful to females in media and instructional materials, (e.g., textbooks), and have looked at the quality and content of pictorials and content in written instructional materials. As technology becomes more pervasive both in our classrooms and in the business world it is important to examine for any gender disparities that might exist in computer software. Researchers are turning to analyzing images from art files in software programs for evidence of gender bias (Dyrud, 1997; Milburn et al., 2001). Dyrud (1997) examined over 14,000 clipart images in different Windows-based programs and found that only 4.54% of the total images depict women and they are typically represented in stereotypical roles, e.g., secretaries, nurses, and teachers. In addition, Milburn (2001) investigated two top-selling computer clipart packages and found that more males were shown in more diverse/active roles than females, which again perpetuates misperceptions of gender roles, as females taking a more passive role versus the males being more assertive.

The world of computing is inescapable and inextricably tied to children’s socialization. As it is the responsibility of educators to help reduce the bias that exists within accessibility of use and the software that is available for children, it also lies with society as a whole. Beginning in the early years of females’ lives, equitable software needs to be introduced to generate interest in technology. In order to improve the situation, open-mindedness must be encouraged and the cultural stereotypes, which perpetuate the inequalities, must be eliminated. By increasing the number of women in the computing field, this will encourage young females and other women to pursue the profession. Unless issues of equity and fairness are promoted, females will continue to be at a disadvantage in an increasingly technological world, which will have serious repercussions for the world itself.

“Crossing the Great Divide”: A tale of inequity

Long ago in a faraway, harsh, and barren land lived two groups of troll-like beings known as the Binefs and the Uninefs. How these creatures came to inhabit this land had long been forgotten and the history of how the Binefs came to rule over the Uninefs was similarly lost to both groups. The feeling was, especially among the Binefs, that this was how things always were and how things should, in fact, be. The two-headed Binefs believed themselves to be superior in every way to their one-headed ‘cousins’, the Uninefs. This inferiority myth was passed on from generation to generation and was widely accepted by both groups of Nefs. In fact inferiority myth justified many things, especially the enslavement of the Uninefs by the Binefs.

The land inhabited by the Nefs was hard and rocky and required brutally intense labor and much sweat and toil to prepare the soil for food production. The Uninefs worked in the fields year after year, generation after generation, planting and harvesting food for their masters, receiving only leftovers for themselves. This food, called knowledge, had in fact been altered under the direction of the Binefs and a hybrid was created. Hybrid knowledge food could only be easily digested by the Binefs, and since it was the only legally produced food in the land, it left the Uninefs in danger of starvation. The enslaved Uninefs did manage to sustain themselves, but their inability to fully digest the food took a toll on their physical abilities. Even those Uninefs who had not fully accepted their alleged inherent inferiority, were weakened after years of compromised nourishment and were unable to effectively resist and win out over the Binefs.

The ancient land of the Nefs lay south of an enormous chasm referred to as the Great Divide. Nef mythology held that the northern border of their land marked the end of the world for physical beings and further claimed that the lush green land on the other side was occupied by gods and goddesses. Many Uninefs had plunged themselves into the chasm in attempts to escape their oppressive existence while numerous Binefs perished in their attempts to discover a means of crossing the divide. However, after countless failed attempts, the Nefs were successful in developing a mechanism for reaching the mythical lands. Of course the tools needed to make such a journey were initially available only to the wealthiest of Binefs and to none of the enslaved Uninefs. After all, there was no reason to provide for the escape of the ruling Nefs’ free labor. In addition, because of their compromised diet, the enslaved Nefs were physically weaker than their masters and unable to endure the long, arduous journey across the Great Divide.

The Binefs were truly amazed at what they found in the mythical land of the northern region. To them, the fertile rich soil was truly enchanting and magical. With little effort they grew fields and fields of their hybrid knowledge crops and the new settlers flourished without the help or need of slave labor. They became comfortable and fat. The passing years brought new groups of Nefs to the region and, in addition, many generations were actually born in the land north of the great chasm. Most Nefs of any means had long ago escaped the southern region, leaving that harsh land primarily to the Uninefs, who, incidentally, had been freed from slavery as a result of the massive migrations of their masters. A few Uninefs did manage to make it across by hook or crook, but for the most part, though free, the Uninefs were physically too weak to make
the journey and still lacked access to the mechanisms, regardless of how rudimentary or advanced, necessary to venture across the chasm. The small number of superior Binefs that remained in the harsh southern region did so also because of economic reasons. After all, not all ancient Binefs had been wealthy slave owners, just most.

The Nefs that tilled the rich soil of the northern region began to take pride in their labor and accomplishments and soon forgot how they eschewed such work in their ancient lands. These new generations of Binefs, in fact, put a high value on hard work and rugged individualism. Moreover, they publicly claimed to have put aside their feelings of superiority over the few Uninefs that were living among them or the many that remained in the barren southern region. Furthermore, they claimed no responsibility for how their ancestors had enslaved the Uninefs and had treated them badly. The fact that generations of Uninefs, though few in number compared to the Binefs, were flourishing as their neighbors was evidence that past enslavement or ill treatment was no longer of any consequence. Even the Binefs that held on to the ancient inferiority myth had come to believe that it was wrong to enslave fellow Nefs. But all that was in the past and this was a new time and day. It was widely believed that any Nef with the wherewithal could escape the southern region and was free to work the rich soil across the divide. In fact, for those who still held fast to the inferiority myth, the large numbers of Uninefs that failed to make the journey or who perished in their attempts was further proof of their inherent inferiority.

Even after Uninefs on either side of the divide were free to produce food crops of their choosing, they continued to plant and harvest only the hybrid knowledge food. This was all they knew. Though this food still was not easily digested by Uninefs, over time their systems began to accommodate it more readily. Having adequate amounts of food that the rich soil so graciously yielded and being released from the rigors of slavery allowed the Uninefs to gain physical strength. These Uninefs who had an abundance of hybrid knowledge food did, however, discover some side effects not reported by their enslaved ancestors. After ingesting a full meal of hybrid knowledge they would experience hallucinations wherein negative, grotesque, and often demeaning images of themselves and fellow Uninefs would appear. At other times they would recall or have visions of life south of the divide as being just, democratic, and ideal. Still yet, if they overate or indulged in extremely rich varieties of the food knowledge, they would have bouts of amnesia about the past life of Uninefs and forget about their brothers and sisters still residing south of the Great Divide. When they relayed these strange incidents to their neighboring Binefs they found that, generally speaking, the Binefs felt and thought that way much of the time. Binefs viewed the negative visions and images of Uninefs and the altered recollections of the past (or the lack of recollections) as normal and healthy. In fact, they credited the food knowledge for keeping things in perspective and for keeping their thinking in line with reality. In any case, the Binefs believed that the past was not so bad after all and, even so, why dwell on the negative.

Hybrid knowledge crop production became as important in the northern region as it had been in the south. It continued to be the economic base for Nef societies and ultimately gave rise to experts who, in later years began to focus their attention on the tools and means of crossing the divide. After all, it was obvious to all, crop experts included, that the rich northern soil produced the hardiest crops. Yet many Nefs remained stranded in the ancient lands and needed to avail themselves of the opportunities that
awaited them elsewhere. The most radical of northern Binefs and Uninefs wanted to close the divide altogether. They believed that the ravages of slavery, poverty, and/or poor diet and health had taken its toll on the southern Nefs, especially the Uninefs, leaving them unable to recover well enough to cross the divide. However, this was a radical view held only by a small number of northern Nefs who had not been affected so profoundly by the amnesia inducing knowledge. They remembered the strength-sapping labor that most ancient Uninefs endured and acknowledged the fact that no Nef would have had the strength or resources to cross the divide and explore the mythical lands without the benefit of slave labor. They argued that all generations of Nefs owed a great debt to the enslaved Uninefs of past ages and believed one way to repay the debt was to close the divide, making the journey to the fertile northern lands easy for the feeblest of southern Nefs. But because the Great Divide was ever so expansive, their ideas were dismissed as illogical, impractical, and, most of all, too labor intensive. Most of the northern Nefs, on the other hand, who voiced concerns about their brethren in the southern region looked for other ways to allow them to share in their bounty. Special groups of these crop experts across the northern region would travel miles and miles to council meetings concerning the theory and practice of crossing the Great Divide. However, despite their best rhetoric, nothing really changed from year to year. This is not to say that some Nefs did not benefit from the concerns and efforts of their cousins to the north and succeeded in journeying over the chasm. The overwhelming majority of Uninefs remained in the harsh land of the south while more of the unfortunate southern Binefs were able to make their escape. In either case, the most robust of the Binefs and Uninefs were able to take advantage of the opportunities and aid offered by the northern council. The departure of the strongest Nefs increasingly left the burden of southern crop production on the weakest Nefs. The Uninefs that were repeatedly left behind because of their lack of physical strength continued to struggle with the unrelenting soil to produce the hybrid knowledge food that, unknown to them, served to keep them in a weakened state. Their systems never had a chance to adapt so they were unable to gain the strength that the fortunate few northern Uninefs enjoyed. But despite the lack of progress in remedying the situation and because of the historical amnesia that flourished in the northern lands, the Nef council continued to meet year after year and talk about the unfortunate conditions that continued and were worsening in the ancient lands, proposing new and innovative means of transporting the southern Nefs across the Great Divide.

Deconstructing the Divide

Critical Race Theory maintains that racism is endemic and pervasive in American society to the extent that all but the most blatant, egregious racist behaviors and attitudes are considered normal. Thus, Critical Race Theorists, most notably Derrick Bell (1987) and Richard Delgado (1995), have used storytelling to bring into focus issues of race and racism in American society. The use of allegory allows the reader to view all too familiar issues and situations from new angles and perspectives. In ‘Crossing the Great Divide’ the author uses allegorical storytelling to illuminate issues of racial inequality in the United States and to explain why the gaps in educational opportunities, including access to information technology, persist into this century. In this story, the Uninefs are faced with these insurmountable gaps in the form of a vast and expansive chasm. This chasm represents the enormous inequalities in access to information technologies that exists between racial, ethnic and social-economic groups; a phenomenon that has come to be
known as the digital divide. However the chasm or Great Divide is also a symbol of the many inequities that began and were nurtured long before the information or digital age. This immense chasm represents an ‘analog divide’ wherein historically disadvantaged racial groups, specifically Black Americans, have been denied equal access to economic and educational opportunities. Thus the stage was set for the digital divide, which widened the gap or compounded the problem, once this nation and globe passed into this age of information technology. One cannot understand why the Uninefs in this allegory are unable to cross the divide without understanding their history of oppression. By the same token, one cannot effectively address issues digital inequity as it pertains to African Americans without understanding the history of their oppression and how that oppression initiated and continues to support and foster inequalities in educational opportunities and achievement. One cannot in fact offer viable, long lasting solutions to the digital divide without seriously looking to alter attitudes and institutions in the general society. There is little hope of closing the digital divide while leaving the analog divide untouched.

The hybrid knowledge food represents a dominant epistemology that is riddled with theories of inferiority and consists of a body of ‘knowledge’ and ‘truths’ that support the superiority of the dominant group. African Americans have had a steady diet of education grounded in this dominant epistemology that has served to influence their views of themselves. In “The White Architects of Black Education”, Watkins (2001) describes the role of philanthropies in the establishment of Black educational institutions not long after slavery was abolished. He maintains that some of the most influential philanthropic organizations served to maintain the social order that found Blacks at the bottom. Blacks schools were used as instruments of social engineering wherein the curriculum prepared students for occupancy of the lower layers of society only. Furthermore, the curriculum was absent of any African history or experiences that would engender a sense of pride in the African American student. In his work concerning reparations, Robinson (2000) states, “[f]ar too many Americans of African descent believe their history starts in America with bondage and struggles forward from there toward today’s second-class citizenship. The cost of this obstructed view of ourselves, of our history is incalculable. How can we be collectively successful if we have no idea or worse, the wrong idea of who we were and, therefore, are? We are history’s amnesiacs fitted with the memories of others…. America’ contemporary racial problems cannot be solved, racism cannot be arrested, achievement gaps cannot be fully closed until Americans—all Americans—are repaired in their views of Africa’s role in history. (p. 16)."

Like the Uninefs in the tale, African American children know little about their history beyond enslavement and therefore cannot truly understand the predicament they are in. Their history and even their oppression is blatantly left out of American art and history. There is little to comfort them in their struggles. There is no past to take pride in or to foster self-esteem. Furthermore, they have little to counteract the negative images of themselves and their innate abilities that have been ingrained for decades, even centuries, by means of their educational experiences. Robinson further states, “Blacks and no less whites, need to know that in centuries preceding that Atlantic slave trade and the invention of a virulent racism to justify it, the idea of black inferiority did not exist (p. 17)”. However a dominant epistemology that supports racism and inferiority theory severely alters and omits the accomplishments of those from oppressed groups and the
history of their oppression that would explain why they fall short in almost every measure of economic and educational achievement. Many Black Americans are trapped in the most impoverished urban areas in this nation without truly understanding the ongoing effects of slavery and the social and economic discrimination that followed slavery and prevented the escape of all but a relative few. Wilson (2001) states, “[o]ne of the legacies of historic racial and class subjugation in America is a unique and growing concentration of minority residents in the most impoverished areas of the nation’s metropolises (p. 15)” He further explains that “[i]f large segments of the African-American population had not been historically segregated in inner-city ghettos, we would not be talking about the new urban poverty (p. 23). However, according to Wilson, segregation alone does not explain the emergence of what he defines as the new urban poverty. “I mean poor, segregated neighborhoods in which a substantial majority of individual adults are either unemployed or have dropped out of the labor force altogether (p. 19).” Job discrimination, residential segregation, public policy that allowed for the concentration of low income housing, in addition to the absence of effective labor-market policy have all contributed to blight of the inner city and the continued entrapment of the ghetto resident. Like the weakened Uninefs who were unable to journey into the mythical northern regions, many African Americans are living in a cycle of poverty without the resources or strength to pull themselves up the socio-economic ladder. They attend poorly funded schools, with poorly trained teachers, and with uninspired curricula. They are not told that they are the victims of decades institutional racism that created their dire situations. Rather they are told to look to the growing Black Middle Class as proof that it is possible to ‘be anything you want to be’. The message is that failure to achieve means one is inherently unable to achieve. How else would one explain the incredible numbers of African American children that find themselves in impoverished homes and who fail or drop out of school. If a history of racism and truncated opportunities do not account for the schools described in Kozol’s (1991) “Savage Inequalities”, then inferiority theory must. That is the message that poor African American children are ingesting and internalizing daily. The analog divide must be faced for what it is and American institutions challenged to accept responsibility for closing gaps that they were complicit in creating. The fact remains that most minority children attend schools with high minority enrollments and often scandalously absent resources. Educators interested in closing the digital divide for some of America’s poorest and most despised children should perhaps first look at the true source and nature of the problem. If one cannot or will not get to the root cause of a problem, it is unlikely that one will uncover the most effectual solution.

Bridging the Digital Divide: A School’s Success Story

Edmundo F. Litton
School of Education
Loyola Marymount University
United States
elitton@lmu.edu

Abstract: This study is meant to contribute to the discussions on the digital divide. The goal of this project was to study the role of technology in the educational experience of diverse learners. "Diverse learners" in this study refer to students who share one, two or all of the following characteristics: female, an ethnic minority, or economically poor. This study explores issues surrounding the digital divide and documents what a high school has done to encourage their female Latina students to see the importance of computer technology in their lives. Data was gathered through observations and interviews with students, teachers, and administrators of the school. The results show school leadership and parental involvement are among key factors that can assist students see the importance of computer technology in their lives. Interviews with students also revealed that having access to a computer at home has an impact on computer literacy.

Introduction

Many educators believe computer technology has the power to improve the education of diverse learners in elementary and secondary schools. This belief has led to major investments in computer technology in schools. Massive amounts of money are being spent on purchasing equipment, connecting classrooms to the Internet, or providing professional development for teachers. "The investment in technology for schools resembles the investments being made in many 'dot-com' Internet companies. In both cases, the investments are based on the potential of new technologies, in the hope that this potential will be fulfilled in the coming years" (Kleiman, 2000, p. 7).

While computer technology has improved the educational experiences of many students, research has shown that there are still members of the educational community who are not included or represented in the technology agenda. Computer technology has fallen short of its promises to students who are female, ethnic minority, and students who are poor. The gap between those who are able to fully participate in the technology agenda and those who are not is often referred to as the digital divide (Bracey, 2000).

My goal is to study the role of technology in the educational experience of diverse learners. Diverse learners in this study refers to students who share one, two or all of the following characteristics: female, an ethnic minority, or economically poor. For this study, I explored issues surrounding the digital divide and documented what a Catholic high school in the Los Angeles area is doing to encourage their students to see the importance of computer technology in their lives.

Background

Computer technology allows students of different backgrounds to arrive at a solution to a problem by sharing diverse viewpoints. Despite this major benefit of using computers in teaching, research has shown that some students are not benefiting from learning through computers.

Female students are less likely to see the importance of computers in their lives than male students. Gender inequity in education is nothing new. Sadker and Sadker (1995) first showed how schools perpetuate the underachievement of female students, especially in Mathematics and Science. Gollnick and Chinn (1997) explain that the underachievement of females in school is a product of a system that perpetuates the belief that female students are not as academically capable as male students. Teachers expect less of their female students. It is therefore not surprising that female students are less interested in computer technology. Kelly (2000) states, "one of the first indicators of this gender disparity may be the Advanced Placement exam in computer science. Girls accounted for only 17 percent of the test takers on
the A exam and 9 percent on the more difficult AB exam" (p. 155). Huber and Schofield (1998) studied the attitudes of male and female elementary school students in Costa Rica. Their study revealed that female students have a less positive attitude towards computers than the male students due to a number of factors: male biased software, the stress on competition in most computer classes, stereotypical view of computer use as a male activity (even by female computer teachers), less teacher assistance for female students, and less computer use of female students outside of the classroom. As a result of these school experiences, female students are less likely to seek a career in the computer industry and are not able to enjoy the same economic prosperity as their male counterparts.

Economics also plays a role in how computers are used in teaching learning. Access to computers is a major factor that prohibits all students from learning through computers. The high cost of computers still prevents many schools from making computers available to students. Schools in affluent neighborhoods are also more likely to have a full-time technology coordinator and teachers in less affluent districts have less access to professional development (McAdoo, 2000). Furthermore, students in poorer communities use computers for drill-and-practice type of activities while students in affluent communities use computers for inquiry-based lessons and collaborative learning (Kleiman, 2000). Thus, in poor communities, the computer leads the student. In rich communities the students control the computer for their own purposes. In order to bridge the digital divide, researchers and educators need to come up with ways to make computer usage meaningful for people who are poor.

There is belief that the digital divide will fade due to "market pressures, with decreasing hardware and connectivity costs inevitably leveling the digital playing field" (Carvin, 2000, p. 3). However, some researchers have been able to show the members of ethnic minority communities may not see computer technology as important to their lives even if they have the money to purchase computers. Holmes (1997) notes that many African Americans do not see the Internet as a relevant part of their lives. Hoffman and Novak (1999) show that the absence of relevant multicultural content on the Internet makes surfing the World Wide Web less interesting to ethnic minority communities.

Schools can play a major role in bridging the digital divide. While access to computers in schools have increased dramatically, Becker (2000) notes that most the most creative and frequent uses of computers in schools are still not related to the general curricula. Most usage of computers is still only a part of specialized classes, such as computer classes. Becker (2000) discusses several factors that affect computer usage of schools. First, access to computers in the classroom often dictates how much work a teacher may assign a student. Becker points out that teachers with at least one computer in the classroom are more likely to assign computer work more frequently than those teachers who have to bring their class to a computer lab. Teachers who also had computers in the classroom, were also more likely to use various software (e.g. spreadsheets for Math and Science teachers, word-processing for English teachers) than those who had access to computers in a lab. Secondly, Becker shows that teachers must have the necessary expertise to use computers effectively for teaching. "To use computers effectively in their classroom, teachers must have certain levels of expertise in basic computer operations" (Becker, 2000, p. 54). Teachers must also believe that the use of computers can really make them more effective educator.

Computer technology has the promise of making learning and teaching a more meaningful experience for diverse populations. No one has quick solutions to the problem of the digital divide in schools. However, "as a society, we need to establish a comprehensive strategy that addresses it from all angles. Access, literacy, content, cultural relevance, and community needs are just a few of these factors" (Carvin, 2000, p. 13).

There have been institutions that have addressed the problem of the digital divide. Furger (1998) discusses the success of "The Odyssey Project", a project designed to integrate computer skills and activities across the curriculum at the Albany Academy for Girls, New York. The project was specifically for middle school students because "there's no more critical time than middle school years to expose girls to the many and varied uses of computers, to give them rich opportunities to explore their capabilities, and to lay a solid foundation that will give girls the skills and the confidence they need to explore other aspects of the technology during their high school years and beyond" (Furger, 1998, p. 142). The project was successful because he students were empowered to select the appropriate technology to complete the activity. The use of computers was not the focus of the activities. Technology was a tool to complete the activity.

The Computer Clubhouse (organized in collaboration with the MIT Media Laboratory) in Massachusetts sought to provide access to technology to inner city youth. "The Clubhouse is based not only on new technology, but on new ideas about learning and community – where young people and adult
mentors work together on projects, using new technologies to explore and experiment in new ways” (Resnick, Rusk, and Cooke, 1999, p. 266). Children who came to the clubhouse were given the tools that were necessary to learn how to design and create computer based products. They were not merely consumers of the technology.

**Methodology**

This project is an ethnographic study of an educational institution that is attempting to eliminate the digital divide. St. Matthias High School in Downey, California is an all female Catholic high school. About 90% of the students are Latina and fall at or below the poverty guidelines set by the government. Despite the fact that these students fit the profile of people who are part of the “have nots” in the digital divide, an initial analysis of the documents presented to me reveal that the school is doing many things to ensure ethnic minority female students who are poor are benefiting from the technology revolution. My goal is to describe what the school is doing correctly to bridge the digital divide by interviewing students and teachers and observing technology classes at St. Matthias High School. Interviews with key administrators were conducted.

**Results**

My case study of St. Matthias High School in Downey shows that schools can bridge the digital divide. 90% of the students who attend this all-female high school are Latina and come from low socioeconomic backgrounds. Yet, 100% (n = 30) of the students who were interviewed (representing different levels of computer proficiency) all stated that they felt comfortable using computers. These students were also able to describe how they use computers for their schoolwork and believed that knowledge of computer skills are important for their future. The students appreciated the computer training they are receiving at their school.

St. Matthias High School is able to bridge the digital divide because of the following qualities:

a. **Vision for Technology:** The school created a multi-year plan for technology. The plan is updated every year and is revised in consultation with a technology committee composed of school administrators, students, community representatives, and higher education professionals. In 1995, the school did not have a single computer. By 2001, the school had over 100 computers (purchased and donated), a server, digital cameras, and a satellite connection for the Internet. All the teachers in the school have a computer in their classroom. All of the classrooms are wired for the Internet and have software appropriate for the teacher’s content area. The school also has several labs that teachers and students can use.

b. **Leadership:** The school has an administration that is an advocate for technology. The administration and teachers in the school truly believe that their students need to be computer literate in order to have a better future. Technology is a priority and the administration continues to set aside resources for equipment and professional development. The administration also spends time developing partnerships with all of the school’s stakeholders. The community shares leadership for technology. The school has established an advisory board composed of students, parents, teachers, parents, university professors, and community leaders.

c. **Professional Development for Teachers:** Teachers were given the opportunity to attend seminars and training sessions related to technology. The school administration set aside money for teachers to attend national conferences. Teachers were given paid time-off to attend conferences and workshops. In the questionnaire administered for this study, the teachers stressed in their responses that the professional development that was provided to them by the school was invaluable. The professional development allowed them to explore how computers can improve
their teaching. The teachers also stated that the school administration empowered them to learn about computer technology at their own pace based on their individual needs.

d. Parent involvement: The school administration knew that the parents of their students had to believe in the importance of technology. In order to do this, the school created an opportunity for parents to see how technology can change their lives. The school began offering tuition-free Microsoft Office certification classes for the parents. Parents attended classes in the evening and on weekends. At the end of the training period, the parents received a certificate of proficiency. They were then able to use these certificates to get better paying jobs. The parents have now become advocates for the use of computer technology.

e. Successful fund raising: The school administration knows that they need money to purchase equipment or professional development. Every year, the school hosts a carnival that raises about $50,000 for technology. The entire community is involved in the carnival. Aside from the carnival, the principal writes several grants every year.

f. Meaningful computer use in the classroom: Both teachers and students used computers in meaningful ways. The use of computers is integrated in the curriculum. Teachers used computers for attendance, grades, research, and preparing lessons. Students can connect to the Internet to check their grades or look at assignments posted by the teacher. Students used computers to complete school projects. In an Art class, students created web pages to display their photographs. In one Religion class, students used PowerPoint to present their reports. In all instances of computer use in the school, the curriculum drives the use of the technology. In one Spanish class, students used language software to practice vocabulary exercises.

g. Leadership opportunities: Students who decide to take the advanced level computer classes, become technology leaders in the school. They assist teachers and other students. These students also maintain the school server and web sites. Whenever a contractor comes to the school to do routine maintenance on any computer equipment, these students are asked to observe the work that is being done. These students, in many ways, receive technology training that is beyond using computers for school projects.

St. Matthias High School is doing an exemplary job of bridging the digital divide. However, many of the students felt that the absence of a computer at home prevented them from becoming even more computer literate. Students who do not have computer access at home are less likely to use the Internet for schoolwork. Students who have computers at home often spend time learning software on their own time. This “anytime, anywhere” access is important for empowerment.

Conclusion

Schools can be a catalyst for bridging the digital divide. “Schools play a critical role in ensuring equal opportunity for less-advantaged children by providing access to a wide range of enriching experiences including exposure to computer technology” (Becker, H. J., 2000, p. 45). Schools have the power to motivate or discourage students from participating in the technology revolution. It is clear that schools must be willing to make the necessary commitment in personnel and finances. Schools must also start with a vision of technology use that includes use of computers by all members of the school community (administrators, teachers, students, and parents). Involving all stakeholders will lead to ownership of the technology vision of the school. Lastly, schools need to make an effort to assisting students to have access to technology at home.
References

The National Institute for Community Innovations (NICI) in collaboration with the PT3 program's digital equity task force, has developed a free toolkit pointing preservice and inservice educators and teacher education faculty to free resources enabling them to address the digital divide in their classroom and community.

Inequitable access for students and educators in low-income communities to learning technology resources remains a vexing and substantial problem in the US and in many other nations. At the same time, foundations, corporate philanthropies and public sector initiatives are investing enormous sums to reduce the digital divide in classrooms and communities. Yet, future and current educators and those who provide teacher preparation and professional development remain almost entirely unaware of these resources, how to tap them, and how to integrate them into educator inservice and preservice.

NICI has developed a free web-based Digital Equity Toolkit to point educators to free resources to reduce the digital divide. The Toolkit currently focuses on US-based resources but will become a more internationally oriented resource over time. NICI is working with several national educational organizations to assist in bringing the Toolkit's resources to the attention of educators and teacher education faculty.

In this session, participants will learn about the toolkit, explore how to use it in teacher preparation, and recommend enhancements in the toolkit's format, contents and usability.
Embracing Critical Perspectives on Multicultural Pedagogy in Teacher Education: An Online Intercultural Exchange

James C. McShay, Iowa State University
Israel Colón Jr., New York City Technical College

The multicultural literature clearly documents the challenges teacher education programs face in preparing competent culturally responsible teachers for our nation’s schools. Many educational researchers support the notion that teacher education programs are not doing enough to prepare predominately White, female, and middle-class teachers who come from homogeneous settings to embrace emerging critical perspectives on multicultural pedagogical practices in schooling. The literature also suggests that numerous socialization factors affect preservice teachers perspectives on race, ethnicity, gender, social class, and ability. The purpose of this ongoing project is to explore how computer mediated communication (CMC) can be used to create new and varied opportunities for prospective teachers to explore, and as a result, broaden their own perspectives on critical issues facing cultural diversity in education.

This paper reports on a work in progress that will share information about the design, implementation, and evaluation of an asynchronous eight-week online intercultural learning exchange between two distinct groups. These two groups consisted of 44 preservice teachers enrolled in a teacher education program at a Midwestern university and 18 preservice and inservice teachers enrolled in a teacher education program at a college located in an urban setting on the east coast. A web-based course management software program, WebCT, was used to support this online intercultural learning exchange between both groups of students. WebCT’s discussion board feature was used to create a learning environment that promotes reflective discourse and interaction among the participants. After exploring the process of creating a culturally diverse online community of educators; this paper identifies specific strategies for enabling predominately White preservice teachers to understand powerful socialization factors that influence the way in which they think, feel, and behave. Furthermore, preservice teachers explore how their participation in various social systems help to construct their own perspectives on multiculturalism and schooling through reflecting critically on their collaborations with inservice teachers who live and work in an urban populace. Observations on the inservice teachers’ reactions to this multicultural experience will also be shared. Finally, this paper calls for further research on how computer mediated learning environments can help teacher education programs prepare competent culturally responsible teachers for the multicultural classroom.
Creating Accessible Powerpoint Presentations for Students with Disabilities

Tamara L. Pratt, Mercyhurst College, US

Description
Learn how to incorporate Power Point with instruction for students with physical disabilities in order to enhance their learning experiences.

The intended objective of this poster presentation is to expose teachers to the many adaptive uses of Power Point as a teaching tool. Participants will see how Power Point is used to assist students with disabilities. Participants will be able to think ahead of adaptations needed for their students with disabilities, to make students active participants of their learning. Prerequisite skills participant skills include basic knowledge of computer use, how to import and export files, and the use of a scanner.

The presenter is a current graduate student in the field of Special Education at Mercyhurst College working with the PT3 grant. She has experience developing accessible Power Point presentations for students with multiple disabilities.

I. Universal Design – means it’s accessible to most students with disabilities.
   A. Visual Disabilities
      1. Less distracting environment
      2. Color reversal
      3. Large font – simple
      4. Mouse over to describe pictures, buttons, directions...
      5. Consistent placement of buttons
      6. Text voice over
      7. Screen reader for web browsing
   B. Hearing Disabilities
      1. Minimize background distractions such as music, animation.
      2. Minimize excessive noise levels in work area such as other students.
      3. For students with partial hearing loss use headphones to listen to presentation.
      4. Limit text to clear and large – bold key ideas, phrases, and vocabulary words.
      5. If you import an iMovie make sure you have closed captioning.
   C. Physical Disabilities
      1. Use mouse over to eliminate need for mouse click to progress to next slide.
      2. Consistent button positioning to eliminate too much mouse movement.
   D. Learning Disabilities
      1. Highlighting text, key points vocabulary words.
      2. Voice over for reading text
      3. Minimizing background distractions
      4. Headphones
      5. Consistent placement of buttons
      6. Larger text
      7. Color reversal
      8. Chunking content (short sections)
      9. Ability appropriate text, age appropriate content

II. Achievement of Objectives
   A. Mouse over
   B. Voice over
   C. Button placement
   D. Slide transitions
   E. Voice recording
      1. slide narration
      2. inserting voice on a slide
   F. Changing font size, color
G. Bold or highlighted words, phrases
H. Cursor speed
I. Automatically open as presentation or does student need to start presentation
   1. show begins automatically
   2. slide begins as an outline
Equity Lenses: Diversity-Responsive Use of Advanced Technologies for Math and Science Education
J. David Ramirez, CLMER/CSULB
Kim Williams, Northwestern University
Kevin Rocap, CLMER/CSULB

The work to be shared in the proposed SITE paper was supported by a seed grant from the Center for Innovative Learning Technologies (CILT), as part of an NSF grant administered by SRI. CILT is an organization made up of partner institutions and individual members nationally involved in the design, development, implementation and evaluation of advanced technologies in math and science. Apropos to the “Digital Divide” theme of the CILT2000 conference the goal of this seed grant project was to help inform an agenda for equity and diversity-responsiveness within CILT and with regard to educational technology efforts in IT and educational associations similar to CILT.

CILT has a commitment to addressing the digital divide, yet there is a recognized need within CILT to define criteria for what we mean by equity, diversity and action in a CILT context. Without a framework for identifying issues and strategies, it's difficult for us to move forward with this commitment strategically and to support and inform CILT members about approaches to addressing equity in R&D efforts. The paper authors facilitated the development of equity lenses, guidance and criteria, through the use of which we may view, assess, recognize and transform, as appropriate, CILT-type endeavors with regard to their contribution to addressing issues of diversity-responsiveness and equity, particularly with regard to the Digital Divide.

To accomplish this, we involved key technology, math/science and community leaders as well as collaborating partners in the development of an “equity lenses” framework for identifying issues and strategies synergistically, across the four CILT
themes - Visualization and Modeling; Ubiquitous Computing; Community Tools; and Assessments for Learning. The equity lens project was initiated with the overall goal of identifying promising research and development, educational and community-based activities and other programs that consider issues of equity and diversity as integral to their work. Members of the equity lens group, though bringing different experiences to this project, all held a collective belief in the importance of developing helpful rubrics or guides for considering equity and diversity issues in the research design of CILT-type projects.

We engaged in several key activities in order to draft key issues, rubrics and guidelines. 1) We queried colleagues about projects that they were aware of which consider issues of equity and diversity in at least one phase of their work (e.g., design, piloting, data collection); 2) We met with SRI researchers (February, 2001) to obtain permission to review CILT seed grant abstracts. Our goal was to examine the abstracts to see if, or where, diversity and equity issues were addressed. We also considered how equity and diversity issues could have naturally been included. 3) We met as a group in late February to discuss our projects and what we'd learned. 4) We met in June, 2001 to develop a broad-based survey designed to query the CILT membership and members of the advanced learning technology community and the educational research community about equity and diversity issues. 5) We presented our platform to a group of IEEE conference attendees in Madison, WI. We also asked these attendees to review our survey and provide feedback about the questions we proposed to ask of those described in #3. 4) Through on-line discussions and phone conferences we planned a focus group meeting in California for Fall 2001. 5) We are gathering and analyzing surveys to further
the development of criteria, guidance and rubrics that will be shared through this SITE presentation.

This paper will share the findings and the guidance and criteria of this CILT seed grant effort and will engage participants in considering specific issues in the design, implementation and evaluation of advanced learning technologies in K-12 math and science education.
'Facelessness' and its Impact on Democracy and Diversity in Virtual Communities

Carol Reid
School of Education and Early Childhood Studies
University of Western Sydney
Australia
c.reid@uws.edu.au

Abstract: This paper investigates the relationship between new technologies, pedagogy and cultural diversity. The importance of this research for teacher trainees cannot be underestimated. Teachers are expected to use new technologies in classrooms often without any critical understanding of their impact on the social and cultural dynamics of classrooms (Lankshear and Snyder, 2000:121). In this paper, the contradictory socio-cultural dynamics produced by 'facelessness' in an on-line community are examined.

Introduction

The research project on which this paper is based was entitled 'Framing Technological Literacy: an ethnography of social space in teaching and learning on-line'. It was an ethnographic study of the socio-cultural dynamics - including pedagogical frameworks - when using Information and Communication Technologies (ICTs) in an undergraduate subject - Cultural Diversity and Learning. This was a first year social science subject that I authored and taught to primary teacher education students. Students used a discussion board and email as well as a subject website and other materials within the teaching platform called 'Blackboard'.

In focus group discussions at the end of semester, students talked about their experiences of using ICTs in this way. All four focus groups, in addition to many of the discussion threads, made reference to the absence of visual clues, and in particular to the absence of face. For some this was liberating and for others it created a sense of vulnerability. To contextualise these socio-cultural dimensions, the elements of the subject Cultural Diversity and Learning need to be outlined.

The subject Cultural Diversity and Learning takes a critical approach1 and has two strands. The first is concerned with developing concepts and understandings about the ways in which cultural diversity is constructed at the national, local and global level. There is an examination of traditional, liberal and critical ideologies and pedagogical frameworks in education and how they shape space for cultural diversity (Solomon, 1995).

These understandings are then applied to cyberspace to critically analyse knowledge and information found on websites, as well as the material contexts from which they have been produced. Two main approaches are introduced: neo-Marxist and feminist post-structuralist. Neo-Marxist theories regarding the commodification of information and entertainment are used to explore the potential for democratic use of the Internet. This is not only about production but also about the way in which children are being turned into consumers as the defining principle of childhood. Feminist post-structuralist analysis of the same sites shifts the focus to textual analysis - the design, representation and reproduction of identities in cyberspace. Indeed, the design of the website incorporates a background visual metaphor of a brick wall on every page. This idea was borrowed from Pink Floyd’s album, "Another Brick in the Wall"2.

Part of the subject is an on-line module in Weeks 79 entitled 'Cultural Literacy'. Cultural literacy is understood in this context as "a connection between the recognition, production and retrieval of what is constituted as information, on the one hand, and its use or deployment as a communication practice on the other" (Schirato and Yell, 2000:36). Students use on-line readings from journals and other cultural studies websites worldwide3 as well as film reviews provided by Paul Byrnes, a Sydney Morning Herald journalist. During the three weeks, students discuss focus questions around readings - individually - in on-line forums. Once a week they respond in groups to a substantive question on all the weekly readings, which is an assessable item.

---

1 See Reid, 2000 for full discussion of this approach.
2 In the lyrics, education in general was seen as 'thought control' with the outcome being conformity and loss of diversity.
3 Particular thanks to Douglas Kellner of UCLA for permission to link to his very useful website.
Disney is used as a focus for critique as Disney enterprises are strong examples of the commodification of entertainment and information. In addition, Disney is widely critiqued by academics - and everyone knows Disney. Disney images and characters largely convey a homogenised view of the world by erasing or crudely stereotyping the diversity of sexualities, genders and ethnicities found globally. Perhaps not surprisingly this erasure is often understood more by those marginalized than other groups. For example, Arabic teacher education students are quite critical of Disney Enterprises as the Disney studios were well known for their anti-Arab sentiment during the Gulf War as well as the fact that Arabs are often portrayed as the bad guys in Disney films for children. For other students there is dismay that their beloved Disney is the object of critique!

When students have completed this module, they search for their own sites, then compare and contrast their findings (in pairs) using the analytical skills and concepts derived from the on-line module and understandings developed earlier. Students combine visual, communicative and technological literacies with social and cultural theory to critically analyse information and entertainment on the Internet. In this way, they develop pedagogical understandings about the way in which ICTs can be used to teach critical literacies. The knowledge gained from both forms of literacy practice - communicative and socio-cultural - frames their exploration of the Internet and enables a socio-cultural analysis of websites for children. Analyses are presented using PowerPoint slide shows or constructing websites thus learning practical skills and knowledge about the pedagogy of software in the context of socio-cultural analysis.

In the remainder of this paper, there is an exploration of the students' responses to the on-line component of this subject. Their responses reveal the connections between the knowledge or content of the subject, the medium - in terms of the communication literacies employed - and the nature of the interactions, in terms of whether or not they were democratic and inclusive.

'Facelessness'

In the [embodied] tutorial you might think 'oh this person might think I'm a bit of a dropkick', but if it's on the Internet people are less inhibited and they're going to write what they think. [Young woman - focus group]

The analysis of discussion threads in this subject, and focus group discussions at the end of semester, revealed the centrality of 'face' - both its presence and absence - in social relations. The decoupling of faces and names, and time and place, appears to afford students a perceived degree of anonymity despite the fact that their names appear next to their contributions. The fact that peers are not able to judge them appeared to be more important than the fact that the lecturer was able to do so. This indicates a perception about social relations - indeed power relations. Are we, for example, more afraid of judgement when it is faceless? Is judgement harsher when those we judge are unknown to us? In an attempt to answer these two questions, the paper examines the tensions created by 'facelessness', in particular how 'facelessness' shapes democratic space in a culturally diverse community.

'Oothering' versus 'deliberating'

I think it must be a personality thing. People being hard on the strangers that they didn't know, because they haven't developed friendships and they don't all know what everyone's like... (woman - focus group)

The 136 students involved in this project were largely unknown to each other as they were in their first semester of study in primary teacher education. In a sense then, they were unable to construct an image, or face, of authors who contributed to on-line debates, nor were they able to do so in other classes since their tutorial groups were different for every subject. For some this caused anxiety but for others a lack of knowing the embodied Other appeared to provide opportunities for a more deliberative democratic ethos (London, 1995). Deliberative democracy, London argues, "is rooted in the ideal of self-governance in which political truths emerge not from the clash of pre-established interests and preferences but from reasoned discussion about issues involving the common good" (ibid: 34). As argued elsewhere (Reid, 2000) the desire to "read off" difference (as in the process of "Othering") as opposed to negotiating difference is hegemonic among undergraduate teacher education students. A shift from a focus on the presumed identities of students appears to have been enabled when the relationship between the subject content, the student demographics, and the medium, merged in sometimes-powerful ways.

4 See end of Reid, 2000 for graphs of local population in terms of religion and number of overseas born.
I think the online really suited cultural diversity — the online part of it - because it [reality] is like that. There are lots of different points of view and I don’t think you would have got as much out of the subject in a tutorial situation, face-to-face. [mature woman - focus group]

This particular observation was supported by another student, a mature-aged female, who commented that some students spoke more for themselves [my emphasis] on-line than in embodied space. She explains:

They are quiet [in embodied tutorials] — Muslim ladies are quiet, very quiet. Their names on the discussion board... had a lot to offer. It must have been incredible for them too, to voice their opinions. It was easier for them...

It certainly appeared that some students felt comfortable drawing on their own cultural knowledge and sharing it with their fellow students. At times, this appeared to be an outlet for pent up resentment or frustration for those who had felt themselves subjected to the ignorance of others. For example on one discussion thread:

- An Islamic student expressed the annoyance she felt when people assumed that wearing a scarf [sic] was ‘a Turkish thing, and not an Islamic one.’
- Another Islamic student agreed, protesting against the ignorance and stereotyping which often insists that all Arabic speakers must be Lebanese, that all women who wear a scarf [sic] must be Lebanese, and that all female followers of Islam must be oppressed. This student insisted that ‘the solution here is pure and simple - education.’

A large number of students exchanged information about their personal biographies in order to explain their different reactions to their learning experience. This sort of exploration was of great relevance in a subject like Cultural Diversity and Learning where the students are encouraged to explore the intersection of their own biographies and their ideological positions in relation to the social construction of difference and diversity. This positionality became evident when students considered their audience and whether or not they felt constrained on the discussion board.

Definitely —because it is so—it’s a touchy subject, and everybody is so multicultural, here especially. [young female - focus group]

That was the point that I had, but also too, to make sure that I didn’t offend anyone, that I had said the exact thing that I wanted and it couldn’t be taken out of context I suppose. It made me concentrate a lot more on what I was actually thinking and what I really felt about the subject. [mature female - focus group]

The tension created by ‘facelessness’ is also assisted by certain literacy practices. Students disagreed over what text types are liberating in terms of on-line discussion. Some like the fact that you can use a narrative approach and state your own ideas drawing on personal experience while others found this tone acted to filter or exclude their voices because they felt uncomfortable with personal revelation. This has considerable implication for literacy practices in terms of text types but also cultural literacy in terms of the social and cultural dimensions of the Internet, as a cultural field. The apparent ‘search for voice’ is typical of the new ways in which those with cultural capital in one context have to learn new forms of literacy (Lankshear and Snyder, 2000), as cultural capital in one field is not necessarily as powerful in another cultural field (Shirato and Yell, 2000).

Productive Literacy Practices

You can say more, and you can tell people off more. You can write a load of waffle, you can be rude, you can have a considered response, but yeah it’s different, it’s very different. [Mature woman - focus group]

Agger’s (2001) tentative social theory of the Internet suggests that authoring (websites, homepages, hypertext) is an essential part of struggle in the democratisation and humanisation of the Internet. The text types students use are very diverse as the woman above astutely observes. Creating democratic spaces requires openness to a range of literacy tools that people use to connect to new knowledge. However, not all literacy practices are productive. Two mature male students in this project discussed some aspects of what they saw as productive literacy practices.

That critique of each other [on-line] is good...sometimes, it puts people back in their places so to speak whereas in tutorial sometimes...you just let it go...sometimes you can say real crap and people agree with you...they don’t even listen, they’re not even there.
I thought about what I was going to say, which maybe you don’t do in a normal tutorial. You don’t know what questions necessarily are going to come up, but I can remember definitely thinking you know—maybe I perhaps started tending to think, you know, should I or shouldn’t I say something radical, you know what I mean?

However, while this direct type of literacy practice was productive in terms of providing a much broader dialogue of ideas across the student body, the ‘faceless’ aspect of the discussion created a rebound effect in ways that were not predicted. One of these was related to the use of peer-based assessment.

Some Effects of Recoupling Names and Faces

...we came together and we didn’t know anyone... I think peer marking became a bit hard, but then again I guess it was good too because you did it genuinely. [mature male - focus group]

Despite the fact that many students were liberated by 'facelessness' it was not necessarily because identity was removed. The fact that others are complicit in the construction of our identities, embodied and virtual, is evident when the removal of an embodied identity was replaced by a cyber identity in the on-line discussions. For example, one all female focus group had a prolonged discussion on the relationship between the cyber identities they had come to know and the emotions they attached to the names based on these cyber identities. When the recoupling of names and faces occurred it produced effects of power that in the context of face-to-face peer marking became difficult for some students who had been outspoken on the discussion site. One student commented:

You learned all these names and now you’d go 'oh yeah, you put a name to a face'. Not that you’d remember what they spoke about, you just remember the feelings.

Others found that a lack of personal embodied knowledge produced an almost 'ferocious objectivity':

You just took everything that they said and you marked them on what they’d said. Critical, I think.... Ferocious is a strong word, critical I think because you didn’t have that personality, like the personal side.

While this sense of alienation was not felt by all students, the effects of recoupling names and faces demonstrates the unintended consequences of 'facelessness' in teaching and learning on-line, in particular its link to technologies of power such as assessment and profiling activities (Robins and Webster, 1999).

Conclusion

'Facelessness' in this social science subject produced socio-cultural dynamics that were enmeshed in both virtual and embodied communities (local, national and global). This created an environment of greater risk whereby strategies of negotiation, dialogue and deliberation were most valued. Literacy practices which best supported the ability to produce such complex texts were based on knowledge of social and cultural structures and processes. Such knowledge framed technological and communicative literacy. This critical approach demonstrates that pedagogically, science (including social science) "is a social and historical activity" which cannot ignore "the social and communitarian dimensions of cognition based as they are in language" (Olssen, 1996, p.289).

Thanks to Gina Anderson for research assistance and the University of Western Sydney for funding to carry out this project.
Since 1996 the center for Minority Education Research (CLMER) at California State University, Long Beach has worked closely with multilingual, multicultural, critical educators to develop professional development communities of practice meaningful, diversity-responsive uses of computer and telecommunications technologies in K-12 teaching and learning and teacher preparation. This work was initiated as a K-12 inservice teacher and parent professional development program with CLMER as the lead agency for the Pacific Southwest Regional Technology in Education Consortium (PSRTEC) and has been expanded and enhanced to address pre-service preparation issues as part of a PT3 Catalyst grant. Our purpose is to work in partnership with cadres of 20-30 teachers, parents, pre-service teachers and/or faculty as communities of practice, to learn together what we can do to improve access to information and communication technologies, to develop high-quality multilingual, multicultural learning approaches and to develop critical pedagogical strategies. We draw on theories and practices of multilingual, multicultural and anti-racist educators that include Paulo Freire, Alma Flor Ada, Sonia Nieto, Gloria Ladson-Billings, Jim Cummins, J. David Ramirez, KimOanh Nguyen-Lam and others.

The design of the CLMER Telementoring model has been to ensure that all participants engage as a community of practice around the following key CLMER Telementor "lenses:"

- Critical Pedagogy
- Language (multilingual education and language rights)
- Anti-Racist Education
- Standards
- Community Learning Theory (relates to school-home-community collaboration, as well as to adult learning, community organizing and diversity-responsive approaches, e.g., culturally-based approaches such as Razalologia, born out of Chicano/Latino organizing strategies and culturally-responsive community wellness approaches).

Technology Fluency

CLMER Telementoring goes beyond teaching about technology and is about improving critical approaches to teaching and learning while understanding, applying and critiquing issues of meaningful technology integration in the context of participants' practices.

CLMER Telementoring Methods

We have several ways that we make the lenses above a concrete part of the process. We engage in readings drawn from such sources as our own Virtual Power publication and the Beyond Heroes and Holidays anti-racism across-the-curriculum text that we helped to produce. We also draw, as mentioned, from practitioners and theorists of multilingual, multicultural education such as Sonia Nieto, Jim Cummins, Alma Flor Ada, Paulo Freire and others (including making use of a critical pedagogy framework for planning learning activities and agendas). We also draw on sociocultural learning theories and practices associated with Computer-Supported Collaborative Learning. We then use technology communication and collaboration tools (e-mail, listserv, WebBoard, ICQ, etc.) to develop K-12 learning projects and to encourage reflection on diversity-responsive teaching and learning in the context of participants' current and anticipated practices. Participant learning projects may be as small as a learning activity and as large as the creation of a Community Learning and Technology Center, with most reflecting participants developing diversity and equity-themed project-based and/or problem-based thematic learning activities. Participants also have specific responsibility for mentoring others, making use of online and face-to-face approaches.

CLMER Telementor Requirements

- There are some requirements of Telementors:
- Active participation in all planned professional development activities
• Agreement to create a project or unit of practice to be carried-out in one's own classroom/learning environments (these have varied from project-based learning activities to the formation of Parent Centers or Community Learning and Technology Centers. We don't have a cookie-cutter requirement for these except that they reflect integration of the CLMER Telementor lenses).
• We expect administrator support at a participant's site for their work as CLMER Telementors, for providing 8 days of paid release time and free professional development opportunities we ask administrators generally to grant 6 days of release time to their teachers at a later date to allow them to mentor and support others, as a way of sharing their knowledge/experiences.
• Participants give back by agreeing to a plan to mentor others, in their own schools, communities, or in other venues. Some of our sessions engage participants in dialogue about the purposes and practices of mentoring in order to strategize and action-plan together on their own mentoring plans.
• Active participation in planned online communication between face-to-face meetings.

**Workshop Purpose**

This workshop will share readings, resources and strategies associated with the CLMER Telementoring community of practice approach to professional development, as well as engage participants in active review and critique of learning projects designed by CLMER Telementors and invite sharing among participants of issues and promising practices for developing technology-enhanced, diversity-responsive teaching and learning approaches that target success and participation for underserved K-12 learners. Strategies and purposes for integrating visual and creative hands-on arts activities while developing critical multicultural approaches and developing technology fluency will be shared. Further, we will share the experiences and processes of working across diverse stakeholders, including teacher education faculty, teachers, low-income parents, pre-service teachers and others to “level the playing field” in the development of high-quality, diversity-responsive, community-connected learning projects.
The Robot League: Lego Mindstorms RIS in Schools

William Rust, Kansas State University, US
Kevin Kramer, Kansas State University, US

The Robot League is a bootstrap initiative of Kansas State University. The concept is to encourage interscholastic and intramural competition using Lego® Mindstorms™ Robotic Invention Systems™, RIS, kits. Participants, in classes, clubs, other school groups or homeschool groups, build autonomous robots that compete in pre-defined events. While all students are invited to participate, special emphasis is given to members of groups traditionally underrepresented in engineering, including females, minorities and low SES students.

Membership in the league is self-selecting. An open invitation was sent to area schools and those who asked to join were admitted. Teachers signing up were provided with one or more RIS kits. The two main requirements for accepting the kits were participating in one or more interscholastic competitions hosted by Kansas State and a 1-2 page written evaluation at the end of the year.

Participation ranges from 5th grade to high school. Some teacher initiatives pair high school students as leaders with middle and elementary school groups. Some participants are identified as gifted while most are not. At least one participant has been identified as marginally learning disabled.

The fundamental purpose of the league is to change attitudes among students. Many of the participants do not view school as particularly relevant or engaging nor do they view fields requiring higher education as viable options. By providing manipulables that require higher order thinking to accomplish well defined goals in a competitive environment, the league hopes to encourage students to take more math and science classes in high school and be better prepared for college. In addition, the league hopes to foster better feelings towards the school and encourage school spirit by having both intensely competitive but also light-hearted competitions.

This presentation will focus on how to set up a robot league and what were the short-term effects on the students participating. Other issues include multi-age classrooms and the relevance of technology in schools. The hands-on workshop includes building and programming a robot and participating in one of the league tests.
Bridging the Digital Divide through Technology Integration in an Urban Elementary School: A Study Report

Amy Staples, Ph.D.
Department of Exceptional Education
School of Education
University of Wisconsin-Milwaukee

Elizabeth Buchanan, Ph.D.
School of Information Sciences
University of Wisconsin-Milwaukee

Teachers who possess strong content knowledge and embed technology across all aspects of their teaching as a central means of creating active, engaging, and challenging learning communities have the potential to close the perennial gap in achievement between students in urban schools—who typically are members of minority, and often lower socioeconomic, groups—and their counterparts elsewhere (Children's Defense Fund, 1999). Statistics show that children of color in urban environments have fewer opportunities to access technology than their Caucasian counterparts of comparable income (Hoffman and Novak, 1998). Further, Caucasian Americans are more than twice as likely to own a computer than their peers of color (Hoffman and Novak, 1998). Even when children are placed in schools with computer technology, children in urban environments tend to engage in drill and practice activities rather than more meaningful activities which entail higher order thinking (CEO Forum, 1999). This finding may be due in part to teachers' feelings of inadequacy regarding effective technology use (NCES, 1998). NCES (1998) reports that only 20% of teachers feel well-prepared to integrate technology into their teaching.

In an effort to ease the digital divide, faculty and staff from the Schools of Education (SOE) and Library and Information Sciences (SLIS) at the University of Wisconsin-Milwaukee (UWM) and faculty at Starms Discovery Learning Center (DLC) in the Milwaukee Public Schools (MPS) forged a collaborative effort to address three key issues: teacher preparedness, technology availability, and technology integration. Students and teachers participated in a community-based project designed to narrow the digital divide through increasing students’ knowledge of the local community and civil rights movement via the construction of a multimedia documentary.

Subjects in the study were kindergarten through fifth grade students in an inner city school, 80% of whom qualified for free or reduced lunch, 80% of whom were African American, and 20% of whom had disabilities. In other words, children who, due to their race, socioeconomic status, disability, and location of residence, are the very children who are typically excluded from enrichment programs such as the one herein. Teachers received staff development in various technologies and consulted with technology staff regarding the conceptualization of classwide projects which integrated technology. Students used digital cameras, digital video cameras, scanners, and various software tools to learn and share information about the civil rights movement in their city.
and nation. Information was obtained through traditional print resources as well as interviews with notable public activists, prominent local individuals, and neighborhood families, visits to the Black Holocaust Museum, and presentations by journalists who documented and archived the civil rights movement. Teacher and student attitudes, skills and beliefs surrounding technology were surveyed via questionnaire, interview, videotape, and worksample review.

The proposed presentation will discuss the projects and share findings, including student technology projects.
Considering Digital Equity in Teacher Preparation Programs:  
A Framework for Integrating Issues of Equity Across Content Disciplines

Nancy Allen, Paula Hamm, Patricia McIlveen, Martha Martini, David Ramirez, Paul Resta, Amy Staples, and Joy Wallace

The Preparing Tomorrow's Teachers to Use Technology (PT3) initiative sponsored by the Department of Education funded Schools of Education (SOE) across the country to support the integration of technology into teacher preparation programs. This funding affords SOEs the opportunity to reform or revise their teacher preparation programs in a number of ways including: revising or offering explicit technology coursework; integrating technology into existing methods courses; and helping faculty increase their technology skills. The goal of this work seems clear. The intent is that new teachers will be better prepared to integrate technology into their classrooms, to the betterment of the education for all of their students. In order to better the education for all students, the notion of digital equity must be addressed.

Digital equity exists when two conditions are met. First, every student must have equal physical access to technology tools, computers, and the Internet. Secondly, and equally important, this access must be occur with a meaningful teaching and learning context that directly responds to the needs of diverse students with regard to gender, race/ethnicity, culture, language, language proficiency, and special educational needs. How can we help teacher candidates develop this sensibility.

In this session we will present a Digital Equity Framework that SOEs can use as a guide to develop and assess the extent to which technology and equity issues are successfully integrated in their teacher preparation program. This framework draws upon the collaborative experience and expertise of representatives from PT3 projects with a commitment to digital equity and who have formed the Digital Equity Learning Community.

The Digital Equity Framework can be used with faculty and students to facilitate the systematic integration of technology and equity issues across teacher preparation courses. The Framework allows teachers to plan instructional activities within subject areas, determine appropriate uses of technology and review the degree to which student diversity is being considered. Examples of how this model might be used will be provided.
Self, Visual Representation, Voice and Online Social Identity

Sharon Tettegah, University of Illinois, Urbana Champaign, US

Purpose

This paper documents key issues in electronic mediated visual representations of social identity, based on the teacher's psychological capital, in an online web-supported teaching and learning environment. Visual representation is very important because of a teacher's psychological capital. Psychological capital is defined as the memories, attitudes, experiences, and beliefs, which serve to provide the foundation for behaviors and practices. How teachers talk about things, do things and practice things in a classroom.

The concepts of social identity embedded in visual electronic representations of voices are new and recent phenomena. The first question I pose deals with, how does culturally embedded social identity emerge from textual representations of the person who is expressing their voice? If the visual as a mode of representation is systemic, rule governed, and an effect of the values of the culture and social identity in which it is used, then can we as researchers come to know what culture someone is from or their social identity merely by there visual representations in electronically online mediated environments (Bruner, 1977; Kress, 1998)?

Online studies on social identity (SIT) will become a very important issue in education. According to the research on SIT, social identity theory is defined as that part of an individual's self concept that is based upon the value and emotional significance of belonging in a social group (Jones, p. 214). Abrams and Hogg, 1990, defines social identity as 'the individuals knowledge that he belongs to certain social groups with some emotional and value significant to him of the group membership (p. 7)(Tajfel, 1972a). Many other researchers contend that communication, talk and discourse are all culturally embedded (Trudgill, 1974; 1983).

For example, Wertsch presents arguments using Bakthin's notion that utterances and utterance meaning are inherently situated in sociocultural context. He states, because the production of any utterance involves the appropriation of at least one social language and speech genre, and because these social speech types are socioculturally situated, the ensuing account assumes meaning is inextricably linked with historical, cultural, and institutional setting (Wertsch, 1991), p. 66.

As we immerse ourselves in on-line text production, different modes of representation will be extremely important relative to issues of culture and social identity. Many educators and researchers in online education claim that the online teaching and learning environment removes such variables such as gender, race, class, ethnicity, etc. The change in landscape is here, moving from voices being seen and not heard, as would occur in a classroom where education courses are taught (Kress, 1988; Paton & Neilton, 1999).

Methods

Subjects

Data were obtained from sixteen intern teachers in an online web supported multiple subjects credential program in California. A qualitative methodology was chosen for investigating the text relating to on line discussion forums. Various qualitative methods such as discourse and content analyses were used.

The sixteen participants in this study are enrolled in a statewide California web supported multiple subjects pre-intern and intern credential program. The participants are in a cohort directly under the supervision of learning support faculty. The learning support faculty directs, supervises and mentors the intern teacher through four stages until completion of the multiple subjects program. The intern teacher completes all of their assignments online in an activity forum. The primary method of communication between the intern and learning support faculty is through the activity and discussion forums. Some other forums are also used to communicate, such as, synchronous (chat) rooms and a virtual teacher's lounge. The participants' ethnic background, sex, and age are diverse.

The main objective was to conduct exploratory and descriptive research methods that addressed the following research questions:
1) Does an intern teacher's psychological capitol influence how they begin to discuss and facilitate volatile issues on race, gender, ethnicity, sexism, ableism and ageism on-line? 2) Are intern teachers more or less likely to freely discuss issues related to social justice on line? Can patterns be distinguished in the textual representations of voice depending on the gender, age or ethnic group of the intern teacher? First the researcher sought to see how the participants responded to the general question on what is multicultural to determine what prior knowledge the teachers held on this social construct. Next, the researcher sought to determine if the teachers would discuss the issues stated above openly and freely. The results follow from threaded on line discussions. I write the words exactly as the teachers wrote them on line. I believe that it is best to represent the textual print from the teacher's own voice.

Therefore, this paper discusses visual representations of voice by selected intern teachers.

Data transcript from asynchronous forums (online discussion forums) required methods of analyses that would yield a higher resolution of detail, much of which was descriptive in nature. Qualitative methods described in Kvale (1996). Miles and Huberman (1984) were thus used to examine transcripts of focus group discussions. Content analyses and meaning condensation were conducted to note patterns and clustering of responses. Two independent raters coded the transcripts first using "open coding" techniques that determined logical groupings of responses, and then "focused coding" methods that identified emergent themes (Emerson, Fretz & Shaw, 1995). Coding of transcripts was accomplished collaboratively, as raters deliberated emergent themes and any discrepancies until a consensus was achieved.

Written comments on transcripts were also analyzed for content and themes. The researcher developed and then applied codes to the discussion forum transcripts and revised the codes to capture the essence of what was revealed in the data. These data was used to develop individual and cross-case narratives of the participants and to identify the sources of changes on participant's
visual representations of voice. The same qualitative process of analyses used for focus group data was used to examine responses from the surveys. Results are reported as content “themes” and patterns.

Results

The intern teachers were asked what is multicultural education the following responses were stated contextually on-line. The following responses were

Teacher #1

Multicultural education covers two areas: 1) education that is aimed at reaching students from all cultures and 2) education about all cultures. I believe, we, as teachers, need to educate ourselves about the cultures represented by our students. We need to try to understand nuances of the cultures. For example, what a teacher's status is in the eyes of that culture and whether it makes a difference if that teacher is male or female. I also believe our students need to learn about cultures that may be different from their own. They need to realize that, though culture may be quite different, it is not better or worse than their own...just different. I believe conflict often comes from ignorance and misunderstanding. If our students know something of each other's cultures, I think they will understand each other better and, hopefully, get along better now and as adults.

Debra

Teacher #2

Multicultural education to me is two ways of communication underscored by a respect for diversity of all people. I mean two ways in that students and teachers bring their varying cultures, experiences, preferences, language, dress, religions, etc. to a common place with the result that all students and teachers may become familiar and more aware of other cultures. In turn they take away a better understanding of other backgrounds.

Understanding and respect need to be stressed, when discussing various cultures and traditions. We don't have to argue all the merits and deficiencies of each culture. To find the best culture is not the object. There is no such thing. We may remind students that a bouquet of flowers is much more lovely and more interesting if there are many types of flowers in the arrangement. In our diverse school populations, the students make up an excellent multicultural pool to draw from.

Frances

Teacher #3

I don't have a lot of experience or understanding of multicultural education, per se, so I am glad we are focusing on it in our discussion. This said, to me also, multicultural education is more than heroes and holidays. It includes awareness and understanding of the cultural backgrounds of our students and members of the larger community. When referring to culture, I include ethnicity, language, heritage, religion/spirituality, and ways of interacting. Regarding our classes, I think we should be prepared to expose our students to multiple perspectives and be prepared ourselves to be exposed and accept multiple perspectives. More importantly have students analyze why the perspectives of oppressors and oppressed differ.

Janet

Education Significance and conclusions

The teachers engaged in ongoing textual representations of social identity and social justice issues begin to generate questions that occurred in their classrooms and apply the concepts of social identity and social. For example, one teacher said, "I had an interesting 'aha' day where I was able to apply what I was learning on-line. I work in an urban school district, and this question comes up more often than I ever expected it to, from white teachers, parents and teachers of color and the community in general. I had yet another experience with the question, "Do middle-class, white teachers have any business teaching students of color in an urban, low socioeconomic level school? Can they be successful? Or are they doing more harm than good? These questions generated many on-line discussions regarding issues of diversity, social justice and bilingual education. One teacher responded, "This is a very good question..." In fact, my dad and I were discussing this very issue over the holidays. My dad is a retired, over 65 Jewish, white male. He commented that most volunteers and teachers, who help children read, are white and that there needed to be more diversity." From this comment many other teachers got into the pros and cons to teaching in such environments. Another teacher commented, that she believed that if we had more teachers of different races teaching it would be wonderful, but not based on the fact that the children have cultural needs or culturally relevant pedagogy, but just by virtue of the fact we needed diversity.

The benefits of this research are numerous. In our current age of electronically mediated environments such as on-line courses and degree program, this research will explore the possibilities of developing specific curriculum that deals with issues on social identity in a web-supported (on-line) environment. It may also allow for a more in depth discussion of social constructs, such as, volatile issues as race, class, gender, and disabilities since the participants are not engaged in face-to-face interaction. It also allows for immediate responses to classroom issues because the teacher can immediately get on-line to engage in a threaded discussion without having to wait for next week's class.

The author concluded that an on-line environment provided a different method of communication about such issues, but in general individuals were still reluctant to deal with issues particularly around race. I found that more people were able to freely express themselves without having the sneers, rejection and embarrassment that sometimes occurs when in a face-to-face classroom environment. Research in this area also targets populations who would normally not be able to engage in such discourse due to limited access to colleges and universities.

This study only touches on a minute aspect of voice as it relates to web-supported online teaching and learning environments; it generated more questions than answers. Some others questions, which may be investigated in the future include: Is psychological capital so embedded that changing environments from face to face talk to online textual representations will not matter how the others may see or experience the person's voice? How much culture can emerge from the textual representation of the person who is expressing their voice? If the visual as a mode of representation is systemic, rule governed, and an effect of the values of the
culture in which it is used, then can we as researchers come to know what culture (race, ethnicity) someone is from merely by there visual representations (Kress, 1988; Paton & Neilson, 1999)?

Bridging the Differences on the Web Through Effective Communication and Collaboration

C. Y. Janey Wang
Doctoral Candidate
The University of Texas at Austin, U.S.A.
janeywon@mail.utexas.edu

Abstract: This paper explores how effective communication and collaboration among online learners of diverse backgrounds are encouraged by design. In addition, communication techniques utilized by members in the Web-based learning community in bridging differences, achieving group goals, and optimizing individual learning are explored. The researcher suggests that the ideal curriculum bridges diversities by encouraging, inspiring, and inviting multiple perspectives within a highly flexible environment of multiple communication methods, learning styles and approaches.

Introduction

Globally, market expansion and course offerings are increasingly assisted by use of the Internet. In education, the Internet has been widely used in preparing learners for “future responsibilities” and “success in life” (Dewey, 1938, p. 17). Cross-nation collaborative projects on the Internet across disciplines have exponentially increased internationally in recent years. Amidst the hype of cutting-edge technology, however, it is often overlooked that computers do not think, only humans do; computers do not have agency, humans do; technological difficulties do not limit intellectual advancement, humans do. Technology potentially provides an array of resources, but also presents constraints. Indeed, humans ultimately decide how to utilize new technologies, and these decisions are often based on both proven (or unproven) and discovered strategies. To integrate technology into instruction and learning, it is essential to focus on human needs, strategies, perceptions, and experiences communicating and collaborating in the cyber-learning environment — rather than solely on the functionality of technological tools.

As Web-based learning communities and online school partnership projects exponentially expand globally, effective communication and collaboration is, as never before, of vital significance. Web-based instruction provides opportunities for a diverse body of individuals to interact. In order to optimize individual learner’s strengths and talents, Confucius said, instruction should be tailored to meet individual learner’s needs. While instructors are challenged to understand and be sensitive to the needs of learners in their design and implementation of Web-based courses, learners’ success hinges not only on their willingness, attitude, and devotion to achieve shared goals in a sea of information, but also on how they handle the challenges of consolidating fellow learning community members’ multiple views, perspectives, and approaches.

Based on my experiences as a student, researcher, course moderator, instructional designer, and teaching assistant in a Web-based collaborative learning curriculum model, this paper explores how effective communication and collaboration among members of diverse backgrounds may be encouraged in the design and implementation process and what intercultural communication techniques may be or have been utilized by members in the Web-based learning community in bridging differences, achieving group goals, and optimizing individual learning. This paper examined a Web-based collaborative learning course model at the University of Texas at Austin. In this course model, multiple perspectives are valued and group diversity was considered in forming collaborative virtual teams. Factors such as ethnicity, gender, computer skills, and geographic locations were also considered in building virtual teams. Students engaged in activities where knowledge is constructed through negotiation among collaborators from diverse backgrounds.

Diversity, Communication, and Web-Based Instruction

The Internet is a global society involving users of diverse backgrounds, and this global society is comprised of various communities with unique cultures. This Internet society is constantly evolving due to the evolution of tools and stakeholders involved. In this society of communicating collaborators, the methods of
communication and collaboration evolve along with technological tools and human interaction dynamics. Web-based instruction has often been implemented to supplement, enhance, and transform existing curriculum. Some instructors use the Web to post syllabus online, to supplement face-to-face class teaching, to broaden the scope of their instruction, or to deliver courses in their entirety. Many distance-learning courses, however, have encountered high attrition rates (Galusha, 1997), unequal participation and individual commitment, role ambiguity in group contexts, absenteeism, inattention to social relationships, and students feeling overwhelmed (O’Hara-Devereaux & Johnasen, 1994). The viability of effective communication and collaboration in the absence of face-to-face interaction has been questioned (Handy, 1995). Students may feel isolated, unmotivated, or unchallenged when they find course content irrelevant, perceive the environment as impersonal, can not obtain immediate technical or instructional feedback, and feel disconnected from fellow learners. These shortcomings originate from a lack of understanding and sensitivity to the dynamics of human interaction and the nature of human learning.

Communication in this Web-based collaborative learning environment includes both task and social aspects. Due to communication limitations, online collaborators easily spend a large portion of time understanding, checking, confirming, coordinating, and negotiating to obtain mutual understandings and to construct shared knowledge. With the limitations in Web-based communication tools and the resultant reliance on interpretations and assumptions, effective communication among learners of diverse backgrounds is very challenging. A few examples of Web design that may be open to cultural interpretation include: various expectations for communication, the amount and type of information desired, communication styles and preferences, level of task orientation, variation in understandings, group orientations, and group dynamics.

Communication among people of congruent cultures, societies, and backgrounds – or even from the same family – is challenging. Communication among people of different cultures, societies, and backgrounds is even more challenging. Collaborative communication across cultures in the online learning environment requires the willingness of community members to listen, respect, and accept different perspectives and to accommodate and negotiate to reach shared meanings. Community members must also be flexible in accepting ambiguities; provide mutual respect, trust, and support; and develop cultural sensitivity and understanding of the value of multiple perspectives. Finally, community members must negotiate shared meanings in obtaining mutual understanding in order to reach consensus for the achievement of shared goals and needs.

Conclusions

Given the diversity of the global Internet society, cultural sensitivity and flexibility are essential to collaborative virtual classroom success. Future studies should focus on in-depth understanding and analysis of the needs of learners from diverse cultures. Web-based instructional designers, instructors, and moderators should employ multiple approaches and strategies in designing, developing, and implementing their courses and in assessing students in order to meet the needs of learners from diverse backgrounds and to inspire and encourage constructive communication and collaboration. Cultural sensitivity may assist in bridging the cultural diversities and contributing to overall course success. Building global communities of diverse learners requires that courses not simply represent an autocratic instructor’s curriculum in the absence of consideration of multiple needs and resources; the ideal curriculum should encourage, inspire, and invite multiple perspectives, provide a highly flexible environment where multiple communication methods, learning styles and approaches are invited.

Together We Form a New Culture: Students' Perspectives on the Influence of Diversity in a Web-Based Collaborative Learning Community

C. Y. Janey Wang
Doctoral Candidate
The University of Texas at Austin, U. S. A.
janeywon@mail.utexas.edu

Abstract: This paper investigates students' perspectives on how cultural diversity impacts learning in an online collaborative learning course. Specifically, how students successfully achieve optimal learning in this online learning community as they collaborate with members of diverse backgrounds was explored. Study participants were eight Instructional Technology Planning and Management (ITPM) students. ITPM was offered in Spring 2001 at the University of Texas at Austin (UTA), and was conducted within a Web-based collaborative learning environment. Findings suggest that collective and individual successes are enhanced by the formation of a collaborative group culture within this setting. Evidence that diverse views on culture and that new cultures evolve within the Web-based collaborative learning environment were found. Results suggested that Web-based collaborative learning course instructors should consider group diversity in their collaborative team assignments in order to further facilitate group dynamics and optimize learning.

Introduction

The development of computer network technology provides opportunities for dynamic human collaboration. Educators of all instructional levels are learning and integrating technology into curriculum and instruction. Internet access in public schools and instructional sites in America has increased from 35 percent in 1994 to 89 percent in 1998 and is expected to grow further. Student computer use has also increased from 27.3 percent in 1984 to 68.8 percent in 1997 (U.S. Department of Commerce, 1998). Major reasons for this rapid growth include technology's capacity for reaching remote locations while providing immediate and engaging communication, its promise of collaborative opportunities, and the human need for connection and interaction. Given the increasing opportunities and challenges for global communication and collaboration among members in the learning community, it is essential to assess methods of bridging the differences among community members and to establish curriculum that facilitates meaningful interactions and collaborations among members of divergent backgrounds.

The current study is an extension of a previous exploratory study conducted by Wang (2001). The four participants of that exploratory study represented four different ethnic backgrounds (American, Chinese, Latino, and Southeast Asian) and were all Computer Supported Collaborative Learning (CSCL) students, which was offered at the University of Texas at Austin (UTA) in Fall 2000. Based on the same course model and offered by the same instructor, participants of the current study were from another course, Instructional Technology Planning and Management (ITPM), offered in the following semester, Spring 2001 at UTA. The CSCL 2000 and ITPM 2001 courses both employed Web-based collaborative learning to both on-campus and tele-campus students. A major finding of the previous exploratory study was that, due to the overwhelming reliance on text communication and concomitant lack of non-verbal communication cues in the Web-based collaborative learning environment, collaborators relied on their own assumptions and interpretations in communicating and interacting with the instructor, staff, and peers. As a result of these missing non-verbal communication cues, misunderstandings frequently occurred while group success relied on individual's communication and management skills. Culture, as described by participants, impacted communication and collaboration within this setting. Yet, cultural-related communication factors were largely taken for granted, perhaps because communication is so routine.

The Study

The current study sought to include diverse views. In recruiting prospective participants, diversity in participants' course accessibility (on-campus and tele-campus students), gender, and ethnicity were striven for. In all, four on-campus and four tele-campus ITPM students were recruited on a volunteer basis to participate in this study. Participants (five European-Americans, one Korean, one Mexican-American, and one Chinese) were all 25 to 55 years of age and evenly divided by gender, and were interviewed either face-to-face or by phone. To ensure data triangulation, three types of data were collected: individual interviews, online discussion archives, and focus group audio conferences. Participants were asked to define cultural diversity, to describe how diversity affected their
communication, collaboration, and learning in this ITPM Web-based collaborative learning course, and to discuss strategies they have used or may use to bridge in-class cultural, social, and individual differences in order to achieve optimum collaboration and learning. The individual and group interview tapes were transcribed, categorized, and analyzed. The online discussion archives, e-mail responses for follow-up questions, and online chat transcripts were also analyzed.

Findings

Findings suggest that diversity is viewed as being beneficial but challenging in that group diversity, while providing collaborators opportunities for exposure to multiple perspectives, views, and approaches in which to further reflect on their own learning also challenges collaborators with divergent views and personalities, ways of communicating, approaching issues, and work styles. Results indicate that certain communication, management, and social skills are essential in order to achieve effective group collaboration while optimizing individual learning. Study participants viewed group diversity as necessary for meaningful interactions and endorsed the idea that group diversity provided multiple perspectives and "reality-check" opportunities. Participants thought collaborative group intellectual exchange was facilitated by the diversity of members in regards to gender, geographical region, community, work, personality, and frames of minds.

Participants said dialogue is essential in drawing strength from diverse expertise within the learning community. An emerged theme expressed by participants is that a unique online collaborative learning culture forms within these settings. This new culture entails unique approaches to communication, interpersonal skills, information management skills, and knowledge about global cultures and values. Further, this environment spurs new manners and need to multi-task, to interact with others of multiple and diverse backgrounds, and to not simply obtain information, but manage, make connections, apply, and reflect. This requires an infusion of variations in expertise, frequent information sharing and exchange, positive and constructive feedback, and knowledge construction, co-construction, and re-construction. Participants reported that learning is more meaningful when collaborators identify themselves to the group and find their contributions useful for group success. In order to work online to achieve goals and produce joint effort products with those of divergent cultural or socio-economic backgrounds, worldviews, values, and interests, communication skills in expressing, negotiating, and decision-making are essential, participants indicated. Further, the willingness to be committed, accountable, and responsible to group success, as well as information, time, and people management skills are also essential to success within this setting, respondents indicated.

Conclusions

While successful collaboration within the cyber environment is impossible without interfacing with a computer, it is equally reliant on effective human interaction and cooperation. Results indicate that an unique collaborative culture in the online learning environment arises, based on mutual respect, effective communication and management skills, cooperation, positive interdependence, commitment to a collective goal, and amalgamation of strengths from diverse expertise among community members. The challenge within the cooperative and collaborative environment is to discover how individual members' strengths can be melded into collective outcomes that are greater than the addictive contributions of individual members. The instructors, instructional designers, and online moderators/ facilitators should be aware of and avoid imposing or framing their values on learners when designing and implementing courses. Collaborative learning community members should learn to not only express and respond to ideas, but to also listen and facilitate fellow members' ideas in order to enhance overall group success while simultaneously optimizing individual successes.

Teaching and Learning in Intergenerational and Intercultural Classrooms: Report on a Classroom-based Research Project

Minjuan Wang, San Diego State University
mwang@mail.sdsu.edu

Terre Folger, Westminster College
folgert@jaynet.wcmo.edu

Abstract: This study describes and relates the experiences of Dr. Wu, a junior, female foreign-born faculty member at a west coast U.S. university. Dr. Wu and her students faced the challenges of a culturally diverse classroom in her first teaching assignment, "Technologies for Teaching," a graduate-level course offered for in-service teachers and students enrolled in teaching credential coursework. We will address issues of intergenerational and intercultural communication and suggest effective strategies to facilitate communication and learning in classrooms with instructor and student diversity. The paper discussion format will offer the opportunity for sharing this information with those interested and involved in college classroom research, as well as provide feedback to our research efforts.

Purpose

College classrooms are becoming more complex in nature. Changes in the professoriate, the student population, and rapidly developing technology contribute to this complexity. Finkelstein, Seal, and Schuster (1999) suggest that radical changes are occurring in the academic profession as more women, foreign-born, and minority scholars become college professors. In regard to technology, students have diverse backgrounds, levels of expertise, and learning needs. Kellner (1998) writes that faculty face the "challenge of providing people from diverse races, classes, and backgrounds with the tools to enable them to succeed and participate in an ever more complex world," (p. 211). This study describes and relates the experiences of Dr. Wu, a young, female foreign-born faculty member at west-coast U.S. university. Dr. Wu and her students faced the challenges described above in her first teaching assignment, "Technologies for Teaching," a graduate-level course offered for in-service teachers and students enrolled in teaching credential coursework.

In this paper, we address issues of intergenerational and intercultural communication and suggest effective strategies to facilitate communication and learning in classrooms with instructor and student diversity.

Theoretical Framework

The authors hold the social constructivist belief (Ernest, 1995; Rogoff, 1990; Vygotsky, 1978, 1986) that shared knowledge develops through joint activity and communication. This belief accords classroom communication a central place in the study of teaching and learning (Barnes, 1976; Edwards & Mercer, 1987; Edwards & Westgate, 1987). Diversity also impacts communication and attitudes in the technology classroom (Chamberlain, Guerra, & Garcia, 1999; Freedman & Liu, 1996; Kay et al., 1983).

Intergenerational and intercultural classroom dynamics affect pedagogy. Kay et al. (1983) report that an intergenerational classroom had greater student participation than a comparable classroom. Wlodkowski and Ginsberg (1995) report ways to motivate people in culturally diverse classrooms, emphasizing fairness and respect as they suggest strategies that facilitate diverse people's learning together.

Methods

The interpretive paradigm (Maykut & Morehouse, 1999) provides the methodology and directs the case study method (Yin, 1989, 1994) used in this study. In the case study, two class sections are considered two holistic cases, and the groups and individuals are considered the embedded cases.
Participants

Dr. Wu taught two sections of the required course, "Technologies for Teaching" (Section 1, n= 19; Section 2, n= 18). Both sections included in-service and pre-service educators, ranging from 23 to 60 years in age. The age range in Section 2 was larger (ages 22-60) than in Section 1 (ages 23-33). Section 2 was also more ethnically diverse.

Dr. Wu was born in a small village in northern China. She attended Beijing University, receiving her B.A. in Chinese Literature. Dr. Wu then earned her Master's degree in Comparative Literature at a major U.S. east-coast university. She received her Ph.D. in Information Science and Learning Technologies from a large mid-western university, where she embraced a constructivist approach to teaching and learning. At present, she is an assistant professor at a U.S. west-coast university.

Course Description

"Technologies for Teaching" is an introductory course that provides hands-on experience with computer technology in education. The goal of this course is empowerment of pre-service and in-service teachers as users of computer-based technology with instructional and professional applications.

Data Sources

In this study, multiple data sources were used. Web-based Incoming and End of the Semester Surveys, administered in Week 1 and 16 are data sources for assessing learning outcomes and students' perceptions of the classroom environment. In Week 9, the students completed an informal, voluntary email survey on diversity awareness. The email survey provides information regarding students' perceptions of cultural and generational diversity.

Dr. Wu, assuming the role of participant-observer, took notes during the students' in-class group activities and wrote reflective memos of classroom communications. The structure of the class, a combination of instructor presentation and students' hands-on activities, made observations possible.

Part Two of the End-of-Semester survey and Dr. Wu's determination of students' grades assessed learning outcomes. Determinants for evaluation were (a) portfolio projects, (b) journal entries on readings from the textbook and the course website, (c) a PowerPoint presentation related to teaching and learning (with an emphasis on technology), (d) degree of development in a web-based learning unit, and (e) classroom participation. For grading purposes, all students submitted a one to two page reflection on their collaborative process. The students completed their written reflections at the end of the semester.

Data Analysis

Quantitative and qualitative methods were combined in data analysis. Initially, we analyzed the quantitative survey data from the two web-based surveys. These data are accompanied by description of the themes and patterns discovered in line-by-line and axial coding of the narrative data (Strauss & Corbin, 1998).

Results

Results are reported for incoming student data, students' learning and attitudinal outcomes, student-written reflections, and learning outcomes. Part Three of the End-of-Semester survey assessed students' attitudes about the "Technologies for Teaching" curriculum. The e-mail survey produced limited, but interesting results regarding students' awareness of generational and cultural diversity. Written reflections regarding students' perceptions of collaborative group work revealed three major themes.

Incoming Student Survey
The Incoming Student survey showed that the students in the two Sections were similar in enrollment status. No statistically significant differences were found between the entering self-rated computer skills, awareness of ethical use of computer or technology, and the integration initiative of the students in the two sections.

Learning Outcomes

An independent t-test (p=0.5529) performed on response data indicates no statistically significant differences between the two sections' self-perceived technological skills at the end of the semester. However, the average grades of the two sections were significantly different (p<0.005).

Attitudinal Outcomes

End of Semester Survey

Part Three of the End-of-Semester survey assessed students’ attitudes about course curriculum. Students’ attitudinal outcomes are related to the level of their engagement and the learning outcomes. Section 2 students had a more positive (p<0.005) reaction to the course.

Email-Survey on Students’ Diversity Awareness

Three Section 1 students and five Section 2 students responded to the non-obligatory email survey. Six themes emerged. Themes identified in Section 2 responses are (a) respect for the instructor (b) sympathy with the challenges of teaching in a foreign country (c) enjoyment of the intergenerational and intercultural diversity and (d) appreciation of the instructor’s cultural background. Section 1 students’ responses resulted in two identified themes: (a) their lack of recognition of classroom diversity and (b) Dr. Wu’s position as a role model for Asian American students.

Students’ Written Reflections on Group Collaboration

Dr. Wu encouraged students in both sections to work in collaborative groups. Individual differences in students’ attitudes towards learning and each other shadowed their teamwork orientations. The reflections reveal that Section 2 students’ collaborations were motivated by common interest, and Section 1 students collaborated to complete assignments.

Discussion

Based on interpretation of the data, we consider the impact of cultural and generational diversity on communication. We also reflect on the influence of intercultural and intergenerational communication on learning outcomes.

Cultural and Generational Diversity’s Impact

Cultural and generational diversity in these classrooms could have been an obstacle for effective learning. In this case, the instructor and students used their diversity to develop a supportive learning environment. Dr. Wu provided the opportunity for students to form groups based on their own criteria. As a consequence, some of the groups had members of similar backgrounds, while others reflected the diversity of the section. The groups discovered their own ways of communication and collaboration.

One group reports that they formed a group based on the strength of each member in designing, developing, researching or gathering information. The members disregarded age and ethnicity when looking for collaborators. Through his comments one student in this group implies that he is a member of a culture that transcends age and ethnicity, a teacher culture based on effective and open communication.
Communication's Impact on Learning Outcomes

It seems that diversity was not an obstacle but motivated students' engagement in learning tasks. In Section 2, the students formed groups that were diverse in both culture and age. They admitted there were differences in their styles, how they approached cooperative learning group tasks, for example, but also agreed that being able to openly express conflicts in opinion led to resolution. Resolving conflicts regarding learning tasks clarified their thinking and affected the quality of their work. They recognized intergenerational differences as well, but were able to arrange a "comfort zone" so that experience contributed to their projects as much as expertise.

Educational Importance

This research has implications for teaching in multicultural, generationally diverse classrooms and with regard to student-teacher interactions when diversity extends to faculty. Student and faculty diversity have enriched but also complicated the technology classroom. Because the course objective is students' incorporation of technological tools in teaching and learning, the students' diverse experiences provided more opportunities for the class to explore technology integration. On the other hand, the students' large variance in entering computer skills, learning styles, and English fluency created challenges for effective instruction. Instructional style, building supportive learning environments, and facilitating group collaboration were important factors in addressing these variances.

Dr. Wu balanced whole-class instruction with individualized learning. She reduced direct instruction and allowed individuals to self-pace their learning. She also paired students of different backgrounds during in-class activities. Students' reflection on their positive collaboration experiences is tangible evidence of success.

As Wlodkowski and Ginsberg (1995) noted, "people who feel unsafe, unconnected, and disrespected are unlikely to be motivated to learn" (p.2). Classrooms of diversity face such challenges if diversity is ignored and devalued. Dr. Wu was aware of the diversity and attempted to build a positive learning environment through that awareness. In this study, giving students sufficient latitude to form groups through choice and explore methods of collaboration provided a naturally formed "comfort zone." Student-student communications should be monitored and mediated by faculty. Instead of eliciting compromise as a solution to conflict, students should be encouraged to resolve the conflicts through negotiation and rational debate (Derry, Gance, Gance, & Schlager, 2000; Mercer, 1995).

Hall (1992) notes that individuals from different racial and ethnic backgrounds have subtle variations in the ways they communicate. Often, members of other cultures are unaware of these variations. Lack of recognition can lead to misunderstandings. Using examples, both culture- and nonculture-specific, to illustrate a point or an abstract idea is a common instructional strategy that has twofold application in a culturally and generationally diverse classroom.

Diverse Faculty Issues

Dr. Wu interacted with the Section 2 at a more complex social level because of a higher level of acquaintance. These students related to her that pivotal points to successful teaching were a) the instructor's attitudes and efforts and b) students' perceptions of faculty as knowledgeable, enthusiastic, supportive, and patient. Dr. Wu found that she incorporated student suggestions into classroom instruction.

Students from other countries, preparing to be teachers in the U.S., noted that they might "feel a cultural shock when meeting very challenging students." Dr. Wu responded that she had had similar feelings. Dr. Wu's experience implies that faculty born in foreign countries may find it necessary to adopt a more democratic and issue-oriented stance to encourage community-building in a culturally and generationally diverse college classroom.

Conclusion

From this experience, Dr. Wu drew three important conclusions. She observed that a) her own cultural expectations caused her to be offended by a student's critique of her teaching; b) students have expertise and expectations that can improve her teaching; and c) age and culture differences can build classroom community if facilitated positively. Likewise, as college classrooms become more diverse, it is important that our "teaching culture" recognizes and benefits from this diversity.
References

The educational computing course for pre-service and in-service teachers continues to change and evolve as it tries to meet national technology standards, NCATE accreditation standards, the needs of the different school districts, as well as the needs of the individual candidates themselves. The designers of the educational computing courses, each at his or her respective universities, base their course revisions on input from all these entities (ISTE, NCATE, ISD's, candidates) in addition to feedback from candidates who have taken the course and colleagues who have taught a similar course. This section helps to further the change and evolution of the course with the theme still being the preparation of the beginning teachers and the professional development of the in-service teachers.

The papers for this year reflect this process, some more than others and some in very different ways. One paper by Ray advocates the establishment of a basic computer literacy exam. “As a result of this study it was determined that pre-service teachers should be tested on their overall basic computer literacy as well as participate in courses to enhance established computer skills in an effort to be well prepared to lead a twenty-first century classroom.” She found that many teacher candidates, whom they hypothesized would be more computer literate than teacher candidates in the past, still did not many of the basic computer skills.

Other papers advocate changing the structure of the educational computing course. Whitaker and Hofer’s paper describes a new model for pre-service educational technology classes in which “efforts are being made to tie the content of the class to the content of methods and content-area courses – which, if successful, will strengthen students’ experiences with all classes”. The paper by Crawford and Willis questions if standards can be met and evaluated through an online teacher education technology course. “The continual evolution of the national technology standards creates a continual state of flux within the world of instructional technology. However, this creative online environment offers the possibilities that may not be available within other specialization areas; namely, the opportunity to reinvent conceptual frameworks of understanding and creative endeavors.”

And finally Brownell proposes integrating media literacy into the educational computer course for pre-service secondary teachers. He believes “an important step in doing this is application of an acquisition model of media literacy, where skills gained with technology (production) and knowledge about media messages and the system that brings us to them are presented in a positive way. At a time when the most powerful communication means to ever exist interacts with our students (and us) every day in literally thousands of ways, we must not teach about technology without recognizing this fact and the impact such interaction has on our personal, professional and civic lives. The course mentioned here is a natural place to start integrating these important concepts and skills into the education of future teachers. Knowing how, without knowing why, invites manipulation. Knowing how and why invites participation.”

Wren Bump is a clinical assistant professor in the Instructional Technology Program at the University of Houston. This is her ninth year to teach the educational computing course at UH and before then she taught the same course at Texas A&M University and Texas Southern University. Her other educational experience is in elementary education and special education. She can be reached at wren@uh.edu or 713-743-4296. Class website: http://pilts.uh.edu/~wren/courses.htm
Integrating Media Literacy into a Technology Course for Preservice Secondary Teachers

Abstract: This paper, after briefly explaining the content, placement and delivery method of EDTL 367 - Computer Utilization in the Classroom - Secondary, presents a definition of media literacy and a rationale for integrating media literacy concepts and activities into the course. Examples of appropriate activities are given and a number of relevant resources for further information about media literacy are cited. As available, student and instructor reactions to a pilot introduction of media literacy concepts into the course are offered.

Introduction

Strong initiatives to integrate technology into the schooling of children in the U.S. have been constant for almost two decades, going back at least as far as the report "A Nation at Risk" (Gardner 1983; Martinez & Mead 1988). This discourse historically centers around the notion that skill with technology will be important for employment in the global economy and that therefore, skill with technology is, and will be, a necessary (and empowering) experience for our youth, especially as they become working citizens (Gilder 1993; Marshall & Bannon 1988; Naron & Estes 1986). Such interest has led to the general acceptance of the integration of a technology component into the K-12 curriculum and to the curriculum to prepare K-12 teachers (Brownell & Brownell 1998; Brownell, Haney & Sternberg 1997; Handler & Strudler 1997; Strudler, Handler, & Falba 1998; Ohio Department of Education 1996).

This movement, at times successful but always constant and kept in the public's sphere of attention consistently over time, does, however, have credible critics. Such critics question the reality of the proposed educational benefits of technology in schooling, the inequities of access to powerful technologies in school and in the greater society, and the sociological effects of a range of technologies in the schools and in society (Bowers 1993; Bromley & Apple 1998; Cohen 1987; Cuban 1986 2001; Giroux 1997; Marvin 1988; Ragsdale 1988; Sutton 1991).

Amid this debate, two (among other) intriguing areas emerge as a positive focus regarding both K-12 experiences with technology and preservice and inservice teachers' technology education. One area is the ongoing investigation and use of technology in learning to help teach problem solving, critical analysis skills, and encourage creativity (Jonassen, 2000; Papert 1996; Papert 1980). This is especially interesting since some make a case that creativity is the determining factor in success in the global economy, not skill with technology (Reich 2000). The second area is that of broadening the scope and understanding of technology in the schools to include a media literacy perspective, which addresses important skills and issues beyond the "technology equals computers equals workplace skills" rationale/approach and also offers important opportunities for experiences with problem solving, critical analysis skills, and opportunities to enhance and encourage creativity. Integrating aspects of this second approach also offers the benefits of gathering insights from well-developed

486
Page 425
bodies of research in areas such as communications, literacy research, popular culture, and curriculum studies (Brownell & Brownell 2002, in print; Brownell & Brownell 2001; Hobbs 1998; Hobbs, 1997; Kubey & Baker 1999; Tyner 1998).

This paper will address the integration of media literacy into a required course for secondary majors, EDTL 367 - Computer Utilization in the Classroom – Secondary. A brief explanation of the course will be presented and followed by a definition of media literacy, relevant example activities, and several resources for further information about media literacy.

EDTL 367 - Computer Utilization in the Classroom – Secondary

The EDTL 367 course was originally piloted in the spring of 1994 and became a required course for secondary majors in 1995. The intent is to provide learning experiences regarding relevant pedagogical concepts, as well as skills with technology, tailored to preservice students who will teach grades 7–12, though most expect to teach at the secondary (8–12) level. Although not a methods course, it is scheduled within a methods block wherein students concurrently take a methods course and engage in field experiences. The course description is: “Impact of the computer on educational methods and applications in the classroom. Evaluation of software. Integration of the computer and associated technologies into the content areas.”

Media Literacy

Media literacy may be defined as the ability to access, analyze, evaluate and produce communication in a variety of forms (Aufderheide & Firestone 1993). As a part of the curriculum for schooling children and adolescents, media literacy is well established in every major English-speaking country in the world, except in the United States. That has begun to change over the last several years (Tyner 1998; McBrien 1999). Across the U.S., media literacy has begun to be addressed in state standards, the K-12 classroom, and in teacher education (Brownell & Brownell 2000; Kubey and Baker 1999; Hobbs 1998).

Beyond the brief definition above, there are several concepts about media literacy that are important and which focus on the media messages generated through various media (T.V., video, film, music, the web, computers, radio, etc.): 1) All messages are constructions; 2) Messages are not representations of social reality; 3) Individuals negotiate meaning by interacting with messages; 4) Messages have economic, political, social and aesthetic purposes; and 5) Each form of communication has unique characteristics (Hobbs 1997). Developing an understanding of these concepts through reading, discussion, activities and hands-on experiences with relevant media and tools to create media, can be a powerful experience for preservice and inservice teachers.

Additionally, scholars such as McChesney (2000, 1999), Rushkoff (1996), and Beder (1998) would hold that understanding the system that allows us to interact with powerful media/technology is an essential part of media literacy. This will be especially true in any society working to establish and/or maintain a representative/participatory democracy where access to relevant information and knowledge of its source, accuracy, “spin,” and intent are crucial for informed decision making by citizens.

Media Literacy & Computer Utilization in the Classroom – Secondary

The basis for understanding our interactions with media (such as the types of media/technology mentioned above) is developing the skill of critical analysis and applying it to such interactions. The creation of media products is an essential component of such learning (hence the definition of media literacy above which includes the ability to, “...produce communication in a variety of forms.”) Because of the ubiquity of media, opportunities to tie meaningful media literacy experiences to every subject are plentiful. Some, and usually almost all, forms of media with which we regularly interact provide opportunities to address (to name a few) subjects such as science, literature, math, the arts, history, politics, economics, writing, and reading (both in the traditional alphabetic sense and also in “reading” of art forms such as movies), etc. This can often be done without creating a separate course of study. Rather, by introducing key media literacy concepts within any subject area, the existing curriculum in that area can be addressed from a media literacy perspective. One other
The benefit of this approach is the comprehensive view that technology equals more than simply computing, while at the same time affording opportunities to use important, empowering technologies to create products that apply media literacy concepts and help develop problem solving and critical analysis skills, as well as encourage creativity.

Activities can be built around interaction with specific media/technology (T.V., video, film, the web, radio, computers, and so on) with attention to media literacy principles and media messages. In the broad sense, activities can include asking questions such as: What is the reason for (intent of) this media message?; What is its economic purpose?; What is its source?; What characteristics does the medium it is offered through possess?; How successful is it?; What is its target audience?; How can I appropriate the medium (technology) it uses for my own viewpoint?; etc.

In science, media messages can be examined in one or more formats (e.g., T.V. news, documentaries, film) about a controversial issues such as cloning (or toxic waste disposal, or nuclear power, or the extraction industries, or global warming). The use of different media techniques, and the various viewpoints expressed on the issue, can be compared to each other, and to the views of mainstream scientists. In math, the use of statistics can be explored in various media settings in relation to topics in politics (the 2000 election), the economy, the entertainment industry, advertising, and much more, to unravel the constructions where the numbers are used (or abused), such as commercials, stock market reports, political sound-bites, newspapers, etc. In literature, a greater understanding of film as an art-form can lead to a better understanding of novels and stories, both their structure and meaning, including their unstated purposes such as social control/influence or even blatant propaganda. As one teacher stated, “I can’t teach a novel without students ending up talking about films.”

The web can be a rich source and an important source for understanding media literacy principles. Applications in library/research skills, writing and reading are obvious, as well as specific content found on the web. Students can take a topic (say commercialism in schools) and: 1) search the web to find sites on the topic; 2) analyze each site as a construction with an ideological/political, social, and economic purpose; 3) compare the site, as a construction, to student’s views of social reality; and, 4) analyze the media techniques used in the construction of the site (not the technical techniques/design parameters) and evaluate the effectiveness of the site. Students can also compare sites on the same topic with different points of view. In a recent class, students did a similar activity to prepare for a debate (one side for, one against) on commercialism in the schools and then held the debate. The chance to look at the web in this way and to prepare for and then debate the topic proved highly motivational and sparked student involvement and excitement about both the topic and the idea of the web as a provider of carefully constructed media messages.

Students, after a brief introduction to public relations and propaganda techniques, perhaps from the view of advertising, or of politics, can make audio, video, or web-based constructions for a specific purpose, to convey their own media messages. Undergraduates can role play being secondary students and make a commercial for a calculus course, or for their school, or to support a levy issue (all of which teachers in our graduate media literacy course have had their secondary students do). Undergraduates could divide into two groups. One group could make a video attacking Wal-Mart’s practice requiring that edits be made to lyrics and songs that they find objectionable before they will sell the CDs. A second group could make a video supporting the policy. (This is especially interesting when students learn that Wal-Mart is the largest retailer of CDs in the U.S. and is willing to use that power to gain compliance with their imposed standards from many artists and labels.) Adopting one of the many music video styles and the techniques of that medium, students can create a music video supporting a political candidate and, using the same results from the same research, create a music video against the candidate.

Resources

The brief sketch above is just that. Through the web especially, instructors and students can gain access to a wealth of materials about media literacy including background information, lesson plans and ideas, organizations and projects, videos, books, speakers, and, in a few cases, media literacy standards from forward looking states and districts. The following are a few places to get started on the web:

- Center for Media Literacy: http://www.medialit.org
- Media Literacy Clearinghouse: http://www.med.sc.edu:1081
- Just Think Foundation: http://www.justthink.org
- PBS Teacher Source–Media Literacy: http://www.pbs.org/teachersource/media_lit/media_lit.shtm
Conclusion

Media, and technology, are often referred to as “powerful,” as in, “T.V. is a powerful medium.” Gaining skills with technology, and learning about technology, must include an understanding of what makes media and technology powerful when we interact with them. Media literacy offers a way to gain this essential information; a way to get to the why, as well as the how, of modern communication media/technology; a way to understand how media messages are constructed, with what intent and success they spread; and a way to understand the system which brings us to these media messages.

An important step in doing this is application of an acquisition model of media literacy, where skills gained with technology (production) and knowledge about media messages and the system that brings us to them are presented in a positive way. At a time when the most powerful communication means to ever exist interacts with our students (and us) every day in literally thousands of ways, we must not teach about technology without recognizing this fact and the impact such interaction has on our personal, professional and civic lives. The course mentioned here is a natural place to start integrating these important concepts and skills into the education of future teachers. Knowing how, without knowing why, invites manipulation. Knowing how and why invites participation.

From Video Tutors to Electronic Portfolios: Using Advanced Screen Capture In Support of Educational Technology Instruction

John Bryner, Southern Utah University, US
Matthew Nickerson, Southern Utah University, US

Among the many burgeoning "support" applications that can enhance the technology training of preservice teachers there is new group of simple and inexpensive "advanced screen capture" programs that should not be overlooked. Also referred to as video screen capture or moving screen capture they perform a rather simple yet powerful service. Like "older" screen capture applications, video screen capture can record whatever is displayed on a computer monitor but instead of a single "screen dump" video screen capture allows the user to record the monitor's image over time and create, as the name implies, a movie of what is happening on the screen.

At Southern Utah University's College of Education we have employed advanced screen capture techniques to enhance our educational technology course. At present this technology is helping in three important areas: 1) it supports faculty and lab assistants in teaching the basic software applications required for information literacy, 2) it enables teacher candidates to create powerful artifacts for their electronic portfolios, and 3) it introduces a new tool for K-12 teachers.

Educational technology faculty first used this capture technique in support of basic software training. There are several software applications that are covered in all sections of the course and instructors are anxious for their students to master the basics as quickly as possible so the important issues of integrating technology into teaching/learning can be discussed and practiced. As reported throughout the country and in the literature, students are coming to college with a wide range of information literacy and computer skills. While some arrive having already mastered many productivity and Internet applications there is still a significant percent that come with considerable reluctance where computers are concerned and with few or no computer skills.

In an effort to reduce class time devoted to software basics and to support intimidated or less prepared students the faculty have created small video vignettes using movie screen capture that demonstrate basic operations for each of the principle software applications used throughout the course. These vignettes, or video tutorials, are saved as Quicktime® movies and made available to students through the Internet via online course syllabi. Students who are struggling or who just need a simple reminder can open the video tutorial whenever they need assistance. This is especially helpful when the teacher or lab assistant is not available. The tutorials open in a small display window and can be viewed simultaneously with the application they are learning for quick and easy reference. The Quicktime® format allows students to pause, reverse or fast forward the tutorial in order to view the exact process in question and to view it as many times and at whatever speed they wish.

Reports in the literature attest to the successful use of similar video vignettes to support classroom instruction in a variety of different disciplines. Their use in training teacher candidates is proving equally successful. The ISTE standards are a prime focus of our educational technology curriculum and as candidates progress through their course of study they not only learn and practice the use of technology in the classroom, they are also mastering the tools necessary for creating and maintaining an electronic professional portfolio. Advanced screen capture tools are proving very useful in preparing artifacts for their portfolios that demonstrate competencies described in the ISTE standards. For example, a student can create a screen capture "movie" documenting their step by step creation of a PowerPoint® presentation. Because these advanced screen capture applications can include a sound track, candidates can narrate the process and add important pedagogical notes and/or personal reflection to their computer demonstrations that are destined for their portfolios. Even more powerful is the use of advanced screen capture with sound to record their lecture synchronized to the presentation slides demonstrating their appropriate use in the classroom.

Every hardware, software, or Internet application introduced to our candidates is taught and practiced at four levels: 1) basic functions of the application is demonstrated by the instructor, 2) candidates demonstrate basic mastery through projects that require direct application to a teaching problem or situation, 3) use of the application in the
classroom is modeled by the instructor, and 4) candidates demonstrate appropriate use of the application in the classroom via individual or group projects (most often these projects reflect their emphasis or major area of study.)

Educational technology faculty at Southern Utah University are pleased with the teaching/learning outcomes resulting from our ongoing use of advanced screen capture as a part of our educational technology repertoire. Online tutorials, creating portfolios and modeling new teaching strategies make advanced screen capture software a very useful tool and we encourage educational technology faculty to consider this inexpensive and easy-to-use application as part of their instructional strategy.
Redesigning the Educational Computing Course to Incorporate the ISTE Standards

Wren Bump, University of Houston, US

Abstract

This paper describes the restructuring of the Educational Computing Course CUIN 6320 Technology in the Classroom, a graduate class at the University of Houston. The purpose of the restructuring was to model to the students the integration of the technology standards for instructional purposes so that they could learn what each standard meant to them as teachers and what it looked like in the classroom. There were many activities included throughout the semester that referenced the standards directly. There were also many opportunities for the students to reflect on the standards and how they applied to different instructional situations.

Proposal

In the next few years the state of Texas will be incorporating new certification tests that will require the prospective teachers to be competent in technology use and integration. Not only will the teachers need to know how to use the different technologies, they will have to be able to integrate those technologies into their classroom preparation, presentation and assessment. They will have to integrate in all areas of their lessons so that the students will be using the appropriate technologies as they learn, create, report and produce.

The semester began with a self-assessment based on the technology applications standards that have been adopted by the state of Texas. This gave the students an opportunity to reflect on their own skills and competencies while getting an overview of what the course would involve. Each class period involved some form of collaborative activity so the students could see how collaboration could lead toward more learning and involvement with the technologies and the standards. Individual activities gave students the chance to develop the technology skills that would be required for successful completion of the class.

Collaborative extensions were assigned throughout the semester so that students would have to seek out resources in the community or at their schools. These collaborative extensions involved the use of technology in a practical way that could be applied even after the completion of the class.

A group project was begun in the middle of the semester that was based on the NETS-S learning activities. The students used collaboration in class and online to develop a learning activity that incorporated technology and met both technology standards and subject matter standards. The results of their efforts were compiled and added to the class website so that others could use them as a resource.

The final self-assessment and the final online portfolio tied the whole semester together and provided the students with a record of the development of their technology skills and competencies in technology integration. They left the course with a concrete product to share with others and use as a resource when they begin to teach.
Online Optional – Offering Choices

Abstract: Online-optional class sessions provide students in classes offered via video distance education with an option of attending class in an online mode if they qualify as online-eligible. Students determine which instructional delivery mode they prefer, and then work to be eligible to attend class in that mode. Choices may be based on preferred learning style, or on personal or professional schedules that sometimes interfere with class attendance. Student reactions, as well as lessons learned, are included.

Technology and education – these two words are frequent companions as the concepts are becoming increasingly intertwined. Although technology was once considered an add-on in education, a supplement to the established (classroom-based) educational system, its role has expanded greatly. Various types of technology may now serve as the basis for new modes of instructional delivery at varying levels and for differing purposes. Some of these are basically an expansion of the concept of Distance Education (DE), although the approach may vary drastically from the correspondence courses that began the DE movement in the 18th century, long before the term was coined in the 1960s. Moore and Kearsley (1996) trace the history of distance education from those early days when correspondence courses were conducted via postal mail, through the early use of audio and video in the Open Universities in the 1970s, through the appearance and improvement of two-way videoconferencing (a concept in wide use today), to the use of computer networks to provide access to instruction from home or other ‘distant’ locations (as in today’s expanding field of online courses). Much has been discussed about the changing face of higher education, as some traditional classroom-based classes may be supplemented (or replaced) by alternative instructional delivery methods. Some people have suggested that there may even be a demise of the university as we know it today. The more optimistic, though, suggest that expanding options available to students will but enhance the role of universities.

Students are at the heart of any educational system. Even as the relationship between technology and education is changing, so are today’s students. This is especially true of those in higher education – at both undergraduate and graduate levels. Many are juggling work and family, along with their university classes. Time and distance often provide potential barriers to further higher education. Students who are unable to travel to campus at times when classes are offered are looking for alternate approaches. Universities are addressing this need by expanding to offer web- and video-based courses that may be taken via distance education. Community colleges and universities are increasingly reaching out to offer classes either face-to-face or via distance education, with promises that students will be able to complete most if not all of their coursework without traveling to the originating institution’s campus. In this day of increasing competition, these options are becoming more prevalent, but generally, the delivery-mode options are on a per-course basis. A course is offered either face-to-face, online, or via videoconferencing. Often a course is offered in one mode only – so that at some time, a student will have to take it in that fashion. With the growing numbers of returning students (those who have been out of school for many years), we are faced with people who feel they know how they best learn, and this may cause some internal conflict for a student who must take a course through a delivery mode with which he does not feel comfortable. With that in
mind, some courses are being offered via different delivery modes for different sections—so students can sign up for the method with which they feel most comfortable.

Instructors should consider the delivery modes that will best serve themselves, their students, and the content of each course. There are advantages and disadvantages to each mode, as well as to the way each of the elements (student, instructor, content) reacts to it. The role and/or relationship of the different delivery methods have been discussed by a variety of educators. Greek (2000) discussed this as a continuum:

Rather than treating computer-and Internet-based education as a replacement for the classroom, I prefer to consider new technologies as creating the potential for a plethora of instructional delivery options. At one end of the spectrum would be a traditional face-to-face classroom environment that makes no use of new instructional technologies. These are likely to decline in number as students request Web sites, forums to post questions, etc., from all faculty and instructors. At the other end would be courses taught entirely using technology as a mediator between instructor and students. In between these two extremes are dozens of mixed mode options open for experimentation. Live classes may be less essential, and could therefore meet less frequently, in courses that feature email, discussions, chat, computer software, and/or video-conferencing. On-campus courses are also more likely to have distance learners in the classroom as Web-based video-conferencing comes more easily accessible. (p. 64)

This intermingling is occurring more and more frequently, and it is sometimes used to help prepare instructors and/or students for totally online or other distance education courses. This paper will describe a somewhat different approach—a video-based distance education class that includes some online optional class sessions, in which students who qualify as online-eligible may select the mode of instructional delivery for designated class sessions.

The Program

The need for qualified and certified teachers has become a major concern in many school districts, and programs to help alleviate the shortage are being developed. Some are aimed at recruiting people who have been working in other careers and who, for a variety of reasons, would prefer to change fields. One such program is emergency certification, where a person with a bachelor's degree takes education (and content area) courses leading to teacher certification, while actually teaching in a PK-12 (pre-kindergarten through 12th grade) classroom. Each required course is generally offered in one delivery mode—via traditional classroom, videoconferencing, or online—although some are offered in different modes for different sections.

Each delivery mode has its advantages and disadvantages related to students, instructors, and even content. Although most courses are taught using one primary approach, there is an increasing trend to include online activities within classes of all types. This may be an add-on optional activity, or may be an essential component of the course. Generally, though, every student participates in all the activities. Instructors, by integrating the Internet into their non-online classes, have the opportunity to take advantage of the unique characteristics that each delivery mode offers. Referring to similar situations, Chamberlin (2001) explained:

Many of us use the Internet to supplement our campus courses or teach hybrid courses, partially on-campus and partially online. Some of us teach fully on-campus and fully online courses at the same time. But all of us who teach in both worlds are double agents, caught in a struggle to bridge those worlds, and make effective use of both face-to-face and online environments to ensure successful teaching and learning.

By taking advantage of the pedagogical strengths of on-campus and online teaching, instructors can offer students the greatest chance to discover their strengths and weaknesses as learners and the best opportunity to find their path to achieving success. (p. 11)

We have expanded this concept to include videoconferencing, along with online class meetings, and have discovered advantages and challenges for students and the instructors in our technology class for the emergency permit students.

The Students and the Course
Students in our teacher-education classes come from a wide geographical area, and some must travel an hour or more to get to class either on our main campus, or on a branch campus in a metropolitan area about an hour away. Most students have over-full schedules, with their families, their teaching duties, and their university classes, in addition to periodic extra evening job responsibilities (parent conferences, etc.). Their experience with technology varies greatly, from those who have never (or rarely) used computers, to those who used them on a daily basis in their previous careers.

As part of the emergency certification program, students are required to take a technology integration class at the graduate or undergraduate level (after completing or being exempted from an introductory computer skills class). The course is taught each semester in one of three different formats – either face-to-face (summer 1), online (spring), or via 2-way interactive video (summer 2 and fall). Students with computer experience often opt for the online, or the videoconferencing class, while those with little experience often prefer not to take the online course, and often try to sign up for the undergraduate course (based on availability). Theoretically, the availability of different levels (graduate and undergraduate) and different delivery methods should help students address their scheduling concerns, and accommodate their learning preferences. However, we have discovered that this is not always the case – students often sign up for courses based on when, rather than how, they are offered.

But what about offering a course in which students have the option to choose the delivery mode for their class participation each week? This would provide flexibility for students, and it would also provide additional support for students who need it, as well as promoting collaborative activities to encourage development of networking skills to be used throughout their careers.

The concept was piloted during a summer subterm (4 hours a day, 4 days a week), with 2 online optional days per week. Several students took advantage of the opportunity, and it meant that students who were in class were able to receive more attention. It also encouraged people to complete activities quickly so that they would be eligible for the online option. To be online eligible, students needed to meet 3 criteria:

1. A student must have all activities/assignments completed satisfactorily, and
2. The student must have read the assignment message (sent out the evening before class) and feel able to complete all activities without assistance.
3. Send the instructor a message stating that the online eligibility criteria had been met, and saying that the online option was being exercised.

The course was taught via 2-way interactive video, with a facilitator (an ETEC Master’s student who had previously completed the course and who had a technology position on her campus) at the remote site, and a computer lab available for use during (and before and after) class-time. The class focused on Integrating Technology into Curriculum, and activities were designed to relate directly to the students’ activities in their K-12 classrooms. Students were aware of the wide range of experiences, from those who have grown up with computers and feel they know everything (but may have uneven knowledge and skills), to post-baccalaureate career changers who have been in the business world for up to 20 years and who may not have touched a computer, to those who have used computers on a daily basis on their previous jobs and in their personal lives. The intimidation factor was great at first, but as the experienced students took the online option, the technology fearful gained confidence as they worked in the labs. Attending class gave them the opportunity to ask questions, and to share their joys and concerns with instructor, facilitator, and/or classmates. Online students expressed appreciation for that option – one student wrote, “I enjoyed today having the online option. I was able to get everything done...I do have a class at 1:00 and also had a teacher team meeting tonight...so I was a little late it finishing up.” Another student did not feel the same, and said, “I do not feel confident enough to stay at home and work. I need to have more direction than what on-line gives to me.” After coming to class that day, he did exercise his online option the next class, though. A student who wasn’t quite sure, wrote, “I am going to attempt to do the 7-17 class online. The section 11-5 concerns me a little but I was successful at home and did not need to come for assistance.

As a pilot activity, this was considered successful, based on the student responses, as well as those from the facilitator who worked with students who attended the class sessions. The instructor had mixed feelings, and did not feel comfortable taking advantage of some of the specific characteristics of the video system – students were concerned that everyone did the same activities in the same way – but that may have something to do with the fact that it was such a condensed course in the summer, and there was little time to reflect on what had been happening, what they would be doing, and how this related to their professional teaching responsibilities. And it was close to the beginning of school, so people were getting ready to go back, but did not have access to their rooms (and
resources) yet. With the success of that summer session, though, we were ready to approach the fall in the same manner, with a few minor changes.

The Fall

As always, scheduling problems arose with the fall class. The course would again be offered via videoconferencing, and the facilitator at the remote site would handle the video sessions as well as the lab activities there. However, there were more students wanting into the remote site than we had computers. Therefore, before class began, I had already told some students that we would be having online optional classes several times throughout the fall semester. Several students who were not able to get into the class at the remote site registered in the section on our main campus (where we had twice as many computers available), since they understood that they would not have to drive to campus each week. It was interesting to note that two of those people, though, did actually come to campus each week for the first half of the semester.

At the first class meeting, it was announced that to address the range of technology skills, as well as the time and location problems of persons juggling teacher/parent/student roles, some class sessions would be offered as online-optional, where students who qualified as online-eligible would have the option of 'attending' class in any location of their choosing. To qualify, all work must be up-to-date, with no missing or incomplete assignments, and the student must have read through the assignments for the class and must feel confident about completing the activities without assistance or questions. The assignment was scheduled to be sent out the night before each scheduled class meeting, so that students could determine if they were online-eligible or if they would need to come to class. The plan was met with joy from some, and skepticism from others. To provide everyone with the opportunity to 'try it out', the first class period was devoted to providing people with the skills to negotiate online assignments in our course management system and on e-mail, and the second week of class was totally online for everyone – building on the skills from the first night of class. That gave everyone the opportunity to experience the online environment, and it was interesting to see that some of the doubters on the first night were among the most enthusiastic after the online experience. After that first online class, one student wrote in her weekly reflection,

I am glad we had Monday night's class online. Since it was a holiday, I would have hated driving to Commerce, especially since the thunderstorm would have messed up our class time. This was certainly convenient. I was not able to complete the assignments on Monday, due to the server being down. As it happened, everything has worked out well. This assignment was different. I did like the quiz over the chapter, even though I barely passed it.

Another student wrote, “Good evening, Dr. Espinoza. I am mentally exhausted after tonight's activities but enjoyed every minute of it”, and a third said,

This is my first experience with an online system for class and I am thoroughly enjoying it. I like working at my own pace in learning the lesson so I can absorb the information when I feel more refreshed than on a Monday night after working eight hours.

Each of these students exercised the online option at times during the semester, but all felt there were times when they wanted the social and instructional atmosphere of the classroom (at the local and remote sites).

The third class meeting was a required session where everyone came together and it was interesting to see and hear about the differing reactions to the online class of the previous week. With everyone present, we were able to have some interactive activities over the video system, and the 2 sides began to work together as one group. However, there was not another required in-class attendance meeting until the 9th week, and the tone of the class changed because of the attendance options.

I had told students that the lesson would go out on Sunday evening, so they would have an opportunity to determine if they would be needing to attend class in person the following evening. However, as an instructor, I found this somewhat limiting – it was difficult to change assignments when they had already gone out. So on Sunday evenings, a preview message would go out, telling what type of activities we would be having in class – then the ‘real’ message would go out the next day. This was still somewhat confining, though, for I did not feel able to make spontaneous changes, based on new ideas, student needs, and other items that might surface close to class time. However, I did make some adjustments – students were generally assigned to complete a chapter quiz (available at the publisher's site for our textbook), and students who were in class were able to work in pairs to
complete it. Other activities were carried out in groups by students in class, whereas the online students used chat sessions to meet with fellow onliners. One student, in her weekly reflection, said,

I chose to go to class rather than exercise the online-optional class last week so that I could meet with real people concerning the scenario chat. I do not care for chatting online and find it cumbersome, slow, and difficult. I prefer to meet with others if possible; therefore, the drive to class was beneficial.

On the whole, though, students were anxious to spend in-class time on actual hands-on assignments in the lab, and the video sessions often became a time to review the assignments and to answer questions about them. The number of online students grew slowly, but never quite reached the half-way mark, in terms of total class members.

The online optional class concept appeared to benefit students who wished to work from home, as well as the students who needed assistance (since the instructor/facilitator had fewer students with which to work during class, and could spend more time with them). There were other reasons for coming to class, though. One student said, "I like having the online optional classes, but after attending last week, I may decline online. I was able to finish most of the assignments in the lab, drastically reducing time spent on work and increasing time spent on studying." Her comments led to a discussion about time management, and what that means in online classes — and how it relates to contrasting comments — some the online folks talked about there being too much work, but the people who came to class didn't feel that was true. When people come to class, they spend a concentrated period of time on classwork, but when doing the same work online, there may be many distractions that extend the time that it takes to complete activities. Another student mentioned,

This week activities were a little frustrating since I took the online option, and got a little behind on some activities that I did not clearly understand how to perform but the reading was very interesting [had difficulty with assignments].

She learned to think more carefully about what she might and might not be able to do, and appeared in class more often.

Lessons Learned

The lessons learned have been many. The facilitator at the remote site asked, about half way through the course, if this didn't make double work for the instructor, and without thinking I said "Not really." However, that is not necessarily true — because the people who were online would often send comments and questions, and while I was online each evening (I'm online for one hour each evening for my online students — I was also teaching 2 totally online courses), they would send requests for chat sessions — and the questions would sometimes be about the week's assignment, despite the fact that they were to go to class if they had questions. We will set up some additional guidelines for online eligibility, and anticipate having one or more of my Master's students serve as online mentors. I will also develop more parallel activities that take advantage of the specific characteristics of the online and the video systems, and will have all student exposed to each, so that they can make informed choices.

One student summed it up, when she said,

Although this course was part "regular" and part "distance learning", I would readily sign up for another course of this type. This course gives you options: go to class for assistance or do not go to class if you can complete the assignments on your own. This aspect of a course is the "best of both worlds".

Consistency and Communication: The Benefits of Using an Online Course Management System in a Multi-section Introductory Computing Course

Christina M. Goode
Instructional Technology, Curriculum & Evaluation
University of Tennessee, Knoxville, TN
cgoode@utk.edu

Abstract

As the Internet evolves, more instructors are learning how to create Web pages to support classroom activities in order to communicate with their students and provide anytime/anywhere access beyond the four walls of the classroom. While this method has been a valuable resource for students, the multi-section course provides interesting challenges, especially when different instructors are responsible for each section. In this presentation, I will discuss how we use an online course management system as a tool to help us coordinate multiple sections of a required introductory computing course for all pre-service teachers at the University of Tennessee, Knoxville (UTK). I will also outline plans for expansion and discuss future initiatives for using online learning environments to support teaching and learning.

Background

At UTK, all teacher education students are required to enroll in an introductory computing course. Each semester, five to seven sections of the same course are offered, in order to keep class sizes small enough to meet the capacity of our computing facilities. Full-time instructional technology faculty and graduate teaching assistants take responsibility for different sections. In the past, though the overarching goal to help preservice teachers learn to use technology was consistent, it was not unusual to have varying sets of expectations in different sections, based on who the instructor happened to be. Although the variety of instructional methods and approaches had its benefits, students did not necessarily share a common set of skills and knowledge. When conducting a focus group session with a group of students during their student teaching internship year, it was apparent that students were exposed to different experiences although all had completed the same general course offering. Statements such as "we didn't do that" came up quite frequently as their peers recounted their technology class experiences. This type of situation cause ripple effects in other areas of the teacher preparation program. Without a core set of skills, methods faculty are less likely to be able to depend on students possessing a certain level of technological prerequisite skills from which they can continue to build.

In an attempt to coordinate efforts among multiple sections, we decided to adopt a course management tool to help us create a master template for the overall course. UTK has adopted Blackboard's CourseInfo, an online learning environment that can be customized, to provide courses with Web-based materials. The idea behind the template was to focus our efforts on providing a solid foundation that included all core skills and common requirements.

Expectations and Reality

Upon completion of the template, we were able to replicate the core site across five sections, at which point each instructor could take over and include their own additions to their own site. This method allowed us to find a good balance between consistency and flexibility, and allowed us to share resources without having to re-enter large amounts of information.

The key to using CourseInfo to enhance communication and consistency among the instructors is getting all the instructors to adopt it. This was the first and most pressing hurdle. Not all instructors adopted CourseInfo. Thus, although the course site was available to the instructor, it was not used in the course. For the instructors who adopted CourseInfo, the template worked well for both them and their students and provided a consistent look and feel to the
course. CourseInfo also provided several features to enhance the overall communication and coordination of each
course for and between the instructor and the students. Instructors could use their CourseInfo sites to post quizzes,
assignments, and notes; record grades; post additional links to their Web site; maintain a calendar; distribute
announcements; access email, chat, and discussion boards; and take advantage of a Digital Drop Box to reduce
unnecessary paperwork. Students learned to check their class Web site on a regular basis, as all tools were available
for "one-stop-shopping" in the same location.

Another hurdle was underestimating the space needed to replicate the course material for each section. Instead of
replicating large files within each section, we discovered it was best to place a copy of the larger files on the server
and allow each section to link to the files.

Conclusions

Although two sections did not adopt CourseInfo, we considered the initial approach to be a success. Future plans
include expanding the use of the online communication tools to provide discussion forums and chat sessions
between the sections. Also, the current bimonthly instructors' meeting can be augmented with special chat sessions
as needed. Though the course is taught in a lab setting, for certain topics, plans are underway to moving more
instruction online through learning modules/tutorials and videoconferencing.
Preparing Teachers for Digital Distance Education
David D. Keefe
Linda M. Koudelka
Zahrn Schoeny

ABSTRACT

Teachers today are required to integrate technology into their lessons at an ever-escalating rate. Teacher education institutions must prepare their students to teach in tomorrow’s classrooms. Today’s teacher education students will teach their students as they are taught in their universities today. The National Council for Accreditation of Teacher Education (NCATE) Task Force on Technology and Teacher Education, a group of educators from diverse institutions and backgrounds, was assembled to consider ways that NCATE can provide leadership and support initiatives to meet the technology challenge facing teacher education institutions. The first recommendation of this Task Force was to stimulate more effective uses of technology in teacher education programs.

Teachers in K-12 classrooms have an obligation to prepare their students for a successful transition from the college classroom into the real world of the 21st Century. The convergence of high-speed communication and Internet-based digital technologies is creating new platforms for the delivery of instruction. The University of Virginia’s (UVA) Curry School of Education has developed an outstanding model for this recommendation through it’s course offering entitled Introduction to Digital Distance Education. For the past two summers, the course has been offered simultaneously in a classroom at the Curry School, connected to a classroom at the UVA School of Continuing and Professional Studies Northern Virginia Center.

Learners in the class are increasingly able to use a wide variety of methodologies for collaborative education, such as streaming video and audio, online discussion forums, interactive simulations, and case evaluation. The course provides an introduction to these technologies for application in synchronous and asynchronous learning environments in education, business, and government. The course focuses on the proper application of these technologies to enhance the interactive learning experience of the students. The “new” role of the instructor is addressed, as the shared learning experience provided through the use of advanced digital technologies requires the teacher to become part of
the learning experience as a participant along with the students in the class. Practical examples of these instructional technologies are provided, including videoconferencing, electronic whiteboards, courseware tools, and discussion groups. Internet-based collaborative connections between UVA classrooms in Northern Virginia and the grounds in Charlottesville are used to model the process and provide practical experience for the student in the class.

Learning activities that have proven beneficial during the course include Web-Quest development, student reports applying chapter material from the text (Peloff, R. and Pratt, K. (1999). *Building learning communities in cyberspace*, Jossey-Bass), use of digital technologies for teaching the class and demonstrating through application of material in the class website (http://curry.edschool.virginia.edu/curry/class/edff/589_idde/).

The presentation will focus on critical course development and delivery issues that the authors have discovered. Summary recommendations will be presented to help those interested in providing similar course experiences.
Technology in the Classroom: A Teaching Unit for K-12 Teachers; Professional Development

Chien-Chih Lee, Chengshiu Institute of Technology, TW

I. Introduction

According to Duhaney (2001), more than 50% of teachers feel "not prepared at all" or "poorly prepared" to integrate and use technology in the classroom. Saye (1998) stated that four general factors must be considered before teachers will accept and use technology: time, preparation for future, knowledge, and availability. One goal of this article is to create a teaching unit that teachers who participate will feel more prepared to use technology in the classroom and to integrate it into their lessons. This course is designed as a professional development course for use with classroom teachers and school personnel at K-12. The purpose of the course is to develop in participants an understanding of the importance of technology integration in the classroom. The four goals of technology in the classroom are control, empowerment, enrichment, and efficiency (Saye, 1998). Upon completion of the course, the participants will be able to integrate technology into classroom instruction and feel prepared to use technology for instructional and personal use. Bennett (1999) emphasized that better use of technology by teachers can conserve time so they can focus on educating students.

II. Using technology to enhance professional practices

Based on International Society for Technology in Education (2000) standards, teachers should demonstrate understanding of technology operation and concepts, implement curriculum plans to maximize student learning, and use technology to enhance productivity and professional practices. This unit meets these standards by teaching participants to use the Internet, Netscape Composer, e-mail, and Microsoft Office applications to teach students and for daily organizational activities such as attendance and grades. Technology benefits teachers by not only providing information, but the real advantage is that these tools can save time and energy in order to offer guidance for research and communication.

Teachers need to be able to use technology in the classroom in order to prepare students for the 21st century. According to Sefton-Green (2001), technology is empowerment for students. Computers as Tutors: Solving the Crisis in Education purports the use of technology "for the welfare of students, teachers, and society" (Bennett, 1999, p. 2). The developers believe that students who learn using technology are better prepared for society. Students who are familiar with technology are able to understand its advantages and to apply their knowledge to real life.

This teaching unit is designed for K-12 teachers' and school personnel' professional development. The unit should require 25 to 35 hours of instruction time, depending on the time constraints of the instructors and targeted audience. The developers envision the unit being taught in parts throughout the school year. Although it can be taught in 3 to 4 consecutive days, the developers do not believe it will be as effective.

III. Understanding by design

This unit may be modified for use with children by changing the discussion and writing prompts. None of the activities are too difficult for a student at or above third grade level. Also, the final research topic might be modified to one more pertinent to students than professional educators. In addition, the unit may be modified for use in a pre-service education course such as Microcomputers in Education. Modifications may include more activities or shorter lessons.

The unit is designed to meet all six facets of understanding as follows:

<table>
<thead>
<tr>
<th>Facet</th>
<th>Evidence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanation</td>
<td>Participants will relate current research to classmates.</td>
</tr>
<tr>
<td>Interpretation</td>
<td>Upon learning about the Internet, participants will interpret the information to brainstorm ways to integrate the Internet into the classroom on an understanding level. Participants will interpret current research to synthesize it for classmates.</td>
</tr>
<tr>
<td>Application</td>
<td>Participants will search the Internet, utilize e-mail, create a webpage, compose a biography paper (Word), compose a biography presentation (PowerPoint), compare student performance (Excel), and conduct and synthesize research.</td>
</tr>
<tr>
<td>Perspective</td>
<td>Participants will evaluate a lesson for the instructor. Participants will locate and recommend websites for classmates. (The teachers must evaluate the sites for use by other teachers. They must take into consideration the needs of others.) Participants will determine if research information will be useful to themselves or others.</td>
</tr>
<tr>
<td>Empathy</td>
<td>Participants will discuss perceptions of technology (fears, failures, successes). Participants will discuss amounts of technology available in their own school.</td>
</tr>
</tbody>
</table>
When design this teaching unit, the following issues need to be considered. The first issue is to consider what enduring understandings are required. Teachers will understand that technology can improve both teaching and learning. In addition, teachers will understand the importance of technology integration in the classroom. The second issue is to review what the overarching “essential” questions are such as what do you know about the importance of technology in the 21st century and “how can technology affect the efficiency of school personnel?” The next issue is to look at what teachers understand as a result of this unit will. The purposes are that teachers will understand how to use the Internet to search, to use e-mail, to use AOL Instant Messenger and to design a class and/or personal web page. Teachers will understand how to use Microsoft Office applications (Word, PowerPoint, and Excel) to increase efficiency of classroom organizational tasks. Teachers will understand the importance of technology integration in the classroom to improve teaching and learning. The fourth issue is to consider what “essential” and “unique” questions will focus this unit. Some samples are (1) What is the Internet? (2) How can the Internet be a useful classroom tool? (3) How can Microsoft Office applications be useful to teachers? and (4) What does current educational research say about the integration of technology in the classroom? The last issue is, “What evidence will show that students understand technology integration?”

IV. Motivating teachers with activities

This activity will allow teachers to start thinking about technology integration. Though they may be aware of technology, some teachers are not aware of the benefits of technology integration. Teachers will read the article and discuss it in small groups. The article will be used to facilitate a large group discussion of technology integration.

The fist procedure is to distribute copies of the article “Computers, Creativity, and the Curriculum: The Challenge for Schools, Literacy, and Learning” (Sefton-Green, 2001). Then the participants will read the article. While reading the article, the teachers will note uses for technology in the classroom as well as barriers of technology use in the classroom. In groups of 3 to 5, the teacher will discuss their thoughts. Each group will share their thinking in a brief oral presentation. Based on the comments of the groups, a large group discussion will be facilitated. The following topics for discussion are: (1) Why do you think technology can be scary? (2) Why do teachers integrate technology?” (3) Why do teachers not integrate technology? (4) What could be done to make teachers more likely to integrate technology? (5) What differences do you see in the amounts of technology present in various school districts? and (6) How and why do I integrate technology in the classroom? Finally, the teachers will write reflectively according to the following prompt. The teachers will understand the goal of the workshop through reading and discussion and begin to think about the role of technology in the classroom.

The materials will be copies of the article, writing prompt. The instructor will read the reflection of each teacher and will be looking for positive and negative aspects of current technology integration, or lack thereof. In addition, follow-up will occur on an individual and large group basis. The follow-up will depend on changes in thinking from the first day writing prompt to the mid-unit writing prompt.

Conclusion

It was created to prepare teachers to use technology in the classroom. In order for this unit to be successful, each participant will need access to a computer, the Internet, Netscape, Microsoft Office, and a printer. The goal of the unit is to give teachers an understanding of technology uses and applications that will benefit instruction and organization in the classroom. Also, teachers will understand the importance of technology integration. Any instructor using this unit must be highly skilled in technology use. The developers recommend that a district Technology Coordinator be the instructor for this unit. Additionally, the instructor should show knowledge of current educational research concerning technology integration.

DIGITAL TECHNOLOGIES AND CULTURES

Jimmie M. Purser
Professor of Computer Science
Millsaps College
United States
pursejm@millsaps.edu

Abstract: As part of our Liberal Studies Program at Millsaps College, which serves our entering students, I have designed and implemented a "Thematic" LS Section entitled "Digital Technologies and Cultures". This session describes the planning, implementation, and evaluation of this course.

Introduction

LS1000 employs a variety of analytical styles to examine the disciplines that comprise a liberal arts education at Millsaps. The shared experience of being introduced to the humanities, the sciences, and business leadership provides Millsaps students with both a unifying theme in their crucial first year and with the special skills they will need during their college years and beyond. The goals of the course are to teach particular competencies in critical thinking and communication and to instill an appreciation for an interdisciplinary view of lifelong learning and development.

The Course

The four units of LS1000 introduce you to several primary aspects of a liberal arts education:
Unit I: Growing in self-knowledge (Identity).
Unit II: Becoming aware of how you think when searching for the truth about something and learning to think more powerfully (Cognition).
Unit III: Learning to identify and weigh the factors involved in reaching a responsible decision in the most aware and informed way (Responsibility).
Unit IV: Presenting your work in the public community of thought and learning to assess your own thinking according to appropriate standards (Assessment).

Within the course, students write 3 Formal Essays and 2 Informal Essays (in-class).

This thematic version of LS1000 focuses on the impact of digital computing technology upon the humanities, the sciences, and business. Issues addressed will include creativity and technology ("CyberTheater", "IATH"), the effect of computers on society ("CyberCulture", the "Visual Culture", "The Technological Underclass", "Ivan Illich"), Privacy and Censorship on the Internet ("Digital Privacy", the "Electronic Frontier Foundation"), moral implications of copyright laws ("The Digital Millennium Copyright Act"), ethical uses of Internet resources ("CyberEthics" and the "Hacker Ethic"), progress in medicine with computers ("TeleMedicine", "CyberMedicine"), impact of computing technology on the global economy ("TeleCommunications", "E-Commerce"), and addictive behaviors fostered by computer technology ("Internet Addiction Disorder").

Materials

The reading materials for the course are taken exclusively from the Worldwide Web. The class meetings consist of discussions on the readings, as well as "training sessions" with technology. For more information, see the web page for the course at: http://www.millsaps.edu/~pursejm/ls18.htm

Conclusions

Student evaluations of the course have been very positive. The course has helped to spawn a project within the
Associated Colleges of the South (ACS) entitled "Digital Technologies and Cultures". For more information see:
http://www.colleges.org/~dtc/
The IT Fundamentals Curriculum - Online Interactive Technology Skills Modules

Laurie Ralston, Arizona State University, US

In the face of an increasing need for improved technology skills for workers in the United States, The e-Learning Network has created the Informational Technology Fundamentals (ITF) Curriculum. The ITF Curriculum consists of highly interactive online modules, designed to represent real-world scenarios encountered by users of technology. These modules cover subjects such as Setting Up a Computer, Number Systems, Electricity and Safety, Networking basics, advanced Networking, Hard Drives, Device Cards, Peripherals, and Operating Systems.

Each module provides an interactive learning experience, which include animated demonstrations, virtual lab simulations, and video clips. The modules involve frequent user interactions, including drag-and-drop and keyboarding. Since the modules are online 24 hours a day, they truly encompass the meaning of "Anytime, Anywhere" learning. Using a "Reusable Learning Objects" approach, these modules can be utilized in any order, within a curriculum or by an individual wishing to improve his or her technology skills.

As an example, our Setting Up the Computer module teaches the user about the different cables and cords used to set up a computer. The module has original graphics and Flash animations that show close-up views of cable connectors and the ports into which the connectors plug on a computer. It has an interactive assessment with several scenarios of different real-world skill levels. The objective of this module is for learners to be able to completely set up a computer after using the module.

The e-Learning Network is part of the Technology Based Learning & Research department in the College of Education at Arizona State University, and has Cisco Systems as a major partner in development of the modules. The project is partially funded through a grant from the Fund for the Improvement of Post Secondary Education (FIPSE). As such, the ITF modules are available to the general public, free of charge. While not a primary project goal, we hope to improve the basic technology skills of pre- and in-service teachers to enable them to progress towards full integration of technology in their classrooms.

Objectives of the Session:
- Introduce the Informational Technology Fundamentals modules to teacher education and professional development audience
- Give participants methods for using the Informational Technology Fundamentals modules in their teacher education and professional development efforts
- Give participants methods for using the Informational Technology Fundamentals modules in their technology courses with higher-grade students
- Increase usage of the Informational Technology Fundamentals modules

The purpose of this session is to introduce participants to the Informational Technology Fundamental modules and discuss how teacher educators can utilize the modules in teacher education and professional development. Some of the modules can be used to give pre-service and in-service teachers an introduction to basic computer workings as a precursor to learning about technology integration. While organizations such as the National Council for Accreditation of Teacher Education (NCATE) have embedded their commitment to technology into their teacher education standards, others have noted that in general teacher preparation programs do not spend enough time teaching pre-service teachers about computing itself (Duran, 2001). Teachers who are not comfortable with the technology will not venture into attempting integration of technology into their curriculum.

The Apple Classrooms of Tomorrow (ACOT) studies revealed that teachers progress through stages as they learn how to integrate technology into their classrooms. The first two stages are the "Entry" stage, where teachers learn the basics of using computers, and the "Adoption" stage, where teachers begin to use
technology as a support for traditional instruction. Often, teacher education and professional development programs skip the “Entry” stage and leap right into the “Adoption” stage, without giving participants a chance to learn informational technology and computing basics. These modules can be used for pre- and in-service teachers who are in the “Entry” stage, and approaching the “Adoption” stage of technology skill acquisition (Apple, 1995).

The ITF modules are also valuable for pre- and in-service teachers who will be teaching technology courses to students, or who are involved in programs like the Cisco Networking Academies. The modules can be used by teachers to learn the technology content and also with higher-grade students who are learning technology subjects. They can also be used as preparation for various technology certifications, such as A+, Net+, and Cisco Certified Network Administrator.

Audience

This session will be of interest to teacher educators who need an interactive and flexible method for teaching pre- and in-service teachers basic computer and technology skills. Actual pre- and in-service teachers may also be interested in using the modules on their own, since they can be accessed anytime through the Internet. Participants should have experience with keyboarding and using a mouse, as well as basic experience in using a web browser. Most interactions involve using the mouse to drag and drop, or click hyper-linked buttons. There are no prerequisites for this session.

References

The Establishment of Basic Computer Literacy

Do not confine your children to your own learning for they were born in another time. (Hebrew Proverb)

In June of 1999, the Joint Economic Committee met to discuss advances in technology at the High Summit on Technology. These proceedings included a panel of individuals from all areas of the technological industry. The event incorporated high school and college students, via teleconferencing, who questioned members of the Joint Economic Committee and members of the primary panel. One of the chief concerns for the members of the panel, according to Michael Durham (1999), included increasing the number of technologically literate workers. Bill Gates (1999) charged the school systems with this responsibility. The Secretary of Education, Richard Riley (1999) agreed but stated that there must be available government funding in order for the schools to maintain sufficient levels of technology training. Seymour Papert (1998) explained that the culture of children today was so radically different from twenty years ago. Gates (1998) agreed and advised educators not to be afraid of change but rather embrace it and let technology make the classroom for this new student culture a more habitable environment. Don Tapscott (1998) had the same opinion and labeled this new culture the Net Generation.

The purpose of this study was to establish a basic computer literacy proficiency exam for students entering university. Based on the Technology Counts 1999 (1999) report, it was believed that students were already exposed to basic computer literacy courses prior to entering higher education. The Tennessee State Department of Education (2000), through the vocational technical division, offered a technology path that included courses in the application of technology although computer courses were not general
education graduation requirements.

Designing a proficiency exam for students entering a university enabled students already familiar with technology the option of exempting basic computer literacy computer courses or enrolling in computer courses comparable with their level of skill. The participants of this study were declared education majors enrolled in initial teacher education courses. This study examined the computer literacy of these students as well as argued that students should be able to test out of required basic computer courses in university if basic computer literacy skills are present. Testing out of courses enable students who have already mastered the objectives of the course to progress on to more challenging coursework. The study also compared students by year of graduation to determine if most recent graduates maintained proficient computer literacy compared to others. The hypotheses stated that students graduating in the past five years would have an increased opportunity to master computer skills compared to students graduating more than five years ago. The results of the study surprisingly did not support the hypotheses. The following questions were proposed at the onset of this study:

1. Is there a difference between the curriculum objectives required by the state in secondary education and the course requirements for basic computer literacy courses offered at Middle Tennessee State University?

2. Is there a need for a placement test of basic computer literacy at universities?

3. Is there a need for students to test out of the required basic computer literacy course at universities?
Because all of the participants were education majors, a comparison of education versus non-education major was not possible. However, this was included in further study as well as to investigate whether teachers of computer classes in high school should obtain certification in computer science. The study also found that computer courses should be required for all students as a graduation requirement.

This was an exceptional study and resulted in a fundamental web based format for testing overall basic computer literacy rather than specific computer applications. As a result of this study it was determined that pre-service teachers should be tested on their overall basic computer literacy as well as participate in courses to enhance established computer skills in an effort to be well prepared to lead a twenty-first century classroom.
Computer Science as a Discipline in Germany: the Perspective of the Professors

Esther Ruiz Ben
Institut für Informatik und Gesellschaft (Abt. I) Albert-Ludwigs Universität Freiburg

The professionalisation of Computer Science in Germany is still on its way, that means: It doesn't exist a generally accepted basis, recognised in the changing and diversified nature of the field. The lack of delimited fields of competence in the discipline, especially in software development also reflects this tendency.

Engineering, Mathematics and interdisciplinary orientations contribute to outline and define Computer Science and particularly the Software Development as its most prominent professional praxis. The analysis of self-definitions of the discipline and the praxis of Software Development will be used for examining the process of professionalisation of Computer Science and hence for eliciting the participation-chances of women, who are underrepresented in this field.

In this paper we will focus on the development of computer science as a discipline in Germany and how it is considered from the perspective of professors who represent different paradigms inside the discipline.

Peter Denning defines the computer profession as "the people and institutions that have been created to take care of other people's concerns in information processing and co-ordination through world-wide communication systems. (...) The discipline of computer science is the body of knowledge and practices used by computing professionals in their work(...)" (Denning, P. 1998, p.1). Computing experts gain this body of knowledge and practices in the educational field and in the praxis. The process, through which the academic area and the praxis transfer their knowledge to each other and the integration of new knowledge in both fields takes place in two different levels: an intellectual one as well as in an institutional one. The representants of the discipline in teaching and research constitute the intellectual level of the professionalisation-process of computer science, while the set of associations representing the interests of the computer experts working in the praxis shape the institutional level. The struggle for power in the discipline in order to establish its orientation takes place principally in the intellectual level of the professionalisation-process.

While the institutional level of computer science is rather stable in Germany, in the intellectual level there is not an assent about the core-knowledge of the discipline and the delimitation and definitions of the relevant domains for the professional praxis. In this level we can distinguish three knowledge paradigms (Coy 1998):

- Mathematical-formal. In this paradigm logical representations as well as verification and complexity problems represent the most important measure basis for quality. A mathematical/logical educational basis is for this paradigm the most important source of expertise (Dijkstra 1989). Social responsibility is seen as a question of computer programs’ security and certainty (Peschek 1996). Interdisciplinarity is not well considered in this paradigm that is oriented to the delimitation of the discipline through its mathematical-logical caracter.

- Engineering. The focus of this paradigm is in the technical aspects of computer science. Methods of engineering must be combined with the optimisation of time and costs to secure optimal Software-products. Technical application and configuration of technique are considered as secondary aspects in the discipline (Broy & Schmidt 1999).

- Social-critical. In this paradigm social responsibility is considered as an important aspect to be integrated in the curricula of computer science. Usability and the adequacy of computer solutions for persons as well as the consideration of computers as a tool and not as an objective are the main characteristics of this paradigm (Keil-Slawik 1996; Floyd 1985). Interdisciplinarity is considered in this paradigm as a very important factor for the development of computer science curricula, risking the delimitation of the discipline from other competing disciplines in the IT-field (Engineering, Electronic, etc.).

These paradigms are in a constant struggle in the intellectual level of computer science to establish the orientation of the discipline. Nevertheless the three paradigms are not present in the computer science in this form, but in a mix-form with different weights in tertiary institutions.

In our study we want to analyse which of these paradigms are more present in the orientation of the discipline in the educational field as well as in the praxis of software development. Which are the main skills that professional computer specialist must gain through their educational trajectory? What role does the mathematical basis play in the development of the discipline? What is the importance of social aspects for the development of computer science curricula? How should be established the knowledge transfer between computer science education and the professional praxis? How should be organised the continuing education in computer science by the educational institutions? What role should play soft skills in computer science education? What are the
main deficits of computer science specialists and how could they be solved? What role does interdisciplinarity play in the development of computer science?

These are some of the questions we want to answer in our survey considering the perspective of three relevant groups in computer science: Professors in universities and research institutions; Software Developers; and Personal Managers in Software enterprises. In this paper we will focus on the point of view of professors in universities and research institutions.

1. Methodology

A qualitative methodology has been used to analyse the professionalisation process of Computer Science: Open interviews have been used to elucidate the inner models and the self-definitions of the field as a science and as a profession in several industrial sectors. We have considered the point of view of three representative groups in computer science:
- Intellectual (Representatives of tertiary education and research institutions of Computer Science; N=6),
- Industry/Software Development (Software Developers in software companies in Germany; N=30),
- Industry/Human Resources development (Personal Manager in software companies in Germany; N=12).

The interviews have been conducted during 2000 and 2001.

2. Analysis

After the transcription of the interviews we have conducted an analysis for each group and in a further step we conducted an analysis of the three groups together comparing the different perspectives of each one of them.

3. Some results of the group of professors in tertiary education and research institutions

Computer Science is considered as an apply discipline and therefore it is very important from the point of view of the professors to include the knowledge of other disciplines into computer science. Nevertheless computer science is characterised as a technological field that should use engineering methods.

The recognition of structures for modelling practices is very relevant in computer science and must be trained during the educational trajectory of computer science specialists. Mathematics play in this sense a basic role, since it helps to acquire this kind of structural thinking. Nevertheless, computer specialists must be always willing to gain and apply new knowledge. From the point of view of the professors this is a basic competence that computer specialists must have to survive in the praxis.

There is not a clear assent among the professors in relation to the three mentioned paradigms. Nevertheless, the importance of interdisciplinarity and the relevance of soft skills for the professional praxis is supported by all of them. Specially these skills are considered as the main deficit of computer specialists.

Allen Steckelberg, University of Nebraska-Lincoln

Technology plays an important role in facilitating teaching and learning and many teacher preparation programs have made a commitment to prepare graduates to utilize it effectively. An essential element in this process is the identification of methods that allow both students and colleges to demonstrate that prospective teachers have indeed mastered the necessary knowledge and skills. One approach utilized at the University of Nebraska-Lincoln has been the creation of a Web-based technology skills certification course. The course has evolved over a three year period and has been offered to over 250 students. This session will describe and demonstrate the development, content, delivery, and management strategies utilized in the course.

Approach/Design Issues

Several factors were considered during the design of the course:

(1) The Web site uses a project-based approach to demonstrate competencies. The emphasis is on the products that teachers create rather than a specific strategy or step-by-step approach to learning a skill. Students use the tools at their disposal to complete the projects. The projects are designed to relate to tasks that teachers perform rather than specific equipment or software.

(2) Emphasis is on both fluency with software and hardware and the integration of technology in both teaching and learning. In addition, social, ethical and professional issues are addressed.

(3) The technology available to teachers changes continuously as new tools and new ways of applying them are developed. The ability to teach themselves how to use new software and hardware is more important than the specific steps in using one particular piece of software. Resources are provided in each module as a starting place but the emphasis is on activities that encourage the use of available tools for learning the technology. These include built-in help, manuals, and Web-resources. They may also include others with technology expertise, including other members of the class.

(4) Teachers College operates under a Scholar-Practitioner Model. The class represents our efforts to learn how to use the Web to teach. We are attempting be innovative while seeking to improve. We ask for feedback on both learning and on the strategies and approaches that are being implemented and we are developing systems that allow us to continuously improve the resources and activities of the course.
Course Content

Participants must complete a series of nine modules designed to develop skills and demonstrate competencies related to the National Educational Technology Standards (NETS) adopted by the International Society for Technology in Education (ISTE). Each module contains an overview of the module, requirements for completing the module, a mastery project, and a set of resources and support for completing the project, and a reflection on the module activities. Modules are created around the following topics:

(1) Basic Computer Operations and Communication Tools
(2) Basic Productivity Tools
(3) Integrating Basic Productivity Tools in Instruction
(4) Instructional Support Tools – Multimedia and Instruction
(5) Integrating Instructional Software and Learning Tools
(6) Application of Telecommunication Tools in Teaching
(7) Technology and Assessment
(8) Social, Ethical and Human Issues
(9) Technology for Professional Growth

The session will highlight and demonstrate sample components and mastery projects from the modules.

Management Issues

Because the course is Web-based it has allowed us the opportunity to design strategies for tracking student progress, displaying student work in ways that are convenient for the instructor and the student, and providing students relevant feedback on their work. We are currently investigating strategies for implementing self, peer and instructor feedback relative to student work on the mastery projects.
A New Model for Pre-Service Educational Technology Classes

Abstract:
EDLF 345, the required course in educational technology at the Curry School of Education, is being restructured by its instructors in recognition of the fact that technology cannot be used or taught out of a larger context. In the case of this class, the context is the set of methods and content-area courses that education school students must complete. Changes being made to the course include the modeling of technology-driven lessons specific to certain content areas, the requiring of student-developed projects and plans that demonstrate both technological and pedagogical proficiency, and the development of partnerships with other school of education faculty members to include considerations of technology and teaching methods in classes other than just the technology course.

As the integration of technology into K-12 classrooms becomes a standards-driven requirement across the country, teacher education programs are struggling to design courses that prepare educators to successfully incorporate computers into their classrooms. The successful pre-service educational technology class can no longer be just a training course on software use; rather, it must be a methods course that seeks to model appropriate technology use across content areas. The class, like the technology it teaches, cannot exist by itself; instead, it must be part of a larger and more meaningful context. The class must be made into a tight-fitting component of the teacher education program in which it is offered. Such a goal can only be met by changing both the technology class (it must incorporate other curricular content such as learning theories) and other methods classes (which must refer to technology use when discussing content and pedagogy). This paper describes the attempt at the University of Virginia's Curry School of Education to make such changes to EDLF 345, the required undergraduate educational technology course. Although the discussion here is limited to this one course, there are important reasons behind the changes – and consequences of them – that can be useful to any college or university with a teacher education program that wishes to appropriately offer technology courses to its students.

The restructuring of EDLF 345 ("introduction to educational technology") began with the conceptual idea that technology use in the classroom is meaningful only when the technology aims to enhance teaching or learning. Although obvious, this goal is not always the driving force behind technology and computer use in K-12 schools. At times, the pupil-to-computer ratio, the average student computer use time, or the notion of a "computer in every classroom" supercedes any real educational purposes. Because the actuality of appropriate technology use differs among the various content areas, EDLF 345 was divided into separate course sections representing these areas; there is at least one section per semester apiece for students concentrating in math and science, secondary humanities, and elementary education. Language, health and physical education majors typically enroll in one of the two latter sections and have course content modified for their particular foci. This division of content allows instructors of EDLF 345 to better differentiate the software and technology used, to decide how it is best used, as well as to model lessons that are unique to each content area.

It is this feature of the class – the teaching of appropriate technology-enhanced lessons – that is at the heart of EDLF 345. Less time is spent in class teaching the tool and more time is devoted to teaching with the tool – that is, modeling lessons that make appropriate use of technology. During each meeting of EDLF 345, students are
introduced to a new tool or technology via their participation in a lesson that teaches content using that tool. These lessons may be developed in conjunction with content-area faculty. Students in the secondary humanities section, for instance, may learn about the effects of a region's geography and location on its seasonal temperatures through the use of the graphing features in a spreadsheet application. Instead of focusing solely on the skills involved in using such a program, students use the program to better visualize and interpreting data. They are therefore allowed to reinforce (and, in some cases, to learn) subject matter in their content areas, to see an example of a suitable lesson using technology, and still learn how to use the tool as well—the last quarter-hour of each class is dedicated to an introduction to the current tool for those students who wish to remain; students are also expected to work through tutorials outside of class time.

By focusing on the content and participating in model lessons, students in EDLF 345 are perhaps better prepared for their own efforts as future teachers to enhance learning and teaching with technology. This approach also appears to have the added benefit of removing at least some of the anxiety students seem to have when approaching computer use. With the focus squarely on methods and content, and with the role of technology altered to a supporting one, many students are put more at ease in EDLF 345 than they might otherwise be in another technology class. They may also become more motivated to learn the tools when they see how those tools can immediately benefit their students and classrooms.

Another important consideration in the restructuring of EDLF 345 is the idea that students need to be taught how to be critical users of technology; the successful teacher also knows when not to use computers. To that end, students enrolled in EDLF 345 are asked to read various articles concerning the use of technology in the K-12 classroom. Some articles, such as a series from the Washington Post Magazine in September 2001, extol the use of computers in education and highlight exemplary teachers and lessons; others, such as Todd Oppenheimer's The Computer Delusion, are far more critical of technology use. After reading the articles, students write brief reactions to the readings, post these reactions to their web sites, and use them to begin class discussions on the benefits and disadvantages of K-12 educational technology. These discussions are held at the expense of class time, but often provide participants with new viewpoints and ideas. Students sometimes choose to revisit their initial reflections after the discussions.

With these foundations in place for a thoughtful and critical approach to technology use, EDLF 345 is designed to expose students to a wide variety of tools and methods of teaching with them, as well as the chance to explore a few of those tools in greater detail. This 'breadth and depth' perspective is accomplished in several ways. First, students are required to demonstrate their competency at a basic level on all technology used in the class. Each week, they create and turn in (by posting to their personal web sites) samples of the types of educational products that can be developed with each tool as well as a rough sketch of a lesson plan involving the tool and product. These assignments tie in nicely to students' current methods classes, which are often concurrently teaching students how to develop lesson plans in general. Elementary education students learning how to teach with database programs would be expected to create a database-enhanced lesson that they as future teachers might employ, as well as an example of the type of database their students would use of create as a result of the lesson. Such competencies provide practice for the students and allow instructors to gauge individual and class abilities. Second, in addition to their basic competencies, EDLF 345 students are required to develop a large semester project that incorporates one or more of the technologies they have used. This project may take the form of a fully-developed lesson or unit plan that teaches content in their specific areas of concentration, or it may be a technology-enhanced extension of a project for another methods course in which they are enrolled. In any form, it is designed to allow students to explore the tools that they have found most useful or interesting. As with all other work, these projects (when possible) are posted to students' web sites.

Another important component of EDLF 345 is the creation by students of a web-based technology portfolio that showcases not only their technical proficiencies but also demonstrates critical thought about the use of technology. This portfolio, due at the end of the semester, consists primarily of students' work to date for the class. Little extra effort is required for this part of the portfolio as all assignments are turned in via the web; students are merely asked to write a brief description of each competency that they include. Additional pieces of the portfolio, which students generate at the end of their time in the class, include a "technology autobiography" which describes students' experience with, and attitudes towards, technology in general and educational technology in particular; a reflection piece on a chosen learning theory focusing on its application to educational technology; and any additional work that a student has developed that includes technology (e.g., a presentation for
This portfolio, once in place, can be updated after a student completes EDLF 345 and can eventually be used when a graduate is seeking employment.

A final feature of EDLF 345 is its place among other education school classes. To create a relationship between the technology class and these courses, several components of EDLF 345 ask students to make connections between content in those classes and the tools being used in their technology course. In the example noted above, students are asked to consider, with specific regard to technology use, the various theories of human learning to which they are being exposed in another course. A student might, for example, choose to discuss how the use of multimedia presentation software can be made to fit with Howard Gardner's theory of multiple intelligences, or how "skill-and-drill" software is an extension of behaviorist concepts of learning. This component of the course serves to reinforce content from other education classes as well as to extend that content to a practical and useful end. Additional ties between EDLF 345 and other courses can be seen in the content-driven lessons that students develop and their incorporation of sound pedagogical and classroom management techniques into those lessons.

The description above focuses on the changes made to the technology class itself, but this is only half of the effort being made in the Curry School. These changes are the result of a dialogue that is taking place among instructors which seeks to 'cross-promote' technology use and teaching methods. Ultimately, technology classes must consider pedagogy — how to teach with the tools, and pedagogy classes must refer to technology — how to use the tools when teaching. This is a long-term process and can only be successful if all stakeholders are involved and see the importance of making the changes. To start the process, instructors of EDLF 345 met with content-area and methods faculty to describe the goal of altering the technology class to emphasize the relationship between educational technology and certain curricular components of the other instructors' own courses. With the first changes only affecting EDLF 345, the process required methods and content-area faculty to act in an advisory capacity (e.g., providing a standard lesson plan template for students to follow when developing their competencies) rather than restructing their own syllabi as well. There was an enthusiastic response to this initiative, with faculty supplying their notes and texts to EDLF 345 instructors and volunteering to review the lessons being used as models.

These first steps were followed up with the joint development, by a technology instructor and a content-area instructor, of one such lesson. Each person acted as an expert for his or her particular field, and the lesson that resulted served as the prototype for the creation of a rubric that allows instructors to evaluate student-generated lesson plans for the appropriateness of technology use in those lessons. This rubric can be used by both instructors in their respective courses. Ultimately, exemplary lessons will be collected and posted to a web site. These lessons may serve as future model lessons to be included in EDLF 345, and will certainly be used as references for students enrolled in the course.

These changes mark the beginning of what will hopefully be a lasting and fruitful partnership between technology instructors and other education school faculty. Although the results to date have been promising, there is still much work to be done before the course can be said to fulfill the goals of its instructors. Although untested, future plans may serve to provide a clearer picture of those goals and will be briefly discussed here. Further changes within the technology course itself include requiring students to join the International Society of Computers in Education (ISTE) in lieu of purchasing a textbook (and at approximately the same price as a book). ISTE membership will allow students to receive a subscription to Leading and Learning with Technology, whose articles may provide new ideas concerning technology use and will serve to illustrate the feasibility and benefits of implementing technology-enhanced lessons in the K-12 classroom. Membership in a professional organization will also benefit students when they embark upon a job search after graduation. Other plans include having students develop lesson plans in groups, and perhaps team-teaching one of their completed lessons to the class towards the end of the semester; participating in real-time and asynchronous discussion forums to experience various systems for possible use in their own classrooms; and working with content-area graduate students to collaborative develop lesson plans. Changes to methods and content-area courses are also being considered, including the incorporation of the technology-enhanced lesson rubric described earlier; the collaborative development of additional technology-based lessons; and the incorporation of technology issues when discussing classroom management and pedagogical issues.

This paper has described the changes to EDLF 345, the required technology course at the Curry School of Education. Although these changes are specific to that class, the idea behind them can be applied to any such course in a college or university school of education. The driving force behind the restructuring of the class is the...
idea that a course in educational technology, like the technology it seeks to teach, must be considered within context. In the case of EDLF 345, efforts are being made to tie the content of the class to the content of methods and content-area courses – which, if successful, will strengthen students' experiences with all classes.
Can Standards be Met and Evaluated Through an Online Teacher Education Technology Course? A Case Study

Caroline M. Crawford
University of Houston-Clear Lake
United States of America
crawford@cl.uh.edu

Jana Willis
University of Houston-Clear Lake
United States of America
willis@cl.uh.edu

Abstract: The continual evolution of the national technology standards creates a continual state of flux within the world of instructional technology. However, this creative online environment offers the possibilities that may not be available within other specialization areas; namely, the opportunity to reinvent conceptual frameworks of understanding and creative endeavors. Innovative teacher education units across the United States of America are reaching for opportunities to maintain the bleeding edge of understanding and integrating technology in successful and appropriate manners, which may also lead to thoughtful reflection as to the state and reasoning behind "why we do what we do".

Introduction

Web-basing coursework has been a major focus of universities around the world for the past five- to ten-year period and has resulted in a bell-curve fallout of subject-specific quality coursework. However, the teacher education units have more carefully begun to review the positive and negative aspects associated with the possibilities of Web-based teacher education coursework. Can standards be met through Web-based teacher education coursework? Can standards be evaluated through Web-based teacher education coursework? The simplistic answer to such questions is, "Yes!" Standards can be met and evaluated through Web-based teacher education coursework.

Since Vannevar Bush (1945) first imagined an intelligent machine that could maintain the full knowledge of the world, man has been steadily moving towards the realization of the Information Age. With the rise of and open access to the World Wide Web since the early 1990s, insurmountable efforts towards communication and knowledge dispersal has been realized. As early as 1980, Seymour Papert envisioned a computer interface that would offer access to learning environments.

I believe that the computer presence will enable us to so modify the learning environment outside the classrooms that much if not all the knowledge schools presently try to teach with such pain and expense and such limited success will be learned, as the child learns to talk, painlessly, successfully, and without organized instruction. (Papert, 1980, p. 9)

With prophesies such as Papert's, the dawning of the Information Age, with the creation of numerous possibilities, has become a reality. However, the importance of learning environments, instructional design, learning environments and superior facilitators has become an area of utmost importance to the success of Bush's and Papert's visions. After all, "Computers are not an end in themselves. The goal of technology integration into the classroom and curriculum is not to expose students to computers and the Internet. Technology, by definition, is a tool" (Dockterman, 1998, p. 21). With such a tool in the hands of exceptional, creative persons, the ability to create learning opportunities has become a reality. Web-based courses are on the rise, with research results creating an intelligent conversation concerning both positive aspects and areas for improvement to the Web-based learning environments available today.
Cognitive Flexibility

Cognitive flexibility creates a theoretical view through which to create a conceptual understanding of the learning environment. The nature of learning is often enironed within complex and ill-structured opportunities to obtain and understand knowledge. Spiro and Jeng state that, "By cognitive flexibility, we mean the ability to spontaneously restructure one's knowledge, in many ways, in adaptive response to radically changing situational demands.... This is a function of both the way knowledge is represented (e.g., along multiple rather single conceptual dimensions) and the processes that operate on those mental representations (e.g., processes of schema assembly rather than intact schema retrieval)" (1990, page 165). Additionally, one may note that cognitive flexibility "is largely concerned with transfer of knowledge and skills beyond their initial learning situation" (Kearsley, http://tip.psychology.org/spiro.html, paragraph 2). As such, cognitive flexibility is delineated towards a conceptual understanding of Web-based learning environments to support the integration and success of interactive technologies, such as a Web-based teacher education technology course.

Through this complex and ill-structured domain, the creation of a conceptual framework of understanding must arise for each learner. This is where the instructional design element is of utmost importance. Only through the careful creation of a learning environment, with all activities created and implemented appropriately and successfully, will the learner's understanding of the information become successfully integrated into the learner's conceptual framework.

Instructional Design

The instructional design process offers the standardization of materials to each of the teacher education courses; therefore, the consideration of adjunct faculty dismissing imperative knowledge and activities is no longer a consideration due to the standardization of the Web-based courses that have been designed over an extended period of time by faculty with numerous years of experience associated with the subject matter.

National Standards Integration into Web-based Coursework

As stated by the International Society for Technology in Education (ISTE), “Technology must become an integral part of the teaching and learning process in every setting supporting the preparation of teachers” (International Society for Technology in Education, 2001, paragraph 2). Further, “A combination of essential conditions is required for teachers to create learning environments conducive to powerful uses of technology. The most effective learning environments meld traditional approaches and new approaches to facilitate learning of relevant content while addressing individual needs” (International Society for Technology in Education, 2001, paragraph 1). Therefore, ISTE is one of the leading international associations that support the integration of technology into the learning environments. Taking such integration of technology a step further the learning environment may be mediated by the technology, as in the world of the Web-based course environment.

Specifically, the teacher education technology course offers the opportunity to focus upon ISTE standards for both the teachers (ISTE National Educational Technology Standards for Teachers, also referred to as NETS*T) and the learners (ISTE National Educational Technology Standards for Students, also referred to as NETS*S) so as to emulate the importance of both ISTE standards. NETS*T offers 23 indicators which are organized into six umbrella categories:

I. Technology Operations and Concepts;
II. Planning and Designing Learning Environments and Experiences;
III. Teaching, Learning, and Curriculum;
IV. Assessment and Evaluation;
V. Productivity and Professional Practice; and,
VI. Social, Ethical, Legal, and Human Issues.  
(International Society for Technology in Education, 2000, paragraph 6)

Standards Evaluation

An important aspect to any educational endeavor is the evaluation of the learning objectives. More clearly delineated, an assessment of the assignment(s) that exemplify the learner’s grasp of the learning objectives for the unit of study. As numerous forms of assessment are appropriate and successful within a learning environment, following are the assessment formats currently integrated into the Web-based teacher education technology course. Each of these aspects are integrated into each unit of study within the course.

- Knowledge-based quizzes;
- Project-based assignments and products, with assessment rubrics available for review; and,
- Reflective journals.

For purposes of this course, there is also a capstone project that each learner must successfully design, develop, formatively and summatively evaluate. As well, a full project expectation description and an assessment rubric is available to the learner for purposes of guidance and self-assessment.

Web-based Teacher Education Technology Course

The Web-based teacher education technology course has been developed through which to exemplify and designate the ISTE NETS*T (International Society for Technology in Education, 2000) standards. As such, the following units of study have been integrated into the course:

- Internet
- Copyright/Ethics/Equity/Legal
- Hardware/Software/Networking Tools
- Software Tools/Emerging Technologies
- Software Evaluation
- Learning Theory/Assistive Technology
- Storyboarding/Project Management/Assessment
- Web Design
- Graphics
- Video/Audio/CD-Rom
- Word Processing/Desktop Publishing
- Spreadsheets
- Databases
- Presentations

Within each of the units, the following instructional design elements are implemented for purposes of flow and to develop a comfort level within the learner’s conceptual framework of understanding:

- Objective
- Instructional Events
  - Readings
  - Best practice examples
  - Guided practice/tutorial
- Product Creation
- Peer Evaluation
- Discussion
  - Bulletin board
  - Chat room
- Reflection
  - Synthesis of skills and knowledge gained
  - Application of skills and knowledge gained in a learning environment
As may be concluded from the above Web-based teacher education technology course scope and sequence, the expectations for each learner to successfully complete the course are significant. As such, the teacher candidates maintain a level of technological understanding at both the theoretical and practical levels as they progress towards methods coursework within their specialization areas.

Conclusion

The continual evolution of the national technology standards creates a continual state of flux within the world of instructional technology. However, this creative environment offers the possibilities that may not be available within other specialization areas; namely, the opportunity to reinvent conceptual frameworks of understanding and creative endeavors. "The most obvious benefit of the electronic classroom is that it achieves what progressive educators could only dream of: a union of work and play.... There is no certainty that the electronic classroom will actually fulfill this promise, but it is this hope that makes the realization so attractive" (Ravitch, 1987, p. 28). Innovative teacher education units across the United States of America are reaching for opportunities to maintain the bleeding edge of understanding and integrating technology in successful and appropriate manners, which may also lead to thoughtful reflection as to the state and reasoning behind "why we do what we do".

laurenc@tamu.edu

Abstract: The purpose of this study was to determine to what extent teachers (a) alter their teaching methods and (b) integrate technology into their classroom curriculum during, and after a technology training course designed to prepare teachers to use technologies that support their teaching and student learning. Case study methods (Wiersma, 1995) were applied to gain understanding of teachers’ experiences as they moved through an online (OL) or face-to-face (F2F) course designed to prepare teachers for integrating technology into the curriculum. Complementary data collection processes (Shulman, 1986) were used in eight cases to provide depth and breadth towards identifying and analyzing barriers and processes affecting the impact of the training course. Recommendations from this study contribute to the future development of an effective model of teacher training in technology integration for different types of teachers.

Introduction

Teachers must be comfortable with technology tools, be prepared to integrate technology effectively into the classroom curriculum, and be able to incorporate the new teaching methods enabled by technology (CEO Forum, 2000; U.S. Department of Education, 2000). Teachers need experience with technical skills and knowledge if they are to develop a vision for technology integration within their own individualized environment. They need models of effective teaching practices that integrate technology. They need access to resources that promote or support technology integration in the curriculum. Educating teachers in the processes of integrating technology into the curriculum must replace current practice of simply training teachers in computer applications (Brownell, 1992; Ertmer, 1999; Roblyer, Edwards, & Havriluk, 2000; Schrum, 1999; Simonson & Thompson, 1997).

In response to the challenge for preparing teachers to use technology and teach with it, campus technology teams, colleges, universities, and other organizations are focusing on technology training programs. Traditionally, teachers have been forced to attend courses at training facility or college campus to receive face-to-face (F2F) technology instruction, thus taking time away from their other duties. Many teachers are too busy in their work to participate in instruction outside of their own campus environment. Sharp (1996) reported that, “recently, higher education institutions have used distance education to reach a diverse audience that would not be accessible through ordinary traditional classroom instruction” (p. 277).

The innovation of Web-based instruction (WBI) brings courses to individuals and groups who might not otherwise have access to them (Brownell, 1992; Khan, 1997; Reeves & Reeves, 1997; Relan & Gillani, 1997). The effectiveness of training received in a traditional (F2F) classroom setting versus training delivered through distance learning is under constant debate. But as the Information Age evolves, our society is undergoing massive changes that impact our educational systems. Advances in information technology, coupled with the changes in society, are creating new paradigms for education. Teachers in these new educational paradigms require rich learning environments supported by well-designed resources (Reigeluth & Khan, 1994). While, the World Wide Web, as a medium of learning and instruction, has the
potential to support the creation of these well-designed resources, the traditional F2F classroom environment should not be discarded (Khan).

Web-based instruction (WBI) brings courses to individuals and groups who might not otherwise have access to them (Brownell, 1992; Khan, 1997; Reeves & Reeves, 1997; Relan & Gillani, 1997). The effectiveness of training received in a traditional (F2F) classroom setting versus training delivered through distance learning is under constant debate. Advances in information technology, coupled with the changes in society, are creating new paradigms for education. Teachers in these new educational paradigms require rich learning environments supported by well-designed resources (Reigeluth & Khan, 1994). The World Wide Web, as a medium of learning and instruction, has the potential to support the creation of these well-designed resources (Khan).

The Study

The purpose of this study was to determine to what extent teachers (a) alter their teaching methods and (b) integrate technology into their classroom curriculum during, and after a technology training course designed to prepare teachers to use technologies that support their teaching and student learning. The course under investigation was offered in both OL and F2F delivery formats. Therefore, comparison of the impact of both modes of instruction on teacher professional development within the subject area of technology training and implementation was conducted.

Case study methods (Wiersma, 1995) were applied to gain understanding of teachers’ experiences as they moved through an online (OL) or face-to-face (F2F) course designed to prepare teachers for integrating technology into the curriculum. The cases illuminated the processes of technology integration for elementary and secondary teachers possessing low and high levels of technology skill and use. Complementary data collection processes (Shulman, 1986) were used in each of the eight cases to provide depth and breadth in identifying and analyzing the barriers and processes affecting the impact of the training course. In this study, the integration of survey, interview, and observational approaches offered the researcher an opportunity to develop a complete analysis of participant behavior from a holistic perspective (Gall, Borg & Gall, 1996).

INST 6031: Applications of Technology, a core graduate-level course offered by the School of Education at the University of Houston – Clear Lake, introduced students to the tools and skills necessary to understand and operate computers, navigate the Internet and World Wide Web, and create hypermedia products. The course included educational applications of instructional and information technologies to promote the integration of technology into the curriculum. Emphasis was on the comprehensive integration and implementation of the Technology Applications Texas Essential Knowledge and Skills (Texas Education Agency, 2001), Secretary’s Commission on Achieving Necessary Skills (SCANS) 2000 report (U.S. Department of Labor), and those tools that have important implications for the creation of products with the technology. The course was offered either in an OL format or in a traditional F2F setting. The OL course met for an initial orientation session prior to the start of the semester and all other interaction was conducted on-line. The F2F course met weekly for 15 three-hour sessions. Within both delivery methods, a combination of hands-on lab assignments and content material was offered through a student-centered approach. Students and faculty worked together to identify learning requirements, learning strategies and assessment criteria based on students’ prior skills and areas of interest. Students gained experience in the educational use of such technologies as productivity tools, presentation graphics, multimedia, and telecomputing technologies; however, they did so by applying tools to practical problems and opportunities as the basis for understanding, developing, and demonstrating activities that enhanced both student and teacher performance.

The PK-12 teachers enrolled in all sections of the graduate level INST 6031: Applications of Technology course at University of Houston – Clear Lake made up the pool of 30 participants. A Computer Use Survey was administered and collected prior to any classroom instruction. The survey scores were based on a point value associated with the level of skills selected by the individual, levels 1 - 4 were given point values of 1 - 4 accordingly, no response resulted in zero points for that question. The participants were divided into two groups, which were representative of the participants’ teaching grade levels Elementary (PK-6) and Secondary (6-12). The Elementary and Secondary groups were then divided by course delivery method. The two course delivery methods under investigation were OL and F2F. Therefore, the cases for investigation were selected from a sample of Elementary – OL, Elementary – F2F, Secondary – OL and Secondary – F2F. A systematic sample using circular lists, rank ordered by skill level from

Page 464
highest to lowest composite score, was used to ensure representation of varied technology skill levels within the grade levels. A sample size of 2 was chosen for each of the delivery methods within each of the grade levels, resulting in a total of 8 participants.

Findings

The study suggests that teachers in both groups increase their use of technology in the classroom during and after training in the process of integrating technology into the curriculum. Further, teachers do not alter their existing teaching methods as they integrate technology, but use technology in ways that support their current classroom practices or educational experiences. The study confirmed the existence of intrinsic and extrinsic barriers that interfere with teachers’ abilities to integrate technology into the classroom curriculum.

When comparing delivery methods groups, this study found that the OL group began the course with a higher average skill level in all parts of the survey instrument than the F2F group. The skill level growth in Basic Computer Use (Part A) was the same for the OL and F2F delivery groups. The F2F group had higher levels of growth in Advanced Computer Use (Part B) and Teacher Internet Use (Part C). The posttest scores indicated that the OL delivery group completed the course with higher skill levels than the F2F delivery group in Basic Computer Use (Part A). The F2F delivery group completed the course with higher skill levels in Advanced Computer Use (Part B) and Teacher Internet Use (Part C).

There were noted differences between the OL section and the F2F section in their identified Stages of Concern. Both groups focused early on informational (Stage 1) and personal (Stage 2) concerns. Both groups indicated low levels of concern related to time, logistics, and management concerns (Stage 3). Both groups indicated increased levels of concern over time for the consequences of using technology with their students (Stage 4). Only the F2F section teachers indicated increased concerns about collaboration (Stage 5). Only the OL section teachers indicated increased concerns about modifications or alternatives to technology integration.

The level of use was a greater among those teachers enrolled in the F2F section of the course than those enrolled in the OL section. The teachers in the F2F section used cooperative groups more frequently than the teachers enrolled in the OL section. The use of demonstrations increased among those enrolled in the OL section. This could indicate that the F2F population benefited from the ability to see and interact with technology integration in an environment that closely resembled their own classroom settings. This is consistent with research on the influence past learning experiences have on current teaching practices because the F2F group had increased opportunity for cooperative group work and the OL section relied on demonstrations for a large percentage of their content materials (Dwyer et al., 1990a, 1990b). Both groups indicated improvements in classroom management with the use of technology.

Conclusions

Although the number of cases and the unique characteristics of each teacher investigated limits the generalizability of this study, the study provides insight into the individual experiences of seven PK-12 teachers as they participated in technology training, moving beyond the training classroom to the application of teaching methods that facilitated the integration of technology into their classroom curriculum. The success of the educational technology revolution cannot be judged like other educational innovations. It is the belief of this researcher that teachers and not technology are the driving force in the current movement. Therefore this study focuses on the experiences of the individual and not the aspects of the integrating technology.

The intent of this study was to provide developers and instructors of technology integration courses and teacher preparation programs with information that would support the future development of an effective model for training teachers and support staff to integrate technology into the classroom. This study adds to the existing literature on effective training in technology integration by focusing on the individual skills, needs, and classroom environments of those individuals involved in the training rather than the implementation of the innovation. “Cookie cutter” courses that focus on basic skills and application training will not enable the transfer of skills from the training environment to the classroom. Frequent modeling of technology-enhanced instruction directly related to the classroom environment would better facilitate transfer of technology skills and use (Studler & Wetzel, 1999). Training for technology
integration must incorporate in its structure the instructional methods and classroom practices that facilitate technology integration.

If teacher educators are to facilitate technology integration for different types of teachers, they need to design and implement learning environments that (a) are learner-centered, (b) encourage collaboration, (c) promote discovery, and (d) provide activities that are engaging and relevant to the individual needs and environments of the learners. Teachers will develop visions of technology integration based on their own educational experiences. Therefore training programs must provide rich extended experiences in technology integration and model effective practices and innovative uses of technology that improve teaching and learning. Through the results of this study, instructors will understand better how to facilitate training in the integration of technology for different types of teachers. In addition, insight will be provided in differential impact of OL training and F2F training.

Web-based Teacher Education Technology Course

Caroline M. Crawford
University of Houston-Clear Lake

willis@cl.uh.edu

Abstract: The teacher education technology course that is a standard throughout the teacher candidate’s plan of study at the majority of teacher education institutions has become a course under a constant state of revision.

Introduction
Due to the numerous areas of growth and further understanding of educational technology over the past five year period, the growth in the hardware and software tools available for use within the course structure, as well as the inclination of university faculty facilitating methods coursework and the inclination of these faculty to integrate technology at a growing rate, the teacher education technology course must be revised to maintain the leading edge of appropriate and successful technological inclusion.

History
Over the previous three- to five-year period there has been an unprecedented growth in Web-based and Web-enhanced coursework. As an area of significance, the Instructional Technology specialization area at the University of Houston-Clear Lake has designated that the teacher education technology course be Web-based. The incremental shift in technological possibilities and support factors has introduced numerous levels of strength, as well as areas in which dedicated decisions must be emphasized to ensure the highest levels of learner support and technological inclusion within a learning environment is available. The inclusion of national technology standards are also of primary importance, to ensure the teacher candidates meet their own educational technology needs as well as the needs of the learners. Therefore, the inclusion of national technology standards for both the teacher candidate and the PreK-12 learners, instructional design that emphasizes the real-world design and development of age-appropriate and technologically infused lessons for the learning environment, and a clear understanding of the theories, philosophies and curricular elements that must be considered are integrated into the Web-based teacher education technology course.

Analysis and Design
An analysis of the teacher education technology course, whether this be the traditional face-to-face mode of instruction or a Web-based model of instruction, indicated a lack of consistency and overall structure to the course. Due to the important nature of this course as the springboard for the integration of instructional technology within the teacher candidate’s methods coursework, the designation of an exemplary Web-based teacher education technology course was deemed imperative. This model course structure would become the standard through which the face-to-face, Web-enhanced and Web-based courses would focus its efforts.

The design of the Web-based teacher education technology course has been through several revisions over the previous three-year period at our university. The latest project manager and subject matter expert to oversee the design and development of the course is the latest of three persons.

Development
The development timeline for the Web-based teacher education technology course consists of a year’s period, wherein one semester is allocated for design, one semester is allocated for development, and the final of the three semesters is allocated towards testing and evaluation. The course is delineated into the following units of study, which have been integrated into the course:

- Internet
- Copyright/Ethics/Equity/Legal
- Hardware/Software/Networking Tools
- Software Tools/Emerging Technologies
- Software Evaluation
- Learning Theory/Assistive Technology
- Storyboarding/Project Management/Assessment
- Web Design
- Graphics
Further, there are specific aspects delineated within each of the units of instruction. The instructional elements, which are implemented for purposes of flow and to develop a comfort level within the learner’s conceptual framework of understanding, are noted below:

- **Objective**
- **Instructional Events**
  - Readings
  - Best practice examples
  - Guided practice/tutorial
- **Product Creation**
- **Peer Evaluation**
- **Discussion**
  - Bulletin board
  - Chat room
- **Reflection**
  - Synthesis of skills and knowledge gained
  - Application of skills and knowledge gained in a learning environment

The units of instruction are laid out in a similar manner, so as to develop a sense of flow and comfort for the learners. Due to this level of comfort the learners can focus upon the information included within the unit, instead of focusing upon the unit layout.

**Implementation and Evaluation**

The Web-based teacher education technology course is scheduled for implementation at the beginning of the third semester within the development cycle. During such time, the course will be evaluated within a “live” classroom environment, wherein both instructors and teacher candidates will offer constant feedback concerning positive factors related to the course as well as areas for further consideration.

**Conclusions**

The scope and sequence for the Web-based teacher education technology course has been developed in order to meet the ISTE NETS*T (International Society for Technology in Education, 2000) standards. Further, the International Society for Technology in Education (ISTE) states that “Technology must become an integral part of the teaching and learning process in every setting supporting the preparation of teachers” (International Society for Technology in Education, 2001, paragraph 2). As such, “A combination of essential conditions is required for teachers to create learning environments conducive to powerful uses of technology. The most effective learning environments meld traditional approaches and new approaches to facilitate learning of relevant content while addressing individual needs” (International Society for Technology in Education, 2001, paragraph 1). As the purpose of the teacher education technology course is to aid the teacher candidates towards the integration of technology, it is appropriate to offer the most appropriate methods towards modeling the appropriate and successful integration of technology.

Personality Assessment of Educational Leaders via Technology
Pamela T. Barber Freeman, Ph.D.
Michael L. McFrazier, Ed.D.
Prairie View A.M. University
Department of Educational Leadership

After almost two decades of school reform efforts in America, there are still millions of children being left behind. Specifically, the Texas Public Schools Statistic (1999) indicates that African American students comprised 18.7% of dropouts while Hispanic Americans made up 51.3%. According to research, one reason for this failure is due to the quality of leadership as well as the lack of sensitivity to the cultural dynamics within our nation (Wallace-Reader’s Digest 2000; Astin & Astin 2000).

There is a critical need for educational leaders to develop a keen understanding of the challenges faced by students. Today’s students’ come from a variety of cultures, religions and economic levels; consequently, arriving to school at different ability levels. In addition, environmental conditions may have circumstances that challenge students’ time and attention that could or should be devoted to learning. To cope effectively and creatively with these emerging trends, future leaders will need to possess new knowledge and skills as well as displaying a high level of emotional and spiritual wisdom and maturity (Astin & Astin 2000). As the public sector becomes more sophisticated, as well as impatient, critical questions are being asked and stringent limitations will be placed on institutions of higher education. Institutions of higher education play a major role in developing and shaping the quality of leadership in modern American society (Astin & Astin 2000). Thus, it is imperative that institutions of higher education begin to develop a conceptual framework to train and support leaders who will expand the variety and character of their school district’s educational programs. After all, it is character, not money that fosters prosperity.

The face of our society is literally being altered due to the tremendous changes in the economic, educational, and demographic forces. The rapid change in the demographics of the United States has made diversity one of the most significant social facets of our society. Due to differential birthrates and immigration patterns, America is experiencing a major ethnic shift with increased numbers of African Americans, Hispanic Americans, and Asian Americans becoming more evident within our schools. In Texas, African Americans and Hispanic Americans youth constitute 53% of the school age population and have the highest dropout rate of any other ethnic group within the state. In postsecondary institutions enrollment of the diverse groups are declining. With the continuous increase of a diverse population, it becomes quite apparent that the dynamics of the culturally heterogeneous world have become both complex and problematic. In fact, one of the most compelling needs of our time is to reach for the “forgotten half” of our population who have the capability of leading but are being left behind by the new economy. Specifically, educational leaders do not begin to reflect public school diversity with only 12% of the nation’s superintendents being female, and only 5% being people of color. In addition, leadership positions are expected to increase by 16% by the year 2008, making it the largest increase of any other major occupation (U.S. Department of Labor, 2000). Thus, creating a greater need for more inclusion of all ethnic groups who have the theoretical and methodological tools to help frame and answer questions that concern all Americans. Accepting the premise that higher education is the pipeline for developing productive citizens, academia must take the opportunity to lead the way and demonstrate to the rest of the nation how to accept and nurture a
diverse community of leaders. Consequently, the question is whether institutions of higher education are up to the challenge of meeting the needs of this diverse population. Therefore, it seems practical as well as necessary for those institutions (HBCUs) that are graduating the largest numbers of diverse students to become an active and viable component in developing leaders, in reforming curriculum standards and providing training for personnel who will lead and educate America’s future citizenry. Because education is a continuum (not just K-12), it is imperative that programs/institutions that educate and train pre-service and in-service leader become active with educational reform. Since HBCUs facilitate the largest numbers of diverse leaders on the educational continuum, there are needs for leadership centers on HBCU campuses to provide our nation and the world with leaders equipped with new knowledge and strategies for educational reform.

During the sixteenth century, Martin Luther is noted for stating, “...when a man knows his own heart, he knows the heart of other men.” Specifically, if educators have a strong grasp of their attributes, learning styles and personality preference they become more intoned to their students regardless of ethnicity. Consequently, this research was based on the above premise in order for future educational leaders to reach their educational, professional and personal potential, they must be actively involved in developing and implementing instructional models. The primary outcome sought through this research was to promote what Franke, Carpenter, Fennema, Ansell, and Behrend (1998) call “self-sustaining, generative change.” Self-sustaining, generative change is when individuals make changes to improve their methods of leadership and instruction to ensure continued growth and problem solving. To ensure that self-sustaining, generative change is on going, a personality assessment was conducted. One’s personality is without question the most important driver influencing career choice, relationships, health and sense of well being (Shaughnessy, 1998). To understand the full potential of one’s personality, it is critical to first measure and then gain insight into your strengths and developmental needs through examining the results of personality.
Advanced Information Technology Training for Teacher Leaders: Hong Kong Experience

Wen-Hao Chuang
Dr. Wen-Hao Chuang was a lecturer in the Multimedia Innovation Centre at the Hong Kong Polytechnic University and now he is teaching at Hong Kong City University Master of Communication and New Media Program. Address for correspondence: Department of English and Communication, City University of Hong Kong, Email: enwen@cityu.edu.hk

Abstract

This paper describes the design and evaluation of the recent advanced information technology teacher training which is a multi-millions project provided by the Hong Kong Polytechnic University for the Hong Kong SAR Government. This training program is a team project contributed by department of electronic and information engineering, department of computing, educational development center, and multimedia innovation center in Hong Kong Polytechnic University. In 1998, the Hong Kong SAR government published a document of five-year strategic planning for Information technology (IT) in education. The three domains of IT in education includes: (1) IT as a productivity tools (2) General integration of IT in education (3) subject-specific integration of IT. In this document, the HK government also defined four levels of IT competency for school teachers. They are: (1) Basic level (about 18 hours of training, focus on basic computer and IT skills), (2) Intermediate level (about 30 hours of training, focus on intermediate IT skills such as using Flash, Internet search engines, etc.), (3) Upper Intermediate level (about 30 hours), and (4) Advanced level (about 120 hours). This presentation will introduce the current status of the advanced level training, share with the audience with the course design, implementation, comments and feedback from participated teachers, and some reflection.
Building an Online Tutoring Program: A Blueprint for Success

Richard Cortell, Cortell PCS, US

Many administrative decision-makers in higher education must deal with the results of the ongoing proliferation of instructional technology systems at their institutions. The result of this dynamic technological climate and the demands of "education consumers", and the job market, is that these administrative decision-makers fall into the uncertain trap of needing to approve the expenditure of tens, perhaps hundreds, of thousands of dollars on equipment and services they may know little or nothing about. These people need accurate and useful information in order to make sound decisions. In the case of online tutoring they need at least a basic understanding of the hardware, software, delivery systems, costs, personnel, and the myriad of other items required to develop and operate such a program.

The reliability of information upon which this understanding is based is critical. It may well determine the eventual success or failure of their program. Administrative decision-makers are often faced with the prospect of having to rely upon inexperienced peers and over-eager sales people for advice and guidance when making decisions about instructional technology implementation. If this is the case, they ask, where can they get the reliable information they need to make these important decisions? Fortunately, there are other accessible sources they can use to gather needed information. These include the Internet, articles containing the recorded trials and errors of other institutions of higher education, paid consultants, workshops, and presentations like this. What is extremely valuable and useful is an understanding of the process of conceiving, developing, and operating an online tutoring program, a blueprint for success, if you will. The presenters use the examination of this process as a catalyst for thought and discussion on the topic and a means of providing education administrators and decision-makers with some insight and information that will help them better understand the issue when they are required to make decisions related to implementing online tutoring programs at their institutions.

This presentation provides a glossary of many of the terms, and an outline of the needs and activities required to plan, develop, and operate an online tutoring program. While it is not complete in every detail, it provides decision-makers with a starting point and enough information to ask intelligent questions. First, we will examine the shift from the elite to the universal system of higher education in America. Next, we will examine the role and definition of technology within higher education and how its dynamic nature has given rise to the popularity of online instruction. Then, we will examine how the development of online courses led to the addition of online tutoring. Next, we will examine the reasons it is important that administrators and decision makers within higher education need to understand basic needs of an online tutoring program before implementing their own. Finally, we will outline the major steps involved in conceiving, developing, and operating an online tutoring program.

ABOUT THE PRESENTERS

Lena Bakir is the Special Needs Tutorial Advisor of the Tutoring Center at Bergen Community College in Paramus, New Jersey. She is a doctoral student in the Higher Education Administration and Supervision program at Seton Hall University, New Jersey. She can be contacted at lbakir@bergen.cc.nj.us.

Richard Cortell is an Information Technology consultant for practitioners and administrative decision-makers in education and industry. He can be contacted at rcortell@warwick.net.

Richard Ranker is the Director of Academic Technology Support at East Tennessee State University in Johnson City, Tennessee. He can be contacted at rankerr@access.etsu.edu

Abstract: It is important to know more about the potential contributions and needs of SITE participants in order to inform further developments of the society and the field. During the SITE 2001 conference 165 participants completed a survey and 38 personal interviews were conducted, with equity at the top of the list of keywords. Analysis shows that SITE participants have concerns, which include collaboration and organizational development and can contribute extensive expertise and resources to our society and teacher education. SITE is acting on this information with online forums, committee work, and a digital scholarship portal in collaboration with CILT and the TEN PT3 Project. The survey will be repeated at SITE 2002.

The Society for Information Technology in Teacher Education (SITE) is an international organization that seeks to encourage appropriate uses of information technologies in teacher education worldwide. In an effort to build a shared community of resources, a coordinated project was undertaken to establish a new collaboration between the memberships of SITE and the Center for Innovative Learning Technologies (CILT) with support from the US imitative preparing tomorrow’s teachers to use technology (PT3). CILT is a distributed research center that excels in fostering community and gathering innovative research in technology for learning and instruction. It is expected that this collaboration will allow both groups to help reinforce each other’s work and philosophy, with an ultimate goal of informing policy development and the reformation of teacher education and the use of IT.

Borrowing strategies from the field of Knowledge Management, ASTUTE aims to help these organizations “renew” themselves, while making fuller use of their existing resources. Knowledge Management has been defined as:

a conscious strategy of getting the right knowledge to the right people at the right time and helping people share and put information into action in ways that strive to improve organizational performance. (O’Dell, Grayson, & Essaides, 1998.)

To meet ASTUTE’s multiple goals, a needs analysis of SITE participants was conducted at the 2001 annual conference in Orlando, FL, USA. An online survey, which incorporated participant wants and needs, was administered to conference attendees. 165 individuals completed this Web-based survey. Additionally, 38 personal interviews were conducted, and a special interactive session was held at that SITE conference. The session focused on core issues for technology in teacher education, while ensuring that equity remains an integral aspect. The session introduced CILT, PT3 Teacher Education Network (TEN), and ASTUTE to the SITE community. The 2002 conference session will present survey data and debate planned developments.

An analysis of the online survey and the personal interviews revealed significant information about how members would like to participate in the IT community. Perhaps the most important was an over-arching desire of SITE
members to be more involved in the organization, particularly in the area of sharing skills and resources with their colleagues. This was evidenced in both the self-identified needs and contributions of the surveyed membership. While many of the identified contributions and needs are vague, several are highly focused and show the depth of the expertise and desire to assist colleagues. A sample of the contributions SITE members believe they can offer the organization, expose the wide range of skills, abilities, and expertise. Two typical examples were:

- I can provide to SITE members mentoring in the use and infusion of technology into pre-service communities, especially diverse populations.
- I can provide SITE members dialogue and reflection on teacher leadership roles, application of quantum mechanics to field of education.

Among the most powerful contributions that members have to offer each other are online repositories and resources. These include virtual libraries, discussion and message boards, directories, and tutorials. These are being collected and will be offered to all members and the wider community.

Perhaps of greater interest are the self-identified needs. Many of these needs reflect a desire to be more involved in both the SITE organization and the profession as a whole. One member, who is attempting to develop a virtual library of resources for preservice teachers and teacher educators, identified this type of need: "SITE members can assist me by/with identifying the kinds of instructional, research and professional development contents they would most like to see made available to them via a virtual library." While the need is specific and identifies a request for information and assistance, it also reflects a desire to be more involved in, and to make a contribution to the profession as a whole.

At the same time, it appears that there is a belief among the SITE participants that the organization may not be as open and accepting of alternative perspectives and philosophies as it could be. One respondent stated: "SITE members can assist me by/providing scholarly information and research from a variety of sources including some that may be different from the norm. Be open and more inclusive." Another member was even more specific in identifying this belief, not only as it affects the organization, but also the effect that our practices may be having on education at large: "SITE members can assist me by being more open to heavy critique of some approaches to education technology implementation and to be more willing to openly reflect on how their own practices may be contributing to the inequities illustrated by the digital divide research, because looking at this from a wider perspective, the people who have always been disenfranchised by the education system (in the US particularly) are the same folks who are being further disenfranchised by the digital divide."

Other members identified a desire for the organization to become more diverse and open in its leadership roles: "SITE members can assist me by encouraging leadership roles in its membership in a variety of forums providing a central community area with active discussions on topics as wide ranging and diverse as its membership.”

Similar opinions and trends emerged from the personal interviews. One interesting trend that did emerge from these interviews is a desire to use the technology to create a shared community of skills, abilities, knowledge and interests. One individual felt that one way in which SITE could help is by providing a clearinghouse for others developing virtual expertise to be used in the classroom. They would like to see a greater practical sharing of what the technology can and cannot do. One member even went so far as to comment that they would like the opportunity to talk with others in the same predicament. A different member suggested that they would like to see the creation of a resource that would provide online access to experts and exemplary materials.

Other members felt that there is still more room for organizational collaboration. In addition to the current collaboration between SITE, CILT and TEN (in the form of this ASTUTE project), those interviewed suggested that there needs to be greater collaboration with such organizations as AECT, and AERA, as well as collaboration between the SITE journal, The Journal of Technology and Teacher Education, and T.H.E. Journal.

The first of the predetermined key words available for surveys and interviewees to assign to their responses was "equity." This was done to encourage participants to address issues of equity in their responses and promote inquiry into equity issues in IT. In addition to the points noted above many respondents seemed to be concerned about the
lack of equity pedagogy in IT and as a result of their observations wanted to contribute their expertise and experience to help promote more equity-conscious practices in IT.

When asked what excites them most, the majority of participants appear to be most excited by learning. They report that they enjoy watching preservice teachers grow and learn to become not only good teachers, but to share in the excitement and love of learning. One person said that they are "looking for teachers where teaching comes first, but they are willing to take a risk to make an impact with IT."

It is expected that, as it grows, the ASTUTE project will inform actions to help fulfill many of these needs, as well as to provide an outlet for the varied contributions members wish to make. SITE, through its president, is employing techniques informed by Havelock & Zlotolow (1995) which were introduced by Niki Davis (2001) in her keynote speech at the SITE 2001 conference and developed discussed within the Preface to these proceedings (Davis, 2002). General themes and specific requests will also be passed on to the committees where appropriate. A number of web-based developments also provide potential activities:

- The TEN's project's clearinghouse, which includes a virtual library and personal learning portal (http://www.teacherednet.org)
- The Digital Scholarship Portal (Bull, Sprague & Bell, 2001)
- The SITE and AACE online forums and career center (http://www.aace.org/site/forum)

A revised survey and panel session will take place at the 2002 SITE annual conference in Nashville, Tennessee, USA. The end result should be organizations that are more responsive to and reflective of their general memberships.

Leading Change in Utah Schools with Technology: 
The T-PLUS Project

Abstract: Western Governors University (WGU), through grant funding from the Bill and Melinda Gates Foundation and the State of Utah, has developed the Technology for Principals Leading Utah Schools (T-PLUS) Project. This innovative distance program provides competency-based in-service education that enables Utah principals and superintendents to take leadership in technological change for instruction in their schools and districts. A collaborative venture, WGU is working with other universities within Utah and Arizona to provide online distance courses with embedded assessments, as well as a supervised action research project. Successful participants earn a graduate certificate in Technology Leadership. This paper presents the design of the T-PLUS initiative, its goals and collaborative delivery through the Web to administrators throughout Utah, and the results to be realized by the project.

Overview

T-PLUS is an intense, technology-rich, leadership-driven professional development program for Utah principals and superintendents. Participants who complete the program receive the Advanced Certificate in Technology Leadership from Western Governors University and earn 144 relicensure points along with eight (8) semester units of graduate credit from the Utah State Office of Education. The $2,000,000 grant allows for 70 percent, or about 670 members of Utah's 949 public and private district and school leaders, to participate in this professional development opportunity. The program is funded for three years and includes the following:

- A WGU faculty mentor assigned to provide personalized assistance and coaching to each participant, as well as guidance in assessing the knowledge and skills each participant already has when she or he comes to the program.
- Learning resources, including coursework, that help participants gain new competencies.
- Access to six distance-delivered group gatherings for connection with other participants via EDNET, the Utah Education Network's interactive teleconferencing system.

The T-PLUS curriculum is designed with a close eye on the evolving work of the International Society for Technology in Education's Collaborative for Technology Standards for School Administrators (TSSA Collaborative) and its March 2, 2001, release of proposed standards for (1) superintendency and cabinet-level leaders, (2) building-level leaders, and (3) district-level leaders for curriculum and special programs. The program also matches to the Milken Seven Dimensions and utilizes the best practices of adult learning.

The learning opportunities consist of multiple elements, including support in the form of online resources and discussion groups. T-PLUS also includes six major satellite institutes delivered throughout the State that are designed to orient, energize, and celebrate the program's completion through the awarding
of a professional development certificate (WGU's Advanced Certificate in Technology Leadership) and sharing the outcomes of participants' action research projects. This combination of competency-based and distance or distributed education makes WGU a compelling and convenient choice for busy administrators to pursue advanced study in technology integration and implementation leadership. It should be noted that for administrators new to the world of technology-assisted teaching and learning, opportunities for basic skills tutelage and practice are provided through the regional service centers and other Utah state resources.

T-PLUS Goals

The overarching purpose of the T-PLUS project is to support Utah's K-12 technology goals through a well-defined, state-coordinated technology leadership initiative that, via professional development opportunities, promotes integration of technology in district- and school-wide teaching and learning and focuses on increased student achievement.

Specifically, T-PLUS is designed around four primary goals:

- **GOAL I:** Identify and critique technology-supported learning environments that address instructional or performance improvement goals.
- **GOAL II:** Oversee and manage a technology-integration project team and its process, including providing for relationships among all stakeholders.
- **GOAL III:** Develop and justify strategies and tactics for introducing and integrating new technology tools and techniques based on change theory or a change model.
- **GOAL IV:** Design and complete an action research project either individually or collaboratively with one or more other participants. The project will be field-based, data-driven, and reflective of outcomes based on a technological intervention.

Program Delivery:

The heart of the T-PLUS leadership initiative is to provide all Utah superintendents and principals an opportunity to gain competency in two domains of knowledge: Technology Implementation and Leadership with Technology. Each participant's demonstrated mastery of the competencies included in these two domains will result in the awarding of a professional development certificate entitled "The Advanced Certificate in Technology Leadership" from Western Governors University.

In addition, demonstrated ability to apply the competencies will be realized through an action research project that participants may do individually in their own school setting or collaboratively with other schools in their district or geographic proximity. This action research project is designed to accomplish two goals of its own: (1) Help participants synthesize their learning, and (2) Provide a context for ongoing growth and development in technology leadership throughout the State of Utah and beyond the life of the T-PLUS project.

The program design contains three basic elements:

1. Six synchronous, distance-delivered, whole-state gatherings.
2. Establishing and carrying out a professional development action plan for each program participant to demonstrate the 12 required competencies.
3. An action research project that synthesizes the competencies and provides a practical application of those competencies and that allows for expansion of the project beyond the grant's three-year life.

The design organizes building principals into regional cohort groups by Educational Service Units. The participating superintendents will comprise a cohort group of their own, wherever they are geographically situated.
T-PLUS Institutes

Six synchronous two-way interactive audio-video institutes are being delivered via the EDNET system which is developed and maintained by the Utah Education Network. The content will include a number of things, such as addressing a current issue in educational technology via an expert on the topic, a review of standards such as the Technology Standards for School Administrators (TSSA) recently set by the International Society for Technology in Education (ISTE), program information and support, and information about the types of action research projects that are occurring throughout the state. Importantly, these events also provide an opportunity to interact with participants statewide and build synergy and teamwork for ongoing district- and school-based technology projects beyond the life of the TPLUS initiative.

These six institutes are being held at various EDNET locations throughout the state in November 2001, March and November of 2002, March and November of 2003, and March of 2004. Each program participant is required to attend at least two of these six synchronous events.

Mentoring and Courses Delivery

Mentors take the place of traditional instructors at WGU. A mentor is assigned to each student upon admission and, with rare exceptions, remains with that student until he or she completes the targeted program of study. The mentor develops collaboratively with each student the individual "Academic Action Plan" that will serve as that student's road map to completion. It takes account of the student's background, strengths and areas still needing growth, interests and goals; it identifies areas where the student may be ready or nearly ready to sit for performance assessments, as well as other areas where new learning will need to occur before attempting an assessment; it identifies courses and other learning resources the student will need for development of the necessary expertise; and it establishes timelines for accomplishing goals. The mentor helps students enroll in the courses they will take, introduces the student to WGU's online library resources, and lines up accessory readings that the student can use. The mentor answers questions, serves as coach, intermediary, and ombudsperson.

Upon completion of the online application, a TPLUS mentor will contact each participant individually. She or he will ensure that each participant fully understands how the program works. Prior to beginning the certificate, participants will complete a skill survey, a WGU pre-assessment, and the (Taking a Good Look at Instructional Technology) TAGLIT survey. The skill survey and pre-assessment assist the student and mentor in identifying strengths and weaknesses as aligned with the TPLUS goals and objectives. While the TAGLIT survey will inform this process as well, it will also provide the mentor and the program participant a focus for the action research project. These T-PLUS mentors will then continue to work with each participant on an ongoing basis throughout the program until its completion.

There are two options for participants. Based on pre-assessment findings, they can go directly to final assessments and take no coursework (a time effective way of demonstrating prior learning), or they can take three specified online courses through Utah and Arizona institutions of higher education that have created courseware specifically written to the T-PLUS goals and objectives. They can also do a hybrid of the above, that is, take final assessments for some of the competencies while completing the remaining competencies via instructor-led courses. Although going directly to the final assessments can be chosen as a "test-out" option for areas of the program a participant already fully understands and is competent in, the action research project will be completed by all participants either independently or in collaboration with other participants, no matter which of the above paths is taken. One of the three course options is an action research course that embeds the final project within it. The mentor assigned to a program participant, in coordination with the participant, will set up an individualized completion plan that can be tweaked as necessary during the participant's progression through the program's requirements.
Since WGU does not offer courses itself, it contracted with other universities in Utah and Arizona for the three graduate courses that support the certificate. Course development took place during fall semester 2001 so that delivery could begin in January 2002. Development entailed customizing the content of a similar course at the hosting institution to the goals and objectives outlined above and/or converting it to a format deliverable via the Web. The objective assessments for this content, consisting of multiple-choice and essay test items, were further refined by WGU from assessments used in its Master of Arts in Learning and Technology degree program. These assessments were integrated into the courses as final examinations. The courses are being delivered via the Web for six to eight semesters (spring, summer, and fall) for two and a half years. The assessments are scheduled by WGU each semester at a proctored site convenient to each student.

**Program Evaluation**

All programs at Western Governors University, including the Advanced Certificate in Technology Leadership, are based on the successful demonstration of competencies. Competency assessments provide a valid, reliable, and quantifiable evaluation of the degree to which the learning goals and objectives are met. In addition, WGU is evaluating program effectiveness through a series of qualitative measures. These will include surveys of participant experiences through various components of the program, such as satisfaction with WGU mentors and satisfaction with the courses and other learning opportunities provided, as well as qualitative evaluation of participant experiences in the synchronous T-PLUS institutes. In addition, participants complete the TAGLIT survey at the beginning and end of the T-PLUS program, a rich source of information for a pre- and post-comparison of whole-school improvement whose results are influenced, though not controlled, by the T-PLUS program design.

Multiple measures of knowledge, skills, and abilities not only assure that program participants have mastered the content of the certificate, but also provide rich data to evaluate the overall effectiveness of the program. The evaluation allows comparison of participant experiences against a number of demographic (i.e., age, gender, rural/urban location) and educational variables (i.e., courses taken, independent learning resources used, grade points earned). All program participants will also be asked to participate in an end of program satisfaction survey. This survey measures not only student satisfaction with program services, but includes also the relevance of competencies to their current and future positions. The assessments and evaluations of this program are being overseen by the WGU Assessment Council, comprised of nine national and international experts in assessing student learning.

**Conclusion**

The professional development that Utah principals and superintendents are undertaking through this initiative will allow them to demonstrate their ability to lead the technology change process in Utah Schools. The TPLUS Project makes it possible for these educators to encourage and inspire sound pedagogy in K-12 environments via technology, providing them access to this exceptional educational experience through online courses, mentor guidance, and the opportunity to demonstrate their knowledge and skills through competency assessments.
Technology Leadership: Shaping Administrators' Knowledge and Skills Through an Online Professional Development Course

Abstract: This research examined changes in administrators’ ideas about technology integration and technology leadership while participating in an online professional development course. Eight administrators, enrolled in a semester-long course, participated in 15 discussion forums related to K-12 technology implementation issues. Pre- and post-course surveys indicated significant changes in ideas about technology integration as well as methods used to support teachers’ integration efforts. Analysis of interview and course discussion data suggests that administrators view technology leadership as a “shared responsibility” that requires both administrative skills and technical knowledge.

Theoretical Framework

According to the SouthEast Initiatives Regional Technology in Education Consortium (SEIR*TEC, 2000) “leadership is the single most important factor” influencing the successful integration of technology within our schools. Based on their extensive work in K-12 schools, SEIR*TEC noted that the schools that have made the most progress toward technology integration are those with energetic and committed leaders. Stegall (1998) reported that this influence held true despite wide differences in schools' enrollments, locations, and operating budgets.

Few educators today would argue with the notion that the principal plays an important role in facilitating technology use in the schools. According to Crystal (2001), building administrators are the “nexus through which all issues flow” (p. 36). Yet many of our administrators are novice technology-users and have gained little experience or training in the knowledge and skills needed to be effective technology leaders. Even though administrators understand the importance of implementing and supporting technology use in their schools (Mehlinger & Powers, 2002), the development of technology leadership skills seems to have been left almost completely to chance. Since it is possible to obtain a principal’s license without knowing anything about technology, how, then, are our administrators expected to develop these critical skills?

Unfortunately, there is very little research delineating best practices for preparing administrators to be technology leaders. Most school administrators are simply acquiring their technology knowledge and skills on the job, with occasional training provided by assorted vendors, professional organizations, and, to a lesser extent, colleges and universities. According to Mehlinger and Powers (2002), "Graduate school programs generally are doing a poor job in preparing school principals and superintendents to be technology leaders" (p. 218).

Still, colleges of education have started to consider ways to address technology needs within their school administration programs (O'Neill, 1999). Furthermore, a national collaborative has recently drafted a set of technology standards for school administrators (TSSA, 2001) that can guide the redesign and/or development of new graduate
courses. Given the number of issues that need to be addressed, however, innovative approaches will be needed if administrators are to gain the pedagogical, as well as the technical, knowledge and skills needed.

**Purpose of the Study**

This study was designed to examine changes in administrators' knowledge and skills, related to technology leadership, as they participated in a semester-long online professional development course. By requiring administrators to use technology to examine issues of technology leadership, we hoped to support the development of administrators' ideas related to technology leadership, while simultaneously building their confidence and competence related to technology skills. Specifically, the questions guiding data collection and analysis included:

- What are administrators' ideas about technology leadership and how do these ideas change while participating in an online professional development course?
- What knowledge and skills do administrators need to affect technology leadership in their schools and to what extent can participation in an online professional development course build both knowledge and skills?

**Methods**

We gathered both quantitative and qualitative data to examine changes in the knowledge and skills of eight administrators enrolled in a 3-credit course, *Integration and Management of Computers in Education*, during the fall semester of 2001. This course was one of two courses that participants were required to take during their first semester in the university's cohort doctoral program in school administration. Although cohort students had been required to take this course in the past, this was the first time the course was offered completely online. Furthermore, this was the first time the course enrolled only administrators; previous offerings of the course included a mix of administrators, undergraduate pre-service teachers, graduate in-service teachers, and graduate students in educational technology. Having a homogenous audience in the course allowed for a more extensive focus on administrative leadership issues than had been possible previously.

All 8 administrators agreed to participate in the study. Participants included 2 females; 4 participants were assistant principals, 3 were principals, and one was a district-wide instructional technology coordinator. Teaching experience ranged from 3 to 18 years, with an average of 7 years, while administrative experience ranged from 2 to 8 years, with an average of 4 years. At the beginning of the course, participants had varied levels of technology skills. Although most (n = 6) indicated that they used e-mail "as an integral part of their lives," only 4 indicated previous experiences with bulletin boards or chat rooms. In general, participants described their uses of technology as being limited to "word processing and surfing the Web." None of the participants had previously taken an online course ("WebCT is completely new to me, as well as chat rooms and message boards."). Participants expressed some initial uncertainty about learning via an online approach ("At this point, I am still uncomfortable using this type of technology to communicate.").

The 3-credit course ([http://tcct.soe.purdue.edu/tipdoc](http://tcct.soe.purdue.edu/tipdoc)) was designed to help administrators gain both the competence and confidence needed to facilitate and support effective learning environments supported by technology. Participation in the course comprised a variety of virtual interactions and discussions and incorporated three primary strategies (modeling, reflecting, and collaborating) that, based on previous research, were judged to be effective in supporting teacher and school change. For example, participants observed (via the Web and CD-ROM) a number of model teachers, engaged in ongoing reflective conversations, and collaborated with each other for the completion of various course activities. As a cumulating activity, each participant created a WebQuest that they planned to implement with their building teachers during the spring, 2002.

**Data Collection and Analysis**

Participants completed three online surveys at the beginning of the semester. These related to 1) previous experiences with technology applications, 2) specific ideas about technology integration, and 3) current technology practices within their schools. The first survey (15 questions) gathered information about participants' current positions, previous uses of computers, and comfort with specific technology applications (e.g., chatrooms, discussion boards). The
second survey (10 items) examined administrators' perceptions of how well they could conceptualize and define various components of technology integration. Survey items were presented in a Likert-style format; participants rated their level of agreement (from 1-strongly disagree to 5-strongly agree) with statements related to the possession of specific ideas regarding technology use (e.g., "I have specific ideas about how to define teacher/student roles in a technology integrated classroom."). The third survey, comprised of 44 items, examined the technology practices of both the administrators and teachers within the participants' school environments. Although this survey provided important information about the contexts in which our participants worked, not all items were relevant to our research questions. However, 13 items, representing two subscales, were particularly relevant. One subscale (6 items) examined administrators' personal uses of technology (e.g., "I use technology to support lectures and/or professional development.") while the other subscale (7 items) asked the administrators to rate the extent to which they supported teachers' efforts to use technology (e.g., "I give individual feedback to teachers during technology use."). On a scale from 1 (entry) to 4 (proficient), administrators rated their current levels of competence. The second and third surveys were completed again at the end of the semester in order to measure changes in administrators' ideas about, and strategies for providing, technology leadership in their schools.

In addition to survey data, all assignments (included the completed WebQuests) and discussion board postings (917 total messages) were used as data. Weekly discussions included, among other topics, administrators' reflections on their current visions for technology use in their schools; roles they play in supporting high-, medium-, and low-level technology users; strategies for supporting teachers' early efforts; incentives and barriers to technology use, and so on. Weekly electronic chat sessions, focusing on issues of technology leadership, were also recorded for analysis purposes. During the 12th week of the semester, during a scheduled campus meeting for their other cohort course, all administrators participated in an in-depth interview that was tape-recorded and later transcribed. Questions built on earlier survey responses; we examined participants' current ideas about technology leadership and probed for any changes that may have occurred during the course (e.g., What does it mean to you to be a technology leader in your school? How have your ideas about technology leadership changed since the beginning of the course?).

Data analysis began during the first week of the course and continued throughout the semester. Both quantitative (descriptive statistics and paired t-tests) and qualitative (pattern seeking) analysis methods were used to determine the extent to which the online course offered a viable method for increasing administrators' understanding of, and capacity for, technology leadership.

Results and Discussion

Perceptions of Technology Leadership

Participants were asked to define technology leadership and to describe the skills and knowledge needed by a technology leader. In general, administrators defined technology leadership as the methods they, and others, use to encourage and support teachers' technology use. Strategies such as visioning, modeling, and coaching were considered key to being an effective leader. Although 7 of the 8 administrators believed that they, themselves, played this role in their schools, most participants noted that they shared this role with others—either their technology-using teachers, the technology coordinator, or some other person in the school. As one elementary principal noted:

I would not say I was the leader. I am more of a cheerleader. I view my role as a role model but also as a cheerleader who focuses teachers on what is the best. I have the opinion that I should not be the smartest person in the building, that it should be the teachers who are the best resources. And that, thankfully, in my school, certainly is the case.

Carr (1995) refers to this style of leadership as participatory, suggesting that power and control are shared, at least to some degree, among constituents. This participatory style was commonly discussed, and agreed upon, by the administrators in this course. Although they believed that the effort should be started and supported by them, they felt that others shared responsibility for seeing it through:

I think it's ultimately my role ... but then we're all in this together. It's a building effort; it's something we all need to take responsibility for.

Although many of the administrators did not think that their ideas about leadership had changed during the
semester, they noted that they had gained many ideas about technology integration as well as how to support teachers' efforts. One middle school principal described this change (posted on the discussion board):

When I entered the class I was unclear about the proper integration of technology. I would encourage teachers to use the Internet, drill and skill software, and word processing. Other than that I did not have a good handle on the many possibilities. Since then I have really begun to better understand the use of technology in the classroom through WebQuests, research projects, presentations, etc. The second idea has been the techniques and confidence to lead staff as a technology leader in the building. It is something that I had not very concerned about prior to this class.

Perceptions of Knowledge and Skills Needed by Technology Leaders

When asked what knowledge and skills they needed to be effective technology leaders, participants mentioned the need to be models for their teachers, but were unsure if they needed to know more than their teachers in order to be effective. One principal suggested that a good technology leader identifies the exemplary users in his school and then "gets out of their way." However, an assistant principal disagreed, "I don't think I am going to be an effective leader ... if I am not using it myself." Another principal suggested that he "had to believe in it, had to use it, and had to model it." Certainly, the administrators agreed that they needed to have enough knowledge to hire the right people, to acquire the best resources, and most importantly, to know what good technology integration looked like so that they could encourage their teachers to continue to grow. According to one assistant principal, "these skills are just good leadership skills, not necessarily technology knowledge skills. These are people skills, management skills."

Administrators agreed that an online course, focused on technology integration and technology leadership, filled an important need for practicing administrators. By requiring them to "live and breathe technology" they increased their own skill levels as well as their expectations for their teachers. They believed that by developing a strong personal vision of technology integration they could, in turn, support the development of their teachers' visions.

Developing the Skills and Knowledge of a Technology Leader via an Online Course

Strudler and Wetzel (1999) stated, "At the core of informed leadership is a person who has internalized the complexity of effective technology integration and who exercises influence to ensure that the various enabling factors are in place" (p. 68). This suggests that technology leadership requires two sets of competencies: 1) understanding technology integration and 2) providing the necessary support to ensure that effective integration can occur. These competencies relate specifically to the knowledge and skills needed by technology-leading administrators. In order to determine the impact that this online professional development course had on the development of administrators' technology leadership knowledge and skills, pre- and post-course survey results were compared.

A two-tailed paired t-test (df = 7) indicated a significant increase in administrators' ratings of perceived ideas about technology integration (survey 2) from pre- to post-course (t = 3.81, p = .007). Average ratings increased from 3.7 (undecided-agree) to 4.0 (agree). This suggests that, as the course progressed, administrators gained ideas about what technology integration should look like, as well as how technology might be implemented within various classroom contexts (e.g., one-computer classroom; in support of content-learning). Given that administrators play a key role in establishing a technology vision for their schools, as well as evaluating teachers' efforts toward achieving that vision, it is critical that they gain specific ideas about effective technology use. These ideas, then, represent an important prerequisite to being able to both lead and support teachers' efforts.

Although no significant differences were noted from pre- to post-course (t = 1.19, p = .14) on the first subscale of survey 3 (administrators' personal uses of technology), average ratings of competency on the second subscale (administrators' support of teachers' technology use) increased from 2.0 (emergent) to 2.4 (emergent-fluent). This increase was significant (t = 2.82; p = .01). Thus, as the administrators participated in weekly discussions, focused extensively on technology support issues, they were able to identify and implement new ways to support technology use among their teachers. As one principal noted:

Taking this course has brought technology to the forefront for me ... it's something that I discuss more with teachers ... I have started conversations with them about what they can do to help bring more technology into their classrooms. I ask them what are some of the things they need in order to accomplish the things they are
thinking about. This course has helped me to go out of my comfort zone and to do a paradigm shift in my thinking on instructional practices in the classroom.

Ongoing discussions with the administrators suggest that this approach to professional development may be an effective way to increase confidence for, and ideas about, technology leadership. Administrators agreed that the course increased their understanding of how to support technology use among their teachers, as noted by the following comment:

(When I was a teacher) I did not have any training on how to effectively integrate technology in my classroom. Actually this is the first course that I have had that teaches how to integrate technology. Too bad I am not a teacher anymore. At least after having taken this class I will have an idea of how to assist someone in integrating technology.

**Educational Significance And Implications**

Participation in an online course, focused on technology integration and leadership issues, appears to offer one means for helping administrators understand the complexity of the integration process and to find new ways to support their teachers' integration efforts. By requiring administrators to deal with technology issues as part of their ongoing course participation allows them to experience, first-hand, both the benefits and challenges of dealing with technology in a meaningful and substantive way.

According to Mehlinger and Powers (2001), "It is no longer possible for administrators to be both naive about technology and be good school leaders" (p. 218). Yet, to date, the professional development needs of the administrator, as a technology leader, have been virtually ignored. Despite the large amount of time, money, and resources being directed toward supporting teachers' efforts to integrate technology in the classroom, little has been done to either recognize or support the needs of the administrator. "Clearly, it is not reasonable to imagine that teachers, the "followers," are going to get very far ahead of the "leaders," their administrators" (Mehlinger & Powers, p. 213). The results of this study highlights the importance of the administrator in helping schools achieve sound technology practices, and proposes one strategy (participation in an online course) for increasing administrators' capacity for technology leadership.

PT³ AND T³L – Teaching Tomorrow’s Technology Leaders: Preparing School Leaders to Use Technology

Ian W. Gibson
Department of Administration, Counseling, Educational, and School Psychology
Wichita State University, Kansas, United States
ian.gibson@wichita.edu

Abstract: This paper describes the symbiotic relationship between school district and university personnel as they collaborate in the technology preparation of school leaders enrolled in programs of graduate study at Wichita State University. By learning to do research as they conduct research for local school districts, graduate students in these programs become skilled in research methodologies and expert in the topic of the research focus. In the example presented in this paper, graduate students conduct a full district evaluation of current information technology practices, needs, and expectations in preparation for the writing of a report designed to assist in the development of the next stage in the school district technology plan. Such a data based approach to the development of educational technology futures provides an information technology decision making platform for the target school district as well as providing a solid grounding for the future technology actions of these neophyte researchers when they assume the mantle of leadership in their own school districts. The paper describes the methodologies used, the results of the research, and the impact of the process and the findings on both the target school district and the graduate student / future school leader.

Introduction

Significant attention continues to be paid to the technology development of tomorrow’s teachers and their ability to use educational and information technologies effectively in their professional practice (see U.S Department of Education, 2001, <http://www.pt3.org>). The tendency to devote unparalleled amounts of federal, state, and local educational dollars to the technology preparation of teachers is on-going and rarely questioned in school contexts. There is an increasing realization however, that teachers, well prepared in their use of technology, are not as effective in their technology integration efforts unless there are well prepared school leaders capable of motivating, collaborating, and supporting these technology integration efforts (Gibson, 2001; Mahmood & Hirt, 1992; Maurer & Davidson, 1998; McPherson, 1995; OTA, 1989, 1995; Rodin, 1997).

Recent action on a national level has attempted to redress this oversight through the development of a set of technology standards for school administrators (see Technology Standards For School Administrators (TSSA) Collaborative, 2001, <http://cnetts.org/tssa>). Other efforts to prepare school leaders in the use of technology on a local scale are also in evidence (Gibson, 2000). Recognition of the need for continued expansion of efforts to focus attention on the technology preparation of tomorrow’s school leaders is growing. This paper explores one approach designed to contribute to this movement.

The activities described in this paper focus on the collaborative efforts of school district personnel and faculty and students from a local university in a mid-western region of the United States. In this on-going project, graduate students enrolled in the doctoral program in Educational Administration and Supervision at Wichita State University in Kansas participate in a research and field based program of collaborative study designed to support the school improvement efforts of local school districts. Graduate students and professors conduct high quality research projects for participating school districts framed around local issues of relevance or need. Many of these collaborative research projects focus on technology issues.

The research described in this paper considers the symbiotic interaction of school leaders / graduate students learning to conduct research on technology issues for a client district at the same time as acquiring research skills and technology related knowledge and understanding that will benefit their own schools and districts. Further, the heavy emphasis upon a constructivist approach to teaching and the integration of information technology as a transformational element in this approach to graduate education provides a fully rounded, authentic, contextualized, and effective example of preparing tomorrow’s school leaders for their central role in the integration of information technology into learning environments.

Graduate Preparation of School Leaders

In a previous paper on the topic of graduate preparation for school leaders, Gibson (2000) described the leader preparation program at Wichita State University in Kansas as a reflective and informed response to calls for reform in educational administration. This doctoral program was predicated upon the belief that a collaborative, situated, problem-based approach to instruction about leadership would generate an authentic approach to the study, replicating as closely as possible the working environment most common to school leadership in highly effective schools. Program activities focus around authentic problems of practice, explored in collaborative team settings, and generating learner-directed and setting-enhanced learning. It is believed that within this problem situations the important concepts and principles associated with the content domain are analyzed and explored and are perceived by graduate students as real problems of practice (Savery and Duffy, 1995). Within this environment, technology integration is modeled by faculty (Biomeyer & Clemente, 1997), and meta-cognitive scaffolding is provided by faculty and peers (Savery & Duffy, 1995). The core tenets of constructivism, including the ideas of cognitive dissonance and negotiation of meaning (Savery & Duffy, 1995), are integral components of this program. In addition to
preparing effective leaders for schools, this program was also designed to emphasize the transformational role of technology on the process of learning.

The approach adopted for the graduate program in educational administration at Wichita State University requires the acquisition of high levels of expertise with selected program technologies designed to provide efficient and customized personal and professional productivity. In this program, students are dependant upon a foundation of technology expertise as they assume the role of participant, collaborator, colleague, leader, and follower, in a variety of learning environments such as seminar, field study, content presentation, data manipulation, research reporting, group/individual comprehensive examinations, and the dissertation. Program graduates acquire, among other things, an understanding of the impact of information technology on their roles as visionary leaders of schools of the future and experience the transformational potential of technology on their own learning process (Gibson, 2000).

Featured in a recent issue of the Journal of Critical Inquiry into Curriculum and Instruction (Vol. 2, No. 1), which publishes exemplary research products of graduate students in professional study, this program has attained both national and international exposure resulting from its unique combination of clinically oriented, field-based, applied inquiry features. The program has separated itself from traditional leader preparation programs through an emphasis upon (a) rigorous admission requirements and low enrollment, (b) release time from district employment for prospective students, (c) integration and contextualization of the curriculum, (d) incorporation of field-based research studies, (e) a collaborative, team-based approach to teaching and faculty load distribution, and (f) a cohort-based student support structure.

The remainder of this paper focuses upon one aspect of this program of graduate education in educational administration, specifically, a description of the process and product of that component of the theoretical framework of the program derived from the field of problem-based learning (PBL) (Boud, 1985; Boud and Feletti, 1991; Bridges, 1992). In this example, the focal points of field- and problem-based program processes and the recurring focus on technology come together in one significant program event extending across a full semester of collaborative field research.

Collaborative Learning, Field Research, and Professional Partnerships

In this program, each semester begins with doctoral field study teams exploring potential research areas with school boards and administrative personnel from local school districts in an attempt to isolate an issue worthy of a full semester of research. Following this introductory discussion, a formal research proposal, complete with rationale, beginning literature review, methodology etc. is developed and presented to the ‘client’ school district for approval. Once approved, the process of exploring the topic more fully begins with each field study team, comprising students and professors, developing foundational understanding, potential research designs, research tasks, processes, data collection tools, protocols, and analysis procedures. Contextualizing the learning and the instruction in authentic problem situations, integrating the supporting curriculum, providing scaffolding though the provision of mentoring roles derived from the cohort construction of the program, and emphasizing the orientation towards constructivist learning approaches allows a natural interplay between theory, research, and practical applications to occur during involvement in the analysis of innovative projects or problem situations in the field. It is this involvement in field study applications, with meaningful participation in internet searches, literature review, field reports, data analysis, report generation, research presentations, file sharing, information retrieval, collaborative study, and sharing of research resources that allows the technology component of this program to be integrated, authentic, and meaningful. In the example that follows, the field study topic selected by the client district focused upon the issues and practical aspects related to the planning, administration, and management of technological innovation and change in the form of the next stage in an already established district wide technology plan. The site for this study was a high performing, small rural school district proud of student achievement scores, and proud of the existing level of ‘integration of technology’ into the educational process.

Field Study Methodology

During an introductory discussion with district leaders designed to establish the general area of concern for the research, the following statements set the scene for the field study: “How do I help my teachers effectively implement the use of technology in the classroom?”, “We’re asking teachers to change the way they teach”, “Guide us to a new spot”, “Veteran staff might make implementation difficult”, “We would start a process that will go on”, “Teachers are going to be asked to re-think how they deliver instruction”, “Most of the kids are going to be way ahead of the staff”, “This is a very competitive district – they want to be perceived to be ahead of everyone else”, “What kind of activities can we involve teachers in that will improve their skills and usage”, “Focus on the pedagogical use of technology in the classroom.”

Following this lengthy discussion with teachers, technology coordinators, administrators and board members of the district, it was determined that the need for additional guidance on the next step of the district plan for effectively integrating technology as a tool in the instructional environment was necessary. A decision was made to make those issues related to curriculum and instruction the focal point of the study. The purpose of the study was therefore to provide guidance to the district regarding strategies related to effective integration of technology into the instructional environment. The study team developed three research questions as a guide for the study:

1. What does district data convey about the status of technology use within the instructional environment?
2. What are students’, teachers’, and administrators’ perceptions regarding the technology needs within the instructional environment of the district?
3. What would improve the integration of technology within the instructional environment of the district?

The study team chose a qualitative paradigm for the study’s design. This design allowed the team to obtain rich, descriptive data from students, teachers, administrators, and technology coordinators. These data provided a thorough description and understanding of the
technology usage in the district at the time of the study. The documents reviewed by the study team provided further data relative to
district technology use.

The research design allowed the study team to triangulate data from various sources to determine findings. Patton (1990) stated, “A
multi-method, triangulation approach to fieldwork increases both the validity and reliability of evaluation data” (p. 245). Triangulation of
various data collection techniques permitted the team to combine the strengths and correct the weaknesses of any one source of data. In
using triangulation as a method of data analysis, “the researcher seeks out several different types of sources that can provide insights about
the same events or relationships” (Patton, p. 115).

The study team used multiple research methods to explore the three research questions. The research methods included focus groups
with students and faculty, interviews with administrators and technology coordinators, and an analysis of district documents. The
combined data were subjected to a process of constant comparative analysis (Lincoln & Guba, 1985) and resulted in the findings presented
below. Following further analysis, conclusions were derived from the findings. Recommendations were then formulated to assist the staff
in the revision of the district technology plan, and the conclusions and recommendations proffered were supported by the review of
literature conducted during the process.

A Study of the Integration of Technology into the Instructional Environment of a Rural School District – Context and
Findings

The small rural school district forming the focus of this study supported technology using a variety of funding mechanisms. The
general fund budget for technology had increased over the last several years with the largest increase during the 2000-2001 fiscal year.
This most recent increase was over 100% from $40,000.00 to $93,000.00. Funds from the general fund also supported staff development
specifically designed for technology. Teaching and support staff perceived that they received support from technology coordinators,
colleagues, and students. Technology coordinators at each building provided limited but beneficial support. Student volunteers provided
support during the semester. The number of computers and other technology available to district staff had increased in recent years. One
hundred and four computers were available in the district for teacher and student use. Every teacher had ready access to a computer. Some
computers were networked and some had Internet access. Other technology reported as available by staff and students included DVD
players, digital cameras, scanners, a mobile lab of wireless iMacs at the secondary level, a classroom set of Alpha Smarts at the
elementary level, and super disk drives. Students, staff, and administrators reported that the district had implemented a student information
management software package. This package afforded students and parents access to grades and assignments. Teachers and administrators
reported using this software to manage grades, take attendance and lunch count, schedule classes, track discipline issues, and maintain
current student demographic information. Administrators expressed optimism and satisfaction with the capabilities of the district’s new
student information management program, appreciating the efficiency it afforded their jobs. They also indicated that communication had
improved with the online capability of the district. Parents had access to this student information via the Internet and this access was
considered beneficial to students and parents.

However, staff reported that support in the form of in-service was not adequate. Many faculty members reported their life had
changed as a result of the integration of current technology. Some openly expressed a reluctance to use technology because of a lack of
knowledge on how to proceed. Apparently, some students had noticed this discomfort, suggesting that, “Except for the computer teacher
and librarian, the rest of the teachers know only as much as we do or less.”

Teachers reported they used technology most for student information management. The district purchase of the online student
information management program changed the way grades, lunch count, and attendance were compiled and reported. This information
was online so that students and parents could communicate with teachers or view the student information. Teachers also had the capability
to communicate with students, parents, and each other through e-mail.

The faculty maintained that one of the best uses of technology at their fingertips was the Internet. Teachers and students used the
Internet primarily for research and for development of lesson plans. This finding was consistent with the results of the faculty survey,
given in May 2000, showing that “teachers used the Internet most often to do research for classroom projects, bookmark sites for student
use, and supplement curriculum.”

Current student technology use was managed by Board of Education Policy and a set of Guidelines for Student Technology Use
contained in the student handbook, and the Acceptable Use Guidelines for Technology booklet, which stated acceptable and non-
acceptable student uses of technology. Students, as well as their parents, were required to sign the agreement contained in the Acceptable
Use Guidelines for Technology before students were allowed to use the Internet in the district schools.

In addition to the findings related to current support, parent usage, administrator usage, teacher usage, and student usage described
above, other findings related to perceived needs and proposed support. For example, most respondents reported a desire for more
opportunities to use technology for research, and both students and teachers indicated that technology should be more fully integrated into
the curriculum and instruction. Teachers and administrators agreed that more effective training was necessary for successful
implementation and suggested that additional training in how to use technology appropriately in the classroom was necessary as was the
need for a full-time technology director and technicians to address technology issues. They also agreed upon the need for additional time
to learn about and use technology. Some teachers were unaware of a long-term vision, or district level planning for technology use.

Conclusions and Recommendations of the Field Study

Following the description of the findings from this study, a picture of the state of the art of technology usage in this school district
appeared, and a clear response to the first research question, “What does district data convey about the status of technology use within the

550
instructional environment?" was achieved. The study team then condensed the findings of the study as described above into the following categories of conclusions:

Current Support, Parent Usage, Administrator Usage, Teacher Usage, Student Usage, Perceived Needs, and Proposed Support.

This restatement of the findings into conclusion statements confirmed the response to the first research question and provided a more concise response to the second research question, "What are students', teachers', and administrators' perceptions regarding the technology needs within the instructional environment of the district?" A response to the final research question, "What would improve the integration of technology within the instructional environment of the district?" was provided by the study team in the form of recommendations which were derived from an analysis of the findings and a synthesis of the literature review and the technology experience and expertise of the members of the study team.

The study recommendations for the integration of the technology into a small rural school district follow:

- All stakeholders should be involved in all phases of the technology visioning and planning processes.
- A district-wide, shared vision should be developed collaboratively with stakeholders to guide technology use.
- The district technology plan should be updated to focus on integrating technology, student-centered activities, and targeted staff development.
- Formative evaluation of the technology plan should be conducted yearly.
- The allocation of funds for technology should continue to increase.
- Funding should be provided for full-time technology coordination/technical assistance throughout the district.
- Resources (personnel, financial, facilities, time, equipment) should be available to support the district plan.
- Access to the Internet should be made available to all students and staff.
- Training should be provided to all stakeholders for effective use of the student information management system.
- Staff development should be targeted to increase awareness of the potential of technology to transform the learning process to focus on student-centered activities.
- Student-free time should be regularly scheduled to assist professional staff in learning about technology.
- Results-based staff development for technology integration should be targeted to learner skill levels.
- Support/encouragement should be provided to all staff integrating technology into the learning environment.
- Emphasis should be placed on innovative ways to integrate the Internet into the learning process.
- Specific resources (websites, professional library, examples of lesson plans, network contacts, site visits, expert colleagues) should be made available to assist teachers to integrate technology into the instructional environment.

Conclusion

Several goals were achieved as a result of conducting this field study. Initially, the partnership between school districts and the local university was maintained and supported by achieving the mutual goals established during the development of the symbiotic relationship designed to foster shared responsibility and collaboration in the preparation of school leaders. Further, the internal goals of the school district were achieved through the development of a new orientation to an established technology plan. With this goal being achieved, the school district has been able to use the process and the report developed by the study team to provide direction for technology improvement efforts throughout the district, and has further used the report to motivate a process of teaching renewal in the district based upon the study recommendations. This district has also re-considered its approach to strategic planning and visioning for school futures to incorporate an a more inclusive orientation to these activities, based upon the results of this field study.

Finally, the process of learning to do research during the process of conducting research has provided the graduate students in this program of leader preparation with the research skills necessary to conduct their own research whenever the need arises. Further, because the topic of the field study related to the integration of technology into the many learning environments of a school district, these future school leaders were provided with firsthand experience of the intricacies of supporting a district wide approach to planning for effective technology use through participating in a full district evaluation of current information technology practices, needs, and expectations in preparation for the development of the next stage in an existing school district technology plan. Such a data-based approach to the development of educational technology futures provided an information technology decision making platform for the target school district as well as providing a solid grounding for the future technology actions of neophyte researchers/graduate students/future school leaders when they assume the mantle of leadership in their own school districts. Unfortunately, the opportunity for future school leaders to experience such grounded technology based experiences in their leader preparation programs are few and far between. To increase the possibility for more of the future leaders of America's schools to experience targeted technology training similar to this, a national funding initiative is necessary. While it would be inappropriate to ignore the need to provide funds for the preparation of teachers in technology use, it would be equally inappropriate to ignore the need for funding opportunities for the teaching of tomorrow's technology leaders.

Abstract: With the changing of the Standards in the NCATE process, in addition to looking at the outcomes of the program, the University of Nebraska – Omaha has created an electronic document center that bridges the gap between hardcopy documents and electronic documents using the web. This presentation is based on the experiences and timeline that took place leading up to and during the site visit in the fall of 2001. As well as the information for NCATE, the document center has created a wealth of information that goes well beyond the site visit. Nevertheless, the document center is and will continue to be a valuable center for all faculty, staff, students, alumni, and the community to gather information. Come and see some of the information presented and also visit us online at: http://www.unocoe.unomaha.edu.

Introduction

Technology is a driving force behind many of the activities that occur in the College of Education at the University of Nebraska at Omaha. This short paper will review the technical aspect of the NCATE (National Council for Accreditation of Teacher Education) visit that occurred in November 2001. Three areas using technology were concentrated on for the NCATE visit. These areas involve: preparing for the document center, creating the document center, and using the document center.

Preparing for the document center started approximately a year in advance of the NCATE visit. The administration of the College met and discussed the unit standards of the institutional report. A draft of the institutional report was created and distributed to the administrative team for input in all areas including the overview and conceptual frameworks, as well as the six standards. Once the report was close to final form, the electronic document center began to take on a first draft look. The first electronic version of the document center was put together by linking certain key words in the report to web pages that supported that word or phrase. Upon watching this technique develop, it became very apparent that so many words were being linked to additional resources that it was becoming difficult to read and hard to pick out each individual link. Even though there was a space between the underlined words, it was very hard to distinguish between two separate Internet links.

After discovering that the first method was not very successful in creating an atmosphere that was comfortable in navigation, a new look had to take place. There was a direction but the team needed to step
back and look at the overall picture of what was needed with the electronic document center and how it should really be organized. At this point, a decision was made to create an index of what related documents support each section and not link directly from the report to the supporting documents. Some of this decision came from past experience of the people that had been involved in being able to easily locate materials according to a hardcopy index. Next, an electronic index was starting to be put together according to each unique section. Some of the documents were referred to in more than one section because it related to more than one section.

The electronic document center was produced and published online. We used a combination of web creation applications to facilitate the making of the page. We used a blend of simpletext and notepad with occasionally Claris Homepage, Adobe PhotoShop, Adobe Acrobat, Macromedia Dreamweaver, and Microsoft FrontPage. Different people created documents that were placed into the electronic document center and then my staff converted them to be web readable. Even though some pages were already in existence from having an ongoing web page, many more pages had to be updated or created for support of the documentation. We also linked to pages outside of our College. Therefore, we had to communicate with people at remote sites and verify that their information was updated and correct.

While the electronic document center was taking shape, one challenge was brought to the forefront. Given the list was getting very long, could the list be broken up to make it more manageable? A second challenge included a discussion that all documents may not be appropriate or practical to be online. Both challenges were brought to the administrative team for discussion and decision-making. As for the first challenge, we decided to have the index in two places. The first index would be a full index from the home page of the NCATE site and the second place an extracted version included at the end of each individual section of the report. This idea worked well also with the report itself. The whole report was available as a single long document, but it was also broken up into each individual section concluding with the extracted index that was referred to from the electronic index.

The second challenge was also overcome. A decision was made to not have everything online, but instead to categorize each document in the electronic index. The document could either be electronic only, paper only, or both. We would also duplicate the electronic index and include it with the hardcopy document center that was located in the NCATE team meeting room while they visited our institution. We also went a step farther and included a search engine that would only search the institution's local domain web pages. Many large search engines offer a University search that can be included in your site and indexed by their search engines. We decided to use the Google University Search engine to be included within our institution's web page. This was a critical piece that brought the index of the document center together with the website of the college. Many people have since used the search engine not just for NCATE purposes, but also for general day-to-day business that is conducted within the college.

Now that the document center index and report were close to their final stages, the college team discussed how best to get the information to the NCATE team. Our first discussion involved the use of the Internet and making sure that is continues to be updated and functioning. The NCATE team could always come to our website at any time and see all of the information that was in the web form. But, we know that not everyone can be connected all of the time. Many members of the visiting team have other jobs and other responsibilities, so we burned a CD (Compact Disk) for them to view our website from any computer that can read a CD. This allowed them to not have to be connected to the Internet, yet still be able to browse the documents that would give them some background to our institution prior to their visit. The downsides to this technique were the inability to get to other referenced websites and the search engine was automated and must be connected. Also, the CD was burned at a certain date, so any new and updated information was not included on it.

All three areas allowed our institution to have a successful visit from the NCATE team. Of course, there was more to the visit than aforementioned information, but it was a great learning experience using technology for communication and documentation for both the college team and the NCATE team. Feel free to visit the website to view some of the above-mentioned information at any time.
Web Publishing Policies: Ethical and Legal Issues

Gerrie Johnson, Southeastern Oklahoma State University, US

As a result of the interest exhibited by individuals at SITE 2001 to the information presented in my session 101 Reasons to have a Classroom Webpage, I have continued delving into the legal and ethical issues surrounding the publishing of students' work on the Internet. A questionnaire sent to a random sample of public school districts gathered data on current web publishing policies. The data will be examined during the poster session.

The poster session examines how the Family Right and Privacy Act, which establishes standards for student privacy in public education, impacts the use of Internet activities or projects. What caution must teachers take when publishing work created by children in their classroom? Do they have to be aware of more than simply not identifying students by personal information, such as, their first and last name, and addresses? Is this information addressed in their district web publishing policies? Is it an accurate assumption that all public districts now have web publishing policies?

The participants in the session will also have the opportunity to compare several web publishing policies in place this academic year. There are those that protect the students, teachers, and district without placing a burden on the teachers. Then, there are those web publishing policies that are so stringent that teachers feel it is not worth the effort to showcase their students' work. In some cases, the district's directive stating what can be on a teacher's web page and the policies for publishing students' work are intertwined. In those cases, one must examine the district's criteria for a teacher's web page in conjunction with publishing students' work.

The participants in the poster session will have the opportunity to assist in drafting a model web publishing policy for public school districts.
Computer Database Model to Teach Legal Issues in Principalship Program

Abstract: Principalship programs need to utilize technology in preparing school principal candidates in legal issues, since technology provides the benefits of acquiring, developing, and storing information in an effective and efficient manner. This paper describes the use of a computer database model and the Internet by principal candidates to study school law. Using the Internet, principal candidates developed a computer database model to better understand the legal and ethical issues in school settings. Technology assists future principals to advance their knowledge and application of school law; thus, addressing NCATE (National Council for the Accreditation of Teacher Education) Guidelines, ISTE (International Standards for Technology in Education) School Administrator’s Standards, and Texas Principal Certification Competencies.

Introduction

Principalship programs need to prepare principal candidates with a strong foundation in school law. This is especially critical today given the litigious nature of society, the number of state and federal mandates in education, and the complexities of a pluralistic society. The NCATE (National Council for the Accreditation of Teacher Education) Curriculum Guidelines for Advanced Program in Education Leadership and the Texas Principal Certification Competencies directly address the need for principalship programs to prepare principal candidates in the knowledge and application of education law. Also, the ISTE (International Society for Technology in Education) Technology Standard 6 entitled "Society, Legal, and Ethical Issues" for School Administrators http://cnets.iste.org/sssa/view_standards.html highlights the need for preparation in relevant legal issues. Principalship courses like School Law, Administration of Special Programs, and Administration of School Personnel, are points of preparation in education law issues. Various types of pedagogical techniques, e.g., case study, are used in coursework. With the availability of computers and the Internet, another pedagogical approach can serve to develop principal candidates' knowledge and application of school law. This student-centered approach has principal candidates produce a computer database model using the Internet in a discovery process to study legal issues in school settings. This short paper will first present the features of the computer database model. Secondly, it will describe the implementation of the model, using a case study approach. Thirdly, it will discuss benefits in using the computer database model as well as suggestions for improvement, based on case study results.

Computer Database Model

The computer database model takes the form of a "matrix" or table of legal topics. The physical component is a Microsoft Word table, which is saved as a file on a floppy disk or other readable storage devise. The table serves as a graphic organizer of legal information. The table is designed with columns of legal sources and rows of legal topics. The columns display those legal sources a principal should consider investigating in regard to a specific legal question. These columns could include federal and state statutes, federal and state regulations, and district (campus) policies, as well as appropriate forms/letters. The rows list the legal topics, and will vary from program to program. For instance a course entitled "Administration of Special Programs" could include special education, bilingual education, and gifted and talented education, to name a few. (See Table 1: Computer Database for Laws and Policies.) The next step in developing the computer database would be to create "links" to separate Word files of relevant education law content in the appropriate cells where the columns and rows intersect, using information from the Internet. For instance, the relevant state statutory law for discipline in Texas would include a citation from Chapter 37 of the Texas Education Code located at www.capitol.state.tx.us/statutes/edtoc.html.
Development of a Computer Database on Education Law and Policies: A Case Study

During summer 2001, thirty-nine principal candidates, who were enrolled in the graduate course entitled “Administration of Special Programs” at the University of Houston-Clear Lake, participated in using the Computer Database Model. In the computer lab, principal candidates were provided an instruction sheet for building the database table. Instructions were given for both Word 97 and Word 2000 since instructions did differ between the two versions of Word. This activity provided verification that participants possessed the proficiency in Microsoft Word to develop the database. With the construction of the database table, principal candidates were ready to research education law and policies to be appropriately placed in the cells of the matrix. The text in the “cell” was limited to a few words to identify the Word file containing the saved legal information. They could not simply place the substance of a Word file in the “cell” because it would swell the table in size to unmanageable proportions. They had to place a “link” in the “cell” to a related Word document. Participants “double-clicked” the “link” in the “cell,” which opened the “linked” Word file containing the saved information in its entirety. Within this Word file, they could also add “hyperlink” web site URLs. As class discussions moved from topic to topic, the instructor provided principal candidates key Internet references. Participants were given websites containing text of the United States Code, the Code of Federal Regulations, and the Texas Education Code. Participants were also responsible for searching (discovering) other appropriate Internet sources, e.g., school district policies, to be placed in the database.

Benefits of Using the Computer Database Model

The pedagogical use of the Computer Database Model produced benefits to the principal candidates in the “Administration of Special Programs” course. The search or discovery process along with typing and cutting/pasting information provided an opportunity to actively engage principal candidates, in contrast to the lecture and note taking style of instruction. During this process participants realized that much pertinent legal information could be accessed on the Internet. They gained computer technical skills using Microsoft Word in constructing the database, which provided an electronic collection of legal information. Through the process of developing the computer database, principal candidates had a better understanding of legal concepts from federal and state laws and legislation to school policies. In one exercise, the class traced the evolution of a legal concept from a Supreme Court case, to federal regulations, then to state administrative guidelines, and finally to school district policy. The concept traced was special education’s “child find.” Participants followed its development from the PARC case (Pennsylvania Association for Retarded Children v. Commonwealth, 334 F. Supp. 1257 (E.D. Pa. 1971), 343 F. Supp. 279 (E.D. Pa. 1972), to federal legislation, then to state legislative and administrative directives, and finally to the school district’s policy statement on “child find. Moreover, a discussion arose regarding the consequences of noncompliance and the possible litigation by advocacy groups. This process created the opportunity for participants to discuss differences between statutory law and regulatory law, both at federal and state levels.

Area for Technical Improvement of the Method

Complications arose when participants attempted to store the database on one floppy disk. Some of them were creative and divided the table into parts and saved them on different disks. Another technical solution would have been to save the database on a CD, but not everyone had access to a CD burner. A better solution would have been for participants to be selective in choosing pertinent information, instead of copying and pasting whole chapters of regulations and statutes. The value of the exercise in developing the computer database was not the amount of material collected, but in the knowledge gained regarding legal topics affecting educators and in the skills achieved in accessing those legal sources on the Internet.

Preparing School Administrators to be Technology Leaders

Don Knezek
ISTE's National Center for Preparing
Tomorrow's Teachers to Use Technology
University of North Texas
United States
dknezek@iste.org

Abstract: This paper discusses the connection between leadership for technology in schools as documented in the Technology Standards for School Administrators, and accepted wisdom for leading systemic educational change. The information is of particular interest to programs designed to prepare school and district administrators.

Using technology well across a school system is, in itself, significant systemic reform. When technology is appropriately integrated system-wide, work is different and who does what work changes. With the infusion of technology, tools change, learning resources are different, and learning environments are transformed dramatically. Supported by modern information technologies, communication changes, and decisions are made very differently. Educators and school leaders who understand technology and its roles in schooling and in society establish new priorities, and they highly value new learnings.

The single most important element for success and sustainability of systemic change in education is effective leadership. Evidence gathered from study of organizational change in general, and change within schools specifically, is consistent and very clear on this fact. Effective leadership of school change is the essential condition to successful change.

It is a tiny leap of logic and faith, then, to conclude that effective leadership for technology in schools is critical to success and sustainability. In fact, direct evidence arising from major systemic technology initiatives serves to confirm the important role of leadership. And it is precisely this observation that attests to the incredible importance of the administrator standards projects of the Collaborative for Technology Standards for School Administrators and of the ISTE National Educational Technology Standards (NETS) Team.

Within a framework of effective change characterized by:
• a shared vision and clear expectations,
• support strategies and essential conditions,
• ongoing, broad-based assessment and evaluation, and
• meaningful and substantial response to assessment and evaluation findings,
ISTE National Educational Technology Standards for Administrators, or NETS*A, present a rich package of guidance and support well positioned to return optimal educational benefits on our technology investments.
Effective technology leaders understand the roles technology plays in schools and in society. They establish a shared vision among all stakeholders that succinctly captures the expectations of the school community for a focus of technology use in the enterprise of schooling. Through an emphasis on standards and benchmarks, the administrator clearly and frequently reminds all involved of the expectations of them related to technology.

System conditions related to access and connectivity, supportive policy, modern infrastructure and technical support, expectations of continuous improvement, standards-based curriculum, student-centered learning activities, and community support are priority concerns of the administrator committed to providing necessary system support to achievement of technology expectations.

Using a wide array of sources, strategies, and measures to assess and evaluate achievement of the shared vision for technology within a system of schools, the technology leading administrator keeps both self and colleagues-in-leadership in touch with an authentic picture of progress. The administrator leads staff and stakeholders in collaborative review and interpretation of data and information pertaining to technology use and school effectiveness.

Finally, in the fourth critical phase of this cyclic formula for leadership of educational change, the effective technology leading administrator guides an inclusive process of establishing and executing responses to assessment and evaluation findings.

So, the bottom line? The picture for leading effective integration of technology is coming into sharp focus, and our best guide is knowledge we already have in our grasps about successful and sustained systemic change in education.
Teacher Change Processes and Student Products of Exemplary Technology Integration Sites in Kansas

Marilyn May, Brenau University, US

Research Abstract

Accountability for public investment in educational technology has been reported in terms of quantity of equipment and infrastructure ['1st generation'], not in terms of classroom technology curriculum integration with teachers as stakeholders ['2nd generation'] (Milken, 2000). Level of teacher use is key factor in evaluating effectiveness of technology on student learning (ISTE, 2000; US Dept. Ed., 1999; CEO Forum, 2000), yet no studies to date have focused on practitioner use with standardized national frameworks used for data analysis.

Research consensus concludes that technology curriculum integration is needed, as is stakeholder involvement in planning, implementation, documentation, and assessment (Hansen, 1995). Lewis (1998) and others call for more empirical research on actual instances of curriculum change, with school districts, schools, and teachers as units of analysis.

The purpose of this study was to increase contextual knowledge of integration of technology into individual school classrooms by examining teacher-identified classroom change processes and products brought about by technology used in exemplary schools. Qualitative naturalistic inquiry using the grounded theory, issue-based approach (Guba & Lincoln, 1989; Stake, 1995) provided data, which was reported in a case study format. Interviews, documents, and records were used to develop contextual knowledge (Yin, 1989). A panel of state experts both defined exemplary technology integration and identified model sites for participation. Criterion sampling allowed stakeholders to identify exemplary peers for the study. Bloom's taxonomy, the STEP model, the ISTE Technology Foundation Standards and Milken's Seven Dimensions of Progress Technology Evaluation Frame were used for theme analysis.

Constant comparative analysis and open coding of a variety of information from "elite" interviews allowed for thick identified-site descriptions and theme emergence. Cross-case analysis developed key themes which emerged from the data. Meta-analysis provided a basis for naturalistic generalizations and assertions. Naturalistic generalizations can then be used for extrapolation to similar circumstances and reflection in relationship to established frameworks.

Cross-site analysis identified levels of technology integration development within the exemplary models and a greater connection of higher levels of development to teaching teams and supportive mentoring than to funding per student. The ISTE framework identified assessment/curriculum, teaching methodology, and classroom structure to be areas of change present at any level of technology integration development. Findings supported the need for more effective district wide planning and teacher training that incorporates the use of team mentoring for support.

Levels within data were indicative of technology integration demonstrated progress along a continuum comparative to the Seven dimensions of progress (Milken, 2000). As progress was made toward higher levels of technology integration, hardware and software moved from center of process focus to a support position for the content activity and issues of equity of access became critical (meta-assertion).

District technology coordinators were found to be key resources in the development of effective technology integration programs. Organizational support for coordinators needed to be directed toward providing access to resources, current literature, and training opportunities (meta-assertion).

Findings analyzed using the ISTE model of classroom change exhibited discrepancies in terminology and pedagogy, which emphasized the need for more effective teacher training. Emerging themes support the meta-
assertion that defines the needs of staff development to provide ongoing technology skill training, distribution of current literature shaping technology integration in education, and demonstration of effective integration models with mentoring or cadre teams to support change. Teachers were enthusiastic about technology integration but frustrated with limitations of time and training necessary to maximize the potential of technology as an effective educational tool.

Time and funding needs increased as technology integration improved (meta-assertion). "Time factors" included not only time to plan and experiment with technology applications but also the added time needed for students to accomplish in-depth assignments that utilize technology. Student work time leads to the issue of funding needed to supply equity of access. The greater the level of technology integration the greater the need for student access. Technology resources shape classroom activities and ultimately the learning opportunities available to students. Resources must be available and directed toward providing equity of access for students.

All reference to changes in student products failed to include a reference to standards, assessments, or scores. Lack of student achievement data indicated a great need for alignment of content and technology standards with outcomes and assessments. Without this connection it is impossible to validate improvements in learning that teachers believe is produced by technology integration. Research findings support the meta-assertion that alignment across all sites between technology and content standards, district outcomes, and assessments needs to be addressed by curriculum and technology planning to provide student achievement data.

Technology planning is critical to all aspects of implementing an effective program. Although formal Technology Plans exist, evidence has identified this as an area of constant change creating the need for improvement. Effective planning must incorporate information collection and distribution representing administrators and teachers. It should provide direction, pinpointing areas of need from physical resources such as hardware and software, to curriculum and instructional goals that integrate technology standards with content standards and outcomes (meta-assertion).
Developing a Relevant Technology Course for Administrators

Barbara K. McKenzie, Department of Media and Instructional Technology, State University of West Georgia, United States, bmckenzie@westga.edu

Nancy G. Mims, Department of Education Leadership and Professional Studies, State University of West Georgia, United States, nmims@westga.edu

Abstract

The design, development, and evaluation of a technology course for school administrators and instructional technology leaders is presented. This paper reviews two years of course design stages including the content changes, teaching/learning modifications, more and less successful teaching practices and student requirements. Design considerations, future directions and future research are presented.

Introduction

Integrating technology into the school’s curriculum require teamwork in order to infuse it seamlessly into the curriculum (Brooks, 1997). While significant efforts have been made towards improving technology training for teachers across the nation, administrators have not received the same attention (Hope, Kelley, et.al 1999; O’Neill, 1999). Despite this lack of emphasis school administrators must make sound decisions when it comes to providing leadership of their school’s technology plan.

Several studies indicate that administrators knowledge in technology make a positive difference when supporting technology use in schools. (Anderson & Pigford, 1987; Thomas, 1999; Virginia Department of Education, 1998). Costello quoting Mergendollar (1997) stated, “The role of the principal is crucial in promoting school technology use. For technology to become diffused across a district, leadership by the central administration, especially the superintendent, is critical.” (58). In a previous study Mims & McKenzie (1995) also found that administrators knowledgeable in technology were more inclined to support instructional media (1995). Technology training is important if principals are going to have the necessary knowledge to administer and oversee the school’s total technology program (Mohr & Evans, 1999). This includes developing a school technology plan, purchasing hardware and software, providing technology support, offering curricular integration training programs, and overseeing the school’s technology assessment.

The Educational Leadership Department at a medium sized southeastern university began the planning process for adding a master’s level component in technology to their administrative program. Some courses did include technology, however, not to any great extent and the department decided to add Administration of Instructional Technology Programs to its required courses.

The class was a collaborative effort between the departments of Media and Instructional Technology and Educational Leadership and Professional Studies. The course was designed for students who were working on a M.Ed. in the Educational Leadership and a M.Ed. in Instructional Technology.

Because many non-traditional students are working full time, many traditional classes are disappearing from this campus. An increasing number of students want classes delivered through online technologies either as a course supplement or a full course. This format offers many advantages to students seeking to continue their education. These advantages often include access to their course at any time /any place so individuals determine the hours of working online, the pace in which to complete work, and control of their learning environment. Knowing the students’ schedules and their need for flexibility and access, the planning team designed the initial course 52% online.

The Design and Implementation of the Course

The research team redesigned and implemented the first course for technology leaders in the school (principals, teachers, instructional technology trainers) fall of 2000. One member of the team was a faculty member.
in the Educational Leadership and Professional Studies Department who had extensive experience in instructional
technology, and who was familiar with the needs of the master's level students in Educational Leadership. The other
member was an instructional designer. Since a similar course was in place for instructional technology master's level students, the two faculty
members examined the existing course objectives, activities, evaluative measures and teaching strategies.

The course designers considered students' needs in both disciplines, reviewed accrediting standards in
technology for administrators and instructional technology leaders, reexamined course content and evaluation
techniques used in the course, and modified many of the teaching and learning strategies to better meet the needs of
all learners. Some of the initial changes included providing more hands-on technology training, increasing the
technology software covered, adding several new content areas such as grant writing, state and federal laws and
funding.

The course delivery was changed from a face-to-face class to a 52% on-line course delivered through the
WebCT platform. The course designers wanted to prepare students for the future by exposing them firsthand to
distance technologies. Nine of the 17 class meetings were online and 5 were face-to-face. During the first class
students were given an introduction to WebCT, shown the course tools, and how to access the course. The other
face-to-face meetings were used for presentations from experts in the field and/or the instructor, hands-on training
sessions with selected computer applications, and student’s research presentations. The online classes provided
students with weekly assignments, course content, opportunities to use the web for searching for technology related
material, posting assignments in the class bulletin board, and taking exams.

The online content section contained a wide variety of information such as the weekly assignments, student
research topics, instructor presentations and training tutorials that included PowerPoint, Excel, Access, laserdisc,
overhead production, analog video, web page design, e-mail.

The fall 2000 course introduced the educational leaders to a variety of technology topics. The research team
believed that the more familiar students were with technology, the more they would be able to model its use and
oversee effective integration into the schools. The major course components included some of the following:
knowledge of the use of computers and related technologies in the schools, hands-on training with software
programs addressed by In-Tech, school technology plan, staff development, integrating technology, technology
resources, grant writing, fundraising, and technology for special needs students.

During the course students were required to participate online and complete class assignments by posting
their work or their group’s work on the bulletin board. They were required to do research in technology on selected
topics and make two presentations using multimedia, develop an instructional manual based on class materials, and
take two online exams. The grade breakdown was as follows: attendance and participation = 10%, research project
on IT issue = 20%, group research and multimedia presentation = 25%, IT manual = 25%, and tests = 25%.

The course offered every semester during the past year and a half has varied in utilization of distance
technology. Spring of 2001 the course was 71% online. During the summer the class was reduced to 64% online.
Fall of 2001 the course increased its use of distance technologies to 65% online as a result of using two distance
platforms, WebCT and Epic Learning.

As the technology standards for school administrators have emerged, Technology Standards for School
Administrators (TSSA) and the International Society for Teacher Education (ISTE) standards for teachers and
technology leaders developed, the research team made course modifications to reflect the new standards. Course
objectives were revised and additional content was added to the course. Some of the changes were:

- Adding more hands-on technology training opportunities to keep technology leaders up to date. This included
  more training sessions in class, distributing handouts, and posting tutorials on the class web page (i.e., digital
  cameras, digital video recorders, filtering software, track star, scanner, smart board, web page design and
  creation, web quest). One of the researchers was taking her second In-Tech class and scanned and posted the In-
  tech handouts for the class.

- Adding more technology/leadership content (i.e., social, legal and ethical issues; distributive learning;
  assessment of technology integration in the schools; assessment tools for technology; teaching with a one
  computer classroom, DSL, and filtering devices)

From the fall 2000 to the present time, the Administration of Instructional Technology class has been
revised based on the research team's observations, formative and summative evaluations from the instructor, the
university, the Distance and Distributed Learning Office, and the changing student needs and attitudes toward
technology. The advances in telecommunications have also had an impact on the course design. Technology training
needed to be up to date and prepare the students for new and emerging types of technology as well.

Findings from the general university course evaluations revealed the mix of students favorably received the
course. The most frequently occurring suggestions for improvements were:
• Reduce the amount of course content presented
• Reduce the number of required online postings for class assignments
• Use Epic Learning for more classes to increase student/instructor interactions online
• Increase the weight given for student attendance and online participation in class
• Do not require so much collaborative work
• Change the book. The online resources are much more up to date and informative.

The evaluative data from the Distance and Distributed Learning Office for fall of 2000 and spring 2001 also revealed the Administration course was effective in its delivery. Students, volunteering to take an online course evaluative survey at the end of the course, were supportive of distance technology being used for this course as shown in Table 1 below.

Table 2 – Students likes and dislikes with the course (fall 2000 and spring 2001)

Design Observations

In preparing future technology leaders in this course the research team is aware of the following important points.
1. Teaching through distance technologies is an effective way of delivering the class as long as there are ample opportunities for students to interact with other one another and the instructor. This can take place through chatrooms, bulletin board posting, private email, and using the Epic Learning's platform for synchronous presentations and enabling students to use two way audio.
2. Students enhanced their technology skills and expertise as a result of the taking the course. Many students were highly motivated to continue their professional development after the course was completed.

564
Page 503
3. Participants in the class gained a better perspective of instructional technology and where it is headed in the future. Information on new and emerging types of technology was of high interest of the students.

4. Students with little technology background have difficulties with online platforms initially and must be monitored closely to ensure they succeed and have the support as needed. Help lines, virtual office hours for the instructor, handbooks on how to use the system, and the class bulletin board or email are helpful in student problem solving.

5. Due to students' diverse learning styles, they need to be given options in collaborating with other students in class. Permitting students to work independently or in small groups when completing assignments was well received.

6. Class participation should be at least 20% of the grade. Since most of the assignments were online students spent a substantial amount of time searching for information, problem solving and posting their assignments and/or e-mailing their classmates. The weight of the class participation aspect of their grade needs to match the amount of time the student put in to the course.

7. Timely feedback is essential when doing online classes. Students need to have access to the instructor and receive timely feedback on class work. Posting online office hours or listing the days and times the instructor will check the class is helpful to students.

8. The creation of student PowerPoint's at the beginning of the course to introduce themselves (along with a digital photograph) was an excellent way for students to get to know one another.

9. Posting rubrics used in evaluating assignments was an effective method of informing students of the expectations on major assignments. Students used this as a checklist for self-assessment purposes.

10. After completing the class students saw themselves as role models and were eager to serve as leaders in integrating technology into the curriculum.

11. The mix of multimedia used by the instructor provided students with an opportunity to see technology use modeled in the classroom as well as present timely information in instructional technology (i.e., textbook, handouts, instructor produced videotapes, and online resources).

**Future directions**

Spring of 2002 the class will be delivered 70% on-line and a printed textbook will continue to be used. WebCT will be discontinued and Epic Learning used to distribute class information to students online. This platform is more user friendly and enables students to access course information from a single page instead of going back and forth in the course web pages. The blended learning approach provides increased interactivity between students and between students and the instructor.

From the weekly schedule of events students will be able to access information on their assignments, go to websites connected to the topic, review weekly assessment procedures, participate in selected web based tutorials (i.e., PowerPoint, Excel, Access, Word) and view archived presentations. Students will also be able to see when asynchronous class sessions are scheduled for class chats or real time PowerPoint presentations.

During the real time PowerPoint presentations delivered by the instructor using the Epic system, students will be given a wide variety of tools to use. This includes the polling of student responses to instructor-designed questions (i.e., student background, class pace, content related questions), students typing questions during the presentation and sending them to the instructor for feedback, students verbally asking questions of the instructor through the use of a microphone, and small group e-mail discussions between students and/or the instructor when seated in the same row. The platform also will enable students to use seat colors in the presentation room to indicate their readiness for the presentation and/or to identify problems as they emerge. If both students and the instructor have microphones, two way audio communication will take place between students and the instructor.

The instructor's control of the learning environment is greatly enhanced through the use of the Epic platform. During live presentations the instructor can push web pages to students to have them explore and problem solve. Instructors can also deliver team taught classes through the use of multiple computers by releasing control back and forth. A white board can be posted and used by students and/or the instructor to display information to the group. Other useful features include student tracking of course activities and a variety of presentation enhancement tools to highlight selected course information within the PowerPoint slides.

During summer of 2002 all online resources will be used for the course given the rapid changes in instructional technology. Students have reported they enjoyed their online readings and learned more from them.
than the class textbook. The timeliness of the materials, the no cost factor, and accessibility have been the
predominant reasons given for this preference.

A more extensive student orientation program is in the process of being developed. This will include a
more thorough needs assessment at the beginning of the course plus moving student verbal and electronic self-
introductions to the first and second nights of class. This may increase student-to-student interaction during the
course and reduce the number of times students report to the instructor. The number of postings on the bulletin
board should be reduced in the future. At the end of the fall course students read over 750 postings. They reported
this was too much to read plus keep up with the other required course assignments. More controlled topics for
bulletin board discussions and added emphasis on student-to-student interactions on weekly assignments may better
meet students’ needs. In addition, students will be placed into collaborative learning groups, randomly matched by
the computer. Groups of 3 to 4 will be formed so students can share their ideas with the group, problem solve and
post their collective thoughts to the bulletin board.

The research team continues to keep abreast of the changes in instructional technology and student needs in
order to make further course revisions. Wireless computers, virtual reality, and e-learning will be addressed in more
detail in the future so that as effective leaders students will be familiar not only with the existing types of
technologies in the field, but the new and emerging technologies.

Future Research

Informal formative evaluation techniques that obtain feedback from students in this course and assessing
the effectiveness of this course after technology leaders are working in the field will be valuable.

Understanding the Role of School Leaders in Realizing the Potential of ICTs in Education

Thomas L Otto
Department of Education, University of Southern Queensland, Australia, otto@usq.edu.au

Peter R Albion
Department of Curriculum and Instruction, Purdue University, USA, palbion@purdue.edu

Abstract: Although Information and Communications Technologies (ICTs) are now widely available in schools they appear not to have been integrated into teaching and learning either as widely or as thoroughly as was hoped. One influential factor, which may not have been given the attention it deserves, is the role of school leaders. Relatively little is known about how the beliefs of principals influence the uptake of ICTs in their schools. This paper attempts to describe a conceptual framework for understanding that role and an exploratory research project based upon that framework. It opens new lines of enquiry about the crucial roles of school leaders in the adoption of ICTs.

Information and communications technologies (ICTs) are now widely available in schools. The level of equipment available and its quantity vary widely but there is both wide support for, and considerable progress in, deployment of ICTs in schools. In 2001, USA schools were reported to have one computer for every 5 students on average and around 60% of those were connected to the Internet or had multimedia capabilities, although there were substantial variations by state and other factors (Education Week, 2001). In Australia, 40% of schools report having a computer for every 10 or fewer students (Meredyth, Russell, Blackwood, Thomas, & Wise, 1999). An international survey conducted in 26 countries during late 1998 and early 1999 found ratios ranging from 7 students per computer in Canada to 238 in Bulgaria but with the most common values around 15 (Pelgrum, 2001). The same study reported evidence that, for most countries, the availability of computers in schools had increased from 1995 to 1998 suggesting a continuing commitment by education authorities to support the adoption of ICTs. Nevertheless, “insufficient number of computers” remained the top ranking obstacle to integration of ICTs although its prevalence was considerably less in those countries with the most favorable student/computer ratios.

Integration of ICTs in Education

However, mere deployment of ICTs in schools is not sufficient to make an educational difference. For that to occur the ICTs must be used purposefully. Even where access to ICTs is comparable there are variations in both the kind and frequency of use to which the equipment is put. In the USA, computers are reported as being used weekly for language arts in 26% of classes at Year 4 and just 8% at Year 8 with the respective state to state variations reported as 8% to 74% and 2% to 20% (Education Week, 2001). The same report describes similarly wide variations in usage by teachers for other purposes. Internationally, on a composite measure of skills acquisition during secondary education, the reported variation was from 21 to 70 on a 100 point scale (Pelgrum, 2001). The application of ICTs to teaching and learning has been aptly described as “patchy” (Galligan, Buchanan, & Muller, 1999).

Various reasons have been offered for the failure of ICTs to produce widespread changes in education. It has been argued that developing teachers’ technical competence with ICTs is not sufficient in the absence of building knowledge about how to apply ICTs to teaching and learning (Oliver, 1994). Even the effects of such knowledge may depend upon attitudinal factors. It has been suggested that teachers’ self-efficacy for teaching with computers (Albion, 1999) and their visions for integrating technology in their teaching (Ertmer, Johnson, & Lane, 2001) are factors which may influence the uptake of ICTs for teaching and that these are issues which should be attended to in teacher development programs. Becker (2000) examined Cuban’s claim that computers are incompatible with the requirements of teaching. Using data from a study of 4000 teachers in 1100 schools across the USA, Becker
concluded that computers have not transformed the teaching practices of a majority of teachers but that, where teachers have the necessary computing skills, some freedom in the curriculum, convenient access to equipment and personal philosophies which support constructivist pedagogy, computers can be a valuable instructional tool.

Australian policy lists two goals for ICTs in schools, namely that students should exit as “confident, creative and productive users of new technologies” and that schools should integrate ICTs to “improve teaching and learning” (Toomey, 2001). The same report expresses the hope that ICTs may act as a catalyst for whole school reform. However, there is evidence to suggest that, rather than ICTs catalyzing educational change, the adoption of ICTs by teachers is most likely to occur where school culture provides support for such changes (Dexter, Anderson, & Becker, 1999). These findings are consistent with studies of exemplary computer using teachers, which identified the importance of contextual factors including support from peers and administrators (Becker, 1994; Hadley & Sheingold, 1993). Further evidence may be found in studies on factors influencing teachers’ adoption of computers based on which Marcinkiewicz (1996) concluded that the most influential factor was “subjective norms” or the perception within the professional environment that computer integration is expected. He argued for the importance of modeling by administrators, colleagues and other significant persons in establishing this expectation.

The Role of Leadership in ICT Integration

ICTs can be a valuable instructional tool where the appropriate conditions prevail (Becker, 2000). Many of those conditions, including professional development opportunities to build skills, convenient access to ICTs and freedom to innovate in the curriculum are subject to the influence of principals and other leaders in the schools. For teachers, developing a coherent vision for integrating ICTs into their practice while attending to various other imperatives represents a significant challenge, especially if the school culture is not supportive of such change. In Britain, the National Grid for Learning (NGfL) project has recognized that achieving its long term goal of fully integrating use of ICTs into all aspects of the school system will require a cultural shift in the way schools approach ICTs and that this, in turn, may necessitate “a considerable change in the roles that school leaders and managers will be expected to play in their institution’s use of technology” (Selwyn, 2000, p 410).

Recent studies of successful school reform point to the importance of cultural leadership in schools. Consideration of the leadership dimensions associated with successful innovation in an Australia-wide study of school innovation led to conclusions which indicated the importance of an holistic approach, in which innovation is aligned with school-wide vision and shared pedagogy so that it meshes with school culture, and where leadership incorporates the contributions of both administrators and teachers (Crowther, Hann, & McMaster, 2001). A study involving 40 public school teachers in Ohio found a positive correlation between leadership style exhibited by the school principal and teacher attitudes towards integration of technology as an instructional tool (Hughes & Zachariah, 2001). Teachers who perceived their school leadership as democratic were much more likely to have positive attitudes towards technology integration than teachers who experienced authoritarian leadership.

Another report based on data from the study described by Becker (2000) examined the proposition that “technology leadership” drives “technology outcomes” in schools (Anderson & Dexter, 2000). The “technology outcomes” investigated were evidence of teachers integrating technology into teaching, network and Internet utilization and student use of applications. “Technology leadership” was conceived of as a characteristic of the school rather than an individual and a measure was synthesized from data about eight organizational policies or actions present in the school. These included existence (or not) of a committee and budget for technology, principal involvement in technology use and planning, district support and staff development. The study found that overall technology leadership was stronger than infrastructure as a predictor of technology outcomes and that leadership and student to computer ratio were the only significant predictors of the three outcome variables. It concluded that, although infrastructure is important, leadership is the critical element in establishing technology as a part of school culture.

Recent efforts by a broad collaborative in the USA have resulted in the development of Technology Standards for School Administrators (Knezek, Rogers, & Bosco, 2001). Listed first among the six tasks in the framework is “Leadership and Vision”. The remaining tasks include learning and teaching; productivity and professional practice; support, management, and operations; assessment and evaluation; and social, legal, and ethical issues. Clearly the capacity of school principals to develop and articulately, in collaboration with their school community, a vision for ICT integration is seen to be a critical element in the process.
The Role of Principals’ Beliefs in Leadership for ICT Integration

Even if “technology leadership” is a characteristic of the school community rather than an individual such as the principal (Anderson & Dexter, 2000), a strong case can be made that principals’ beliefs and understandings are crucial in the development of a school culture that will support creative integration of ICTs for teaching and learning (Otto, 2001). Understanding the nature and origins of principals’ beliefs may be the first step towards assisting principals to work more effectively to develop appropriate school visions for the integration of ICTs. Prior research, including self-efficacy theory, provides a useful starting point for developing a framework to guide such research.

Bandura (1997) defines self-efficacy as the "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (p. 3). In the context of this paper, "beliefs in one's capabilities" refers to the confidence a principal has in his or her beliefs about teaching with ICTs, and "courses of action" refers to the effectiveness of the principal as a visionary and agent for change. Non-teaching principals have few opportunities to test their beliefs in a classroom over extended periods of time. While a principal may have read about teaching with ICTs and observed teachers teaching with ICTs, personal classroom experiences may be limited to print based pedagogy. Principals with low self-efficacy for leadership in respect of ICTs may be less willing to advise teachers, and their evaluation of teaching with ICT may be limited to comparisons with print based pedagogy. However, at some point, pedagogical principles for teaching with the new technologies depart from print-based learning, otherwise teachers will use the technologies in the same way they use print. This is one of the problems identified by educational commentators such as Luke (2001).

In their study of the relationship between self-efficacy and willingness to act, Dimmock and Hattie (1996) concluded that high self-efficacy is not only a factor in creating conditions for change, but also reduces principals' stress levels and enables them to cope with unfamiliar situations and challenges. As well, high self-efficacy is linked to school reform because the principal has the confidence to take advantage of new opportunities. Self-efficacy is an element of empowerment, that is, 'taking charge of ones own growth and resolving ones own problems' (Ghaith & Shaaban, 1999, p. 495). Furthermore, principals with high self-efficacy are more likely to assume collaborative leadership styles and allow participative decision making, while maintaining confidence in their influence as leaders (Dimmock & Hattie, 1996).

Planning a Way Forward

A study is proposed to develop an understanding of critical factors and identify key variables as they relate to the 'beliefs and understanding' principals hold in relation to ICTs and teaching and learning generally. Based on consideration of the literature the following research questions have been identified.

1. What beliefs do principals hold about teaching with information and communication technologies?
2. What factors appear to be significant in the formation of those beliefs?
3. How confident are principals in rationalising and articulating the educational value of teaching with information and communication technologies?

The researcher, who himself is a principal, will be one of three principals to participate in the study. This is to account for beliefs that the researcher brings to the study (Miles & Huberman, 1994). The focus is on understanding the cases (Hammersley & Gomm, 2000) rather than making statistical generalisations to the population although that might follow in a later phase. A story for each 'case' will be developed during a series of structured and semi-structured interviews, or episodes, that draw on a range of research techniques. Contact will be made with the principals over approximately one month, during which leads will be followed, interesting concepts pursued and perceptions checked and rechecked. Care will be taken not to force a view on the principals, nor to introduce terms that give clues to answers. Narrative research techniques will be an important feature of the episodes. According to Mattingly (1991), narrative accounts focus on the changes that occur through the actions of people, and that "Simply asking practitioners to reflect on the stories they already tell can provide a natural bridge to a serious enquiry about the very deepest layers of value and belief that under gird the decisions they make" (p. 255).
Biographical research techniques will be applied in the first episode to investigate factors in the principal's development of knowledge and skills in pedagogy and ICTs. Questions modified from an Australian national study will center on pre-service training, teaching experiences, lesson observations and in-service development (Meredyth et al., 1999). Additionally, there will be questions about home use of ICTs as this is another important area of experiences. Each principal's responses may be compared with national data.

During one of the episodes, questions will relate to scenarios of traditional and constructivist teaching practices (Ravitz, Becker, & Wong, 2000). In another episode, the principal will be asked to react to statements made by teachers talking on video about their experiences in teaching with ITC. The video was produced by Gibson and Albion (1999) as part of a computer file package to support pre-service teachers, and depicts classroom scenes and issues familiar to principals of Queensland schools. "Through reflection, (the principal) can surface and critique the tacit understandings that have grown up around the repetitive experiences of a specialized practice, and can make new sense of the situations of uncertainty or uniqueness which he may allow himself to experience" (Schön, 1983, p. 61). Even if the principals are aware of related theories and techniques, they may find it difficult to explain reasons for their judgments of teaching, including the statements made by teachers on video. To assist the principals in the process, Schön recommends that questions focus on noticeable features, criteria in making judgments, procedures enacted in performing the skill and framing of the problem that is to be solved.

Additional data will be collected from school documents including the Annual Operation Plan, Management and Learning Technology Plan and Equipment Replacement Schedule. The principals will be asked to highlight features in the documents, not only as a reflection of their beliefs in practice, but also because principals with high self-efficacy are more likely to be aware of the potential of school planning and policy making in developing their schools (Dimmock & Hattie, 1996).

At the conclusion of each episode, the principals will rate their confidence in discussing their beliefs on a five point Likert scale. The procedure relates self-efficacy to confidence and assumes that principals are conscious of their self-efficacy (Dimmock & Hattie, 1996). To improve honesty of answers, they suggest the principal be assured the information is confidential, and the situations presented include a range of tasks with positive and negative aspects and differing levels of difficulty.

During the course of the study, the process of collecting data will itself become a factor. The subjects themselves will become researchers as they reflect on their beliefs and activities in their schools (Mattingly, 1991). In the relatively new field of teaching with ICTs, principals "handle situations for which there are no techniques. They must develop their own kind of artistry, involving reflecting in practice in the midst of intense activity without interrupting the flow" (Schmidt, 2000). Participation in the study will provide the principals with an opportunity to reflect on their beliefs without the distraction of school routines. They will consider scenarios in various forms and make comparisons with practices in their schools, and for a period of a month their attention will focus on one topic. By being aware of this effect on the principals, the researcher may detect changes in beliefs not only as a feature in the data, but also as a record of the potential of the process to assist principals in their development.

It is anticipated that the data obtained from the study will open up new lines of inquiry about the crucial roles of school leaders in the adoption of ICTs. Schools are in the transition of re-culturing to accept teaching with information and communication technologies. Education Queensland, for example, is undertaking curriculum reviews that oversee major changes in approaches to teaching and learning. Unless schools begin to address change now, they will soon be left behind. Principals are the on-site educational leaders who shape and communicate visions of teaching and learning within their schools, and by their action or inaction influence school activity. An evaluation of the beliefs, understanding and self-efficacy of principals will contribute to decisions about future developmental needs because more will be known about their preparedness for change. The contextual information about existing processes for developing skills and knowledge in pedagogy and information and communication technologies will further contribute to those decisions.

Disinformation, Academia, and the Web: The Anonymous Battleground

Introduction
Before the Internet, much information spread as one friend told something to another. Although not very efficient by today's standards, it was powerful because the source had credibility. People tend to put more faith in the opinion of a friend or than in the pronouncements of any anonymous source.

Now that email and the Web are everywhere, the change in the speed with which word of mouth communications travel is nothing less than amazing. Expending less energy than was previously required to convey information one-to-one, a message can now be transmitted, with little to no cost and instantly, to enormous groups of people. With a very basic Web site, almost anyone can instantly post a cyberspace billboard that can be viewed by the world. Message boards, online forums, discussion groups, and chat rooms also allow nameless messages. And that anonymous person can feel like an instant friend with all the credibility of a fraternity brother.

Companies felt the sting of anonymous Internet communications early. With the growth of online communities, such as Geocities, Xoom and Angelfire, offering free Web pages to members, it has become increasingly easy for anyone with a grievance to reach a worldwide audience.

Attacks on Academics
With increasing frequency, anonymous attacks are being directed toward the academic world. A profile of the type of individual who engages in this type of activity will be provided. The academic victims include individual faculty members by way of "evaluation" Web sites posted by students and entire institutions attacked by students (Claremont McKenna College), faculty (The University of Louisiana), and alumni (Columbia University). Examples of each type of attack will be provided.

Legal Issues
An overview of the legal issues surrounding anonymous Web sites or "cybersmearing" will be provided, including a discussion of defamation, libel, and malice along with summaries of recent court decisions. In general, victims of such attacks have had little success in court, with attackers protected by the First Amendment. Although each case has its own individual issues, generally speaking, a number of criteria must be met before an anonymous Web posting can be considered illegal. First, statements must be presented as fact rather than opinion. Second, the statements of fact must be false. And third, the victim must show that the Web site posting was made with actual malice (that is, with reckless disregard for the truth).

Protecting Reputations
A good reputation is important to success; it deserves the same attention given physical, financial and intellectual assets. Reputation influences a university's ability to attract quality students and faculty, and to earn and keep the support of other stakeholders in the community and among alumni. Reputation is equally important to the successful career of an individual. Reputation has a direct impact on how well any organization or individual succeeds.

Four suggestions are offered for dealing with the increase in anonymous Internet-based attacks on the reputations of individuals and institutions in academia.

1. Know the Internet World
Search the Web regularly. It is time consuming, but any organization or individual that is not monitoring the Web could find serious trouble because of slanted, malicious, and libelous information. What an organization or individual does not know can hurt. Go to a site like DejaNews (www.dejanews.com) and use the UseNet search. The results might provide quite a surprise.

Know the Internet audience. Be aware of the places where this type of communication might occur.
Understand the "netiquette" required to make the correct response to anonymous attacks.

2. Analyze your communication skills.
Stakeholders need to feel comfortable sharing both positive and negative feedback. If they do not, a communication skills audit may be in order. Actively encourage criticism. Criticism as an early warning system: it is better to hear it from your stakeholders directly than from an anonymous attacker on a Web site. Ask for feedback often enough that people take such requests seriously. Make it easy for people to provide the information. This can be done at regular meetings, at one-on-one meetings, or through requests on a Web site. Ask for feedback and then allot enough time in the meeting for people to really speak their minds. Thank them for their critical comments.
3. Prepare a Web disaster plan.  
   If an institution becomes a target for disinformation, a Web disaster plan should be in place. It might be advisable to have the infrastructure of a public relations Web site sitting on the server in case it is needed. Some organizations purchase potentially negative Web domain names such as “ihate...com” or “...sucks.com” as a preventive measure.

   Try to get to the source and negotiate some kind of compromise. Use legal action only as a last resort. Besides the difficulty in proving such a case, suing can be a very bad idea, giving the owner of the negative Web site even more attention. If the suit is lost, the individual or organization bringing the suit to court can look even worse.  

Conclusion  
It is increasingly important that individuals and institutions in academia understand the potential threat of anonymous Internet attacks. Supreme Court Justice Louis Brandeis wrote almost seventy-five years ago that the best answer to evil speech is more speech. Today, the Internet makes it possible for anybody to say anything. Instead of trying to silence someone on the Web, being proactive and speaking up in the same arena may be the best defense.
Implementation of Information and Communications Technologies in Australian Schools: The Perspective of the Principal

John Schiller
The University of Newcastle
NSW, Australia
john.schiller@newcastle.edu.au

Abstract: This paper will report on initial analysis of baseline data gathered from a survey of all elementary and secondary principals in the coastal Hunter region of New South Wales, the most populated state of Australia, in terms of their use of, and concerns about Information and Communication Technologies (ICT). Findings indicate that although most principals in the region are over the age of 40 and have been principals for more than 6 years, there are marked variations in their perceived competencies and use of ICT. Staff development, availability of technical support and maintenance assistance, and funding are major concerns. Interviews with selected elementary principals indicated greater familiarity with administrative uses of ICT than teaching and learning applications.

Introduction

Computers, the Internet and other information and communications technologies (ICT) can alter how schools are led, how teachers teach and how children learn. State governments in Australia have invested millions of dollars to prioritise integration of these technologies in schools; where the principals are major decision makers. Research has identified the principal as a key factor in successful adoption and implementation of change, yet little is known about the principal's role in implementation of Information and Communications Technology (ICT) in schools.

Background to the study

Recent Australian government priorities recognise that ICT plays an important role in schools, but without support of school leaders, particularly the principal, the educational potential of ICT may not be realised. Principals are expected to make complex decisions about how to integrate ICT into learning and teaching and assume a major responsibility for initiating and implementing school change through use of ICT but are themselves unsure of how to cope with these issues.

Educational change literature identifies factors in early and late adoption of educational change and points to the principal as a key facilitator in implementing educational change and school improvement (Fullan, 1996). Moreover, an 'Initiator' change facilitation style leads to greater implementation success (Hall & Hord, 2001).

There is also a growing field of literature on guidelines for school leaders about integrating ICT into schools (see Mauer & Davidson, 1998; Picciano, 1998). The role of the principal in supporting IT integration is seen as critical (Hoffman, 1996) but there is limited research to substantiate how these implementation strategies actually work (Michael, 1998; Riffel & Levin, 1997) and little Australian research on the role of the principal in the implementation of ICT although integration of ICT is current government policy. Finally, although examples of 'best practice' in ICT include a key role for the principal (Michael, 1999) there are no established criteria against which Australian schools can be compared.

Results of preliminary investigations

Research in the Hunter area of NSW, Australia by the author has shown that implementation of ICT in schools is complex and fraught with difficulties (Schiller, 1997). Identified issues of concern of school leaders included: access to and maintenance of appropriate hardware and software, apprehension about
personal computer use, providing appropriate staff development programs, and coping with strategic planning processes required to integrate ICT into teaching, learning and management practices. Concerns about these issues have increased recently in terms of pupil and teacher access to the Internet (Schiller, 1997) and as a result of government priority for increased ICT use.

Further, the Change Facilitation (CF) style of the principal (that is, the combinations of interventions they use), has been identified as a key factor in successful implementation of ICT (Schiller, 1997). Successful CF Styles of ‘Initiator’, ‘Manager’ or ‘Responder’ have been identified where ‘Initiator’ principals have greater success with innovation adoption and teacher success in change can be directly correlated with their principal’s CF style. This style is located on a continua according to their ‘concern for people’, ‘organisational efficiency’ and ‘strategic sense’ (Hall & Hord, 2001).

However, findings from this research are limited by a small sample size, a focus solely on ‘early adopters’, a lack of comparative data, and lack of currency of some of the data due to rapid changes in ICT and recent changes in government ICT priorities (For example, by the end of 1999, all principals in NSW government schools were required to be familiar with computerised school reporting systems and to use a personal email address provided by the NSW Education and Training Department).

The preceding arguments lead to the following research study which is the focus of this paper. The following question guided this investigation. How do principals facilitate the implementation of information and communications technologies (ICT) in their schools? Specifically, What is the extent of principal use of and concern about ICT in elementary and high schools? How do elementary principals facilitate ‘best practice’ in ICT to improve teaching, learning and management processes in their schools?

This study is the first in a series to examine the influence of the principal in determining ‘best practice’ in using ICT in Australian schools. It was conducted in two phases involving quantitative and qualitative research methodologies.

**Phase One: Mapping the extent of principals’ use of, and concerns about ICT in schools.**

To determine the extent of principals’ use of, and concerns, about ICT in their schools all principals in four local area School Districts of the NSW Department of Education and Training (n=288), the Maitland Diocese of the Catholic Education System (n=61) and the Independent schools in the Newcastle area (n=20), were invited to complete a questionnaire. This questionnaire provided baseline data to determine the extent of personal use and concerns about ICT by principals in one geographic area and allowed for comparison between groups of principals on criteria such as age, gender, school context, experience and perceived levels of computer competency.

The questionnaire has a variety of components including a Competency Rating Scale to determine use of ICT. All principals rated themselves on a series of competencies such as use of word processing, databases and spreadsheet applications, knowledge of educational and management software, and use of the Internet. Competencies were determined using a 4 point Likert-type scale ranging from ‘not at all competent’ to ‘highly competent’. Responses to a series of statements about implications of ICT on management and learning styles were also explored using a similar Likert scale. Open-ended responses were sought to add ‘richness’ to the data. In addition, demographic data were collected.

This questionnaire was posted to the principals with pre-paid return postage. Follow-up letters and phone calls were used to improve the response rate. Competency data were analysed through SPSS statistical processes focussing on analysis of variance using a number of independent variables such as age, gender, school context, experience and perceived levels of computer competency.

**Phase Two: Mapping implementation strategies of elementary principals leading to ‘best practice’ in ICT**

Current implementation strategies used by primary school principals were examined as follows. Audiotaped interviews with District level Technology Advisors in government and non-government schools identified examples of ‘best practice’ in ICT and established a short list of elementary schools regarded as ‘early adopter’ and ‘late adopter’ in terms of ICT. The Technology Advisors rated the implementation success of each school. From this list of schools, a sample of 12 elementary schools was selected to provide ‘early
adopter' and 'late adopter' schools so that examples of government/non-government, size and location of school, and initial/established use of ICT could be examined.

The principals of these schools were interviewed (on audiotape) using a semi-structured interview schedule piloted in preliminary studies (Schiller, 1997). This interview identified the extent and nature of principal interventions used to implement ICT in their schools, and focussed on; (a) initial use and current practices, (b) overcoming 'computer phobia', (c) perceived benefits/impediments, (d) changes in roles and responsibilities resulting from use, (e) policy and planning processes used, and (f) anticipated future implementation strategies.

From transcribed interview data, factors such as ICT access rate, leadership potential, ICT planning, staff development, and technical support, which are measurable indicators from the model of 'ICT Best Practice' (Michael, 1997), provided a framework for analysis and comparison between schools. This paper will report on preliminary findings from this Australian study.

Findings

Despite the length of the survey (11 pages) 217 principals (62%) responded. Many principals also included comments. This willingness to elaborate seemed to be in contrast to requests for information from principals several years ago when only a small proportion of principals commented on their role in ICT. In this study 66% of the respondents were male. Only 3.7% were below the age of 40 and 65% had been principals for more than six years. Most principals (93.5%) used computers at home and school. Most computers used by principals (88%) were PCs with 86.6% of all principals' computers connected to the school's network. Interestingly, 45.2% of principals use a laptop computer at work. Principals spend a lot of time working at a computer with 56.7% indicating more that 5 hours per week on their work computer and 60% indicating more than 3 hours per week on their home computer. Although 30% indicated slow typing speed, 60% stated that they could type 'reasonably well' while 10% stated they could type 'very rapidly'. The majority of use of both their work and home computers was in word processing, sending and receiving email and accessing the World Wide Web while construction of spreadsheets, databases and presentations (such as Powerpoint) was either 'never' or 'occasionally' used, either at home or at work. Only 20% of principals stated that they read spreadsheets 'frequently' at work with 40% indicating occasional use. 30% indicated that they had never read a spreadsheet. Many principals (35%) indicated never having used a digital camera or scanner but 58% indicated frequent use of WWW search engines.

As all principals in government schools have been provided with an email address in the last 18 months, it was not surprising to find that 51.6% receive more than 20 email messages per week and that the receipt of attached files is high with 45.6% indicating 25-50% of email messages with attached files and 20.7% indicating more than 50% of their email messages having files attached. Feedback during interviews indicated that this management of electronic information is becoming a major issue of concern to principals as they try to determine whether to save printed versions of attached files, who should take responsibility for filing them and where to locate them for appropriate and easy access.

Table 1 indicates responses to the question “how competent do you regard yourself in undertaking the following tasks?” and demonstrates wide variation of perceived competencies.

Table 1: Perceived ICT competencies of principals

In response to the question “how have you learned about computers?” 86% stated that experimenting (or
playing) with a computer at home was ‘very useful’ while 70% said that playing with a computer at work was ‘very useful’. 86% of principals stated that getting help from a colleague was very useful in helping them learn about computers. In contrast magazines and books were regarded as either ‘useless’ or of ‘low usefulness’. Assistance from Technology Advisors at the District level and participation in workshops were both viewed by 60% of respondents as being ‘very useful’ whereas undertaking a course in computing was only seen by 39% as ‘very useful’ while 43% regarded courses as low in usefulness with 18% regarding them as ‘useless’.

From a list of 15 concerns raised by principals during preliminary investigations for this study, five areas of concern were ranked highly. Staff development for effective use of ICT was the highest ranked concern with 89% of principals indicating concern. Availability of technical support and maintenance assistance was of concern to 85% of principals while funding for ICT (75%), the impact of ICT on changing approaches to teaching and learning (74%) and time for the principal to acquire new skills in using computers (73%), were also of high concern. Although not of the same level of concern, issues such as rapid obsolescence of hardware and software, how to facilitate implementation of ICT in the school, deciding on appropriate hardware/software and infrastructure, using ICT for management and leadership, equity and access to ICT, and appropriateness of ICT for teaching and learning, also ranked highly with approximately 54 - 63% indicating concern. When asked to nominate areas of ICT to be addressed over the next 12 months, the most frequently listed concerns of principals were staff development, technical support and coping with the impact of ICT on teaching and learning.

When asked to indicate extent of agreement to a series of 20 statements about ICT in schools on a 5 point Likert-type scale ranging from ‘definitely agree’, ‘tend to agree’, ‘neither agree or disagree’, ‘tend to disagree’ to ‘definitely disagree’, four groups of statements resulted in common patterns of agreement. In the first group there was strong agreement about costs being a barrier to effective implementation of ICT, that ICT has applications in all subjects, that a comprehensive school ICT plan requires regular updating and that the principal expected teachers to create a classroom environment where ICT is an integral component. In the second group of statements there were wide variations in the principals’ levels of agreement. For example, there was a wide range of views on the adequacy of maintenance and technical information to support ICT in teaching and learning, on the availability of professional development being adequate for the needs of teachers, and whether the role of ICT in teaching and learning had been clearly identified at the school. The third group of statements about which there was strong agreement focused on the principal. Principals strongly agreed that data re finance, student and staff records, timetabling etc must be available on their desk computers, that reading and responding to email as well as using ICT generally has increased the principal’s workload but that personal use of ICT has helped them become more effective as principals. The fourth group of statements did not reflect any consistent levels of agreement in that a wide range of responses was indicated. The statements about the principal for which there was no agreement included ‘I am sufficiently informed regarding incorporating ICT into the curriculum and into my role as principals’, ‘the role of ICT in administration has been clearly identified in this school’, ‘I have resources to effectively integrate ICT into my work as principal’, ‘I dread having to deal with ICT related problems’ and ‘using ICT saves me time’.

Interestingly, when asked to indicate the current stage of development in teaching and learning at their school on a five stage model starting at ‘entry’, and moving through to ‘adoption’, ‘adaptation’ (where ICT is integrated into traditional classroom practice), ‘appropriation’ (which focuses on cooperative, project based work using ICT as a tool where necessary) and ‘invention’, most principals classified their school at the ‘adoption’ stage (33.6%) or the ‘adaptation’ stage (49.3%). On the other hand they classified their schools’ administrative use of ICT as at the ‘adaptation’ stage (44.2%) or the ‘appropriation’ stage (30%), with 7.4% indicating their school that their school was at the ‘invention’ stage of development in administrative uses of ICT with spreadsheets and databases being used to simulate growth projections or digital images being used in projects which combine multiple technologies. The interview data also indicated that the ‘early adopter’ principals tended to explore a wider range of administrative uses of ICT including newsletter production, analysis of student and staff data, planning analysis, student outcome analysis and preparation of student reports.

Conclusion
Although these data were gathered from only a small geographic area of Australia and nothing can be determined about the 38% who did not respond to the survey, this study gives useful material for professional associations of principals to reflect on and for District personnel to consider. The data clearly demonstrate a major concern of principals about staff development of their teachers and of themselves in issues relating to greater use of ICT in their schools. In addition to the quantitative data demonstrating this concern, initial analysis of the qualitative data from interviews with 12 elementary principals in the second phase of this study clearly indicates a major concern that principals have in facilitating greater use of ICT at all levels in their schools. In interview, principals highlighted staff development issues. While stating that all teachers in their schools used ICT, they expressed concern about the wide variations in classroom use. They also commented on their own need for greater input and that more time and effort was needed to assist teachers integrate ICT into their classroom practices. They recognised that the support, recognition and expectations that they conveyed to their staff were critical in facilitating change. Preliminary analysis of data suggests that 'Initiator' principals, that is, those principals who intervene in ways that demonstrate their concern for people while focussing on organisational efficiency and exhibiting a strategic sense (Hall & Hord, 2001) are more likely to facilitate greater implementation success with ICT in their schools.

This study has demonstrated that principals in Australian schools now recognise the critical role that they play in facilitating the implementation of ICT in their schools to improve teaching, learning and administrative processes. However, the study has also demonstrated that there are enormous variations in their use of ICT, in their perceptions of their own competencies in ICT and in the challenges they see in facilitating greater use of ICT in their schools. There is no single factor to indicate which principal is likely to be more successful in implementation of ICT than another. But specific strategies for improving principals' understanding of their role in ICT are evident. Encouragement to explore ways of using ICT, for example, devising more appropriate file and data management strategies for principals, creating support networks among groups of principals and highlighting the critical nature of the principals' role in implementation of ICT in schools will all assist. Further analysis of data collected for this study will include analysis of variance between groups based on independent variables such as age, gender, experience, size and location of school. However, this study demonstrates that more research is needed to more clearly determine the extent and nature of the critical role of the principal in effective implementation and integration of ICT in schools.

References

Executive Summary

As technology is infused into schools, challenges are created for school leadership. Such challenges include understanding the total cost of ownership (TCO), ergonomics, Internet filtering, data warehousing, online learning, authorized use policies, and technology competencies for school administrators, to cite only a few. Administrators need to be aware of such challenges to ensure a proactive, not reactive, response. However, many school administrators have little, if any, knowledge about such issues and associated questions as:

- Digital divide. How can administrators reduce the digital divide within a school? Within a school district? Is there a single “right” way?
- TCO. What is the true cost of having technology? Does it impact on continuing to have Macs and PCs?
- Ergonomics. What is it and how does it impact on technology use in classrooms and offices? How is it connected to TCO?
- Internet filtering. What are the pros and cons of installing filters on your Internet access? What are the requirements of the CIPA legislation?
- Data warehousing. How can student assessment data be turned into information for decision-making and improving instruction? Why is the data already available not being used?
- Online learning. Is online learning (distance education) a coming force in K-12 schools? Is it already here? How can online learning be used for staff development and student learning?
- Technology planning. Who is involved in the planning process, and why? What is the purpose of such planning? Does it really make a difference?
- Technology integration. How can school leaders make certain that technology purchases will result in technology integration in the classrooms? What has to be done so that teachers, and other administrators, will actually use, and use effectively, computer technology in their daily routines?
- Technology competencies. What technology competencies should school administrators possess? How can school leaders acquire such skills?

Too many school administrators are unaware of these and other issues and attendant questions concerning technology in schools until the issues become problems. Once at the problem level, employee efficiency and morale, community support, and the school’s educational mission can be adversely affected. Future expansion of computer use can be thrown into doubt. The first step in preventing the occurrence of
problems associated with technology infusion in schools is to gain awareness of the issues involving technology and then to learn simple methods to deal with such issues.

The main objectives/goals of paper include:

1. Identifying many of the issues that arise from the introduction and use of technology in schools.
2. Learning measures that can be taken by school administrators to deal with issues presented by computer technology in schools.

The overriding challenge for school leaders is making certain that all the new technology actually makes a positive difference on student performance. This difference can be realized either directly at the student desk or indirectly through increased efficiencies so that cost and timesavings fall through to the educational bottom line — classroom performance.

The workshop will consist of a PowerPoint presentation with active audience participation throughout. As a former building and district administrator, the presenter has personally experienced these technology challenges...and survived to tell the tale. Learn from his observations and experiences in introducing computers into school districts. Avoid letting technology challenges becoming issues and then problems for school leaders.

My qualifications and experience include being an Assistant Professor in Computer Information Systems at Buffalo State College where I teach graduate courses in educational technology. My computer experience dates from the early 1980s and includes leading efforts to overhaul technology in several school districts as a building principal, curriculum coordinator, and school superintendent. I have 20+ years of computer experience in K-12 and higher education, beginning with a Timex Sinclair computer and an early Apple computer. I also have chaired a technology committee of 20 school superintendents, taught a graduate course (“Computer Applications for School Administrators”) at the University at Buffalo, and currently teach an online (Internet-based using Blackboard.com) course (“Computers for Educators”) for the University of San Diego.

While a school superintendent, I was responsible for receiving a successful grant for a Goals 2000 award ($103,000) to upgrade teachers’ instructional technology skills, develop a professional teacher training network, and educate teachers and administrators in New York State’s Learning Standards. We also obtained a New York State Learning Technology award ($50,000) to integrate desktop videoconferencing in the classroom to restructure the teaching/learning process. Also, I directed a computer training facility for corporate clients at the University of Buffalo’s School of Management, which trained 9,000 people in six locations over three counties in all aspects of personal computer use.

I have presented computer-related workshops at state and national conferences. In addition to my background with computers, I have enjoyed a wide-ranging career in many other aspects of education and training. My K-12 career included being a school superintendent, principal, curriculum coordinator, and special education, elementary, and secondary classroom teacher in urban, suburban, and rural school districts. My government experience included being the director of training for Georgia and Illinois State governments (70,000 employees each), leading the implementation of a total quality management (TQM) initiative in a 1,100-employee state agency, and facilitating strategic plans for another state agency and a municipality. I also operate my own consulting and training business.

My professional memberships include educational organizations such as the International Society for Technology in Education (ISTE), New York State Association for Computers and Technologies in Education (NYSAC&TE), Association for Educational Communications and Technology (AECT), Computer-Using Educators (CUE), and American Association of School Administrators (AASA). I also served on the New York State Board of Regents Task Force on Technology and Infrastructure.
Project Management: From the Perspective of a Graduate Student

Ling Wang
Department of Curriculum and Instruction
Purdue University
United States
Wang23@purdue.edu

Abstract: This article is about the project managing experience of the author with the VisionQuest© Project in the Educational Technology program at Purdue University where the author is pursuing her doctoral degree. The article contains three sections: (1) a brief description of the VisionQuest© Project, (2) project management methodologies adopted by the author in the position of project manager, and (3) from the perspective of being a graduate student, the benefits and challenges of this experience for the author, as project manager.

Project Background

Technology integration is not achieved by merely providing teachers with access to technology. Research (Marcinkiewicz, 1996; Albion, 1999) has shown that availability and access are not the sole determinants of technology integration. The use of technology may be associated more with teachers' beliefs about teaching and the value teachers assign to particular uses of technology. The purpose of the VisionQuest© Project is to help current and future educators envision and achieve technology integration by providing access to electronic models of technology-using teachers. As an extension of the VisionQuest© CD-ROM and as the second step of the VisionQuest© Project, a Web-based course was developed to engage in-service teachers in conversations about technology use. In this course, teachers are brought together as an electronic community to mentor and mutually encourage each other by talking about their pedagogical visions, aspects of classroom organization, and assessment practices.

When the author assumed management of this project, the project team was in the middle of designing the on-line course format for VisionQuest©. Some course lessons needed to be designed from scratch while other lessons needed to be revised. The tasks included the following:

<table>
<thead>
<tr>
<th>Task Orientation</th>
<th>Potential tasks for the current stage of the project; likelihood that the tasks will be completed by the end of the current semester; tasks from the previous stage of the project to carry over and be given extended deadlines and provide rationales.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Selection</td>
<td>Determine the final list of the tasks to be completed by the end of the current semester; set a deadline for each task; estimate hours to be spent on each task.</td>
</tr>
<tr>
<td>Human Resources Relocation</td>
<td>Staff the tasks and name a contact person for each task; ask the contact person for each task to distribute the deadline information and estimated hours information to members working on the same task and collect feedback from them; meet with contact persons and revise deadlines and estimated hours.</td>
</tr>
<tr>
<td>Organize Meeting Sessions</td>
<td>Set up meeting locations; inform project members of the time, location, and content of each meeting session; prepare agendas for each meeting session; chair the meeting sessions and see to the completion of the planned tasks on agendas.</td>
</tr>
<tr>
<td>Checking Progress</td>
<td>Revisit the deadlines as they approach; check the progress with contact persons; analyze problems if any; re-set the deadlines, if necessary (after consulting with the two directors); assess the completed tasks.</td>
</tr>
<tr>
<td>Reporting &amp; Projecting</td>
<td>At the end of the current semester, write up a report to evaluate the progress, the teamwork, and working environment; project tasks for next semester.</td>
</tr>
</tbody>
</table>

Table 1. The Project Manager's Tasks

Project Management Methodologies

Effective project management is the key to the success of a project. In order to accomplish the role of project manager in a satisfactory way, effective methodologies of project management are crucial. When
managing the VisionQuest® Project, the author has adopted two specific methodologies: a. Goal-Oriented Project Management (Ami, 2000), and b. Just-In-Time Project Management (McDowell, 2001). The following are the benefits of this project from the two methodologies.

- Clear and fast identification of the project’s weak links, i.e., those potential for improvement.
- Focusing management efforts in a way that would best contribute to the project’s overarching goals.
- Allowing system integration and improving the information flow among project units.
- The project’s decision-making process was well-structured and based on complete information.
- Risks and problems were detected during early stages of development and production.
- “Control center” assimilation enabled a significant reduction in “time-to-market”, i.e., marketing the VisionQuest® CD-ROM and the on-line course.

Benefits and Challenges

The involvement in the VisionQuest® Project in the role of project manager has been very beneficial to the author. First and foremost, this project gave the author a sense of what “real-world” management is like. Because it is a real project in progress, every step the team made eventually played a significant role in the project outcomes. In addition, this experience is a good component to enter the resume and will increase the opportunity to “sell” the author well when the author pursues a career search. Specifically, this experience is critical to and helpful in the development of the following skills:

- Written and oral communication skills
- Instructional design skills
- Technology skills
- Teamwork skills
- Time management skills
- Organizational skills
- Problem-solving skills
- Decision-making skills

On the other hand, the amount of work of project management is overwhelming. There was a large amount of work involved at the stages of task analysis and selection as well as coordinating with members on their individual task assignment. What made the work seem more time-consuming is the fact that the author had to figure out solutions whenever a likely problem came up. The author found herself jotting down things whenever they occurred to her and communicating with members whenever she needed to disseminate information to them or collect information from them. It was by no means a job that you can put in a certain time slot of a week and get it done for the week during that time; it was like a job “haunting” you 24 hours and 7 days a week.

Conclusion

In managing the VisionQuest® Project, the author saw herself grow in abilities to coordinate tasks and team members and make quick responses to and decisions on problems whenever they arise. The implications of the author’s experiences for other graduate students would be that, before graduation and stepping into the real world, it is very beneficial to locate an opportunity in which they can exercise some of those “required” skills in order to well prepare themselves for future career pursuit.

An innovation of the early 1990s, an electronic portfolio combines the use of electronic technologies to create and publish a portfolio that most likely will be read with a computer or viewed with a VCR [or DVD player]. (Barrett, 2002)

There were more than 40 sessions selected under the category of Electronic Portfolios. This exploding quantity, and the content covered, represents the current state of the art of electronic portfolio implementation in Teacher Education in 2002. An analysis of these papers, roundtables, poster sessions and tutorials, shows a variety of purposes and different tools used to construct electronic portfolios, and represent levels of program implementation that closely follows the normal stages in the adoption of innovations. It is also clear that NCATE 2000 has been a major motivator and the federal PT3 program has been a major benefactor in the implementation of electronic portfolios in US. Teacher Education.

It is important to emphasize that the electronic portfolios that most of these papers describe are, first and foremost, portfolios in the classic definition of the term, which just happen to be developed with a variety of technological tools and stored in a variety of electronic containers: “purposeful collections of work that demonstrate efforts, progress and achievement.” The components of good portfolio development have been addressed in many of these papers, including purpose, collection, selection, and reflection on work demonstrating achievement of standards, and some papers focus on the role of the portfolio in ongoing professional development.

Purpose of the Portfolios

There are many purposes for portfolios, which can be for learning, formative or summative assessment, and employment. Most of these papers describe electronic assessment portfolios used primarily for demonstrating student achievement of teaching standards, with the INTASC principles most frequently mentioned. One secondary purpose often described was the demonstration of technology competency as described in ISTE’s National Educational Technology Standards (NETS). One paper (Levin) provided an in-depth description of the process their students use to reflect on their work, based on the North Carolina Public Schools’ model of self-assessment. The five-stage reflection cycle describes a well-grounded support system to guide students through this often difficult process.

Tools used for Development and Publishing

At this stage of electronic portfolio implementation, these papers described variations on two approaches:

1. Using common software to construct hyper-linked portfolios (i.e., WWW pages created with a variety of templates and authoring tools was most often mentioned; other software included PowerPoint and other Microsoft Office software, and Adobe Acrobat);

2. Using WWW-accessible databases to collect the evidence and provide an online structure for the portfolio.

Several papers discussed the role of digital video in a student’s portfolio, and one paper (Cunningham) explored the emerging use of DVD-R to store this video. One paper discussed how and where to store the portfolio. Another raised issues of privacy and confidentiality in portfolios published on the Internet.

Types of Presentations

Most of these papers are case studies of implementation decisions and strategies in a School, College or Department of Education. A few Roundtable sessions propose to explore these stra-
egies with interested participants. Only three of these papers reported on data collected and analyzed about electronic portfolio development, beyond the exploration of implementation issues.

Levels of Program Implementation

A majority of these papers have described implementation strategies that closely follow the Phases of Instructional Evolution in Technology-Intensive Environments outlined by Dwyer et al. in the ACOT Research: Entry, Adoption, Adaptation, Appropriation, Invention. Many of the papers represented case studies of entry and early adoption of electronic portfolios in teacher education programs, including a description of the decisions made regarding the technology tools to be used for “electronic” component of these portfolios. A few papers document the process of adaptation and appropriation (widespread use) of the electronic portfolios. At least one program has changed the choice of technology tools based on their experience and further development (invention). There is very limited data collected and reported about the efficacy of electronic portfolio development and publishing. One paper (Barrett) reported on student responses to a preliminary survey, with an invitation for more widespread data collection across education programs nationwide.

Issues

One study (Carney) raised issues about how the tool chosen for authoring (WWW pages) afforded and constrained the portfolio author in representing and communicating teacher knowledge, revealing a tool-related personal revelation dilemma. As she states, “Teacher education programs ought to be aware of this dilemma and take measures to ameliorate preservice teachers’ concerns about exposing problems of practice to potentially critical portfolio readers.” Another paper reported similar issues with publishing portfolios on the Internet. In the two studies that reported on surveys of teacher education candidates, there is evidence that the skills gained in the process of developing electronic portfolios would be useful in classroom instruction. There is another issue that emerges when addressing the technology skills gained from the process of constructing these portfolios: Do students provided with a static template or a dynamic web-based database develop the same technology skills as those students who must create their own structure with common software tools?

Conclusions

Some interesting issues appear in these papers. In the history of human development, our tools have often shaped the outcomes of our tasks and, while many programs require WWW-based portfolios, Carney suggests a problem with that tool limiting the openness of the reflections, which Levin points out is the most important purpose of this process.

While visiting Alverno College, I heard about Dr. Mary Diez’ three metaphors for thinking about portfolios: mirror, map, and sonnet. Based on these metaphors, some questions come to mind. When the portfolio is highly structured (the sonnet), often as in an online data base to meet the organization’s need for uniformity in assessment data, does it lose the creativity of expression that has been a hallmark of paper portfolios for years? Where is the sense of ownership of the portfolio creator in constructing their own paths through their work (creating their own map)? What are the trade-offs between scaffolding the development process with templates or highly structured data bases, and students gaining the knowledge that can result from the process of constructing their own hyper-linked portfolios (seeing their work in new ways—the mirror) while linking and reflecting on their work? Also, at the risk of editorializing, should these online assessment management systems really be called electronic portfolios?

There is a need for more data collection and longitudinal research on the perceptions of teacher candidates and faculty on the value and purpose of electronic portfolios, and whether the benefits extend to the classroom and enhance student learning. The question of efficacy of effort must also be addressed: only one study included here compares paper-based and digital portfolios. The time is right to move beyond implementation issues to research and evaluation.
What is the Perceived Value of Creating Electronic Portfolios to Teacher Credential Candidates?

Abstract: This session presents research findings from a study designed to determine the following: a) the ways in which, and b) to what extent preservice teachers value the experience of creating an electronic portfolio. With the new focus on technology's standards for teachers, this research is an initial attempt to determine what motivational factors encourage students to create an electronic portfolio for a teacher education credential. The process of developing electronic teaching portfolios can document evidence of teacher competence and guide long-term professional development (Barrett, 2001). Its ability to provide teacher candidates with an opportunity to become reflective practitioners is evidenced to be one of its greatest advantages (Barrett, 2001). The research findings from this study will contribute to the knowledge base in regards to creating electronic portfolios, which will be useful for the planning and implementation of teacher training programs.

Introduction

During the past decade, the curriculum for preservice teachers has had to respond to the changing demographics in our student populations. As a result instructional methods for cross-cultural language and academic development was emphasized. Now, as we begin this new century, our curriculum needs have converged on yet another focus: technology integration into classroom learning. National and state standards regarding accountability in technology, cross-cultural language, and academic development have become a catalyst for preparing our teachers and America's youth for the new millennium.

Electronic portfolios have gained an accepted position to improve the interrelationship among technology, multicultural education and instructional theory and practice. It is evidenced in the products of learning that the process of creating a portfolio enhances the ability of each student teacher to articulate these ideas. In keeping with our commitment to model fair and equitable learning environments for all students, the faculty felt a need to include the preservice or newly in-service teachers into the planning and implementation of the electronic portfolio requirements.

Purpose of the Study

This session presents research findings from a study designed to determine the following: a) the ways in which, and b) to what extent preservice teachers value the experience of creating an electronic portfolio. With the new focus on technology's standards for teachers, this research is an initial attempt to determine what motivational factors encourage students to create an electronic portfolio for a teacher education credential.

The process of developing electronic teaching portfolios can document evidence of teacher competence and guide long-term professional development (Barrett, 2001). Its ability to provide teacher candidates with an opportunity to become reflective practitioners is evidenced to be one of its greatest advantages (Barrett, 2001). The
research findings from this study will contribute to the knowledge base related to electronic portfolios, which will be useful for the planning and implementation of teacher training programs.

Theoretical Background

Research (Milman, 1999) has found that the student teachers' experience of creating electronic portfolios allows them to develop technology skills as well as reflect upon their coursework and collaborate with peers. The development of an electronic portfolio, if begun early in the teacher candidate's program, will allow for the growth of technology skills throughout their coursework. Findings indicate that by infusing technology throughout the program it is more likely that the candidate will use technology in their K-12 classroom when they begin to teach (Lawless et al., 2000). By creating electronic portfolios student teachers will be given opportunities to demonstrate their strengths in teaching skills, their understanding of instructional theory and application of instructional methods and their ability to use a variety of computer generated media. Graphics, sounds and animation can be included in their portfolio that can allow future employers to view the person in a richer context and aid them in gaining a better understanding of the student teacher's ability to apply theory into practice. Since the electronic portfolio allows them to express themselves in ways previously not possible, the electronic portfolio becomes a valuable tool to help them secure a teaching position in a district of their choice. This medium allows the student to learn more because it will encourage collaboration with peers and develop reflective practices. Its ability to provide teacher candidates with an opportunity to become "reflective practitioners" is evidenced to be one of its greatest advantages (Barrett, 2001). The inclusion of scanned pictures, teaching videos, reflection pieces and other artifacts allows the student teachers to evidence mastery of the NCATE technology standards as well as state teaching performance standards (Swain & Ring, 2000).

Methods

Teacher credential candidates enrolled in technology courses were given an opportunity to view several electronic portfolios. After the completion of this exercise they were administered a questionnaire.

In order to address the above issues a pilot survey was administered to teacher credential candidates (N=23, Age X=29) enrolled in a computer course to answer the following quantitative questions:

1) To what extent do teachers value the creation of electronic portfolios as a means to improve their technology skills?
2) To what extent do teachers value the creation of electronic portfolios as a professional development tool to enhance their ability to transfer instructional theory to solid, effective teaching practices?
3) To what extent do teachers report that an electronic portfolio would increase their employment opportunities?

To gain a better understanding of these teacher candidates' expressed attitudes the survey was followed up with a personal interview to answer the following qualitative questions:

4) In what ways do teachers value the creation of electronic portfolios as a means to improve their technology skills?
5) In what ways do teachers value the creation of electronic portfolios as a professional development tool to enhance their ability to transfer instructional theory to solid, effective teaching practices?
6) In what ways do teachers report that an electronic portfolio would increase their employment opportunities?

A questionnaire was administered to teacher candidates enrolled in a teacher credential program. This instrument checked for attitudinal measures by asking them to rank order seven outcome statements concerning their perceived value of the experience of creating an electronic portfolios. These outcomes were then evaluated statistically and clustered into the following three variables:

1) value for importance of improving technology skills,
2) value for importance of improving teaching abilities, and
3) value for importance of securing employment.
One male and female was selected from each of the above three groups to participate in an interview. The number of times each individual stated they valued the electronic portfolio for improvement in one of the following areas was recorded each of the following: 1) technology skills 2) teaching abilities 3) job marketability.

Data Sources and Analysis

This quantitative/qualitative study employed a dual-based research approach. A survey was used to examine beginning teachers' perceptions of the value of the experience of creating an electronic portfolio. The survey questions were analyzed statistically in SPSS 10.0 using descriptive statistics. The data from the qualitative interviews were transcribed and coded into a Perceived Value Matrix.

Findings and Discussion

The statistically analysis revealed that preservice or newly inservice teachers were more likely to value the process of creating an electronic portfolio for their ability to improve teaching practices (X = 3.84) and specifically that it would provide an opportunity for them to participate in reflective teaching practices (X = 4.11). Furthermore, they indicated that they believed they would be more likely to be hired (X = 4.21) by a potential employer if they demonstrated advanced technology skills through the use of an electronic portfolio. The statistical analysis also implied that these teacher candidates believed that they would gain skills that would be useful in classroom instruction (X = 3.63).

This analysis indicates that teacher candidates perceive two of the most valuable outcomes of participating in the process of creating an electronic portfolio is: 1) that an electronic portfolio would provide them with feedback that would allow them reflect upon their teaching and “become a better educator,” and 2) that they would be more likely to be hired since they would be demonstrating proficiency in technology that is assumed to be sought by potential employers.

At press time both the quantitative and qualitative data is continuing to be tabulated and analyzed. More detailed results will be available Spring 2002. Interested parties should contact the authors for further information: vamber@nu.edu or bczech@nu.edu.

Significance

An important outcome of this research is that it will enhance methods and techniques for the integration of technology in classroom learning, both at the teacher training level and in the K-12 classroom. Additionally, these findings will aid in the strategic planning and implementation for both the faculty and preservice teachers participating in teaching training programs.

Abstract: This paper is a report on the development process and use of electronic portfolios in the teacher education program at Valdosta State University. Students entering the program begin the process of developing electronic portfolios in an introduction to education course. As they progress through their teacher preparation programs, students add narratives and artifacts to their portfolios to demonstrate and document their knowledge, skills, and dispositions within the undergraduate framework. The development of these portfolios is considered a continually evolving process. As preservice teachers move from the preservice teacher level to the student teaching level and on to the inservice teacher level, the goal is for these teachers to continue to demonstrate progress throughout their professional careers, through these or other portfolios.

Use of Portfolios

A professional portfolio is a collection of artifacts, evidence, and reflections documenting what one knows and is able to do in a professional field. The use of professional portfolios has become increasingly popular in the field of education, becoming a method for creating avenues for reflection and documentation of personal and professional growth and development for both preservice and inservice teachers. Teacher education programs are now considering portfolio development as a valuable process for documenting teaching performance (Costantino & De Lorenzo, 2002). According to Campbell, Cignetti, Melenyzer, Nettles, and Wyman (1997), portfolios are organized, goal-driven, and may be used to document professional growth and teaching competencies. The development of portfolios helps preservice teachers set goals for learning and review goals periodically throughout their teacher preparation programs.

Portfolios may also serve as an instrument for gaining a better understanding of preservice teachers' abilities by examining artifacts (tangible evidence of knowledge gained and skills mastered) they have chosen to use to document what they know and are able to do. Through portfolio documentation, different dimensions of a preservice teacher's preparation program may be elaborated to provide indicators of progress that can be measured. National, state or district standards may be used as a guide for deciding on the areas of assessment. As students near the completion of their teacher preparation programs, the portfolio becomes a tool for them to market themselves to potential employers. After graduation, the portfolio helps novice and veteran teachers...
continue in their professional growth as educators (Campbell et al., 1997). Lyons (1999) purported the process of developing portfolios helps beginning teachers articulate their teaching philosophy and develop their teaching techniques. Van Wagenen and Hibbard (1998) determined that inservice teachers, through the portfolio construction process, developed many effective strategies for studying student work and discovered important connections between teaching and learning. Similarly, Danielson (1996) stated teachers could use portfolios as a method for self-reflection and analysis, as a process to support mentoring and coaching relationships, and to strengthen a resume.

Electronic Portfolios

Similar to a paper-based professional portfolio model, an electronic portfolio is a carefully selected collection of exemplary artifacts that allows demonstration of one’s best work and accomplishments. Electronic portfolios in a teacher education program provide an efficient method for displaying preservice teachers’ work that meets high standards and documents growth throughout the program (Costantino & De Lorenzo, 2002). Electronic portfolios may exhibit benchmark performance measures for preservice teachers by allowing for the evaluation of the effectiveness of teaching strategies. Preservice teachers may also use artifacts that are similar in nature to show their progress towards meeting the standards of their programs. Electronic portfolios have several other advantages. Unlike using paper-based portfolios, the use of electronic portfolios is a multimedia approach that allows preservice teachers to present teaching, learning, and reflective artifacts in a variety of formats, such as graphics, audio and video, and text (Costantino & De Lorenzo, 2002). Artifacts may be easily inserted as a file, scanned, or uploaded to the portfolio. Also, electronic portfolios are easily accessible, can store multiple media, and are easy to update.

Using electronic portfolios also allows for cross-referencing of artifacts. The creation of meaningful links between all artifacts is possible, therefore documenting a preservice teacher’s achieved competence in teaching at the end of his or her teacher preparation program. Ongoing documentation in the electronic portfolio contains the preservice teacher’s best work and gives a portrait of his or her professional competence that can be built upon in the inservice field. According to McKinney (1998), teachers who demonstrate their competence in technology through the development of an electronic portfolio are more likely to incorporate technology into their own classrooms. Similarly, Goldsby and Fazal (2000) indicated student teachers must learn to effectively use technology in their preparation program because teachers with little or no experience with technology are less likely to incorporate its use in their classrooms.

Portfolio Development in Preservice Education

Portfolio development in the teacher education program at Valdosta State University (VSU) began as a pilot program in fall 1997. Using a paper-based model, students enrolled in the introduction to education course (the first education course for students) developed a notebook portfolio using a framework based on standards established by the Interstate New Teacher Assessment and Support Consortium (INTASC). The INTASC standards were chosen because they serve as the basis for VSU’s College of Education’s Conceptual Framework. The standards are generally applicable for teachers of all disciplines and all levels and are aligned with National Board for Professional Teaching Standards (NBPTS). To infuse additional technologies into the teacher education program the paper-based model was changed to an electronic format in fall 1999. Continuing to use the INTASC standards as a framework, a template was developed in Microsoft’s FrontPage 2000. Currently, students enrolled in the introduction to education course use the template to begin the development of their electronic portfolios. The process begins in labs conducted during class meeting times. To gain access to the portfolio template students are provided a login name and a password. During labs faculty members who teach the introduction to education course provide basic instruction in FrontPage 2000. Portfolios at this level of development are identified as working portfolios in which faculty members require assignments that will be used as artifacts. Required assignments include a current resume and reflective writing activities, such as a philosophy of education and education dispositions. Students are encouraged to perceive their portfolio, not as a file of course projects and assignments, but a professional portfolio organized to document their professional growth and achieved competences in teaching. For viewing and grading purposes faculty members have access.
to their students’ portfolios which are posted on VSU’s College of Education website. Faculty members do not have access to students’ passwords and may only view the portfolio, not open a student’s web page folder. Portfolios are graded using a standard rubric.

As students continue to progress through their teacher preparation program they begin to include narratives and artifacts that may be assigned by faculty members who teach courses in their particular program or artifacts may be self-selected. Students are required to select artifacts that demonstrate evidence of an achieved goal or the attainment of particular knowledge and skills. Then, as students complete coursework and program requirements, they begin to revise and expand their portfolios as they identify and select artifacts from coursework and field experiences that document their knowledge, skills, and dispositions in relation to a particular standard and what they will know and be able to do upon completion of their program. Students are informed that artifacts will be self-selected for final development during the student teaching experience, reflecting students’ individuality and autonomy as well as providing tangible evidence of the wide range of knowledge, dispositions, and skills they have developed and achieved as a growing professional. At this level the working portfolio becomes a professional portfolio containing a student’s best work, providing a portrait of the student’s professional competence, and can be used for assessment purposes. Portfolios at the student teaching level are graded using a standard rubric.

Students are encouraged to revise and expand their portfolio and use it as a teaching portfolio as they become professional educators. Reasons for this encouragement include the following: (a) many school systems who hire VSU’s graduates are now requiring teachers to develop and maintain teaching portfolios; (b) students who are enrolled in VSU’s graduate teacher education program are required to develop an electronic portfolio or continue their portfolio development initiated in their undergraduate programs if they are a graduate of VSU; (c) a requirement for National Board Certification is portfolio development and submission; and (d) some states require beginning teachers to submit portfolios during the first year or two as part of a state mandated induction program or to obtain teacher certification, whereas, other states, including Georgia, are considering implementing induction programs requiring submission of portfolios for certification purposes.

In VSU’s teacher education program the development of a portfolio is considered a continually evolving process. As preservice teachers move from the preservice teacher level to the student teaching level and on to the inservice teacher level, the goal is for these teachers to continue to demonstrate progress throughout their professional careers, through these or other portfolios. The ability to reflect upon teaching practices and seek opportunities for professional growth are lifetime teaching goals that can possibly be achieved through maintaining a professional portfolio.

Abstract: Around the nation, school districts and teacher education programs have received the Intel "Teach to the Future with Support from Microsoft" grants and as a result, have participated in workshops to learn how to implement the portfolio-based modules into current curriculum. The Intel "Teach to the Future with Support from Microsoft" grant from Intel Corporation has also reached the teacher education programs in other countries. In spring 2001, four professors from the Department of Urban Education at the University of Houston Downtown received this Intel grant. In fall 2001, ten more faculty members from the department attended another Intel workshop offered at UHD. This training is having a positive impact in the way we prepare pre-service teachers as well as in the delivery of instruction. We hope our experience benefits other school districts and teacher education programs that may already be or may become involved in this grant project.

Introduction

University faculty members are at different levels in implementing technology to deliver their courses and prepare the students for the technology age. This situation is of primary importance in teacher preparation programs. Faculty in these departments must be leading the way in the use and teaching of technology since they are in charge of training teachers. The Intel "Teach to the Future with Support from Microsoft" grant has allowed the Urban Education Department at the University of Houston Downtown to continue training its faculty. This paper will include a general description of the Intel training, a brief description of the modules from the Intel binder, the team work of the professors in Urban Education Department to teach the modules, a showcase of some student work and electronic portfolios as artifacts of the grant implementation, and the monitoring of the implementation of the technology component in teachers' classrooms.

Description of Intel Training

In spring 2001, the Department of Urban Education at the University of Houston Downtown received the Intel "Teach to the Future with Support from Microsoft" grant. Four faculty members, each representing the math education program, the language arts and social studies education program, the technology education program, and the bilingual education program, participated in an intensive workshop held in Seattle, Washington. The training focuses on the integration of technology in the teacher education curriculum. The days were very well planned. The first day was a Friday. The meeting started at 8:00 a.m. and ended at 7:30 p.m. The group covered module 1. The team had the opportunity to discuss the technology initiatives in their universities over dinner. It was an interesting discussion since the people were from a variety of universities in the USA. The second day began at 8:00 a.m. with a
continental breakfast and ended at 7:30 p.m. with a required dinner. During the dinner, the discussion was about the role of students' sample works in the pre-service program. The participants went through modules 2, 3, and 4 during this day. The third day opened with a continental breakfast at 9:00 a.m. and ended at 4:00 p.m. The team covered modules 5 and 6. The last day began at 8:00 a.m. and ended at 4:00 p.m. The group covered modules 7, 8, 9, and 10. The afternoon was spent in showcasing the participants' work. Several forms were used to give feedback to each other. Some of the participants exchanged samples of their products to be shared with their students. The last 30 minutes were used for a general assembly where participants gave feedback about the training. The Intel trainers were very open to suggestions but the general opinion from the participants was that the training and the materials were excellent. It was the general consensus that it was a great addition to the curriculum for training teachers. One of the professors who attended the Seattle training from the Urban Education Department took upon herself the responsibility to organize an Intel training for the rest of the faculty in the department. This training was conducted in December 2001. Ten professors from the department participated as well as some professors from other universities in the USA. The Intel grant provides the Intel binders at no cost to the students in the programs for the term of the grant.

**Brief Description of the Intel Binder**

The Intel binder includes information for locating resources for electronic portfolios, creating student multimedia presentations, creating student publications, creating student web sites, developing plans for implementation, putting together electronic portfolios, and showcasing the electronic portfolios. The binder has ten modules. Each module has activities and homework. Module one is "Getting Started". It includes a general description of the Intel grant, creating a program folder, beginning the planning process for a unit, creating a multimedia presentation, and sharing a multimedia presentation with the class. The homework activities consist of exploring copyright laws related to computer and software use, locating curricular resource materials, and creating a works cited page. This last one will help to locate Internet addresses more easily and to cite the sources properly. Module two is "Locating Resources for Unit Portfolios". The activities include using directories and web search engines, locating Internet resources, and locating resources using Microsoft Encarta. The homework is evaluating resources on the Internet. Module three is "Creating Student Multimedia Presentations". The activities are creating a multimedia presentation, reflecting on the sample presentations, and revisiting the plan for the unit. The homework is creating an evaluation tool for the multimedia presentation. Module four is "Creating Student Publications". The activities are creating a publication, reflecting on the student publications, and revising the unit plan. The homework is creating evaluation tools for the publications. Module five is "Creating Unit Support Materials". This module helps with the use of Microsoft Word, Publisher, and Internet Explorer. Activities are creating unit support materials and revising unit plans. The homework is planning student web sites. Module six is "Creating Student Web Sites". The activities are the creation of web sites using publisher, reflecting on the web sites, and revising unit plans. The homework is the creation of web sites tools. Module seven is "Creating Teacher Support Materials". This module presents ideas for using email as classroom projects. The activity is creating teacher support materials. The teachers could create a multimedia presentation, a web site or a publication to introduce or support the unit. The homework is revising the unit portfolio. Module eight is "Developing Plans for Implementation". Activity one is the development of a timeline for both when and how the events are going to happen before, during, and after the implementation of the unit. Activity two is creating management documents. These documents would assist the teachers with the logistics in the management of the equipment and the classroom. The homework is modifying the unit portfolio. Module nine is "Putting Unit Portfolio Together". Activity one in this module is revising completed units, and activity two is putting unit portfolios together. This module allows for final revision of all the components in the portfolio. There is a strong emphasis that all unit components to comply with copyright law. Homework one focuses on locating additional Internet resources for educators, and homework two is the completion of the unit portfolios. Module ten is "Showcasing he Unit Portfolios". The participants have the opportunity to show their products to each other. They receive feedback and suggestions. The participants evaluate the training and make suggestions not only for the implementation of the training but also in the way the binder is organized. The binder also includes a CD-ROM. This is a valuable tool that shows concrete samples of all the components in the binder. It also provides additional Internet links, and useful
information to assist in the planning of the portfolio units. It is important to point out that during the training there was no need to look for any other additional materials. The CD-ROM and the Internet proved to be the ideal tools for this planning.

![Figure 1: Intel Binder Table of Contents](image)

**Team Work to Implement the Modules**

Faculty members at the Department of Urban Education, UHD see the Intel project as an initiative and source of ideas to incorporate technology into the teacher education courses. Extensive discussions among the faculty members have been done to divide the modules into several courses the students are going to take in different semesters, so that by the end of their studies they could cover all components. The nature of the Urban Education Program is very conducive to this teamwork. The programs in elementary, bilingual, and secondary run in blocks of three courses for each block. The students have to complete three blocks to finish their degrees. The professors teaching the courses in a block have to do careful planning among the members of team. The students produce combined assignments. They receive the same grade in all the courses in a block. This dynamic interaction of the courses makes it possible to plan and deliver the Intel module in a more effective way. The students in the bilingual Block II for example focus on modules three, four, six, nine, and ten. These students are expected to have covered the rest of the modules in the ETC course. This is a technology class that all the students take before the blocks. The pre-service teachers as well as the PB seeking certification are also expected to have mastered several software programs such as Power Point, Excel, Publisher, and Words before entering the blocks.

The faculty teaching the blocks is constantly assessing the delivery of instruction. After the first implementation of the Intel Teach to the Future curriculum, there were some issues that needed to be addressed. For instance, the access to computer equipment was critical to the students. More than 90% of the students enrolled in the courses did not own a computer. They depended on the university computer lab to complete their assignments. Since all the assignments had technology components, the students had to expend endless number of hours in the UHD lab and even had to miss work to complete the assignments. The department is fully aware of this situation. Therefore, as part of the Unit Plan the department is hoping to have a wireless lab dedicated exclusively to the Urban Education students. It is also exploring ways to assist the students in purchasing computers. As we move further into the technology age, the need to have a computer is becoming a necessity. However, until this problem is
addressed, the number of assignments related to technology may be reviewed in the blocks as well as the redistribution the Intel modules. The Urban Education Department will continue its emphasis in technology as long as the school districts want to hire teachers proficient in technology.

Students' Works and Electronic Portfolios

The students presented their electronic portfolio at the end of the summer semester 2001. This particular group of students is very unique. Some of the students were PB getting certification and were enrolled in the Master in Teaching program. They came to class for nine weeks. They were enrolled in Block II. They took Teaching Reading and Language Arts in Spanish, Curriculum in Bilingual/ESL, and Assessment. As part of the assignments for the block, this bilingual group of students focused on developing an interdisciplinary unit, a science project, an evaluation kit, and a case study. They were asked to include a multimedia presentation, a brochure or a newsletter, and a web site as part of the interdisciplinary unit for bilingual students. The students could choose a partner for the projects. They could also pick the grade level and the topic for the unit. All the objectives for the interdisciplinary unit had to be at the levels of analysis, synthesis, and evaluation. The students followed the guidelines from the Intel binder for their projects. Two weeks of class time was dedicated to work in the assignments. The students indicated that the binder was very helpful in the completion of their work. There were several products of a very high quality. The students felt that they had learned a great deal, but the work was very intensive. Some samples of their work follow.

Diana and Octavio's interdisciplinary unit was the Water Cycle. They used Microsoft Power Point to do the multimedia presentation of their science project. The presentation was about the formation of clouds.

![Figure 2: Slide from Student PowerPoint Presentation](image)

Ana and Rafael chose Earth Day for their interdisciplinary unit. Their unit was based on the following essential question: How can we as inhabitants of the planet Earth better the environment for the future? One of their activities was to produce the flier below.
Earth Day

**Essay Writing Contest**

"How would Planet Earth be without plants?"

**Submit essays on:**

Date: April 1, 2002
Time: 2:30 p.m.

For more information contact
Ms. Caballero's Room 29
Mr. Roa's Room 31

There will be a winner per grade level. This is your opportunity to express yourself and be creative. Join us on this journey of conservation of Planet Earth.

Each winner will have their essay published in the school newsletter plus a gift certificate to Scholastic Books!

Recycle

**Figure 3: Flier from Student Presentation**

**Conclusion**

In conclusion, we hope our experience will benefit other school districts and teacher education programs that are participants or are going to be participants in the Intel “Teach to the Future with Support from Microsoft” grant. Technology is a powerful tool for the twenty-first century. Universities and school districts will not be able to produce curriculum or students that are at the cutting edge unless they have the community and the business support. The support provided by the Intel grant allowed the University of Houston Downtown, Department of Urban Education to take one step ahead in the preparation of teachers with a strong component in technology. This support is greatly appreciated since our mission is to prepare teachers for inner-city schools. We hope other institutions will take advantage of this program sponsored by Intel. They will be hosting twenty-four training sessions around the country in 2002. The contact person is Cynthia Reed at Cynthia.d.reed@intel.com.

ABSTRACT
This article describes the process of creation of meaningful learning environment (MLE) following a three-dimensional process of activity-artifact-reflection cycle and recording the process of learning in the form of digital portfolios. Production of quality MLE and learning through MLE has been assured by following a method of feedback and evaluation, which consists of self-evaluation, peer-review and teacher-feedback in an integrated manner through various activities, e.g., online (synchronous and asynchronous) discussion, classroom group discussion and presentation; and feedback by the peer and the teacher. The present study is based on author's own practical experience of designing project-based activities. The activities are carried out using ICT and the students created digital portfolios during the course of their study. The learning takes place through individual learning and collaborative learning through interaction with the team members and the teacher.

What is Meaningful Learning?
In order to effectively integrate technology into a meaningful learning experience, we must have a clear understanding of what a meaningful learning experience is. Meaningful learning occurs when learners actively interpret their experience using internal, cognitive operations. Meaningful learning requires that teachers change their role from sage to guide. Since students learn from thinking about what they are doing, the teacher’s role becomes one of stimulating and supporting activities that engage learners in thinking. Teachers must also be comfortable that this thinking may transcend their own insights. Meaningful learning requires knowledge to be constructed by the learner, not transmitted from the teacher to the student. (Jonassen, 1999). According to Jonassen et al. (1999), meaningful learning is:

- **Active (manipulative).** We interact with the environment, manipulate the objects within it and observe the effects of our manipulations.
- **Constructive and reflective.** Activity is essential but insufficient for meaningful learning. We must reflect on the activity and our observations, and interpret them in order to have a meaningful learning experience.

![Attributes of Meaningful Learning](image)

- **Intentional.** Human behavior is naturally goal-directed. When students actively try to achieve a learning goal they have articulated, they think and learn more. Articulating their own learning goals and monitoring their progress are critical components for experiencing meaningful learning.
- **Authentic (complex and contextual).** Thoughts and ideas rely on the contexts in which they occur in order to have meaning. Presenting facts that are stripped from their contextual clues divorces knowledge from reality. Learning is meaningful, better understood and more likely to transfer to new situations when it occurs by engaging with real-life, complex problems.
- **Cooperative (collaborative and conversational).** We live, work and learn in communities, naturally seeking ideas and assistance from each other, and negotiating about problems and how to solve them. It is in this context that we learn there are numerous ways to view the world and a variety of solutions to most problems. Meaningful learning, therefore, requires conversations and group experiences.

To experience meaningful learning, students need to do much more than access or seek information. Moreover they need to know how to examine, perceive, interpret and experience information. In this course the student-teachers experienced the process of meaningful learning by progressing through various activities for creating meaningful learning environment (MLE) using ICT.

Steps in the Creation of MLE
In the introductory courses in Instructional Technology for Teacher Education Programme the trainee teachers were assigned to create MLE by considering all the attributes of meaningful learning as described above. The student-teachers worked in groups particularly in pairs.

Developing an Idea Map using Mind mapping Tools
Student-teacher decided on a topic and did brainstorming on how to include various attributes of meaningful learning in the creation of a learning environment for their students. The student-teacher then represented their ideas in a visual format using the “mind mapping tools” (http://www.mindjet.com).

Another two groups of student-teacher (i.e., two pairs) then reviewed each of these Idea Maps. The feedback was provided to the creators online using the “discussion forum” “Blackboard” delivery platform (http://www.blackboard.com). Based on the feedback received through peer-review the student-teacher then made changes and modifications. Also student-teacher wrote their reflection on how they have found these set of activities useful.

Creating the Flowchart of Activities
Cognitive psychologists have known for decades that most people can only hold about four to seven discrete chunks of information in short-term memory. The goal of most organizational schemes is to keep the number of local variables the reader must keep in short-term memory to a minimum, using combination of graphic design and layout conventions along with editorial division of information into discrete units. The way people seek out and use information also suggests that smaller, discrete units of information are more functional and easier to navigate through than long, undifferentiated units.

Student-teacher then involved in sequencing the activities where they have used the flowcharting techniques. They were introduced to various types of flowcharting such as Grid, Web, Sequence and Hierarchy.

Trainees selected the structure according to their own requirements for developing a student-centered learning environment. Trainees followed four basic steps in organizing the information and activities. These are: to divide the content into logical units, establish a hierarchy of importance and generality, use the hierarchy to structure relationships among chunks, and then analyze the functional and aesthetic success of the complete system. After sequencing the activities the trainees started working towards the detail design of individual screen for display in the form of storyboard.

Designing the Storyboard
Storyboards are a visual representation of what an interface (CBT, Web, Movie, Book, etc) is supposed to look like. It is a sketch. Three key items were considered by the student-teachers when drafting the storyboards:

- **Navigation** - What and where will it appear on each page? What technology will be used to implement it?
- **Identification Info** - Each page needs some type of identification information such as (title, menu link, home link, etc) and
- **Content** - What should be visible on a particular page?

Before creating the storyboard the trainees learnt the techniques and strategies of searching information on the Internet. They also learnt about evaluating the resources. They searched information relevant to the chosen topic for MLE.

Developing the Meaningful Learning Environment
Student-teachers finally used the MS Powerpoint application software for developing the MLE. Trainees concentrated on three aspects for creating MLE: Context (creating a real-life, complex and authentic scenario), Activities (designing activities for collaboration, sharing, decision-making and knowledge construction) and Tools (providing tools for searching, thinking, reflection and creativity). Student-teachers learnt and used the advanced features of the MS Powerpoint software. They also concentrated on media selection for maximizing the learning effectiveness. Student-teachers also made the workstation presentation of their final artifact of this project, the MLE. Peer-evaluation was conducted for feedback for making modification and changes before final submission.

Integration of ICT in Education
Trainees learnt to use different learning technologies during the process of working towards the final product of MLE. The process of completion of this project through a set of learning activities of designing and developing artifacts, taking part in online (synchronous and asynchronous) discussions, reflecting on various tasks were represented in the form of a learning portfolio on the web.
evaluation was done using different rubrics for different activities. A rubric for the evaluation of student-teachers' reflections on various activities was also created (Bhattacharya, 2001).

The integration and link among the different activities performed by the students in a course is very crucial for understanding the connection and integration of in this process students can visualize the learning as a whole and not as bits and pieces of task to complete (Bhattacharya and Richards, 2001). The author's purpose for introducing of eportfolio is to assist students to better understand and be able to articulate their learning as they developed their personal professional knowledge and skills about IT in education. The electronic portfolios show a more complete picture of student progress and achievement than traditional approaches to assessment. Students can demonstrate a variety of competencies, take greater responsibility, and became skilled at self-evaluation by developing electronic portfolios.

Electronic Portfolios in Pre-service Education—Distinguishing Between Process and Product

Dr Christine Anne Brown
Faculty of Education
University of Wollongong
Australia
christine_brown@uow.edu.au

Abstract: This paper explores the use of electronic portfolios in the Faculty of Education, University of Wollongong, from 1997-2001, through the lens of ICT integration. Three subject cases are described noting the purpose of the portfolio, the degree of infrastructure support, the lessons learned and the issues that are informing our future program-level decisions. Electronic portfolios are not a uniform entity or a magic solution. Hartnell-Young and Morriss (1999) describe three types—formative (developmental), summative (assessment) and marketing. These translate simply into either a process emphasis (long term, foundational and iterative) or a product emphasis (short term, polished and highly audience specific). Students developing electronic portfolios require sound information management skills to support a sustained process, and clear understanding of target audience and assessment criteria for individual products. Without faculty level support via infrastructure and course level planning the true benefits of a process/product balance will not be realized.

Introduction

Lifelong learning, reflective practice, professional development and integration of ICT (information and communication technology) can all be addressed in pre-service teacher education through the use of electronic portfolios. Students have to demonstrate their technical, creative, organizational and reflective abilities to varying degrees, enabling them to explore multiple forms of expression and develop information literacy skills to equip them for greater use of electronic information sources. Lecturers gain the experience of handling bulk electronic material, dealing with issues such as collection, collation and distribution for marking, debating on-screen versus print format for reading, and determining various mechanisms for effective student feedback (Brown 1998). But electronic portfolios are not a uniform entity or a magic solution. They can be used inappropriately, or used to the exclusion of simple and practical alternatives. This paper explores the evolution of their use in the Faculty of Education, University of Wollongong, Australia over the period 1997-2001, through the lens of ICT integration.

Doctoral studies (Brown 1997) identified new activities for the teacher and learner in a constructivist classroom environment. The teacher is a process facilitator, a designer of tasks or cognitive tools, a resource organizer and a source of metacognitive support (strategy sharing, modeling and apprenticing learners as problem solvers). The learner is a producer of resources who needs to learn to organize those resources, share strategies, and work collaboratively and cooperatively with fellow learners. Collectively, the reciprocal actions of teacher and student are at various times active, reflective, individual, collaborative, cooperative, creative, expressive and most important of all—flexible. The background was there for the emergence of electronic portfolios.

Three subject cases are discussed (Tab.1) to illustrate a shift from subject to program-level thinking that now influences the purpose of each portfolio activity. Hartnell-Young & Morriss (1999) describe three types of electronic portfolio—formative (developmental), summative (assessment) and marketing. These translate simply into either a process emphasis (long term, foundational and iterative) or a product emphasis (short term, polished and highly audience specific). Each subject case is explored in relation to the purpose of the portfolio, the degree of support and infrastructure required, the lessons learned, and the issues that are informing our future program-level decisions.

| **Example A.** Undergraduate Multimedia Electives (Primary Program 3-4 yrs) | Formative portfolio – reflective, skill development with different ICT multimedia tools  
*Other tasks*: web site, HyperStudio activity and essay. | Summative portfolio – assessment of skills; teaching strategies to support group project  
*Other tasks*: group project and resource database or concept map/essay. | Marketing portfolio – geared to employer for interview; drawing on past subjects.  
*Other tasks*: client profile, design statement and group project for client. |
| **Example B.** Compulsory ICT Subject in first year (Primary Program 3-4 yrs) | No portfolio  
*Tasks*: Exam, assignments, skill tests | Formative – skill development aligned to roles (learner, manager, designer, researcher)  
(14 options)  
*Other tasks*: online discussion for exam preparation and skill tests. | Formative – skill development aligned to roles - options based on 2000 cohort choices. (8 options)  
*Other tasks*: pedagogical application of skills, software demonstration and online discussion analysis. |
| **Example C.** Compulsory ICT component of Pedagogy (GDE Program 1 yr) | No portfolio  
*Tasks*: Exam, skill tests, assignment) | No portfolio  
*Tasks*: Exam, skill tests, assignment) | Summative – Report, Formative - teaching resources, activities and student work  
*Other tasks*: pedagogical application of skills and online discussion analysis. |

Table 1: Focus of electronic portfolios and nature of accompanying assessment tasks in three class examples for 1999, 2000 and 20001.

**Example A: Undergraduate multimedia elective**

The undergraduate multimedia electives provided the test-bed for electronic portfolios within the faculty and it was the success of the first student electronic reflective “portfolio” in 1999 that drove a desire to adapt it for subsequent groups in different programs. From 1997 two multimedia electives were available for students in the fourth year of the primary (elementary) program – students who had barely touched a computer since a compulsory introductory ICT subject in first year. Electives were run as weekly three-hour workshops that aimed to help students develop technological fluency and problem-solving skills as they used a range of cognitive tools and experienced multimedia construction to support learning. Through 1997-1998 the lecturer was responsible for collating and archiving all assignment work so students could...
