resources to bring him to Michigan as soon as he could to share the power of digital storytelling with others
back home.

Several of his teaching partners on the Michigan Rural Voices, Country Schools team immediately
recognized themselves and their work in his five-minute personal story, and they wept and laughed all over
again when they heard and saw the story being played. Team mentor Dr. Ellen Brinkley, a WMU English
Education professor and Director of the Third Coast Writing Project, recognized its power as a professional
development tool for teachers and for pre-service teachers, and enlisted the support of Dr. Allen Webb, a
Western Michigan University PT3 College of Arts and Sciences Coordinator and English Education
professor.

The Institute

The Institute was held during a hot July week of 2001. Though the institute was scheduled to end
at five each evening, most nights participants didn’t leave Rood Hall until giving in to fatigue and hunger
between eight and nine p.m. Participants were glued to their computers and the other tools of the story-
making process: scanners, digital cameras, audio and video equipment, and the Internet. On Thursday
night, permission was secured from the university for the institute to lock up when they left, and teaching
veterans of thirty years pulled something like all-nighters to finish their stories before the institute was
scheduled to end the next day. Several of the teams took more than forty hours to produce those five-
minute stories.

On the last day of the institute a screening of stories was held at a campus reception for more than
one hundred friends and family members, teaching colleagues and school administrators, guests and
supporters from the university, and members of the media and legislative communities. Teachers briefly
introduced themselves and their pieces to the group, and then let the finished stories have their say. When
the lights came on again some forty minutes later, people got off their feet and started having conversations
with the storytellers and with each other that had been raised by the work: about teaching and technology,
about standards in education, about professional development, about best practice, and about why and how
teachers do what they do. The conversations lasted all afternoon.

Conclusion

At Western Michigan University, work continues to explore digital storytelling as a teaching and learning
tool in the PT3-supported teacher preparation program. With additional support from the PT3 project, Allen
Webb, Ellen Brinkley, and another colleague, Jonathan Bush, are teaching pre-service teachers in a
wireless lab and integrating digital storytelling into their class requirements for English education students.
They plan to invite faculty colleagues who work with pre-service teachers to participate in a seminar during
the summer of 2002 in order to extend digital storytelling into other pre-service and technology preparation
coursework.

Since last summer’s institute Corey has shown digital stories and presented on the institute to
hundreds of people from across the country. He reports that each time he puts the work in front of a new
audience, he experiences again the energy and excitement of digital storytelling that he felt when he was
introduced to it in the summer of 2000. Audiences respond both to the power of personal narrative, and to
the multimedia format storytellers have used to layer and condense each individual piece. At every
conference and forum, people introduced to digital storytelling want to know how they can do it
themselves, or how to bring a mentor to their site to lead a workshop.

We have learned at WMU that it takes a powerful application to get mentor teachers and faculty—
especially veterans—to want to integrate technology into the classroom. They have to experience the power
of technology before they will believe in it enough to use it. Yet so many technology-training programs get
the most important relationship backwards, making the technology more important than the learning it
supports. Digital storytelling does not make this mistake. It immerses storytellers into the process—to
condense their lives and teacher stories into five-minute pieces, teachers have to learn how to use the tools of technology—so in the end there is no difference between the technology and the learning that takes place. This result is precisely the goal of PT3 teacher preparation in the hands of learners who have experienced the combined power of technology and meaningful work: Teaching and learning can be fundamentally changed.

The Benefits of Streaming Media in E-learning

Rich Mavrogeanes, VBrick Systems, US

From students in an elementary school classroom to executives in a corporation, innovations in technology, particularly the introduction of streaming media in the learning environment, have made it possible for learning to be more convenient, more exciting and more interactive. For schools, streaming media has made it possible for students to learn about and understand the importance of technology, while using a new and exciting method of teaching. In universities, streaming media makes it possible for more students to take classes without incurring the cost of building new space to cater to a larger amount of students. It also makes it more convenient for students to take classes, by being able to learn from their computer, at a remote location. Finally, in the case of corporations, streaming media used for e-learning offers businesses a cost-effective and easy to implement method of training employees, which has become increasingly important in today's chilly economic climate.
Interactive computer-based technology in EFL
Alexandra McCormack

Interactive multimedia provides students with highly motivating educational environments and enhanced learning contexts. This computer-based technology allows learners to interact with a variety of multimedia elements as well as to take an active participation in their own learning process. The observation of both students’ poor language competence and lack of motivation in reading comprehension courses led to the design of an interactive multimedia program: Interactive English. The objective of this work is to present this interactive computer-based program for teaching reading comprehension to foreign language learners of English.

Recently, the popularity of the use of multimedia application in education has highly increased. The development of this educational tool has led to a redefinition of the roles of the teacher and student, has intensified teacher training in the area of computer assisted education and has also promoted the analysis of the advantages and limitations of the use of new technologies as an instruction medium. Major changes are widely observed in the utilization of multimedia programs in classroom contexts. While students become responsible of their own learning process, educators play the role of a guide in the learning process by helping students potentiate the use of technology in the process of knowledge construction.

Within this scenario, where students play a major role, it is possible to emphasize certain capacities so that students can face real life learning situations by developing ways of “learning to learn”. Thus, instead of assimilating specific concepts, students are prepared to utilize information, enlarge and process it in a variety of contexts that respond to their own interests and motivation. In this process of active knowledge construction, students are supported by computer-based technologies that provide them with opportunities for developing skills for formulating questions rather than for obtaining responses, thus arousing exploration and discovery. Moreover when students use multimedia or interactive multimedia, they must take more decisions as regards how to guide their learning, and as a result become organizers of their own process.

The development of multimedia technologies in education provide potentialities and capacities on the basis of specific technological concepts. In the development and use of multimedia applications both educators and students are encouraged to have an understanding of the concepts underlying multimedia so as to attain an appropriate selection, design and utilization of such technologies. Traditional media such as textbooks, pictures, or analog video have been used by teachers alternatively with the objective of motivating students and enhancing learning contexts. The combination of these technological media by means of computer programming results in the development of a multimedia application. Currently, computer-based technology combines all those elements or part of them in a single application allowing for direct student intervention. This focus on students’ active participation enhances their opportunities not only for knowledge construction but also for reflection on their own learning process.

This interactive multimedia application, Interactive English, has been designed on the basis of the functional approach to reading and includes functions, vocabulary and grammar contextualized in the scientific and technical field. The target audience for this program is composed of undergraduate students enrolled in Teacher Training and Reading Comprehension courses, at the Universidad Nacional de Rio Cuarto, Argentina. The audience has a high degree of extrinsic motivation as regards:

- accessing bibliography of the students’ specific field.
- achieving objectives through a non time-consuming program.
- exercising individual user control and pacing
- providing immediate feedback and response.
- allowing for different styles of learners.

The program allows for interactive practice that ensures the attainment of the instructional objectives. A non linear approach to instruction provides suitable format to attain the objectives proposed. A storyboard shows an individualized language environment, in which students are able to interact with written texts provided by the program, as well as to receive immediate feedback. The screen layout shows navigation buttons that allow students to choose which section to access: Instruction, Practice or Feedback. Each instruction section is connected to a practice section that provides a variety of activities, depending on the content and instructional objectives. From both instruction and practice sections, feedback is made available, once students have fulfilled the activities. Instructional objectives can be attained by students working at their own pace. All instructional objectives require quick accessed feedback and navigational responses. The display of this presentation exemplifies different aspects of the program taking into consideration that:
The content of the program is mainly text-based. The use of short, readable texts makes the program easily and effectively delivered.

- The program allows for easy delivery of graphics and animation.
- Content items may be accessed in a non-linear format, thus giving control to the user.
- The program provides the user editing tools and the possibility of updating information immediately.
- The program provides interactive feedback in the combination of instruction and practice.
- The program allows for alternative "hints" in the practice sections if the user needs them.

Navigation is presented through screen sequencing, starting with introductory page in which many-colored words attract the users' attention. Next, the title page Interactive English, opens up showing an "introduction" button that familiarizes the user with the main objective of the program, the intended audience, as well as with the form and function of the program. On this page there is also a "help" button that acquaints the user with the navigation buttons and other features required to move through the different sections. On the title page, a "next" button, takes the learner to the next page, containing the main menu. The main menu consists of seven text fields: Defining, Describing, Classifying, Asking/Answering, Suggesting, Narrating and Predicting. The student may click on any of these text fields and is automatically taken to a submenu providing the specific content items for instruction. Each of these content items is connected to a page containing the instruction (explanation, rule, definition or construction) and displays the context (text or graphic) to which the instruction is related. For the sake of facilitating comprehension, one text may be used as a context for instruction of different language functions, i.e., it may be shared by several other content items. Each instruction section is connected to a practice section that provides a variety of activities, such as: multiple choice, true-false, ordering, matching, completing, or drag and drop, depending on the content and instructional objectives.

Feedback is provided, once the students have fulfilled the practice activities, by showing reinforcement prompts or hints depending on whether the user provided a correct or incorrect answer. Individual scores are saved by a record-keeping feature, which can accessed from the main menu. The student is allowed back into the sub menu or main menu from any of the sections, by clicking on "menu" button. Finally, navigation buttons provide different choices, as: next, back, quit, menu. These allow the user to choose which section the user prefers. The screen layout will show small icons to help the student differentiate among the main sections: Instruction, Practice and Feedback. Other reminders of the users' navigation movements are also provided. Furthermore, multimedia elements, such as: text, images, sound icons and animation as well as hyperlinks, buttons or other clickable objects, which relate to interactive multimedia in a computer-based application are displayed.

Interactive English is available under a PC format and runs with Toolbook 4, by Asymetrix, or in a runtime version. The program can be run under Microsoft Windows and has quick access to common features of the Windows environment. The program can be accessed on a runtime version for users who do not have the full version of the program.
Adaptive Profiling Tool for Teacher Education

Abstract: In this paper we introduce EDUFORM, an adaptive questionnaire designed for profiling students in various educational contexts. The idea is to build a probabilistic model from previously gathered data, and use it for profiling other people more efficiently. EDUFORM selects the questions presented to each individual adaptively in order to minimize the number of answers needed for reliable prediction of the profile. Empirical evaluations suggest that 85-90% accuracy can be achieved, while the number of questions is reduced by 30-50%.

Introduction

The information needs involved in organizing effective education are significant. Accurate knowledge of interests, preferences, and motivation aspects is important both for the daily activities of educational institutions and for longer-term research and development efforts. In addition, computer technology enables such information to be used for the immediate benefit of the students. Self-assessment tools can be developed to offer analyses of for example learning styles or metacognitive skills, and adaptive systems to adjust the content or presentation of the material to individual needs. The problem is that nearly all of the interesting and useful information has to be provided explicitly by the students, which easily leads to excessive use of questionnaires. Besides being undesirable in itself, the tedious and sometimes frustrating answering process associated with long questionnaires is likely to reduce the validity of the acquired data.

In order to address this problem, we have developed EDUFORM, an adaptive on-line questionnaire. The idea behind EDUFORM is to build a model from previously gathered data and use it for profiling other students on the basis of a subset of the propositions in the original questionnaire. Furthermore, the propositions and the order in which they are presented are chosen on the basis of the previous answers of a particular individual. Preliminary empirical evaluations suggest that good profiling accuracy can be achieved with a significantly reduced number of propositions.

Modeling approach

The development of EDUFORM was motivated primarily by an observed need to profile students in various educational contexts. Although such profiles can in principle be derived in a theory-driven manner and coded manually, we have adopted a data-driven viewpoint, which means that the profiles are constructed from data gathered previously with similar questionnaires. This leads to the distinction of two phases in the use of EDUFORM: the Profile creation phase, where characteristic groups of students are identified, and the Query phase, where the constructed profiles are used for predicting the answers of other individuals to the same questionnaire. The design is generic and allows the application of any kind of predictive modules suitable for the task. We have adopted the Bayesian approach (Bernardo and Smith, 2000) and use the language of probability distributions to describe the profiles.

If Q denotes the filled-in questionnaire, each group Gᵢ can be described as a mechanism that assigns a probability P(Q | Gᵢ) to the questionnaire. The set of groups G = (G₁, G₂, ..., Gₖ), together with their relative sizes s = (s₁, s₂, ..., sₖ), define a finite mixture (Titterington et al. 1985) that can be treated as a probability model P(Q | G, s) = s₁ P(Q | G₁) + s₂ P(Q | G₂) + ... + sₖ P(Q | Gₖ).

As the adaptive questionnaire is being completed, the probabilities are updated to reflect the new information gained from the answers. The model is used for calculating the probabilities of possible answers to the yet unanswered questions (Qᵤ) on the basis of the answered questions (Qₐ):

P(Qᵤ | Qₐ, G, s) = P(Qᵤ | Qₐ, G, s) = P(Q | G, s).

We can also keep track of the probability that the person belongs to a particular group Gᵢ. If we denote by g the event that the person belongs to the group Gᵢ,

P(g | Qₐ, G, s) = P(g | Qₐ, G, s) = P(g | G, s) P(Qₐ | g, G, s) = sᵢ P(Qₐ | Gᵢ).

The two calculations above let us try to adapt the order of the questions so that we can predict the answers of the unanswered questions confidently enough and/or be confident about the group membership of the student based on as few answered...
questions as possible. Johnson and Albert (1999, 191) have proposed an alternative approach based on the estimation of item specific
model parameters.

Construction of finite mixtures from data is described in Kontkanen et al. (1996) and Tim et al. (1996). The underlying
intuitive idea is to describe the data vectors with respect to a set of prototypes, so that the description of an individual vector consists
of the index of the closest prototype and a list of differences between the expected and observed values. Alternative definitions of the
prototypes can be evaluated on the basis of the amount of information needed to describe the entire data set: the more representative
our prototypes are, the fewer differences there are between the data vectors and their associated prototypes. In addition to being of
significant interest in itself, the resultant model is suitable for the kind of prediction needed in the Query phase.

EDUFORM

Even though EDUFORM is an electronic questionnaire on-line, it resembles traditional questionnaires on paper (Fig. 1). A
few multiple-choice questions are presented at a time, with the possibility of adding comments. The navigation bar is at the bottom.
The arrows on the right allow the user to move to the next or previous set of questions. Clicking the button with the pie chart icon
shows the current profile. When the profile of the user is known with sufficient certainty, the user can quit filling in the questionnaire
before all questions have been asked by clicking the 'cross' button on the navigation bar. On the left, there is a progress indicator
showing an estimate of the amount of questions left. Because of the simplicity of the interface, there has been no need for a separate
help screen. The meanings of the buttons are shown as tool tips (in Fig. 1, the word "Next" above the mouse pointer).

Adaptation in EDUFORM

In the Query phase, we want to find out the profile of the student as efficiently as possible. The profile is represented by a
probability distribution over the groups identified in the Profile creation phase. As the student answers the questions, some of the
groups become much more likely than others, and one of them often reaches almost 100% probability reasonably quickly.
EDUFORM takes advantage of this characteristic pattern by optimizing the order in which the questions are presented, and offering
the student an opportunity to quit once sufficient certainty about his profile has been achieved.

At any point in time, the most informative set of questions to ask next is the one that changes the profile distribution most.
EDUFORM searches for this set by maximizing the expected Kullback-Leibler distance (Cover and Thomas 1991) between the
current distribution and the distribution that would result if answers to a particular set of additional questions were received. The first
questions are the same for everybody, but after that the selection depends on the previous answers of each individual. Therefore,
adaptation in EDUFORM is based on continuous assessment of the expected information gain, rather than being limited to a small
number of hard-coded paths.

Figure 1: The user interface of EDUFORM.

The purpose of this technique is to minimize the amount of questions needed to find out the student’s profile. Additional
questions can be omitted entirely once a sufficient degree of certainty has been achieved. In the current experimental version of
EDUFORM, the termination criterion is defined by setting a limit, which the most probable group in the profile has to exceed. A
limit of 75% to 85% seems to be a suitable range in most cases. It is also possible to specify an additional requirement regarding the
stability of the profile. For example, it may be stated that the most probable group has to stay above the limit for two successive sets
of answers.

Figure 2 shows the format in which the data is saved. The first column identifies the person. In this particular case, a unique
identification string has been created from the questionnaire name ("demo") and a counter. The questions appear in the same order as
they were presented to the user. Question numbers are in the second column. The remaining columns contain the probabilities of the
alternative answers. If the user has actually answered the question, one of the probabilities is 1 and the rest are 0. Probability
distributions for the omitted questions are calculated by the model and saved in the same file. In Figure 2, the first four questions have been answered by the user, and the last two rows are predictions. Additional data include comments, the final profile, and a log of mouse clicks. The main purpose of the log is to record the time used for answering various parts of the questionnaire, but it may also turn out to be helpful in identifying ambiguous questions or making detailed analyses of differences between groups.

| demo-1  | 33 | 0.0 | 1.0 | 0.0 | 0.0 | 0.0 |
| demo-1  | 15 | 0.0 | 1.0 | 0.0 | 0.0 | 0.0 |
| demo-1  | 10 | 0.0 | 0.0 | 0.0 | 1.0 | 0.0 |

| demo-1  | 11 | 0.0084 | 0.0086 | 0.0422 | 0.2451 | 0.6954 |

Figure 2: Format of the saved data.

Empirical results

Perhaps the most important question to ask when judging the value of EDUFORM is whether or not it actually works. The number of answers needed for reliable profiling should be significantly smaller than the total number of propositions in the questionnaire. We would also like the users to benefit from adaptivity and quit when they are offered a chance to do so.

In order to evaluate the predictive performance of EDUFORM, we simulated the operation of the adaptive questionnaire using complete data. The models were constructed from 200 randomly selected cases in each data set, and the remaining test cases were supplied to the models exactly as they would have been received during the course of adaptive questioning. The number of answers given before the fulfillment of the termination criteria was recorded, and the group predicted at that point was compared to the group assigned at the end of the questionnaire. If the predicted group did not match the final group, an error was recorded.

Table 1 shows the main results of the simulation. Two different data sets were available from a questionnaire (Ruohotie 2001) with four sections: “Learning and motivation” (Motiv in Tab. 1), “Study habits” (Habits), “The quality of teaching” (Teaching), and “The effects and outcomes of education” (Effects). Although the sections measure complementary aspects of the same educational setting, they are in the present context best thought of as separate questionnaires. The last data set (Motprof) is from a questionnaire designed for identifying motivational profiles. The second and third columns contain the number of groups defined during model construction and the total number of questions in the questionnaire. The average proportion of questions needed for predicting the group of a test case is in the column labelled “Questions asked”. The next two columns contain the standard deviation of questions asked and the proportion of test cases for which the final group differed from the group predicted upon the fulfillment of the termination criteria.

Table 1: Predictive performance of EDUFORM.

As can be seen in Table 1, an average of 50-70% of the questions had to be asked to achieve an error rate of 10-15%. Every data set contained a few exceptional cases for which 100% or only 15-30% of the answers were needed, but the standard deviations were consistently within 20-25% of the total number of questions in the questionnaire.

The trade-off between questions and errors can be altered by adjusting the termination criteria. The more uncertainty we accept in the profile, the fewer questions need to be asked. Figure 3 shows the effect of additional answers in the Motprof data set. On the horizontal axis we have the number of answers given, and on the vertical axis the average Kullback-Leibler distance between the predicted and the final profile. By setting the termination criteria to appropriate values, questioning can be stopped approximately at the desired point along the line.
Figure 3: Reduction in the distance between the predicted and the final profile.

At the time of writing, two data sets had been gathered with the adaptive version of EDUFORM. The same sets of questions were used as in the simulation study described above. Of particular interest for the present purpose is the attitude of the users towards prediction. When their predicted profile satisfied the termination criteria, they were asked if they want to quit or refine the profile by answering the remaining questions. They could also quit after answering only some of the additional questions. The decision to quit or continue can be seen as a reflection of the user’s opinion about the usefulness of adaptation in EDUFORM.

The results are summarized in Table 2. The first four questionnaires were parts of the same study, and were completed sequentially during one session. The subjects were students from a teacher training programme in the Finnish Polytechnic Institute. In the other study (“Motprof”), motivational characteristics of engineering students from Helsinki University of Technology were examined. The second column contains the proportion of users who quitted before answering all questions. Unfortunately, it seems that adaptivity was not appreciated as much as we thought. The third column shows the number of questions answered by the students who did take advantage of the adaptivity. The second part of the first study (“Habits”) was the longest one with 40 propositions. The proportion of answered questions is high because many students gave a few more answers after they had the first chance to quit, but got tired before the end.

Table 2: The adaptivity of EDUFORM in real use.

Conclusions

EDUFORM is a tool to provide questionnaires with reduced sets of questions. The operation (i.e. the adaptation of the amount of questions) is independent from the questionnaire content. This domain-independence of the adaptation mechanism opens up the possibility to use EDUFORM for more than just a single purpose. For example, EDUFORM can be used in assessing individual differences on-line to support studying in a virtual or traditional campus university. Suitable support material for student self-evaluation could be a questionnaire that provides information of how to study efficiently.

A questionnaire in EDUFORM can also be used as a test for students. Testing the students’ knowledge on the basis of adaptive questioning is not a novel idea. However, the standard approach is that the system adapts directly to the knowledge of the student. When using EDUFORM as a test, adaptation means the optimization of the length of the test. In other words, the goal is to provide the teacher or evaluator enough information about the students’ progress with as few questions as possible.

Because of the particular approach to adaptation, EDUFORM can also be used as a tool for creating user profiles for adaptive educational systems. Sufficient knowledge of the characteristics of the user is a necessary prerequisite for effective adaptation. Some systems are able to accumulate useful data during the course of the interaction, but additional input must almost always be provided explicitly by the user (Brusilovsky 2001). EDUFORM can be employed to gather this information efficiently and create probabilistic user profiles for direct application in the adaptive educational system.

Learning about Learning Objects with Learning Objects

Sandy Mills
AliveTek, Inc.
Seminole, Florida
United States
sandy@alivetek.com

Abstract: The term "Learning Object" has been getting a bit of attention in the world of online education lately, but very few completely understand what a learning object is. There are many definitions out there, but because text is used as the medium, the true meaning is often missed. This paper has been written to further define the term, and to serve as a compliment to an interactive session that will allow participants the opportunity to investigate various learning objects. Since learning objects are usually designed for active learning, this interactive session will allow for participants to see, hear, and interact with learning objects of varying educational levels and subjects. Samples will include objects created with Flash, Director, Shockwave, and interactive databases. Issues such as developmental skill level, funding and organizing learning objects will be discussed. Resources include some of the latest research on learning objects, as well as URL's for online repositories that can be shared with teachers from around the globe.

Introduction and Definition

Many have attempted to define the term, “learning object,” but with the rapid pace of technological advancements and web-based learning theory evolution, the definition is still taking shape. There are many commonalities among the prominent definitions provided by leading researchers, but the exactness of what constitutes a learning object is still being discussed. In many instances, the technical specifications are close to becoming defined as many standards-setting organizations attempt to organize and standardized digital content (Saad, Uskov), but often in these definitions the educational dimensions are barely touched upon or ignored all together.

There are some rather enticing grants offered by educational organizations such as the National Science Foundation (https://www.fastlane.nsf.gov/servlet/A6QueryList) to further advance research in this area but most studies are focused on the technical parameters for the purpose of tagging and storing objects and are in early stages of research. As well, the training and development industry is also attempting to leverage the power of reusable and portable learning objects to further strengthen the argument for designing and developing such items. Organizational leaders such as Cisco, Honeywell, and American Express have all implemented learning object approaches to increase the effectiveness of their learning materials.

Longmire attempts to combine both technical elements with educational elements when he cites “flexibility, ease of updates, searches and content management, customization, interoperability, facilitation of competency-based learning, increased value of content” as advantages of designing and using learning objects. Barron cited Longmire when he wrote, “A new model for digital learning—one in which learning content is free from proprietary ‘containers,’ can flow among different systems and be mixed, reused, and updated continuously is inching closer to reality. At the center of this new model is the learning object, the modular building block that allows such a dynamic approach to managing elarning content.” WBT Systems Ltd. is very focused on providing a learning objects library infrastructure, and wrote in the company’s 2001 white paper, “At its simplest level, learning objects are re-usable building blocks of learning” and points out that it is rather difficult “to quantify how big or small a given Learning Object should be….because the appropriate definition of size depends on many factors such as: subject being covered, instructional design philosophy applied, and media tools being applied.”

Another definition reads, “You can think of learning objects as knowledge granules created by specialists throughout an organization and that are accessible to many others in the organization.” Clark breaks
the term into two classes—1) information or knowledge objects and 2) instructional objects, where the first is the information needed to learn, and the second is the activity or practice exercise that reinforces the first. Learning objects share common characteristics based on the above definitions and current research.
The Use of Internet2-based Videoconferencing in Teacher Education

Abstract: Internet2 has a great potential for high quality videoconferencing. Although over 180 American universities collaborate with each other through Internet2, it is still a blurred concept for many teacher educators. In this study we have interviewed teacher educators who are using Internet2 in their teacher preparation courses, and asked them its pros and cons as well as their projections for K-12 schools.

In recent years one of the most popular terms in technological world is Internet2 even though many do not know what exactly it is and what it does or can do. "Internet2 is, basically, a collaboration of over 180 United States universities, teamed up with industry and government, to develop advanced Internet technology and applications for high-end academic experimenting and research" (CNet, 2001).

At the first sight, Internet2 looks very similar to the actual Internet: the data may be seen in a web browser and it is just a bigger pipeline to transfer data. However, Internet2 has some key qualities, which might have critical implications for instruction. It is faster, with data transfer rates in gigabits, and it is more reliable, because it has safeguards to make sure data packets are delivered. One important point we need to emphasize is that Internet2 uses Internet Protocol version 6 (IPv6) instead of current Internet Protocol (IPv4). The advantage of IPv6 is that it incorporates native multi-casting, high reliability and high capacity. It also allows applications requiring high bandwidth to coexist with each other simultaneously. These qualities also remind us requirements/needs of high quality Internet applications such as videoconferencing systems.

Although Internet2 is only available to a restrict number of institutions, it is expected that the technology will be available to everyone in the near future. This means that the use of Internet2 will expand to schools, community colleges, museums and libraries giving the chance of streaming videoconferencing and other applications. These also means that adapting these applications to the needs of K-12 institutions will require some work, not only in technical or financial terms but pedagogical too. The International Society for
Technology in Education (ISTE), the Consortium for School Networking, and Educause are a few of the groups involved in several educational projects for Internet2.

Although Internet2 is a high-speed network primarily reserved for research institutions, there is a big need about its use in educational settings. In this study we have videotaped teacher educators from Center for Technology in Learning and Teaching (CTLT) at Iowa State University to illustrate its use at university level. Since the CTLT is being the leader of advanced technologies and their use in teacher education we have found it as a great opportunity to apply our study. The selected teacher educators of CTLT are primarily using Internet2 for videoconferencing with other universities to collaborate in research projects as well as to put together students from different universities to share knowledge and to collaborate in various courses’ activities. These teacher educators are also using the Internet2 videoconferencing capabilities to share their expertise with other institutions as well as bring experts from other universities to their classroom environment. Their opinions about advantages and disadvantages of this powerful technology and their projections for K-12 schools are also discussed.

Higher Education and the Internet 2 Project: implications for educational practices

Roberto G. Pérez Galluccio

rgpg@technologist.com

Abstract: This short paper is geared towards those higher education professionals engaged in the design, development, implementation or management of internet-based resources and activities. The Internet 2 Project, a collaborative, cooperative effort carried out by higher education institutions in the United States, is set to revolutionize the way we look at educational communications and technologies. Current design constraints will change radically, forcing higher education professionals to redefine their practices, e.g., their web design strategies, as well as their use of the Internet. This paper provides a heads up on the potential offered, as well as the problems posed by, this cutting-edge technology.

Introduction

Those professionals in higher education who have been involved in the design, development, implementation or management of internet-based materials and activities, have surely more than once heard expressions like: "There's not enough bandwidth", or "The net is clogged", or simply "It can't be done". What's more, some of those professionals might have found themselves using those same expressions, when they tried to incorporate sound or even video to support teaching/learning experiences over the Internet.

Those times seem to be changing fast, mainly thanks to the Internet 2 project, the high speed, next generation academic network that is ready to boost multimedia applications delivered to remote locations.

The Internet 2

This project dates back to 1996, when a group of university and corporate researchers in America [1] started working full time in what has come to be known as the Internet 2 Project [2]. Members of the project have been doing what they know better: academics have been developing instructional content and applications, corporate members have been working on the software and hardware needed to support those applications.

The basis of the Internet 2 is its high speed -hundreds of times the actual speed- which will allow for the delivery of interactive, real-time instruction between remote computers; the sharing of digital (video, audio) libraries; the use of shared virtual reality environments, and every other research and learning activity professionals in the field may think of.

This is of special importance to the areas of web-based training and distance education, which are constantly increasing both in popularity and in technological advances.

The web-applications educators work with will then be delivered through the Abilene Network [3], the backbone of this new superhighway, that already runs from coast to coast in the United States, linking universities nationwide [4]. Unlike the current Internet, only academic and research centers can be part of this new network, which is
seamlessly connected to the present-day Internet. This means that (a) both the current Internet and Internet 2 coexist and work together, but (b) only universities connected to the Abilene Network benefit from this high speed, and (c) only universities can create content for the Internet 2, making it a purely academic network (i.e. no e-commerce will exist there).

Those higher education professionals involved in distance education, for example, who have faced problems while working with multimedia applications delivered to remote locations, will now find that their technological constraints will be changed dramatically (in a positive way) by this new network.

Some problems

As far as the field of distance education is concerned, it is to be noted that distance learners at home will not benefit from this high speed. However, those attending classes at participating Internet 2 universities will be able to engage in collaborative, interactive activities that will overcome the limitations of audio and video broadcast over the current Internet.

There are, thus, some limitations for those outside campus, or in non-university settings: they will need to be on-campus if they want to take advantage of Internet 2. Also, for those universities outside the United States, the Internet 2 will not be available, until they create a local high-speed backbone (similar to Abilene), and connect it to similar backbones in other countries.

However, things are moving ahead quickly, and there are a number of Internet companies from around the world [5] already lined-up to work with the Internet 2 project.

Thus, as soon as the international academic world is interconnected, there will be real possibilities for distance educators in university settings to design and implement Internet 2-related teaching/learning experiences worldwide.

Conclusion

As professionals in the field of education committed to using new technologies to improve the quality and the effectiveness of our teaching activities, the Internet 2 has direct implications for us. The description of the Internet 2 project included in this paper, together with the reflections on its advantages and disadvantages, its potential and its shortcomings, acquire special importance given the constant development of Internet-based applications and technologies in recent years. It is to the advantage of higher education professionals to update their knowledge on the development of the Internet, so as to be able to redefine current strategies, methodologies and procedures when designing web-based instruction or Internet-based activities. Hopefully, this paper will serve as a trigger to motivate the reader to contact their local Internet 2 groups in their institutions, in order to get involved and take a proactive role in the use of this new medium.

Teaching Teachers to Teach Internet Health

Frederik Tautz
ECC Online Relations GmbH
Germany
f.tautz@pobox.com

Abstract: Health-related websites are among the most frequently accessed resources on the Internet. Most young people have already researched the Internet for health matters, more than a third have even changed their behavior because of the information found. But, to some extent, the health contents on the Internet are misleading or even "quacky"- and chances are good that false information will prevail on the Internet: regulation or quality-checking of health-related contents is not very likely within the next few years. Therefore the assessment of quality is for now left to the individual. This paper is a call for action for teachers and offers practical advice on how teachers can start immunizing their students against misleading health information found on the Internet.

Introduction to Young Online Health Seekers

For years now websites providing health information have been among the most frequently accessed Internet resources in the US (GVU 1998). Topics published on these websites cover every aspect of health ranging from anecdotal directions for a healthy lifestyle to well researched clinical guidelines. The information found on the Net not only influences people's health beliefs but also their medical decision making (for a more thorough discussion of this topic, see Tautz 2002). This behavior can also be seen in young online users as reported by a recent representative survey by the Kaiser Family Foundation (Kaiser 2001): About 90% of all young people aged 15-24 in the US are online today, 75% of them have already used the Internet to look up health-related information - compared to 60% of adults online (Pew 2001). What the young find on the Net appears very useful to them (39%, only 6% not so useful), and often so striking that they change their behavior on the basis of the information they have found online (39%).

According to their answers young people get as much health information from the Internet as they get from friends or magazines. While parents, teachers and doctors are the primary and most respected sources for health-related information, many young people rely as much on Internet information as on knowledge obtained from peers or printed magazines. In addition young people say it is better to look up information on the Internet than to ask teachers (young online 58%: 41%, young online health seekers 63%:37%) and friends or to turn to the mass media. So "the time has clearly come to focus more attention on the role of the Internet as a health educator. Additional research (...) would be helpful, including the quality of online health information for young people ..." (Kaiser 2001).

The Quality Issue and a Possible Solution: The Informed Prosumer

As the Internet is a mass medium open to contribution from everyone without any peer-reviewing or independent editorial control, the quality of health-related information on the Internet is often doubtful (i.e. Pandolfini et al. 2000). An official body that effectively assesses the quality of online health information on a large scale is far from being realistic (Tautz 2002), the only ad hoc feasible way to protect people from the effects of bad information is to help the information-consumer to evolve to the stage of the informed prosumer. But to assess the quality of the information, consumers must have access to effective yet easy to use tools and must be educated to use these tools. As the Internet is now a tool as well as a teaching topic in most schools, teachers are in the best position to help young people to become informed prosumers. Teaching them to assess quality is one of the most important issues because: "[i]ncreased access to health information could create a more informed and healthful youth. On the other hand, if the quality of online information is not high or the source unknown, increased reliance on the Internet could lead to greater misinformation and skepticism." (Kaiser 2001). Teachers train their students to use the Internet. But do they train them to use its contents?

What Teachers can do to immunize Students against Misleading Health Information?
Make it a topic in class: General Internet classes, science classes or even English classes might be suitable for discussing the topic with your students. To introduce the topic i.e. in an English class you will find a service called "Hitting the Headlines" a valuable resource (http://www.nelh.nhs.uk/hth/archive.asp). This is a service provided by the The National Electronic Library for Health (which itself is a contribution by the British Health Authority). In "Hitting the Headlines" you will find summaries of health stories recently published in national newspapers together with a complete assessment of the story written by medical experts. Using the assessments you can demonstrate how misleading information can develop "by accident" from simply making up a news story for lay media using medical information. For an Internet or science class you might want to introduce the topic by asking your students to do simple research on the Internet in order to advise parents how to deal with children's coughs. The same Internet research was done by medical experts who assessed the results for general quality, accuracy and reliability. As their method, the medical background and the findings are very well documented (see Pandolfini 2000; full text accessible online) you can just let your students take whatever they found on the Net and assess its quality by comparing it to the article.

Introduce the proper assessment tools: There are two top sources for obtaining information on assessing the quality of a medical website. One is the Health on the Net foundation (http://www.hon.ch), which offers a "Code of Conduct" for the provision of medical information on the web. The other – more practically oriented website is DISCERN (http://www.discern.co.uk) "Despite a rapid growth in the provision of consumer health information, the quality of the information remains variable. DISCERN is a brief questionnaire which provides users with a valid and reliable way of assessing the quality of written information on treatment choices for a health problem." (Discern 2002). Let your students review the commandments on www.hon.ch, let them use the DISCERN questionnaire to assess a good and a goofy website and then discuss the findings in class.

While using the DISCERN tool in class, proceed to show examples of good resources and explain why they are good resources. Of course the Internet offers plenty of high quality health information. You might want to show your students http://www.nlm.nih.gov/medlineplus/tutorials.html. The tutorials explaining a procedure or condition are a good starting point for demonstrating what the Internet has to offer in health-related information, as they stand out because of their very colorful and animated Flash-Movies. They are also very easy to understand.

Show examples of bad resources and highlight the intentions of the authors: A good starting point for choosing a "quacky" site to show to students is Stephen Barrett's website Quackwatch.com. This website "combat(s) health-related frauds, myths, fads, and fallacies (and provides) quackery-related information that is difficult or impossible to get elsewhere" (Barrett 2002).

Explain where to start researching for high quality health information: Let your students use Healthfinder (http://www.healthfinder.gov/) or MedHunt (http://www.hon.ch/) to research a given condition, let your students then use DISCERN to assess the articles they have found.

Inspired by Inspiration

Leo Wells, Barat College of DePaul University, US

Inspiration: The Program

Inspiration was developed in 1999. It is a product of Inspiration Software Inc. A companion product, Kidspiration exists to allow lower grade students a much more visual and kid-friendly experience with the Inspiration concept. I am using Inspiration for not only this submission, but also the outline for another paper at SITE this year.

Concept mapping with Inspiration as its model has been discussed in the literature already (Scappaticci, 2000; Vojtek and Vojtek, 2000).

How Inspiration works

Inspiration is cross-platform, and works in Windows as early as version 3.1; Macintosh OS on Power PC with System 6.0.4 or higher. Inspiration is network compatible.

Fundamentally, Inspiration works in two contrasting modes. Diagram mode is where the "concept map" is best displayed. Ideas are literally "thrown" onto the screen and linked together. Outline mode literally makes a traditional outline of the concepts earlier shown on the diagram. The user moves back and forth between the modes, arranging and modifying the material for the user's purpose.

We have found that Inspiration works best with learners when there has been little formal instruction. Rather, the "learning by doing" method seems to work best for us in using this product with learners.

Inspiration: Audience

The Inspiration audience is generally assumed to be students. However, it can be effectively used wherever it is found. We are looking at SITE attendees that may not have the opportunity to use this type of software in their regular duties. Those that interface with K-12 educators and college-level trainers will be more likely to have had experience with Inspiration.

Educators

Educators can do a myriad of things with Inspiration, planning, mulling over ideas for lessons, preparing written reports, etc.

Students

Students can develop individual ideas, or work in cooperative groupings to plan or discuss ideas. Students in upper grades will be able to prepare, organize, and largely outline written assignments. The product Kidspiration will do similar functions for students in lower grades.

Everyone

Indeed, the uses for Inspiration seem to be endless. Anyone who needs to put ideas together can first put them in a visual form with Inspiration in its Diagram mode.
Session Objectives

We want all attendees, regardless of their role to experience Inspiration and discover the potential it can have for their own role in education, business, or whatever. No experience with Inspiration is expected or required. Indeed, we want attendees to enjoy this software and have fun with it.

Inspiration: Benefits

On the surface, Inspiration is a good organizer, but higher order thinking skills are also in play. Users can see how ideas are connected, construct ideas in a more meaningful way for the individual learner, discover how new knowledge can be integrated into the learning matrix, and find out how misconceptions can be more easily identified.

We would want to have three or four laptop computers with Inspiration already installed for session attendees to enjoy this fun and interesting software. We can provide these laptops if necessary.

Abstract: This paper questions the robustness of empirical evidence regarding technology's ability to promote increased learning. The use of a new technology, by itself, does not seem to increase student learning. Most evaluation research has found that learning can take place with any technology-based medium. However, the literature has shown a significant interaction between instructional approach and student learning style. The introduction of educational technology into the classroom likely affects the patterns in the relationships among variables associated with teaching and learning.

Technology Based Learning

Not long ago, an educator asked to name the tools of technology based learning, would perhaps suggest chalk, a mimeograph machine to cut stencils for handouts, or transparences and an overhead projector. Now, because of the rapid rate of technology improvement, the toolkit is so much fuller. The use of the term educational technology is often less than precise. Thompson, Simonson, and Hargrave (1992) placed educational technology research into five categories which include: (1) evaluation research, (2) media-comparison studies, (3) intra-medium studies, (4) aptitude-treatment interaction studies and (5) alternative research designs. Evaluation research concerns itself primarily in testing the extent to which student learning is impacted by a new medium. Most evaluation research has found that learning may take place with any technology-based medium. In contrast, media-comparison studies compare one type of medium to another or to conventional instruction to determine impact on student learning. These studies, however, have been mired in controversy since the early 1980s when it was suggested that media were mere vehicles that deliver instruction without influence on student achievement.

Ester (Winter94/95) has demonstrated that computer-assisted instruction (CAI) may improve achievement and student attitudes while decreasing instructional time. Ester was, however, concerned about a possible discriminatory effect of CAI on students with different learning styles. He conducted empirical research seeking to determine if student learning style interacted with CAI, and found a significant interaction between instructional approach and student learning style. In effect, abstract learners demonstrated significantly higher achievement with the lecture approach, while concrete learners performed equally well with lecture and CAI.

The literature suggests that student learning styles vary with: (1) age, (2) achievement level, (3) culture and (4) global versus analytic processing. In addition, learning styles have been found to vary within the family. First-born children tend to reveal characteristics of one of their parents while second-born children often evidence characteristics of the other parent. In contrast, the third-born child has a style very different from both older siblings. Several different learning style definitions and inventories have been developed. For example Grasha and Yangarber-Hicks (2000) defined learning styles as the preferences students have for thinking, relative to others and particular types of classroom environments and experiences and created a model of teaching styles used in the classroom which include: (1) expert, (2) formal authority, (3) personal model, (4) facilitator and (5) delegator. The expert style takes the attitude that
“facts, concepts, and principles are the most important things that students can acquire” (Grasha, 1994, p. 19). Formal authority says “I set high standards in this class” (p. 19). Their personal model suggests that “what I say and do models appropriate ways for students to think about content issues” (p. 19). The facilitator adopts the notion that “small group discussions are employed to help students develop their ability to think critically” (p. 19), while the delegator says that “students in this course engage in self-initiated self-directed learning experiences” (p. 20).

Grasha and Yangarber-Hicks (2000) empirically studied the notion that the teaching style of the instructor should be adapted to fit with the learning style of the student. The authors suggest that faculty members need to think about how technology fits into their philosophy of both teaching and learning. While they found that the effect of the introduction of technology on teaching style, learning style, grades obtained and course satisfaction was not robust, the effects of the absence of technology could be observed. Therefore, the introduction of educational technology into the classroom likely affects the patterns in the relationships among variables associated with teaching and learning. Other studies suggest four strategies to develop the compatibility of teaching and learning styles using technology. These strategies suggest an alignment of teaching styles which reinforce specific student learning styles in conjunction with the use of technology. The first strategy uses the expert and formal authority teaching styles to reinforce dependent, participant and competitive learning styles. The second strategy uses the personal model, expert and formal authority teaching styles to reinforce dependent, participant and collaborative learning styles. The third strategy uses the facilitator, personal model and expert teaching styles to reinforce independent, participant and collaborative learning styles. Here, faculty create activities, facilitate interactions and direct instructional processes with a plan to encourage active learning. The fourth strategy uses the delegator, expert and facilitator teaching styles to reinforce independent, participant and collaborative learning styles. Here, the faculty member adopts the role of consultant to students.

Conclusion

Critics may provide a useful service in providing a healthy skepticism about the potential of technology in the classroom. Empirical evidence regarding technology’s ability to promote increased learning is not robust. The use of a new technology, by itself, does not seem to increase student learning. According to Neal, (1998) those who promote technology often emphasizes the delivery of instruction, rather than improved learning for students. In fact, technology often leads to less face-to-face contact among teachers and students, which may result in the promotion of an impersonal atmosphere.

Most evaluation research has found that learning can take place with any technology-based medium. The literature has shown a significant interaction between instructional approach and student learning style. The introduction of instructional technology into the classroom likely affects the patterns in the relationships among variables associated with teaching and learning. In addition the notion of using educational technology to tailor the faculty member teaching style to fit that of the student learning style may be useful. More research needs to be done in this area.

Abstract: This session describes the distinct approaches employed by four of five Colleges of Education in the Greater Cleveland area partnering in the implementation of the MIMIC Project (Modeling Instruction With Modern Information and Communications Technologies), a Preparing Tomorrow’s Teachers to Use Technology (PT3) Implementation Grant. The common goal of this partnership is to increase the level of educational technology modeling in pre-service teacher education classrooms and field experiences. Each institution outlines different methods for technology integration unique to the needs of their specific constituency.

Introduction

The Modeling Instruction with Modern Information and Communications technology (MIMIC) Project is funded by the U. S. Department of Education PT3 program. The overarching PT3 goal is to prepare new teachers to effectively use technology in their teaching. The MIMIC project includes five Cleveland area colleges of education (Cleveland State University, Baldwin-Wallace College, John Carroll University, Notre Dame College of Ohio, and Ursuline College). Each of the partners conducts professional development activities for higher education faculty and classroom teachers involved in pre-service teacher preparation. The teacher preparation programs vary across the five institutions. To accommodate these differences, the MIMIC project supports local management of professional development efforts while promoting the exchange of ideas and solutions across institutions. Despite programmatic differences, all of the partner institutions are guided by a commitment to prepare pre-service education students to effectively integrate technology into K-12 teaching.

Cleveland State University (CSU) serves as the lead institution for the MIMIC Project. Implementation of the MIMIC project was influenced by experiences gained from a one year Capacity Building grant (Abate, 2000). Practices that proved successful during the Capacity Building year were continued in the Implementation project.
Four implementation features have proven critical to the success of the CSU implementation of the MIMIC Project. These features entail: 1) the use of K-12 classroom teachers as mentors for higher education faculty; 2) a focused project management scheme; 3) a sophisticated evaluation plan; and 4) individualized professional development for higher education faculty.

K-12 Classroom Teachers as Mentors. CSU was fortunate to have experience with incorporating the services of master classroom teachers into teacher preparation programs from 1982 to 1990 when the College of Education conducted a K-12 visiting instructor program that featured team teaching of methods courses by higher education faculty and classroom teachers (Takacs and McCordle, 1984). The MIMIC project extends this approach by employing technology-proficient classroom teachers in the mentoring of higher education faculty in educational technology. The K-12 teacher as mentor arrangement provides several benefits. The mentors serve as a support structure for bridging theory and practice. Also, during visits to their mentors' classrooms higher education faculty gain first hand experience of technology integration in "real" classroom settings. On occasion, mentors team teach with faculty in pre-service classes. Most importantly, the classroom teacher mentors supply technical, pedagogical, and content expertise to the mentoring process. The inclusion of classroom teachers in the process has also helped to establish a greater sense of community among CSU MIMIC participants.

Project Management. The goals of the Implementation project include support for the professional development of higher education faculty, the organization of professional development for the classroom teachers who accept pre-service students in field placements, coordination of partner programs, budget oversight, and dissemination efforts. Management of a project servicing five institutions, a diverse higher education faculty, full-time classroom teachers, technology service providers, and hundreds of pre-service teachers is an immense and complex undertaking. In addition to a Project Director, the MIMIC Project employs a full-time Project Coordinator who manages both the everyday and long term objectives of the project. Coordination of the MIMIC Project has a "job description" unique unto itself. Requirements include such unique skills as knowledge of K-16 academic environments and the ability to match personalities, content foci, and technology expertise with needs while setting up and sustaining faculty/mentor teams. Flexibility is a key aspect of Project coordination since the events of any given day may range from conference travel questions, article editing, equipment crises, budget attention, meeting planning, report compilation, and filing. To accomplish this, a Project Coordinator must be able to envision order in chaos and appreciate the intrinsic reward of in seeing the Project goals accomplished on a daily basis.

Evaluation. Project evaluation activities address both formative and summative evaluation questions that examine the validity and impact of the project. A local evaluator directs the evaluation effort for CSU and the partner institutions. The evaluator works closely with the project team to ensure that planned activities occur as scheduled. Progress is recorded via monthly review forms. The evaluator meets with the project team on a regular basis to provide formative reviews and to provide suggestions and modifications for planned activities.

Baseline data is collected via surveys to identify the technology proficiency of higher education faculty and supervising teachers. Information collected from the surveys is used to tailor mentoring, develop specialized workshops for College of Education faculty and to schedule instructional workshops for classroom teachers who supervise pre-service teacher field experiences. Mentors prepare an implementation plan with each faculty member and maintain notes on the support provided. This qualitative data is used to modify mentoring plans. A pre-post review of syllabi developed by the participating faculty members offers qualitative data that documents technology use by participants. End-of-the-year surveys, including a technology use follow-up, are administered to furnish a picture of faculty and supervising teacher skill development. Evaluation is ongoing and the constant interaction among the evaluation team, the participants, and project management leads to timely and effective action. Evaluation is interwoven into the fabric of MIMIC activities. As a result the evaluation team is directly engaged as a partner in the success of the project.

Individualization. The cornerstone of the CSU implementation is the individualized professional development provided participants. All professional development is derived from a "bottom up" perspective.
Novice, intermediate, and advanced faculty participants are encouraged to develop plans that best meet their interests and skill level. Mentors for faculty are selected based on how well their knowledge and skills meet the needs of a faculty member. As a result, mentoring is focused on individualized needs, and acceptance of the technology integration plans by higher education faculty is very high. The Project team also supports individualized technology skill development through selected workshops and continuous technical support. Individualization is further addressed with classroom teacher participants via a wide range of specialized workshops typically tied to specific content areas. As a direct result of this individualization faculty are more likely to fulfill the objectives of the project.

Overall the success of the CSU implementation revolves around the plan, the purpose and the people. Project team staff, participants and evaluators pursue goals that offer individual attention while addressing the larger purpose of the Project. Finally, the people involved in the CSU MIMIC Project see value in the purpose and are highly motivated to achieve this purpose.

Baldwin Wallace College

The MIMIC Project at Baldwin-Wallace College is alive and very involved over the past two years of work. BW has taken advantage of its position as a premier teacher training institution to spread classroom technology skills throughout the campus by pairing pre-service teacher candidates with both education and general faculty. Transformational and measurable results have been achieved. Within the education program, faculty members have adopted both PowerPoint and web resources into their regular classroom routines.

Students are encouraged to enhance their presentation skills through the inclusion of technology-based content. Additionally, a growing number of the faculty members are in the early stages of extending their classroom contact via implementation of BlackBoard postings and discussion exchanges. At BW our method of project management is one that attempts to direct the faculty to actively adapt their course syllabi by infusing technology where appropriate. In the academic year of 2000-2001 we had eight faculty members mentored on our campus. In the current year of 2001-2002 we have six additional faculty members being mentored. What follows are highlights of the accomplishments of these two years of work.

Year 1: 2000-2001 List below are some of the highlights of the first year of the project on BW campus. All of these faculty members were novice technology users prior to the Mimic Project.

- The development of the first online web-based course on our campus – The Geology of the Rocky River Reservation. This resulted in the professor leaving the techniques of Blackboard and creating a CD as a field manual and guide for the students. This same professor then served as the mentor for another professor the following year to creating a CD lab manual for Microbiology.
- Four of the education faculty developed courses in Blackboard (campus adopted) and began development of the creation and use of PowerPoint in the respective courses.
- One education faculty member saw the Mimic Project as a focal point for her sabbatical experience. She was very interested in reading and literacy and centered her study on the use and incorporation of "concept mapping" software into her course syllabi. Therefore, she pursued the use of Inspiration software into here course structures and recent presented a colloquium to the Division of Education on here results and findings.

Year 2: 2001-2002 In the second year of the project the emphasis is not only to continue the successes of the first year but also to expand on the project by dissemination of the innovative ideas to areas beyond our campus. Listed below are some of the current projects in progress.

- One special needs professor is building lab experiences into her course for assistive technologies. She is also incorporating audio-streaming for some assignments normally done in class that now can be linked to her Blackboard component of the classroom.
- Another educational faculty member is making maximum use of using Real Producer to incorporate streamed videos into her courses within the construction of Blackboard.
• A health professor is being mentored in Blackboard and is also planning on using CBL and MBL equipment in probe usage for teaching Health Methods to future teachers.

• A tremendous success story has played out as a result of last year's participant. Our geology professor has organized a trip abroad for the purpose of studying the volcanoes of Iceland. She plans to send downloaded images and videos of the experiences with the students for the remaining students on campus. This to be accomplished via the web as well as via desktop videoconferencing – campus to volcano.

• The Collaboration of the Americas grew out of the original PT3 Project MIMIC grant. The Collaboration of the Americas expands the MIMIC model through the use of desktop videoconferencing as well as into Internet 2 for distance mentoring...whether that is from within US (university to university) and/or in collaboration with foreign colleges and universities, (Argentina and Chile). The project has expanded into three sub-projects: One education faculty member is a MIMIC participant working in the area of early childhood teacher preparation. She will have a mentor who is a current 3rd grade teacher in a local school district. Her mentor is also finishing her Master's Degree in Educational Technology this spring. In addition to these two folks working together, a third tutor is being arranged at a distant University and the plan is to connect these people via Internet2 with distance videoconferencing. This professor works in the area of educational technology but is also interested in early childhood computer literacy.

• Two professors from the Instituto Superior de Formacion in Patagonia, Argentina, have formed a collaboration with Baldwin-Wallace College for Spanish audio files in exchange for technology skills for their teachers in training. The goals of this project are: 1) to actively collaborate with other teachers in a distant environment via email, discussion board, virtual classroom and hopefully live teleconference (iVISIT and NetMeeting) on various teacher classroom methods; and 2) to receive, from Argentina, Spanish audio files (male, female, teenager, different dialects) to assist our Spanish Department on the Baldwin-Wallace College campus in helping future Spanish K-12 teachers. (This is a problem we are experiencing on our campus with the PRAXIS II language test) and finally 3) to achieve cross-cultural pollination of teaching methods and ideas as well as other cultural variations between our two countries.

• A BW music education faculty member has been fortunate to be involved in three Artist Residencies sponsored through the Ohio Arts Council and the Chilean North American Cultural Institute in Chile, South America. Her target projects have been focused in the Chilean cities of Copiapo and La Serena. Her work in Copiapo has been at the Liceo Experimental de Musica de Copiapo which is a grade three through twelve school of the arts in the middle of the Atacama Desert. The Chilean government has declared this Liceo as the model arts school for the country in the development of curriculum, scheduling and programming. Her residencies there have been multifaceted. In addition to guest conducting the bands, orchestras and choirs, she has been charged with assessing and evaluating all perspectives of the school from teacher and student performance in the classroom to scheduling, materials, teacher education, inventory and the coordination of the writing of the National Chilean Music Education Curriculum. It is her hope that the development of her technology skills will enable her to develop a web site that will support sharing web stream broadcasts of quality teaching and performance examples and professional development information. Through the use of video conferencing, she hopes to be able to maintain an ongoing dialogue throughout the year so that she is able to support her Chilean colleagues on a daily basis as they work to further music education in their country.

• Her second project is in La Serena, Chile, at the Universidad de La Serena and Escuela Experimental de Musica “Jorge Pena Hen.” This past August, she spent a week at the University of La Serena leading the “Encuentro de Directores de Bandes de Concierto Escuelas Artisticas del Norte Chileno.” This was a weeklong convention for all of the band directors in the north of Chile. She presented clinics on numerous subjects such as conducting, rehearsal techniques, repertoire, and singing in the instrumental classroom. This was the first time that an event of this type had been presented in Chile and the first time that these thirty music educators had ever met! It was an extraordinarily successful event that ended with a commitment on the part of the teachers to attend every year. The opportunity presented itself to start the very first Chilean Music Education Association. She is committed to working with these dedicated music educators to help them continue their professional growth through the year. She hopes to experiment with distance learning through the use of Internet2, video conferencing and web stream broadcasting to share what she can with her new colleagues.

• Time during the visitation to the BW campus in January by the Universidad de La Serena and Escuela Experimental de Musica participants will be used to train them in desktop video teleconferencing software as well as in Real Producer and file transfer for streaming their future concerts. On Feb. 22nd BW will stream a live concert especially for these two intuitions. This is in preparation for their institution doing a stream back to BW. This maintains the dialogue of the instructors involved in the collaboration from the conferencing and the performance level.
Notre Dame College of Ohio

The MIMIC project at Notre Dame College focuses on three areas: (1) education college faculty members, (2) pre-service teacher courses and (3) cooperating teachers who supervise Notre Dame student teachers.

Education College Faculty Members. Notre Dame College has implemented the MIMIC project at this level through workshops and institutional policy. The education faculty participates in workshops in how to set up a class web presence, Power Point presentations and how to use the laptop/projector in their classroom. They have also added to their syllabi the requirement that in each class the student will produce a digital artifact which will be incorporated into an electronic portfolio when they take a required education technology class.

Pre-service Teacher Courses. In the pre-service integration of technology into the curriculum, the pre-service teachers have been paired with Master Classroom Teachers (MCT) in the development and implementation of a modeling of technology lesson. The pre-service teachers meet with their MCT and plan a lesson integrating technology and then team-teach the lesson with the MCT. Evaluation forms were developed which document the process and the reflections of both the Master Classroom Teacher and the pre-service teacher individually and jointly.

Cooperating Teachers Who Supervise Student Teachers. In each student teaching experience, the cooperating teacher and the student teacher model a lesson integrating technology into the curriculum. This policy has been added to the requirements both for student teachers and cooperating teachers. Each fills out an evaluation form on the modeling of technology lesson.

For the second semester, best practices in the college and field classrooms will be videotaped and the different experiences will be collected on one tape to be shown in the pre-service integration of technology class. The modeling of technology will encompass different content areas and different grade levels.

Ursuline College

The MIMIC project at Ursuline College is comprised of several parts. Implementation occurs during the spring semester of the year, as the methods courses involved are offered during that time.

1. Ursuline faculty responsible for teaching methods courses in the early childhood and middle childhood programs vary in technological expertise. They are, however, quite amenable to guidance and tutelage. These services are provided by technology faculty/directors from two local public-school districts. Methods faculty determine the technological process they would like to teach to students as a teaching/learning tool for the classroom. Joint sessions held with the technology faculty from the school district allow planning of three to five classes for the semester. School-district personnel serve as guest instructors in the methods courses, teaching the process to the college students. Methods faculty then guide students in projects which allow them to implement the techniques learned during the guest instruction. Methods faculty incorporate the processes in subsequent semesters with other students. Thus, the focus of this portion of the MIMIC project is to allow college faculty to learn processes which then become a planned part of future methods courses. This portion of the project has been quite successful.

2. During the first two years of implementation of the project, a school-district administrator served as an adjunct faculty member for the college, and worked with three teachers in the public school (middle-school level) to enhance use of technology as a teaching/learning tool within several sixth-grade classrooms. The goal was to place students from the college for pre- and student-teaching experiences with these three teachers so that the college students would benefit from observing and learning how to use technology in the classroom. Scheduling students to complete experiences in the school has proved problematic. A student teacher has just completed an experience with one of the teachers. However,
due to an extended illness, the teacher was unable to work with the student for the latter portion of the placement. This part of the project has not been as successful, and review of the process is underway.

3. During the spring semester '02, full-time faculty in the Education Department will participate in several in-service sessions which will address additional areas of technology use in the methods courses. These sessions will not occur within the methods courses; rather, the faculty will participate in the sessions first, and then pilot the processes within methods courses during the spring '02 and fall '02 semesters. The "mentor" teacher will be the technology director for a local public-school district.

John Carroll University

John Carroll University’s overarching strategy for the implementation of the MIMIC grant has been to employ the expertise of skilled technology trainers to create fertile and relevant backgrounds in technology implementation for higher education faculty and for K-12 teachers. The goal of this effort has been to allow the higher education faculty and the K-12 educators to share their newfound technological skills with pre-service teachers and students. We have chosen to focus our work with K-12 educators in urban schools and have elected to work with higher education faculty at John Carroll University.

MIMIC in the K-12 Arena

JCU began its implementation of the MIMIC grant working with teachers from one urban, parochial school and later added two urban, public schools from the “alternative/option” school group. Incorporating the training skills of master classroom teacher, Judi Wolf, and JCU Department of Education faculty member, David Shutkin, MIMIC extended learning experiences to K-12 teachers including bi-monthly workshops on software application and Web exploration. Additionally, MIMIC created opportunities for K-12 teachers to work individually with the technology trainers to adapt their training for use in specific curricular areas, such as Social Studies and Language Arts. On several occasions, the trainers observed K-12 classroom teaching and co-taught lessons with K-12 educators, periodically modeling instruction for JCU pre-service teachers who were working as volunteers and work study students within the school setting. These efforts have been met with great enthusiasm on the part of K-12 educators who see technology training as a door to the classroom of the future and a bridge for students marginalized by the Digital Divide.

MIMIC in the Higher Education Arena

The first phase of professional development provided for JCU faculty as part of the MIMIC grant was created in accordance with the CSU implementation plan. Faculty received individualized professional development derived from a “bottom up” perspective and designed to meet their interests and skill levels. This training was very well received and seen as highly beneficial. The second phase of professional development focused on “technology transfer” and utilized a skilled technology trainer to work with higher education faculty from the Department of Education within their student teaching seminar classes. Thus, the trainer was able to extend her instruction across the continuum from JCU faculty members to pre-service teachers while supporting specific instructional goals.

Conclusion

A sense of community has developed among the five MIMIC partner institutions. The flexible project management scheme coupled with the structured evaluation plan has lead to unique and successful implementation at the five university sites. Indications at this point are that university faculty, and classroom teachers are reacting favorably to the various forms of technology modeling. More importantly the modeling appears to provide pre-service students with a context for understanding how technology can improve instruction and why the modeling of technology is so important.

Problem Based Learning with Young Children: Designing and Implementing Action Research Projects in an Urban Classroom

Comfort Akwaji
Curriculum and Instructional Technology Department
Iowa State University
United States
comfortakwaji@aol.com

Abstract: This paper is a report on an early learning project, using technology in inquiry and problem-based learning strategies, by kindergarten children in an urban classroom. The benefits of the problem-based learning project are three fold; it allows young children to engage their natural curiosity through involvement in activities that utilize both real-life and laboratory based experiences, it provides pre-service teachers the opportunity for hands-on training and application of theoretical concepts while working with early learners in an applied setting, and the project affords the in-service teacher the opportunity to focus on instructional design and curriculum that is challenging, student-centered, hands-on and relevant to the students present and future needs. The focus on real-world problems enables students to become problem-solvers, constructors of knowledge, and engaged learners who understand the relevancy of their educational experiences.

Introduction

This project resulted from conclusions derived from the observation of kindergarten students over three years at an urban elementary school. There was a noticeable lack of cooperation, creativity and problem-solving skills among these students as well as frequent displays of inappropriate social skills. Additionally, the project provided an opportunity for teachers' efforts to enhance their personal/professional growth through action research. Base-line data were collected on beginning kindergarten students at an urban math & science magnet school. Included in the assessments were measures that looked at their problem solving skills through the utilization of real world scenarios. Analysis of these data showed that students needed lots of interactions and experiences with problem solving. As a result, I set out to find ways to facilitate the learning of this highly needed skill that would capitalize on social interaction/cooperative learning, one of the best ways to get kindergarten students to learn. Also, one Friday a month, parents and guardians were invited to eat lunch with their child followed by a short technology literacy presentation session or activity which could include a software demonstration, modeling hardware or software or a visit to a highly recommended and appropriate website for young children.

The development and implementation of the early learning activities focused on math, science and technology. This approach took into consideration developmentally appropriate practices in early childhood, best practice principles, national standards and benchmarks and the School District's curriculum expectations for kindergarten students. I collaborated with Dr. Larry Genalo, Professor of engineering at Iowa State University. His course, “Toying with Technology” for elementary pre-service teachers was designed specifically to provide students in non-technical fields, especially elementary education majors, with an appreciation for the basic principles underlying the technological innovations that surround them. One expectation for students taking this course was to assist in hands-on workshops involving K-12 students and teachers from area schools.

Problem-based early learning harnesses the power of creativity, natural curiosity and engages young children in challenging learning activities. Students completed activities that drew on real-world, developmentally/age appropriate problems designed as weekly cooperative learning activities presented in the form of scenarios called “Problems of the Day”. Students had opportunities to construct their own knowledge about how things work (i.e. the technology & engineering involved), through a focus on scientific concepts such as wheels, pulleys and gears. Students planned, implemented and reviewed their solutions in ways that encouraged and built creativity, cooperation, collaboration and problem solving skills. Between sessions
students engaged in learning across the curriculum through activities designed to reinforce the concepts embedded in the “Problem of the Day”. Additionally, students were deliberately involved in a variety of literacy-based activities related to these concepts, to develop and strengthen their emergent literacy skills. The rationale for choosing problem-based learning includes the following reasons.

- It supports the way young children learn – seamless opportunities for exploration and natural curiosity
- It provides skills needed to succeed in the modern scientific and technology-intensive world
- It promotes hands-on, minds-on learning
- It provides for many “correct” answers/possibilities
- It accommodates diverse needs of students
- It encourages more active, less passive, learners

Implementation

On Tuesday October 10, 2000 and the following four Tuesdays (Oct. 17, Oct. 24, Oct. 31, and Nov. 7) a group of twelve students from the Computer Engineering 370 course (Toying with Technology) at Iowa State University, accompanied by a graduate student, went to Ms. Akwaji’s Kindergarten class. It was the graduate student’s responsibility to see that the ISU students understood the challenges that the Kindergartners were up against and to aid Ms. Akwaji in developing challenges for the Kindergarteners. The ISU students were not allowed to do the tasks for the students, but help them to understand the information before them. The ISU students were to understand the goals that Ms. Akwaji had for her Kindergarteners, which included: the ability to work in teams, to better explain themselves, and to understand the information presented to them (wheels, levers, pulleys, gears). Toying with Technology is a program in which pre-service teachers learn how to use technology in the classroom, and how to apply the knowledge in the classroom to the appropriate grade level.

During Phase 2 (the second semester), the early learning project exposed young children to science, technology and engineering in a highly motivational and non-threatening way by having them build computer-controlled LEGO models; a goal comparable with that outlined for ISU students enrolled in the “Toying with Technology” course. As a result of observing and understanding the needs, abilities/capabilities of these students during Phase 1 (the first semester), software appropriate for young learners was developed to enable the kindergarten students to design things and make them “work/go”.

Conclusions

With respect to the objectives outlined for the project, the first phase was successful. Out of the 24 kindergarten participants, only four had difficulty working cooperatively with peers. The goal was to have all of the students assume the role of “group spokesperson” to explain how they solved the “problem of the day” and the rationale for doing it at the end of each session. About half of the students understood and actively participated in this review/share part of the project. Overall I have seen a lot of improvement in both the students’ communication, computational and problem solving skills. Based on observation and information obtained from the ISU students’ journal entries, some of the kindergarten students had difficulty staying on task during the project sessions. Generally these were students who had finished early. As an intervention, those who had finished with an assigned task were encouraged to move on or engage in other appropriate activities. This is a common classroom practice that allows for all to participate and continue to learn/progress at an individual pace and at the same time contribute to the group. Through manipulating legos and the other materials/tools utilized for activities, students enhanced their fine motor skills. Students have also demonstrated individual and group responsibility through caring for materials/tools, taking turns and showing respect for the work of others. With the exception of a few, students focused on learning through exploration, and completed assigned tasks with some support from their “university buddies”. During the first phase (Fall Semester), the time on task for some of the students was twenty minutes. This is typical of students of this age. During the second phase (Spring Semester), the time on task for all students increased.
Mestrado Band: Developing a New Model for Teacher Professional Development in Brazil

Cristiana Mattos Assumpção, Ed. D.
ANE, Colégio Bandeirantes, Brazil
Email: cmattos@colband.com.br

Abstract: The need for professional development in the area of technology integration has been an emerging theme throughout the latest reports released by major institutions (CEO Forum 1999; CEO Forum 2000; OTA Report on Teachers and Technology: Making the Connection 1995; Gibbons 1997; Greene 2000). Researchers have been studying several models to decrease the gap between higher education research and what is actually happening in the classroom (Fishman et al. 2000, 2001). This paper proposes the creation of a new model of professional development in technology integration at the secondary level, where a partnership is being developed between a private High School in Brazil (Colégio Bandeirantes) and Universities both in the United States and in Brazil. The model proposes integrating teacher professional development at the high school with actual research work, by developing an official master’s degree course using the expertise of researchers and professors to teach the courses both face to face and via online learning.

Introduction

Learning to manipulate technology is shifting from a privilege to a requirement in today’s global economy. This is not only true in the United States, but in other growing countries as well. Brazil is the 8th largest economy in the world, and several initiatives are already being implemented to ensure its educational system prepares its students to take leadership roles and participate equally in the growth of this global wealth. The Mestrado Band model is being created based on lessons learned from my doctoral research (dissertation to be published in 2002 - Earth2Class: The Role of Technology in Providing Structure for Science Content Delivery from the Research Scientist to the Secondary (6-12) Classroom Teacher, Teachers College, Columbia University) in professional development using online technologies to integrate the work of the research scientists at Columbia University with the work of Earth Science teachers from various communities in the New York - New Jersey area and beyond (Passow et al. 2001). To view this project, the website is www.earth2class.org. The problems being addressed by this model include: (a) the time constraints teachers face in improving professionally while dealing with the daily routines and requirements of teaching; (b) the lack of effective technology integration in the classroom; (c) the distance between the work of researchers in higher education institutions and the classroom practices; (d) the lack of recognition of the value of the work being developed by the teachers in their classroom; (e) the need to revisit academic standards to measure excellence in contributions to a field of study and (f) the role of strategic partnerships in developing new professional and educational paths for personal and institutional growth.

The Professional Development Model

The Mestrado Band program being proposed will consist of a complete M.A. curriculum in Computers in Education or Instructional Technology, where the teachers will have intensive courses during summer vacations at the partner universities, thus having the opportunity to see functional models of uses of computers in schools in the United States, and complete their coursework back at Colégio Bandeirantes, developing and testing out projects as they teach. The effort will be complemented by online courses, and guest professors will be invited to teach intensive workshops in Brazil, very likely once a month. Strong emphasis will be given to pedagogical theories and applications that use technology in innovative ways to enhance teaching and learning and truly transform classroom practices.
The advantage of partnering with Universities from other countries is to have access to specialists and projects in a country where the use of computers in education has been going on for a longer period of time, thus allowing teachers in Brazil to benefit from the experience already acquired there. As the Internet becomes more widely accessible, the potential for collaborative projects increases and should be taken advantage of.

In this proposed model, not only are there major advantages for the teachers, who can now use their time for personal growth and for school work that is officially recognized as valid research by higher education institutions, but also for the school, as it builds on the teachers' production and develops more advanced projects and products within the school context for their student body, therefore becoming more competitive in the market. The professional development efforts become more consistent and build upon the strengths and diversity of different participating institutions. When teachers are transformed into recognized researchers within the school context, the gap between researchers and practitioners is narrowed. A partnership relationship is developed, as both parties become collaborators in the greater effort of improving education.

This model would not have been possible without the development of the modern technology tools now made widely available to the community. The Master's program is being designed not only to capacitate the middle and high school teachers to teach using technology to enhance their lessons, but also to gain professional growth and research abilities using these same tools to learn, communicate, collaborate and network with the research community globally. The development of a network of education institutions (middle and high schools with universities) is a key element of this design.

As more educational researchers are becoming aware of the importance of building these strategic alliances with the classroom professionals to bridge the gap between theory and application, I propose that it is time to officially develop organized and institutionalized partnerships that build on the strengths of educational institutions at different levels, reflecting the same strengths this new technology has brought us — moving from a model of competition for few resources to one of collaboration to share widely available resources that are now accessible because of the democratization of information.

Strategies for Integrating Technology into Field-Based Teacher Training Programs: Perspectives from Educational Technology and Teacher Education Faculty

Thomas Brush, Kathleen Rutowski, Krista Glazewski, Jean Sutton, Cory Hansen, Doreen Bardsley
Arizona State University
United States
tbrush@asu.edu

Abstract: Most researchers agree that more technology training is needed for teachers, and numerous suggestions already exist in the literature regarding the content of the training and the methods for delivering the training. One of these methods involves the integration of technology with undergraduate methods courses, thus providing students with knowledge and experiences applying technology to their specific content areas. This field-based model is the basis for teacher education experiences at Arizona State University (ASU). A collaborative effort between methods and educational technology faculty worked to identify and implement two key components of a model designed to provide pre-service teachers with the skills and experiences required to fully integrate technology into their future classrooms. This paper will consist of perspectives by the following key individuals regarding the effectiveness and challenges of implementing this new model:

- Faculty in Educational Technology, who will provide an overview of the field-based model and discuss the evolution of the technology integration component of the model over the past two years;
- K-12 site coordinator, who will discuss strategies for obtaining access to schools for use as field-based sites, and will describe how field-based placement teachers are involved in the technology integration activities;
- Methods faculty liaison, who will discuss strategies for collaboration between methods faculty and technology faculty with regards to technology integration activities for pre-service teachers;
- Methods faculty, who will describe the strategies they are using to integrate technology into the field-based experiences for their students, and;
- Field-based technology instructor, who will discuss technology integration activities completed by pre-service teachers, collaboration with methods faculty, and participation in activities with teachers at field-based sites.

Overview

Most researchers agree that more technology training is needed for teachers, and numerous suggestions already exist in the literature regarding the content of the training and the methods for delivering the training. One of these methods involves the integration of technology with undergraduate methods courses, thus providing students with knowledge and experiences applying technology to their specific content areas. This field-based model, also known as job-embedded learning, concentrates on providing pre-service teachers with authentic training experiences in real classrooms prior to their student teaching experiences.

At Arizona State University (ASU), students enter the pre-service teacher education program at the beginning of their junior year. Once they enter the program, they are immediately enrolled in a series of semester-long field-based teaching methods experiences at local “partner” schools. Each of these experiences requires students to successfully complete more traditional methods classes taught by methods faculty at the partner schools, and serve as interns to “placement” at the partner schools in which they spend a minimum of six hours per week in elementary or secondary classrooms observing classroom practices, assisting the placement teachers with instructional activities, and complete methods class assignments to learn about themselves as they begin to assume the role of a teacher.

Students are required to participate in a different methods experience (or block, as it is called at ASU), each semester. Each block focuses on different content and provides students with different experiences. For example, teacher education students who are pursuing elementary certification complete the following sequence of field-based methods experiences: Block I – Social studies and language arts, Block II – Mathematics and science, and Block III
Reading and multicultural education. Students pursuing secondary certification in a content area complete one
semester of general teaching methods and two semesters of teaching methods specific to their content area (these are
also field-based and taught in conjunction with faculty in the College of Liberal Arts and Sciences). Thus, regardless
of their certification program, students are involved in field-based teaching activities throughout the teacher
education program. This field-based component is one of the unique and innovative aspects of the teacher education
program, and also provides a mechanism for infusing technology throughout the program.

Prior to 1999, the integration of technology within these field-based courses was not emphasized. Pre-
service teachers were required to participate in a campus-based educational technology class sometime during their
junior or senior year, but there was no real coordination between what students were learning in this class and what
they were doing in their methods experiences. The movement of methods courses to field-based settings, however,
provided an opportunity to implement a plan to integrate technology skills and experiences with the field-based
methods experiences. Working with the methods faculty, educational technology faculty, and field-based placement
teachers at participating school districts, pre-service teachers were able to create technology-rich learning activities
and implement those activities as part of their methods instruction. This involved a process of working with
methods faculty to integrate technology skills into their field-based activities, providing methods faculty and field-
based placement teachers with additional training (when necessary) in technology integration in education, and
providing additional instructional technology expertise to field-based placement teachers and pre-service teachers at
the point of instruction.

This paper will consist of perspectives by the following key individuals regarding the effectiveness and
challenges of implementing this new model:

- **Faculty in Educational Technology**, who will provide an overview of the field-based model and discuss
  the evolution of the technology integration component of the model over the past two years;
- **K-12 site coordinator**, who will discuss strategies for obtaining access to schools for use as field-based
  sites, and will describe how field-based placement teachers are involved in the technology integration
  activities;
- **Methods faculty liaison**, who will discuss strategies for collaboration between methods faculty and
  technology faculty with regards to technology integration activities for pre-service teachers;
- **Methods faculty**, who will describe the strategies they are using to integrate technology into the field-
based experiences for their students, and;
- **Field-based technology instructor**, who will discuss technology integration activities completed by pre-
service teachers, collaboration with methods faculty, and participation in activities with teachers at field-
based sites.

**Perspectives from Educational Technology Faculty**

*Dr. Thomas Brush – Educational Technology Faculty Member.* In order for pre-service teachers to acquire
the skills and experiences necessary to fully integrate technology into their future, we felt that two key components
were needed:

1. Providing **pre-service teachers with field-based, situation-specific technology training** they are able
to integrate into the initial teaching activities they complete as part of their teaching methodologies
experiences. In order to provide appropriate technology training for pre-service teachers, we collaborated to develop
a set of technology competency activities to serve as a guide for both placement teachers and pre-service teachers.
The competency activities were strategically created to align with both the International Society for Technology in
Education (ISTE) National Educational Technology Standards (NETS) and the content covered in the field-based
methods experiences (or "Blocks"). In this way, the competencies could easily be integrated into the teaching
activities pre-service teachers are required to complete as part of their methods experiences. For example, a major
competency area for Block I of the teacher education program is “Classroom Management and Technology
Integration in Language Arts and Social Studies.” In order to demonstrate this competency, pre-service teachers
were required to design lessons that both focuses on language arts and/or social studies content and utilized some
aspect of technology appropriately. To assist them with this activity, we presented field-based “workshops” in which
we modeled appropriate uses of technology for various language arts and social studies concepts. We then assisted
pre-service teachers in developing their own technology-rich lessons, and implementing these lessons with students
at the partner school.

We are in the process of developing the foundation of a collaborative relationship among educational
technology faculty, educational technology graduate students, and methods faculty that will form the basis for the
alignment of activities across courses and increase the opportunities pre-service teachers have to design, implement, and evaluate technology-rich learning experiences for the children in their placement classes. In addition, educational technology graduate students are available in the partner schools to assist pre-service teachers with designing and implementing their activities with students. Through these collaborative practices, the expectations for the utilization of technology by pre-service teachers has dramatically increased. Pre-service teachers learn a variety of appropriate options for using and integrating technology, demonstrate the use of state-of-the-art technology in their teaching, and understand how this technology can be leveraged to enhance numerous learning activities.

2. Providing College of Education faculty and field-based placement teachers with training, guidance, and just-in-time assistance as a means to more effectively enable them to support pre-service teachers with technology integration activities. Although many of the methods faculty and field-based placement teachers already possess exceptional skills in integrating technology with teaching, there was still a need to provide many of these individuals with additional training regarding effective uses of technology in various teaching domains, as well as available technology resources in those domains. Methods faculty and field-based placement teachers were not expected to possess comprehensive knowledge of the vast number of resources available or which of the resources might be most appropriate for various teaching and learning activities. In response to this need, we developed a series of intensive summer institutes. Working in collaboration with the partner schools, these institutes are led by teams of educational technology faculty, methods faculty, and educational technology graduate students. Each institute is designed to focus on specific content areas emphasized in each of the methods blocks. For example, faculty responsible for the social studies and language arts methods block participate in workshops that specifically address the technology resources available in those content areas and receive hands-on opportunities to use the resources and discuss how those resources could be integrated into classroom activities. These institutes serve as opportunities for faculty and placement teachers to learn about both strategies for integrating technology into teaching and the vast technology resources available that teachers should be using with their students. With this ongoing training, methods faculty and placement teachers are better able to assist pre-service teachers in making informed decisions regarding effective technology integration during their field-based experiences.

In addition, ongoing support is provided in the field to methods faculty and field-based placement teachers by the educational technology faculty and educational technology graduate students. Educational technology graduate students are continually placed in the schools to assist both pre-service teachers and field-based placement teachers. These students have expertise in both teaching and technology integration; thus, they are able to assist the placement teachers with activities they would like to attempt with their students, as well as activities the pre-service teachers are planning. This resource and support structure helps methods faculty and field-based placement teachers better model effective integration of technology into teaching and learning activities.

**Perspectives from the K-12 Site Coordinator**

*Jean Sutton – PT3 Site Coordinator.* As Site Coordinator, I worked directly with the individual schools to schedule and coordinate the PT3 technology workshops for the Fall semester. I found the school principals to be enthusiastic and cooperative when I met with them individually before the school year began. The technology instructors, computer lab teachers, media specialists, and ASU methods professors sometimes attended these meetings. To encourage the teachers from each site to participate in the program, I attended and spoke at a faculty meeting at each school. I distributed flyers explaining the benefits of attending the PT3 workshops with times, dates, topics, and locations.

I built a profile of each school with the information that I obtained from the principal, other school personnel, and the school web sites. This profile included information such as grade levels, number of students, location (written directions), phone numbers, types of computers/programs in computer lab, etc. This profile was made available to the technology instructors.

Overall, the first semester of the program went smoothly. I met with principals at the conclusion of the semester to obtain suggestions and feedback. They all reported no problems and felt the program was successful. One of the challenges has been to motivate on-site teachers to participate in the field-based workshops and summer institutes. Although the principals viewed this part of the program as a “perk” for teachers, in reality, the teachers were overwhelmed with other teaching responsibilities. The principal at one of the schools remarked, “This is a topic that teachers are interested in, they are just too stressed out and busy.”

Two of the field-based schools have been involved in a performance-based pay plan in conjunction with “Section 301,” which is a specially allocated Arizona state tax revenue designated for teacher training and skills...
enhancement. Since the PT3 workshops were included as an option for fulfillment towards the required 15-hour staff development, teachers at these two sites were more motivated to attend.

Any scheduling and staffing problems during the semester were minor. For example, classes that fell on a Monday needed to be rescheduled because of several holidays. Although the on-site computer labs were scheduled ahead of time for the regular workshops, on a few occasions the school had scheduled something else in the same room. This problem was easily solved by temporarily using a regular classroom. If one of the technology instructors was sick or unable to attend, I was available to substitute. In addition, I rotated schools to assist the technology instructors with the workshops.

Scheduling and planning began several months prior to the start of the Spring semester. Many adjustments and improvements have been made. Suggestions taken from school administrators, PT3 staff, methods teachers, and ASU students have been taken into consideration. I have worked closely with the methods faculty liaison to improve the effectiveness of coordinating the activities. Information she has shared regarding student expectations, schedules, and requirements has been invaluable. We hope by anticipating some of the student conflicts, we will be more successful in meeting students’ needs. This next semester should be even more successful and productive with the experience gained from last semester and the comprehensive planning.

Perspectives from the Methods Faculty Liaison

Dr. Kathleen Rutowski – Methods Faculty Liaison and Instructor. In this section of the paper we describe a strategic framework employed to support the development of a collaborative style of interaction among methods faculty, educational technology faculty, and educational technology graduate students. Collaboration was essential to integrate educational technology experiences into the preexisting field-based methods courses in our elementary teacher education program. It also provided the opportunity to model a collaborative style of interaction for our preservice teachers. The ability to collaborate is a critical component for developing productive relationships between teachers and educational technology experts in schools, teaching practices that support diverse learners (Fennick & Liddy, 2001; Friend & Cook, 2000; Pugach & Johnson, 2002; Staintack & Staintack, 1992; Villa, Thousand, & Chapple, 1996), and has been cited by principals as an important consideration when renewing teaching contracts (Pugach & Johnson, 2002).

Friend and Cook (Friend & Cook, 2000) defined interpersonal collaboration as “...a style for direct interaction between at least two coequal parties voluntarily engaged in shared decision making as they work toward a common goal.” (p. 6) They identified several characteristics evident in educational institutions endeavoring to develop a collaborative culture among faculty: collaboration is voluntary; collaboration is based on mutual goals; collaboration requires parity among participants; collaboration depends on shared responsibility for participation and decision making; individuals who collaborate share their resources; and individuals who collaborate share accountability for outcomes. During the course of the initial 18 months of the program we have deliberately worked to develop a strategic framework that fosters the development of these characteristics.

The PT3 grant designed to integrate educational technology into the field-based component of our elementary teacher education program was secured through the educational technology faculty at ASU. Elementary education methods faculty were invited to participate in the project which was designed to better prepare their preservice teachers to use technology using the same constructivist pedagogical approach embraced by the elementary education program. In addition, participation would provide them support to refine and expand their own technological expertise and bring additional technology resources to the partner schools hosting their methods courses. The stage was set for voluntary participation of the methods and educational technology faculty in a three-year project with the goal of integrating educational technology throughout the pre-service teacher program and predicated on evolving collaborative relationships among participants.

During the first 18 months of the project a framework has evolved that provides formal and informal opportunities for methods faculty, educational technology faculty, and educational technology graduate students to interact in ways that enable them to share responsibilities, resources, and accountability for the outcome of the program. The formal components of the framework include: retreats during which methods faculty and the educational technology team share syllabi and align course activities; summer technology institutes; educational technology team meetings that include a methods faculty liaison; joint presentations at professional conferences documenting the program; and the development of a compendium of technology-rich lessons and activities for pre-service teachers. Interactions are structured to establish parity among all participants in the program, faculty and graduate students, by valuing the contributions of each individual and encouraging involvement through a process of shared decision-making. The formal components of the project have stimulated the emergence of informal
collaborative opportunities. Methods faculty have begun to participate in technology workshop sessions at their partner schools. Methods faculty and educational technology graduate students are beginning to engage in ad hoc discussions regarding pre-service teacher participation in and response to workshop sessions. And, there have been several requests by methods faculty for demonstrations of new technologies they think will complement the content of their courses. There is an emerging sense of trust and community exemplified by an increased interest in team teaching and enthusiastic participation in efforts to merge and integrate course content.

Perspectives from Methods Faculty

Cory Hansen – Elementary Methods Faculty. I attended the PT3 Summer Institute and have integrated the knowledge I gained in the teacher preparation courses I teach. As an introduction to Early Childhood Education, students at Arizona State University are required to take a course in child development. Besides developing knowledge about children, we wanted our future teachers to become aware of the resources available on the internet, to be able to access those resources to meet the needs of children and to instruct parents how to find the same information to benefit their families.

In collaboration with other methods faculty, I developed a syllabus based on students using and sharing technology. The students in my ECD 314 class ranged from freshmen to post-bacs with the same goal of applying to our Education program. Each student was required to locate 14 articles to present to the class and 5 website reviews to share. To ensure students had the technological base to complete the course requirements, they were required to complete an internet training exercise for early childhood educators and to attend a Library Research Class to learn how to search ERIC, Education Abstracts, Psych Info and EBSCO. I would not have been confident guiding my students through this process without the experiences of the PT3 Summer Institute.

In order to scaffold this technological-and-learning experience, topics and key words were provided. For example, within the construct of maturationist theory, students were provided with the following key words: Gesell, School Readiness Tests, Developmental Screening. I instructed my students to locate articles within those boundaries, yet still to address individual areas of interest. The resulting conversations were focused and varied. Consistently, my students were surprised at the range of ideas within the topic at hand and pleasantly surprised at how choosing their own articles broadened their interest and knowledge about the subject.

Each student was required to compile a Resource Notebook for future reference. They are now secure in their ability to access the information they will need as teachers. In addition to these assignments, my students were required to observe, interpret and assess levels of child development. Without direction, the majority of my students referred to information they had retrieved through technology to assist them in making these judgments and suggestions.

Before completing the PT3 Summer Institute, I would never have had technology be emphasized as such a strong component in a child development course. Now, I wouldn't do it any other way. My ideas for future sections include power point presentations of child observation studies and, for myself, an electronic grade book.

Doreen Bardsley – Elementary Methods Faculty. I teach two Reading Methods courses and an integrated Children’s Literature course (to the same group of students) in the third semester of the Elementary Education program at Arizona State University. I have been directly involved with the PT3 program for the past two years through attending workshops, meetings and a week-long summer institute.

By the fall 2001 semester some of my reading methods class students had been involved in the PT3 pilot program during their first two semesters, while others had taken a regular technology course instead. One of the major assignments in my methods class was the development of a theme-based unit encompassing all subject areas. Students worked in groups according to grade level interest to develop their unit, and one large component of the unit was the inclusion of technology. We first brainstormed possible ways to include technology, then each group decided how they and their elementary students would use technology to enhance their learning.

As we talked about using technology in elementary classrooms it became obvious to me which students had been involved in the PT3 pilot program and which had not. Students who had been in the program were able to suggest more ways to incorporate technology in their unit planning, and they also were more likely to have used technology in their own teaching during their internships. There was a higher degree of technology knowledge and comfort with the students who had been involved in PT3 and had therefore received more practical experience with applying technology in the classroom. As a methods instructor I, too, felt much more knowledgeable about using technology, especially computers, as a result of participating in PT3 workshops and the summer institute, and as a result I felt more comfortable guiding my students.
In their unit plans my students suggested numerous ways that they could have their elementary school students use technology to enhance their learning: students could communicate with pen pals via email; they could research topics in the internet; they could use spreadsheets for graphing; they could use Web cams to see other places and people; students could use scanners and printers to input and reproduce information; they would use word processing for report writing; they could develop web pages or use power point presentations to show what they had learned; they could use digital cameras to add visual information; they could use computers for tests or educational games, and they could use calculators to help with math activities. The ASU students also saw a use for fax machines, CD players, videos, audio books, telephones and telescopes; they were very able to suggest ways to use technology in their teaching, and many gave evidence that they were already doing so.

Perspectives from a Field-Based Technology Instructor

Krista Glazewski – Technology Workshop Instructor. Instructing the technology workshops proved to be both a challenging and rewarding experience. The first challenge was in setting the context and expectations for the students. Students entered with the expectation that they would learn “computers,” even though we went to great lengths to describe the goals of the PT3 project. Having no previous context for the ineffectiveness of the campus-based model, the students initially expressed disappointment in the realization they would not learn skills. In response, we, as the instructors, continued setting and reinforcing the expectations, which would not change.

The primary manner in which we set the expectations for the students was in modeling a language arts and a social studies lesson which incorporated technology. We as the instructors taught the lesson and the students experienced it as if they were the elementary students. They then received copies of the lessons and experienced a debriefing session in which we examined the preparation for the lesson, delivery of the lesson and the technology incorporated, and the lessons’ overall effectiveness. Students were then asked to plan and deliver a similar lesson in which they taught language arts or social studies content and incorporated technology.

While the students enjoyed the experience of the modeled lessons, they expressed uncertainty in knowing how to proceed, especially since for most this was their first lesson planning experience. Many complained about not having adequate skills, while others had difficulty thinking of an idea. In anticipation of this, we had planned optional workshop time into the schedule; students could attend and receive one-on-one assistance from one of their instructors regarding any stage of the lesson planning with which they were having difficulty. However, only a few students took advantage of the support offered to them, preferring instead to ask their questions via email. Those who did choose to seek support, however, were extremely pleased with the patience and understanding offered by the instructors.

Despite their initial reticence, almost all students were able to create and deliver their lessons, and the final debriefing session proved to reflect the greatest reward for us as the instructors. Students described their lessons and experiences delivering them to each other, and the tone as they spoke reflected a positive, enthusiastic attitude. One student was placed in a classroom where the teacher had never taken the students to the computer lab. During the debriefing session, she related being called “the computer teacher” by the elementary students, and expressed her feeling of pride at providing students with a new and different learning opportunity.

Another student related the continuous technical difficulties she experienced in delivering her lesson, but concluded by showing us her final product, which was a book she had created with her students. With pride, she displayed the book for us, and stated that in spite of the difficulties, she found the experience invaluable because she was able to do something she had not been able to do prior to this class.

As instructors, we saw and articulated the value in having students experience what they would actually be doing as a teacher someday. The overall result was a feeling of effectiveness in our instruction as we listened to our students relate their sense of success.

Abstract: The purpose of this qualitative study was to offer opportunities for mentoring and communication through a telementoring computer-mediated communication project. The researchers wanted to examine the relationships that could develop between experienced teachers enrolled in a Master's of Educational Technology program at the University of Central Florida, Orlando, Florida, and pre-service teachers enrolled in Business and Marketing Education at Morehead State University, Morehead, Kentucky, during their professional semester (student teaching) via asynchronous technology. The results supported and added to the research in telementoring and qualitative research.

Introduction

Like most institutions in a sea of change, the age-old practice of mentoring (a process which establishes a relationship between a protégé and an expert to provide guidance, advice, support, and feedback) is being influenced by new forms of work, technology, and learning. The benefits of mentoring are not only work related, but can provide individuals with opportunities to enhance cultural awareness, facilitate personal and professional growth, and provide the runway for successful admittance into a selected profession.

Mentoring is potentially one of the most powerful influences in a person's life. Whether it emerges out of an intimate relationship (grandparent, parent, sibling, a spouse or life partner), or a professional role (teacher, manager/supervisor, co-worker), most people have been, or will be a protégé, a mentor or both at sometime during their life (Zachary, 1997).

Mentors assist employees in dealing with the challenges associated with entry into and advancement toward successful, productive, meaningful professional lives. Historically, mentoring is based on the traditional apprentice learning from a master. The Industrial Age focused on mentoring to advance careers within organizational hierarchies (Haney, 1997). However, the Information Age demands a wider range of cognitive, interpersonal, and technical skills; therefore, mentoring is bound to change to meet these needs.

Creating new opportunities for students enrolled in teacher education programs to learn and integrate technology into all types of classrooms and to reach all types of learners has been the focus of much discussion in teacher education programs (Web-Based Education Commission, 2000).

The purpose of this study was to determine whether mentoring of pre-service students in their professional semester (student teaching) by in-service teachers could provide support and enhance assimilation into the teaching profession. Additionally, was it possible to mentor over distances, using computer-mediated communication?
Review of Related Literature

Many mentoring relationships today still are rooted in the "old paradigm" of power, prestige and hierarchy, based on the assumption that one learned something from a mentor (more often than not passively) and eventually separated from a mentor. The new mentoring paradigm is a partnership based on mutual learning, growth, and satisfaction. Through active engagement the needs of both partners are met. "Wisdom is not passed from an authoritarian teacher to a supplicant student, but is discovered in a learning relationship in which both stand to gain a greater understanding of the workplace and the world" (Aubery & Cohen, 1995, p. 161).

The academic arena has been reported by students as a stressful and sometimes overwhelming experience (Gunter and Jones, 1999). Many mentoring programs have developed from the philosophy that students need to connect with other experienced teachers and work together as a team to have a more favorable educational experience (National Center for Research on Teacher Learning, 2001). This particular pedagogy lends itself well in pre-service teacher programs.

Technology in itself can be an overwhelming and intimidating factor for students, adding to students' stress level. Teachers who teach with technology to support student learning also share these fears. Knowing this then, a program design could be adjusted to meet the needs of students by providing mentors. At the same time, experienced teachers also might gain expertise at becoming effective leaders and mentors.

Examples of mentoring projects using telecommunications technology are prevalent in the literature (see Web sites listed in References for a host of examples of telementoring projects). The upshot of all of these telementoring projects is that they use peer coaching, cognitive coaching, and other mentoring techniques to increase support for students, teachers, and faculty during all types of new learning experiences. Pre-service teachers who are entering the classroom may need even more support and may not always feel comfortable seeking advice from their peers, supervising teachers, or their university supervising professors. The researchers assumed a telemoror might be able to provide advice and support in a non-threatening, non-judgmental environment. And no formal telementoring project was found that paired in-service teachers and pre-service students in the manner designed by this study.

Methodology

The mode of analysis used to present the data from the study focuses on the content analysis (semiotics) of the telecommunications exchanges. Krippendorff (1980) defines content analysis as "a research technique for making replicable and valid references from data to their contexts." The researcher searches for structures and patterned regularities in the text and makes inferences on the basis of these regularities.

The primary purpose of this study was to investigate the phenomenon of the relationship between graduate students enrolled in a Master's of Educational Technology program who telemored pre-service teachers enrolled in their professional semester (student teaching). Another purpose was to examine whether experienced teachers could assist pre-service teachers at a distance in topics, such as tips and tricks, students, methodology, teaching resources, technology integration, and assessment.

The sample population for this study consisted of five graduate students who were experienced teachers (with an average of 9 years' teaching experience) and nearing completion of their Master's program and five pre-service students during their professional (student teaching) semester. The teachers were matched by teaching areas, personality traits, and other areas of interest. One pair was disbanded when the pre-service student dropped out of student teaching. Therefore, four pairs of students participated in the study.

The researchers created a sense of community at the beginning of the semester by introducing themselves and by creating a personal Web page in a Blackboard course site set up specifically for the telementoring project. Each mentor and pre-service teacher also created Web pages so all participants could get to know each other. After that, the two professors let the paired students communicate via e-mail for privacy. Specific directions and criteria were outlined for the purpose of creating dialogical communication. The only quantitative requirement was that the pairs had to be in touch with each other at least twice a month during the four-month semester.
Findings

The researchers considered they might have to stimulate the communication or facilitate the interaction to keep the messages flowing so both researchers were copied on all messages. However, this proved not to be the case. The communications between the pre-service and in-service teachers were enlightening to the researchers and the students. The telementoring proved to be a successful communication experience. All the participants gained in the process of collaboration, community, support, leadership, kinship, and at the same time learned and shared classroom strategies and techniques. To present the findings, the results are presented in the following categories: tips and tricks, students, methodology, technology integration, and assessment.

Tips and Tricks. As in any profession, experienced workers know or have a few techniques that they have learned to enhance their effectiveness in the job. Teachers are no exception. Telementors shared some of their tips with the pre-service teachers, as follows:

David C: Here are a few goodies I’ve picked up along the way in my 20 years in the classroom. Learn the kids’ names; get to know them; get advice; and whatever you do, don’t run screaming into the night!

Pam: I truly believe that [teaching] is the most important profession and when I see “the light bulb go on” for a student, it is the most rewarding. Learn students’ names right away… I cannot tell you how many times I had my day all planned out and when I came in to school the day had to be rearranged. I had to go into my teacher bag of tricks and pull out an activity… one of the reasons I love what I do is that no two days are exactly alike.

I have trained my students to give me nonverbal signals to show me that they need help. This helps me and it doesn’t disturb the others. Signals also keep the student that I am helping from feeling rushed to finish so I can help someone else because the other students usually don’t see the signal.

William: Respect your students and expect them to respect you. Treat your students like students and not friends.

Pam: Your first day teaching is a day that you never forget. You are definitely stepping into the unknown but it sounds like you are in a wonderful situation. The students may try to test your authority but imitate the discipline/control procedures that your cooperating teacher uses. When students find out that the same rules and consequences still apply, they will stop. Also, don’t worry about knowing the answers to every question. Students understand as long as you are honest with them. Good, constructive feedback is helpful... sometimes we don’t hear our own slang. Proper English will help communicate ideas clearly.

William: How do you rate your time management skills?

Nirsa: The more you teach, the more you will find you will be able to focus on many things at once. You must know your content, though; because if you don’t, then you won’t be able to focus on the other aspects of teaching... I have to be honest—after 11 years of teaching I still feel disappointed in some of my lessons. Because students all have different learning styles, they each need different levels of support to learn a skill and concept... I totally agree with you: they need to know you care and that takes time.

Effective teachers have a repertoire of “tricks” to engage students. Enthusiastic, supportive comments from all telementors laid the runway for solid interactions. As the semester progressed, other tips evolved from the exchanges. The teachers' voice of experience, as well as their love of teaching, was clearly evident.

Students. The researchers noted a definite student-centered approach taken by the telementors. The following comments support this observation:

David C: They’re [Students] all good at something. Or, at least, they all have areas of interest. Find out what they are and figure out a way to make use of them in the classroom... Different learning styles! Don’t try to teach all kids with your favorite style of teaching. [Use] verbal, non-verbal, auditory, tactile, hands-on, writing, reading, pictures, color, etc... It’s a lot more work than “worksheets for everybody,” but in the long run, it’s better for everyone, including yourself.

William: My kids will be testing for two weeks (FCAT) under very stressful conditions. Hey! Did you notice I kept saying “my kids”? Have you started doing this yet? If so, can you remember when you started referring to your students as yours? Kind of cool.

Nirsa: My best teachers are my students and their parents. Recently, I was having a casual conversation with one of my students about a TV show they all watched. She was amazed to know that I
watched the same show and I was talking to her about it. Out of nowhere she exclaimed, "...You are like a regular person." This was the greatest compliment I have ever received.

Pam: I always get very attached to my students. I get emotional when they leave...I have found that students are very accepting to the response "I don't know but I can look it up or ask ______ and I will tell you the answer when I find it."

Our sense was that the telementors were very dedicated teachers and learners; their comments were grounded in experience and in caring whether the students learned and grew as individuals.

Methodology. Methods of teaching take on as many forms as there are teachers. Coupled with a high energy level in the classroom and attention to the "teachable moment" in their students, the telementors provided specific, ready-to-use techniques to enhance student learning.

Pam: Don't feel bad about having a part of a lesson that the students didn't understand. This happens often. I remember one lesson I abandoned for the day and taught it again the next day in a different way when I sensed I was confusing them. The next day went perfectly! A good review of previous knowledge is always worth the time. You can do this in ten minutes and it helps students connect their prior knowledge with the new knowledge...The problem of boredom is always present. I get bored as well as my students. I am constantly reading. I feel that it is important for me to continue to grow and learn. I read professional literature as well as articles with ideas for teaching. I have learned how to adapt these ideas to fit my situation and subject. This is a challenge but my students appreciate the variety.

Nirsa: As we know, repetition is important but boredom is not...one of the keys I have found to make a boring subject more interesting is to anchor it in a real world situation. Create a scenario or find a way to make it relevant to their lives. Nothing makes my students perk up more than when I start relating the subject to where they are.

Flexibility! Flexibility! Flexibility! What great intuition and insight you have on being flexible. Not only did you show how well prepared you are but you did it with a fabulous attitude. The better you handle these unexpected challenges, the more you will love what you do!

William: Congratulations on the grant. I think the SmartBoard is an awesome tool for teachers.

David: My best advice on this topic is "if it's not working, change it!" In response to your question about job searching, have your students search for resume templates and fill them out. I'd also have them start a file of their own personal skills, talents, abilities, interests, hobbies, travels, volunteer activities, accomplishments, etc. Have them keep it updated throughout the year. Most folks are usually pleasantly surprised when they see a year's worth of their value accumulated into a single file.

What great advice from seasoned teachers! Even the researchers learned a lot from the suggested methodologies from the telementors.

Technology integration. Researchers expected, and rightly so, that this was an area in which the telepartners would be able to share and exchange techniques. We were not disappointed.

Pam: I moved into my new lab over the weekend; found out that they are bidding on installing a ceiling and air conditioning for my class. I can't believe that they forgot to put those important things in my lab...I have had to work out a few "bugs" in the network and some software.

Nirsa: Joke for the week: After doing a Web scavenger hunt on the revolutionary war, I asked my students to draw a picture of what they think the Boston Tea Party must have looked like. Much to my surprise some students drew pictures of ladies (some in hats) drinking tea around a table. (True story)

Check out this site (Website inserted) for Monopoly Accounting. BTW, thanks for the commercial Website. I will let them know that my teacher friend in Kentucky gave it to me. You will be the toast of the town!

You won't believe this! I was in my car and my daughter was telling me how her middle school teacher reviewed spreadsheets using Jeopardy...I would sure like a copy of the Jeopardy game so I can modify it for my purpose.

Incorporating higher level thinking skills is an important part of learning. Check out this Web site (Website inserted) and let me know what you think...my students are working on PowerPoint projects this week. One group even narrated its entire presentation.

William: I really like using PowerPoint in my classroom. I also have my students complete a project or two every year that includes using PowerPoint. Using technology takes a lot of planning so that it is truly beneficial to the students...

David: Use every available technology resource at your disposal to its best advantage to most efficiently help children learn what they need to know. And remember, "technology" does not just mean "computers," although computers should be a natural, integral part of what's happening in any classroom.
that is properly preparing kids for their world. A couple of favorite computer integration techniques are scavenger hunts and WebQuests.

I’m attaching two files I use to introduce formatting in Excel…I have other files that I can also send you later. Here’s a Web site (Website inserted) also I found that’s a quick reference guide.

A summary of the exchanges between the telepartners can be summarized in one telementor’s comments: “The measure of success with technology is not so much how well you can teach with it when it cooperates, but how well you can teach with it when it acts cantankerous!”

Assessment. Only one telementor shared comments about specific assessment techniques, as follows:

David: Hopefully, you have been taught about rubrics and project/portfolio assessments as alternatives to traditional written tests, but don’t overlook having the students help design the rubric for given assignments. Given the chance to show some responsibility, kids can usually come up with a pretty legitimate set of assessment criteria.

Summary and Conclusions

The study revealed that the telementors provided support to pre-service teachers in a less stressful learning environment. From the exchange of communication, a rewarding relationship developed between the experienced and pre-service teachers. At the same time, the experienced teachers also gained a great deal from the pre-service teachers. They self-reported a sense of accomplishment and heightened self worth by helping these prospective new teachers. They spent time looking for answers to questions, strategies to suggest, Web sites, lessons plans, and other pertinent suggestions and advice. The researchers found the students communicated at a much higher level and continued the communication far beyond their expectations.

One of the last activities in the project was to meet in the synchronous environment (the Virtual Classroom) provided by the Blackboard courseware. The last exchanges between the telepartners reported very enthusiastic results from the chats. Comments, such as “I really enjoyed our chat last night,” “I was really glad to meet with you live,” and “Wasn’t the chat room fun!” put the icing on the cake for the telementors, the telementees, and the researchers. Concluding remarks in the last email showed the supportive relationships that had been forged: “I really enjoyed working with you. You seem to be a person who puts in quality work [my kind of person]. Good luck and enjoy your graduation. You are going to be so successful!”

The successful conclusion of the telementoring project provided the answer to the research question: Yes, it is possible to mentor over distances, using computer-mediated communication.

Abstract: This article presents the details of a collaborative technology-based science learning project completed through a learning community of students and teachers at four public schools with participation by university faculty. The project involved a study of the impact of the environmental health of the St. Johns River and feeder creeks on residents of Jacksonville, Florida. Through field studies, analysis of data, and the use of educational technology for research and communication, the participants developed new ways to facilitate science teaching and learning.

Project Description

The Riverlink project was a collaborative project among four public schools within the Duval County Public School District in Jacksonville, Florida and the preservice teacher education program at the University of North Florida. The project coupled selected students and teachers in two of the school district’s elementary schools with selected students and teachers at two area high schools. The project incorporated several educational technologies to link the four schools so that students of different ages and cultures could work together to find solutions to commonly shared science learning topics.

Background

The purpose of the project was to develop an awareness of the impact that the environmental health of the St. Johns River has on Jacksonville’s residents. The project created a four-school educational technology connection to monitor the health of selected feeder creeks and streams that flow into the St. Johns River.

One of the elementary schools (Lone Star) and one of the high schools (Sandalwood) is located in suburban Jacksonville. One of the elementary schools (Carter G. Woodson) and one of the high schools (William M. Raines) is located in urban Jacksonville. Participating teachers at Lone Star and Sandalwood worked together on a similar project for two years prior to beginning the Riverlink project.
Through field studies, analysis of resulting data, and the use of educational technologies for research, communication, documentation, and dissemination, project participants discovered new ways to facilitate science teaching and learning through cooperation and collaboration in a learning community.

Structure

To accomplish goals of the project an eleven-member team of experienced educators was formed. The team consisted of three teachers from Lone Star Elementary School, two teachers from Sandalwood High School, two teachers from William M. Raines High School and three teachers from Carter G. Woodson Elementary School. A teacher educator from the University of North Florida participated in the project's planning, training and evaluation. New delivery strategies were developed and used which impacted the roles of all project participants. Project activities were designed to enable teachers at each school to achieve objectives of their school improvement plans and to integrate new teaching strategies and technology-based learning materials and strategies into their classrooms.

Unique Attributes

As a multi-agency collaborative partnership involving public schools and an urban university teacher education program, the project enhanced the effectiveness and productivity of partner institutions by simultaneously addressing related educational concerns. These included the achievement of educational accountability through standards-based teaching and learning coupled with effective uses of educational technology, including the authentic assessment of the academic achievement of P-12 students through the production of their electronic classroom portfolios. The project used a collaborative interdependent change system thereby initiating a redesign of roles for university and school-based faculty. Exemplary classroom teachers examined the link between theory and best practice. The project also provided assistance to participating educators in achieving institutional improvement goals.

Research-Base for the Project

The work of Reeves (1992) provided a useful foundation for identifying four critical success factors used as benchmarks for the project.

1. Clearly defined goals for the project.

Reeves states that "Technology infusion as well as other restructuring activities should be driven by clear goals" (p. 520). Goals for this project involved "authentic achievement" for students and teachers in the form of teacher training, cooperative education, documentation of project activities through digital photography and video, electronic portfolio production and professional presentations at education conferences. Newman (1991) also supports the approach of the project by suggesting that "Rather than reproducing knowledge, students should be involved in producing knowledge, through discourse, through the creation of things, and through performance" (p. 459).

2. Thorough documentation in all phases of the project, Riverlink provided an understanding of where teachers started, where they were at any one point, and where they were going. Reeves states "Documentation attempts to capture all the changes that occur in the process of reform so that interested participants can understand what is really occurring" (p. 522).

3. Formative experimentation is defined by Newman (1990) as follows: "In a formative experiment, the researcher sets a pedagogical goal and finds out what it takes in terms of materials, organization or changes in the technology to reach the goal" (p. 10). The Riverlink project adapted and restructured the project to incorporate new knowledge and improved methods for meeting project goals.
4. Impact evaluation is defined by Reeves as "attempts to assess the effects of innovative instructional practices on factors such as organization, climate, teacher and student self-perceptions, parental and community aspirations, and numerous other difficult-to-measure factors" (p. 524). The Riverlink project used traditional and non-traditional methods of assessment to measure progress toward goals.

The three critical success factors that follow are based on research by Rogers (1983) in which adoption of interactive communication innovations differ from similar processes with other kinds of new ideas or new tools.

Critical Mass of Adopters

The Riverlink project began with four very interested teachers as a core group to influence and persuade school district personnel to get involved with innovations in curriculum, instruction and assessment using educational technology. Rogers found that the usefulness of a new communication system increases for all adopters with each additional adopter. Over 150 elementary and high school students and 11 educators successfully participated in the Riverlink project.

Degree of Use

Continued, supported use of educational technology throughout the Riverlink project was critical to its eventual classroom infusion and diffusion to other users. Rogers also found that the degree of use of a communications innovation rather than the decision to adopt it to be the most important factor indicating the success of the diffusion effort.

Re-invention of Innovations

Rogers defines re-invention of the innovations as the degree to which an innovation is changed or modified by a user in the process of its adoption and implementation. Infusion of technology into school classrooms in the Riverlink project took place as teachers were able to successfully design and implement instructional activities using the educational technologies that met their own specific classroom needs and those of their students.

Seven Project Goals and Their Outcomes

Goal 1: Elementary and secondary students will use technology to collaborate between classrooms and between schools in solving age-appropriate aspects of real-life problems as they develop mastery of related Sunshine State Standards.

Student portfolios created in HyperStudio were produced by elementary and high school students that displayed their new understanding of science and the applications of newly acquired knowledge and skill in using educational technology.

During the year, selected Lone Star Elementary School 1st, 4th, and 5th students traveled to Sandalwood High School where they paired up with high school students to work on computer-based electronic portfolios dealing with science learning outcomes resulting from their study of Gunsmoke Creek, Pottsburg Creek and the St. Johns River. Carter G. Woodson Elementary School teachers and students traveled to the Lone Star site to view Gunsmoke Creek and learn more about Lone Star's science learning activities, materials, experiments and projects.

Throughout the school year, teachers and students at William M. Raines High School and Carter G. Woodson Elementary School worked together to establish a computer laboratory, a Riverlink project laboratory, and establish learning sites at the Pumpkin Hill Preserve. The teachers developed skill in using the educational presentation tool, HyperStudio and the Internet. They also created a distance-learning laboratory to help facilitate communication between the two schools.
Goal 2: A cadre of preservice teachers and veteran teachers will become skilled in the use of high-end technology for classroom instruction.

Partner institutions modified the original goal for the project as project activities were implemented. To guide their students in the display the learning outcomes of their study of the creeks and rivers, all participating teachers received training in the use of Hyperstudio and in procedures for facilitating the development of student electronic portfolios. Participating teachers at Lone Star received additional educational technology training in web page development at New Horizons Learning Center. Web sites were developed for Lone Star and Carter G. Woodson elementary schools. Refinements were made to web sites at Sandalwood and William M. Raines high schools.

Goal 3: The district's professional development model will be expanded to include an experimental learning approach based on the National Writing Project philosophy involving teachers in the same processes and activities required of their students.

Throughout the school year project teachers developed written science lessons, documented science learning outcomes, and created new approaches to science teaching and learning that incorporated language arts learning outcomes.

Goal 4: Students will develop self-initiated learning habits in which they become active questioners and gatherers of information to solve problems.

Students at each project school were actively engaged in science observations, recording data and drawing conclusions to solve scientific problems. The outcomes of the student learning were reflected in their Hyperstudio portfolios and work prepared for posting on the web sites.

Goal 5: The role of the teacher will evolve from a dispenser of information to a facilitator who asks analytical questions, presents challenges, stimulates discussion, and models the learning process.

Students at project schools conducted research, compiled data, and presented it to their peers and students at each other's project schools. The teachers participating in the Riverlink project facilitated the learning and supervised the documentation of science learning outcomes.

Goal 6: The learning environment will change to one in which information technologies are readily accessible to all constituents and one in which questions, discussions, and investigations are at the heart of teaching and learning.

The work with Internet sites provided considerable information to stimulate the students' imaginations. The educational technology provided tools for accessing and effecting scientific communication among students and teachers participating in the project.

Goal 7: Students will understand that science, technology, and society are interwoven.

The artifacts and descriptions provided throughout the project provided considerable evidence that participating students were actively engaged on their own learning. The Hyperstudio portfolios displayed considerable knowledge and skill in the use of technology and the learning of science.

Outcomes and Future Plans

The following dissemination techniques were designed to ensure that other educators had an opportunity to benefit from the outcomes of the Riverlink project.

1. The electronic portfolios produced by each participating student were used in presentations to educators on an invitational basis. Depending on the audience, the presentations were made by either students or teachers.
2. The creation and maintenance of a central website would allow regular student publication of data, articles, and fliers that promote environmental education throughout the community.
3. Students will produce a periodic newsletter that chronicles their investigations.
4. Participating schools will participate in the city's Earth Day celebration by developing and monitoring a public display that describes their involvement in the Riverlink project.
5. Participating teachers developed independent, multi-grade lesson plans and assessments that addressed Florida's Sunshine State Standards in science.
6. Participating teachers developed and presented the outcomes of the project at professional conferences.
7. Participating teachers began the development of their personal professional portfolios.
8. Preservice teachers from the university used the school websites and related Riverlink materials during their clinical experiences in the schools.

Abstract: This paper describes how collaborative teams consisting of arts and sciences faculty, teacher education faculty, K-8 teachers, and teacher candidates worked together during a weeklong summer institute to produce technology-enhanced problem-based learning units of study. Each of the units features a conceptual theme, a metacognitive emphasis, a guided inquiry approach, principles of universal design for learning, and technology infusion. One of the units that was developed during the institute, The Alhambra, is used to illustrate these design elements.

Introduction

Problem-based learning (PBL) is widely recognized as a powerful teaching/learning strategy, but its success depends on both the quality of the problem and the skill of the teacher. Problems must be sufficiently complex to demand an in-depth exploration of important content and sufficiently challenging to stimulate critical and creative thought. Instruction must be carefully crafted to engage students and to model effective inquiry, investigation, and problem-solving strategies. Ideally, a team comprised of a range of education professionals would be involved in the development of PBL units of study to ensure that complex, authentic problems are addressed in a carefully crafted learning environment.
The T² Summer Institute

In June 2001, Project T², Teachers and Technology, held its first Summer Institute. This weeklong institute provided the setting to bring together a team of education professionals to develop PBL units of study for use in K-8 classrooms. Teacher candidates, arts and sciences faculty, teacher educators, and K-8 teachers from each of the three partner institutions and their associated school districts came to the Summer Institute with the express purpose of developing technology-enhanced problem-based learning (TE-PBL) units of study. Two consultants, one in the area of problem-based learning and the other in the area of universal design for learning, worked with institute participants in the design and development of the units.

On the first day of the institute, participants were divided into five teams, each consisting of at least one arts and sciences faculty member, at least one K-8 cooperating teacher, at least one teacher education faculty member, and two or more teacher candidates. Each member of the team had a different perspective and an important role to fill on the team. The arts and sciences faculty members ensured that rich content was associated with each problem scenario. They served as the content area experts and provided the knowledge base necessary to give the unit authenticity and relevance. The teacher education faculty members provided the pedagogical content knowledge. They ensured that appropriate instructional techniques would be used to challenge and guide a wide variety of learners in a wide variety of settings. The K-8 cooperating teachers contributed their expertise and experience in today's complex classrooms. They brought an element of "reality" that ensured the content addressed state curriculum standards and the skills were appropriate for students' developmental level. Teacher candidates were central team members. Since they planned to use the units the following year in their student teaching, they asked the questions that made certain the units were clearly written and usable by novice teachers (or teachers unfamiliar with problem-based learning).

Students and faculty from the three partner institutions were mixed on each team so that there would be an enriched exchange of ideas and techniques. We recognized, however, that it would be important to provide time for team members to get to know each other, so team-building activities were built into the first day's agenda and a number of opportunities for working together were provided during the week. Most participants lived on campus during the institute, which gave them additional opportunities for socializing and working together during the evenings.

Team Collaboration

Participants responded very favorably to working in teams. Teacher candidates later listed the benefits they felt, most frequently mentioning the following:

- Learning from those with more sophisticated skills
- Having experts there to facilitate the process
- Developing confidence and recognizing our own areas of expertise
- Getting ideas from arts and sciences faculty that would not have occurred to us
- Having our teachers (teacher education faculty) there to help us with designing the unit

The Units

Five TE-PBL units were designed, one from each team. We found that we did not have enough time in one week to fully develop complete units, but each was well started with a problem scenario and a basic outline of content and activities. All units feature 5 design elements: a conceptual theme, a metacognitive emphasis, a guided inquiry approach, principles of universal design for learning, and technology infusion. Each is based on state (NC) and national content area and technology standards. In the remainder of this paper we will illustrate these design elements as built into one of the units developed during the institute, The Alhambra, which presents students with the following problem scenario:

A mild earthquake occurred last week and damaged some of the precious mosaic panels in the Alhambra, a palace in Granada, Spain. Many of the most beautiful rooms in the palace have had to be closed. You have been asked to join a team that has been hastily put together to make recommendations to the Granada Municipal Council on whether it would be worth the cost to restore the panels of the Alhambra and, if so, how this might be done.
Conceptual Theme: Patterns

The generalization that provides the underpinning for this unit is "Pattern recognition is fundamental to problem solving." In The Alhambra, pattern recognition is highlighted in at least two ways: one, the pattern in the mosaics and how shapes tessellate to form an authentic design, and two, the pattern of replacement cost change as affected by design change. In this unit situations are set up so that students will come to understand that recognizing patterns is an important skill in problem solving.

Metacognitive Emphasis and Guided Inquiry Approach

A guided inquiry approach is used during each phase of the PBL process. As TE-PBL units are developed, essential questions are built in so that teachers can lead their students to ask questions that will guide them in their information gathering and in their thinking about the problem. During the problem engagement phase of The Alhambra, for example, the teacher may ask students such questions as:

- What questions do we need to answer to begin solving this problem? (e.g., What is a mosaic?)
- How might we find answers to our questions? (e.g., Where could we find pictures of the Alhambra?)
- How can we focus and organize our research? (e.g., What is most important to find out first?)

As teachers model this type of questioning, they encourage students to ask questions, to plan, and to monitor their own progress.

Principles of Universal Design for Learning (UDL)

To ensure that quality curriculum is accessible to all students, T² units are constructed with principles of universal design in mind. Multiple forms of engagement, representation, and expression are considered from the beginning and built into each unit. The Alhambra provides several examples of UDL. For example, to provide multiple forms of engagement, selected websites give students realistic views of the palace, gardens, and mosaics while links to information on tessellations and tiling techniques provide different ways to engage with geometry. The Alhambra also includes multiple opportunities for students to express what they have learned. In addition to the rubric that evaluates the final product, there are "skill and content checkpoints" where students can assess their own progress as frequently as they wish without teacher assistance.

Technology Infusion

Technology is infused throughout The Alhambra unit. As noted above, students can see photographs of the palace and its mosaics at sites available on the Internet. They can also investigate geometric shapes, tessellations, and nibbling techniques by utilizing sites on the Web. There is a sample spreadsheet for calculating cost of renovation designs, and the unit links to an online dictionary of math terms in case students need to look up unfamiliar terms. Test authoring software is used to insert the skill and content checkpoints.

Conclusion

Collaborative teaming facilitated by technology provides an ideal means of developing high quality TE-PBL units. Content knowledge, pedagogical knowledge, and real-world experience combine to lend authenticity, challenge, and accessibility to curriculum development.

Abstract: Recently, the Lilly Endowment announced their latest Community Alliances to Promote Education (CAPE) projects, and Indiana State University was a recipient of $5,000,000. Indiana State University is collaborating with the local school corporations to assist Sullivan County in the implementation process to enhance the educational opportunities of the citizens of Sullivan County. Sullivan County lacks the technology foundation, or delivery system, needed to access the resources to meet its educational challenges. To address the identified changes, the following solutions are being implemented in this project: a fiber optic network to connect the county schools and main library; a community learning center; video-enabled distance education; and training in technology for all the county’s teachers. This presentation will focus on the project goals and successful opportunities and challenges confronted by the venture.

Introduction

Recently, the Lilly Endowment announced their latest Community Alliances to Promote Education (CAPE) projects, and Indiana State University was a recipient of $5,000,000. Indiana State University is collaborating with the local school corporations to assist Sullivan County in the implementation process to enhance the educational opportunities of the citizens of Sullivan County.

To understand the needs of Sullivan County stop – for a moment - and place yourself in a rural community, Sullivan County in particular. Then consider how technology, or the lack of it, affects the people who live there. This project appears to be all about computer technology, video conferencing and fiber optic networks. But is it? This project is about elevating the ability of a rural community to compete in an increasingly technologically driven society. This project is all about leveling the playing field.

Sullivan County is a predominantly rural community located in the southwestern part of the state between Vigo and Knox counties. It has a population of 20,280 people with the city of Sullivan serving as the county seat. Two school corporations, Southwest (SWSC) and Northeast School Corporations (NESC), currently serve the educational needs of the children of Sullivan County. Currently, according to the 1990 census, 26% of adults in Sullivan County do not have a high school diploma and only 10% have four years or more of college compared to 16% of the population of Indiana. Poor education is accompanied by low income, which is reflected by a 20% difference in annual income between Sullivan County and the state of Indiana ($23,141 compared to $28,936) according to the Indiana Department of Workforce Development. Sullivan County also has a large senior citizen population. According to the 1990 census, 18% of the citizens in Sullivan County are over the age of 65 while the state and national levels are 10%.

A representative group of citizens from education, business and industry met to discuss the educational strengths, weaknesses, opportunities and threats facing Sullivan County. While a number of deficits were noted as being serious, solutions to these difficulties as well as opportunities for advanced training for students and economic development of the county were identified in technology. Unfortunately, Sullivan County lacks the technology foundation, or delivery system, needed to access the resources to meet its educational challenges. To address the...
identified changes, the following solutions are being implemented in this project:

- A fiber optic network to connect the county schools and main library
- A Community Learning Center
- Video-enabled distance education
- Training in technology for all the county’s teachers

The schools share facilities with the communities in the evenings and on weekends for educational purposes. Trained students, building their skills for future employment, will staff the computer labs. Studies show training continues to be a significant barrier to using technology effectively in the learning environment. To address this issue, a new generation of staff development programs is being created for teachers in the county. The new in-service program is aligned with Indiana’s Department of Education’s new state standards and guidelines and nationally recognized technology standards.

Fiber Network

In education, rural schools have always been behind urban schools in educational opportunities because of the lack of ability to offer a variety of advanced and elective classes. With the advancement of the technology age the gap is widening because of a lack of resources necessary to provide an adequate number of computers and Internet access to poor rural areas. Ironically, this same technology would lessen the gap if technology were available to rural areas.

In Sullivan County, while efforts have been made to provide students with computers, access to the Internet is very complicated, slow, unreliable and expensive because three separate telephone systems and two LATAs (Local Access and Transport Area) serve the county. 56K lines connect all the schools in both corporations, which is a cause for frustration resulting in limited access. 56K frame relay circuits do not allow for distance learning, voice or video. A fiber optic backbone is being constructed to connect all the county high schools, public library and Community Learning Center to allow for Internet access as well as other distance learning technologies (Figure 1).

Figure 1. Diagram of Sullivan County Fiber Optic Network
This project is replacing the present dependency on lower speed T-1 and 56K leased lines. This issue is problematic to all rural K-12 schools in the state of Indiana and the nation as a whole. Sullivan's Connected Lifelong Learning Community project could be a catalyst for the state of Indiana in demonstrating the capabilities of a fiber optic network in a rural setting. This goal of building a fiber optic network is the foundation on which all programming and training of the subsequent goals are based.

**Community Learning Center**

Network technologies do not become powerful until they serve the purpose of improving the human situation. The Community Learning Center is being designed to offer programs using distance education and instructional technology as a promising solution for lifelong learning in a rural area.

While the Learning Center is being housed in a central location, the services offered to the County are not to be viewed as being in "four walls". The Center is mobile to the extent that equipment and personnel can go out into the community to provide services. Sullivan's Community Learning Center is enhancing skills for lifelong learning through flexible (time, location, method) programming.

**Video-Enabled Distance Education**

This project is providing video-enabled distance education to and from the schools and Community Learning Center within the county and from higher education institutions in the state of Indiana. For example, Southwest School Corporation offers French as a foreign language while Northeast School Corporation offers German. It is financially impossible for each school corporation to offer both, but with video-enabled distance education classrooms, students in both corporations will have a choice of either class. In addition, the two school corporations will offer a complete set of advanced placement (AP) courses for college bound students. Currently, only Sullivan High School offers two AP classes.

The state higher education system offers a plethora of courses available through distance education. The community will be able to access the courses from any one of the high schools and the Community Learning Center in the county with the installed video equipment.

**Staff Development**

Internet access and video conferencing provides schools with resources that would not otherwise be available. Training continues to be a significant barrier to effectively using technology in the learning environment. Connected Lifelong Learning Community staff will be representative of a new generation of professional development with instructional technology. A new generation of professional development is differentiated according to participant needs; it is contextual according to teaching and work assignments; it integrates the technology for teaching and learning; and it is grounded in the standards and professional development guidelines that affect teachers, staff, and administrators in Indiana (i.e., K-12 curriculum standards, Indiana Professional Standards Board [IPSB] teaching standards.)

Programmatically, the staff development is designed for all school corporation and Community Learning Center employees. Staff development utilizes strategies that are shown to be indicative of effective professional development (McKenzie, 1999; NCREL, 2000):

1. **Organizational Technology Planning.** Staff participated in technology planning that begins with assessments to determine the current technology integration abilities and technology capacity of the staff, schools, and district. This assessment utilized the “enGauge Framework for Effective Technology Use in School” (http://engauge.ncrel.org/). This assessment tool was developed with support by the North Central Regional Educational Laboratory (NCREL) and provides baseline data for long-term evaluation, as well as for the purposes of planning.

2. **Personal Technology Planning.** The staff engaged in personal technology planning. Baseline data on personal technology capacity being collected through the web-based tool called “My TARGET”
My TARGET is a tool that allows users to assess and reflect on growth with educational technologies and was developed in Indiana with support from the Lilly Endowment.

3. **Technology Facilitators.** The staff includes the current technology facilitators of Southwest School Corporation and created additional facilitators in the Northeast School Corporation. Technology facilitators are full time staff that assist teachers on the integration of technology into the learning environment and are available to solve technical problems on a continuing basis. The technology facilitators are an integral component of the remaining staff development strategies.

4. **Professional Growth Teams.** As the staff completes the assessment and planning process (which addresses district, school, and personal needs) staff are placed in smaller, support units that coincide with the IPSB Professional Growth Teams. Team members will help each other develop Professional Growth Plans (PGP), work cooperatively throughout the project period, and provide support and feedback. The PGP's will guide the development of the topics and format of the staff development. (For example; instruction over video conferencing would not occur until participants are competent with the technology) The PGP's utilize the baseline data collected and forecast individual objectives and goals that encompass technology standards such as the Recommended Foundations in Technology for All Teachers, developed by the International Society for Technology in Education (ISTE), the Professional Competency Continuum, developed by the Milken Exchange on Educational Technology, and the National Educational Technology Standards for K-12 students, developed by ISTE and related consortium. Teams meet and communicate face-to-face, through electronic technology, and where appropriate through video conferencing.

5. **Connected Student Learning.** The objective of this professional development is to implement new teaching strategies that will engage students and develop their cognitive skills for higher order thinking, not on training for training's sake. Student learning will always be a contextual element present in all staff development. Participants will be expected to map professional development activities back to student learning activities and outcomes.

6. **Create a Knowledge Base.** In order to help teachers understand how instructional technology can be connected to student learning and how it can enhance teaching, learning, and assessment, as well as to aid in planning, all the professional growth teams will work to create a common knowledge base related to instructional technology. A significant portion of the staff development budget is devoted to the purchase, development, and duplication of training materials (books, CD's, online materials, etc.), and research materials (books, journal reprints, etc.) to develop and enhance the participants' knowledge regarding educational technologies.

7. **Hands On Learning with Technology.** Talking about technology will do little to enhance the ability of participants to use technology for teaching, learning and assessment. At all times, participants are active users of the various technologies, and even use a particular technology to learn about its application. For example, teachers who are learning how to effectively deliver instruction over a two-way video and two-way audio system participate in instruction through that system. Experience as a learner will enhance their abilities as an instructor. Active learning with various technologies takes time and staff are permitted the time to "play" with technologies and engage in their own constructivist and discovery learning. Therefore, two important items were necessary to alleviate this time issue. First, staff members that participate in staff development beyond their contracted hours will received a stipend. For staff development that needs to take place during the regular school day, substitute teachers are hired cover classes.

8. **Collegial Learning and Support.** Effective professional development teams provide supportive learning environments. The professional growth teams are one source of support that has already been described. In addition, each participant will identify a "buddy." Participants will select their own buddies from a peer group. This type of support provides invaluable experience for the students and helps the staff to better understand the facilitative mode of instruction that technology can engender. These individuals may or may not be in the same professional development team, but are a connection to share learning experiences, frustrations, celebrations, etc. Consultants also are another form of support for the staff development participants. Consultants do more than just hands-on training activities but continue to participate both before and after a particular training element to provide support and continued learning for participants.
The consultants were selected, according to the outcomes of the planning process. Selected consultants needed to agree to be available for an extended period beyond training to provide online support as needed by participants. Finally, students in the school are an excellent source of support. Whenever possible, students were used to provide assistance with training and technical support. This type of support provides invaluable experience for the students and helps the staff to better understand the facilitative mode of instruction that technology can engender. Formats for learning include but are not limited to: for-credit courses, field trips, visits to educational resource centers, Indiana Department of Education sponsored technology associates, online training, expert consultants, etc.

9. **Mentor Teachers.** There currently exists a number of staff who have a high level of experience and comfort with technology. Their assessments and PGP indicate that they need little actual training but need more "practice" and time at utilizing technology in the classroom. These teachers are prepared early in the process to experiment with technology integration for teaching and learning. These teachers will then be able to serve as mentors to other staff members.

10. **Follow Up Assessment.** The staff development budget includes money for a follow-up evaluation. The project allows for a variety of baseline data to be collected using a number of online tools. These same online tools will be revisited at the end of the third year to determine growth. In addition, an on-site technology audit of both school corporations will be conducted to receive additional feedback.

This presentation will focus on the project goals and successful opportunities and challenges confronted by the venture. When the project is completed students from both school corporations will have the opportunity to use the most up-to-date technology available in preparation for higher education and the job market. Students and teacher will experience the following improvements and enhancements when this project is complete:

- Fast, reliable Internet access for all school personnel (fiber optics is much more reliable and over 100 times faster than our present system)
- Improved network security
- Ability to share resources between school corporations
- Advanced applications such as full-motion video
- Distance Learning
- College credit classes
- Centralized software and data backup
- Centralized maintenance
- Employment of students in the Learning Center and computer labs
- Early education of children through the Learning Center
- Career exploration
- Tutorial instruction

The Connected Life-Long Learning Community from vision to reality is giving the citizens of Sullivan County the educational opportunities they will need to succeed in the 21st century.

Technology for Participation

Dr. Terrie Shannon, Dr. Louis Abrahamson, Lyle Shannon, and Karen Keenan, partners in the Arrowhead Preparing Tomorrow’s Teachers to use Technology (APT3) Project, Education Department, University of Minnesota Duluth, Minnesota, are the presenters for this 2002 SITE Conference interactive session.

Technology for Participation

The Arrowhead PT3 (APT3) project is an innovative teacher preparation program at the University of Minnesota Duluth. Working in collaboration with the Duluth Public Schools, Fond du Lac Ojibwe Schools, Apple Computer, Texas Instruments, and Better Education, Inc., APT3 educators are working to increase student active participation and faculty collaboration through the use of wireless hand held communication response devices. This interactive session will demonstrate classroom pedagogical and group interaction applications enhanced through the use of these devices.

The objectives of Technology for Participation are to provide participants with:

- An opportunity for educators to experience hand held communication response devices
- The pedagogical theory supporting the use of these technological devices
- The opportunity to become familiar with two types of software applications for increasing student participation.
- A venue for discussion about possible research about and applications for handheld communication response devices.

This session is applicable for beginners through advanced technology users.

APT3 educators will demonstrate and facilitate the use of two types of interactive infrared response devices: Classroom Performance System (CPS) and Performance Response System (PRS). Both systems support real-time interaction in traditional classroom settings through teacher questioning and anonymous individual student response. Immediate feedback is provided through graphic and text display. Additionally, each software application allows for saved and tracked digital student records.

CPS and PRS promote active participation for each student in an environment where only the teacher knows the answer each individual student provides. This type of anonymity decreases student anxiety, which in turn promotes better student engagement of the content of the class, rather than a fear of being incorrect. Additionally, teachers who apply PRS or CPS technologies in their classrooms provide themselves with a means to accurately diagnose student learning in a meaningful and formative way. Further, CPS and PRS technologies can be used for collaborative learning that encourages teamwork. Finally, due to the record keeping features, these systems diminish administrative teacher tasks, allowing for time generation, a valuable commodity for any teacher.
During this session participants will experience both systems. Additionally, information about a current research project, The Use of Interactive Instructional Technology to Facilitate Classroom Instruction, by Robert L. Lloyd, Ph.D. will be summarized for participant review and discussion.

This interactive session can accommodate 30 participants. The materials needed include the following:

- Internet access
- A digital projector and screen
- An easel, flip paper and markers
- A power strip with a long cord
TOPS and STAT: Two PT3 Bridges for the Digital Divide

Jennifer Kidd, Old Dominion University, US
David Kidd, Brunswick County Public Schools, US

Aligning Credentialing with Technology Training (ACTT Now) is a Preparing Tomorrow’s Teachers to Use Technology (PT3) project partnering Brunswick County Public Schools, a k-12 district in rural Southside Virginia, with Old Dominion University’s Darden College of Education. It is intended to counter the effects of the digital divide felt so profoundly in this region. ACTT Now consists of five major components:

1. An internship program for Old Dominion’s pre-service teachers
2. A field-based masters degree program for Brunswick’s uncertified and provisionally certified teachers
3. Technology Opportunities for Parents and Students (TOPS): An evening technology-training program for Brunswick County community members
4. Student Technology Assistance Teams (STAT) and
5. Technology Training for Old Dominion’s Methods Faculty

Despite the dismal statistics of its community, including one of the highest illiteracy rates in Virginia, Brunswick County Public Schools has emerged as a leader in technology. Through the innovative leadership of the technology department, Brunswick County has acquired technology resources parallel to those in the rich districts surrounding the nation’s capital. Four instructional technology specialists and the director of technology work to help teachers integrate these new tools into their classrooms and curricula. Now in partnership with Old Dominion University, Brunswick has improved resources with which to accomplish this mission.

Old Dominion University’s Darden College of Education has been a technology leader for the past decade. Its Teletechnet program brings 4-year degree program to students in remote areas throughout Virginia and the nation. Previously focused on the development of the urban area of Hampton Roads, the Darden College of Education now has an opportunity to expand its reach into the surrounding rural communities that are greatly in need of educational and economic resources.

This paper will focus on two ACTT Now initiatives aimed specifically at increasing the technological proficiency of Brunswick’s population: TOPS and STAT. Technology Opportunities for Parents and Students (TOPS) offers free technology classes for adult community members in Brunswick County and entices them to participate with free dinner, child care and nightly raffles prizes. While parents and grandparents are learning basic computer skills, their children are engaged in crafts, games and technology activities of their own. What makes TOPS truly a learning experience at all levels is the instructors. Brunswick teachers participating in ODU’s field-based masters program serve as the adult and student instructors in the TOPS programs, helping the teachers to reinforce their own technology skills and building a stronger bond between the community and the schools. Providing a needed service to their community, Brunswick teachers take pride in their efforts and contribute to the emergence of a technology culture in the county.

Student Technology Assistance Teams (STAT) likewise focus on helping different populations simultaneously. Many good teachers are reluctant to use technology in their classrooms. STAT provides in-classroom support to teachers when and where they need it. At the same time, STAT students learn responsibility and earn respect from their teachers and peers as they take on new roles as technology helpers. STAT encourages Brunswick’s students to explore information technology jobs and programs, a field where undoubtedly, a significant proportion of future jobs will lie. Working as part of STAT, students gain valuable and marketable experience that will give them a head start toward a future career.

Through the efforts of the ACTT Now project staff, STAT and TOPS are working to bridge the digital gap in Brunswick County. As works in progress, these two initiatives are experiencing successes and setbacks. The paper will explore both. Data collected by the project manager and ACTT Now’s external evaluator will be presented to analyze the effects of these two initiatives on the technology literacy and the self-efficacy of Brunswick’s population.
Abstract

This paper and presentation follows the development of a web portal for a PT3 project based at West Chester University of Pennsylvania. Through work with school, business and community representatives, WCU is in the process of strengthening partnerships that enhance pre-service teacher education and building an on-line community of learners among the members of the partnership. Included in the portal community will be pre-service and in-service teachers, WCU faculty, and other project partners. The portal design facilitates ongoing communication and support for teachers whether they are new to teaching, have not yet taught or are experienced veterans. This paper discusses the development of the web portal and outlines the key decisions in establishing its design and in choosing the technology used to implement it. Also, it describes the creation of a community of learners among the partners and the evaluation of outcomes from the portal implementation.

Introduction

West Chester University (WCU) of Pennsylvania graduates 600 new teachers each year. WCU together with their P-12 partners, share a sense of urgency in preparing WCU graduates to meet the challenge of educating P-12 students successfully in today’s digital age (Carlson & Gooden, 1999). To meet current educational challenges, the partners recognize that the teacher preparation program must evolve into one that: models the effective use of technology, requires online learning, and expects that pre-service teachers will use technology daily as a productivity and communication tool. Also this should be a program that engages pre-service teachers in the best practices related to content-specific, technology-based solutions; provides pre-service teachers with field experiences that engage them in authentic effective uses of technology with P-12 students, and teachers; and consistently engages pre-service teachers in high-quality professional dialog and reflection through online communities throughout their preparation into their induction. Building on the extensive work of WCU and its partners through a number of initiatives (including a 1999 PT3 Capacity Building Grant), this strong P-16 partnership plans to develop a “21st century” teacher preparation program.
There is nation-wide, urgent need for technology-savvy teachers who are able to effectively integrate technology for improved teaching and learning environments (Carlson & Gooden, 1999; Green, 1998; NCES, 1999). Recent studies show, when used intelligently as a tool, technology can help to leverage improvements in K-12 classrooms (SIIA 2000 Report; Milken Exchange, 1999; Valdez & McNabb, 1997). The United States Department of Education, through its Preparing Tomorrow's Teachers with Technology (PT3) initiative is supporting the improvement of technology integration in teacher education programs, as are organizations such as the National Council for Teacher Accreditation (NCATE) and ISTE. The CEO Forum, a U.S. business-education collaborative, has recommended that teacher training in computer technology become a mandatory component of licensure by 2002. Locally, in Pennsylvania, this need has been highlighted by evidence showing that simple access to technology resources is not sufficient for the creation of technology-enhanced learning environments (PA Link to Learn Initiative, 2001).

Through this PT3 initiative, cohorts of teacher candidates will authentically experience what it means to use technology as a learning, teaching, productivity, research, and communication tool. The four PT3 program goals focus on technology integration, partnerships for enhanced teacher preparation, university leadership, and communities of learners. The initiative is grounded in research and best practice and based in the reality of the P-12 classroom - critically important for providing pre-service field experience and the supportive environment needed for future technology integration (Bell and Fidshun, 2000).

Existing Partnerships, the Foundation

Many educators have identified that the collaboration between K-12 schools and universities as essential to school improvement. Neither set of institutions can achieve alone what they can when they join together to solve problems which impact both of them. (Goodlad, 1991). Over the past three years, WCU School of Education identified a strong group of partners that has agreed to work with WCU to improve teacher preparation in order to meet educational challenges. Current partners include 7 School Districts, 3 Regional Consortia, and 3 Regional Educational Organizations. Each partner has offered to engage in activities that enhance the preparation experience of our pre-service teachers. The activities offered by each partner depend upon its strengths and interests, for example, teachers from the West Chester Area School District will engage in on-line technology integration courses with pre-service teachers and WCU faculty members as partners. The School District of Philadelphia has offered to host pre-service teachers for field experiences in technology-rich classrooms. Teachers in several local school districts will work with two pre-service teachers to integrate appropriate technology into a lesson or curriculum unit. Pre-service teachers will benefit from enhanced field experiences focusing on the use of technology in real classrooms; teachers in those classrooms receive assistance with technology. The current partnerships built around common interests in effective technology integration and a willingness to support improvement in teacher preparation will be extended and strengthened by development of the portal.

Portal Design and Content

The word portal implies a gateway; an Internet portal is a web site that provides entry into a comprehensive and well-organized collection of content, tools, and value added services. The portal concept is becoming increasingly important as the amount of educational information and resources grow. Educators need quick access to web resources that meet their needs and interests without having to wade through information that is not suitable. Portals can tailor information to different educational audiences with varying interests. Our portal will have specific web pages for pre-service teachers, K-12 teachers, and university faculty and content that is directed to each role group.

Portals also, provide tools that make communication between partners easier. If the PT3 partners can communicate easily at the portal site, they can exchange information that will assist them to more effectively integrate technology and strengthen teacher preparation programs. Portals will supply the tools and resources that support learning communities.
Development Process and Technical Considerations

Development of this portal has taken place over the course of six months and the website will continue to grow and be refined as a tool for the building of the WCU PT3 community. Initial work on the site began with brainstorming sessions that included the ideas of key faculty, teachers, project directors, evaluation team members and the project coordinator. These early ideas and a timeline for their implementation were originally scripted on paper, and then later committed to electronic text forming a set of homespun web pages. An important understanding, learned early on in the development of this web site, was to consider the portal user at all times, from the sequence of pages and the path a user would take through the descriptive text and databases that lay behind each button or choice a portal user might make.

In the beginning, two web site development firms were interviewed and meetings were held with these groups that actually helped the development process, if only through the thought experiments that ensued. One of these firms, a local commercial website company, was selected based on the successful work they had done with a for-profit educational site for K-12 students. Unfortunately, it quickly became clear that their experience with teaching and teacher-preparation was very limited and although our initial work together was helpful, this firm was not retained beyond phase one.

Finally, though collaboration with another PT3 Grantee at the Miami Museum of Science, an agreement was made with their in-house, web site development team. By working with this group who intimately understand teacher preparation, and technology integration through their own work, we have been able to make much faster progress in the development of this site. Many of the types of databases, JavaScript, and other coded programming needed to support an on-line community, have already been used in the Museum of Science site and with some alteration will be useful in the WCU portal as well. An early lesson learned when developing a web portal is that it is helpful to find technical support professionals who understand the key issues and content of a particular project. Without this already-existent shared understanding of the work that a portal is to accomplish, much time will be needed to bring developers "up-to-speed", creating problematic and costly delays in development.

Partnerships Transformed into a Community of Learners

WCU will use its new web portal to strengthen its partnerships by creating a learning community in which partners collaborate, conduct joint projects, review and critique ongoing work and share challenges and successes with other members of the teacher preparation community. In other words, partners will collaborate in a setting, the portal, where they build their future by learning to "implement our best ideas of today" (Jilk, 1999). Technology will serve as the catalyst that enables the partners, which may be distant in time and place, to work more closely with one another to solve problems and build new futures (Reil, M. & Fulton, K. 2001). The web portal now being created links the teacher preparation partnership to enhanced learning with technology. Pre-service teachers who have this collaborative experience during their professional training are more likely to engage in learning communities as they continue to develop as education professionals (Slowinski, Anderson, & Reinhart, 2001) Resources such as lesson plans based on the ISTE/NETS standards, integration strategies for teacher preparation programs developed in this project, and mentors for tech users will be available online. This portal will also serve as the electronic "meeting place" for identified project members and will be a gathering place for collaboration and exchange of ideas. Students from the George Washington High School of the School District of Philadelphia will be responsible for online technology support to the WCU PT3 Partnership for Excellence through the web site. We will disseminate project findings, announce face to face meetings, share resources, materials, advice and connect the entire PT3 Partnership for Excellence membership through the Web Portal.

Early Outcomes and Next Steps
At the time of publication, the WCU PT3 web portal is still in the second phase of its development process. Databases to support in-service, pre-service and faculty members have been designed and are now being configured. Pathways from page one through page fifty-one have been thought out and submitted to the webpage developers using Inspiration as a concept-mapping tool. Colors have been selected for the web site, and a functional site should be available for partners within the next two months (2/02).

Next steps for the development of this portal, which will likely be organic or continuous in nature, include "fleshing out" content descriptions for each web page, adding partner information, adding students at the beginning of the Spring semester, and encouraging in-service teachers to sign-on as hosts and collaborative partners for our pre-service teachers. As we reach toward our goals, we plan to enhance and expand our pre-service teachers field experience, and not simply teach about educational technology integration -- but teach with technology in this university and in the partnering K-12 classrooms with the students we serve. When faculty model effective technology use, students can become more effective teachers. The energy level is up in the WCU School of Education for technology integration and positive change, and our new PT3 Implementation grant will help to sustain our efforts. Tracking the use of this web portal will allow us to see longitudinally the concrete results of an extended, forward-looking effort.

Preparing Preservice Teachers to Use Technology: Program Experiences and the Research

Denise Schmidt, Iowa State University, US
Clyciane Michelini, Iowa State University, US
Deb Versteeg, Iowa State University, US

Teacher preparation institutions all over the world are focused on providing experiences for preservice teachers so they will learn to use technology and then meaningfully integrate those technologies into the learning process. Because of its complexity, this task has been quite challenging for most teacher education programs. It challenges all teacher educators involved in preparing preservice teachers to think critically about the role of technology throughout the entire teacher education curriculum and the quality of field experiences the undergraduate students have in K12 schools. To adequately prepare preservice teachers to use technology in their own classrooms, teacher education programs must develop comprehensive models for technology integration that include meaningful uses of technology to improve and renew the teacher education and K12 curriculum.

Iowa State University has designed a technology-infused teacher education model. The goal of this comprehensive model is to prepare cohort groups of preservice teachers who are ready for leadership roles and who have had technology-enriched course and fieldwork throughout their teacher education program. This model's design is based upon the successful Project Opportunity cohort model developed previously at Iowa State University and uses John Goodlad's model of simultaneous renewal as a guiding theoretical framework (Goodlad, 1994).

In this teacher preparation model, a cohort of preservice teachers begin taking all of their professional education and methodology courses as a group starting their sophomore year. In addition, a three-year relationship with a school district is established, so students can participate in field experience opportunities in classrooms each semester. It is anticipated that these students will accumulate over 250 hours of field experience in schools prior to their student teaching experience. This model also provides extensive professional development opportunities for inservice teachers at the partner school sites. All facets of the model are designed to improve the quality and increase the quantity of field experience opportunities for students in the teacher education program.

A research agenda has been designed to examine the impact this comprehensive model has on the preparation of preservice teachers at Iowa State University. The cohort students have completed two surveys, Survey of the Use and Integration of Computer-Related Technology (Schmidt, 1995) and Cultural Diversity Awareness Inventory (Henry, 1991; Phillips, 2000), to provide baseline data in these areas. Additional data are being collected through focus group interviews, journals, and classroom observations. Results to date will be shared.

In summary, this technology-infused teacher education model addresses the challenge of helping preservice and inservice teachers define and implement technology applications that will expand and enhance curriculum in K-12 schools and will model comprehensive uses of technology to facilitate teacher education renewal.

The NC Catalyst/SAS inSchool Partnership: Universities, Public Schools, and Business Working Together to Help Faculty and Cooperating Teachers Integrate Technology in Teacher Education

Carolyn Sneeden – University of North Carolina
Marjorie DeWert – SAS inSchool

Abstract:

In 2000, the University of North Carolina system received a Preparing Tomorrow’s Teachers to Use Technology (PT3) grant from the US Department of Education. The statewide grant, titled NC Catalyst, is aimed at strengthening North Carolina’s administrative, human, and technical infrastructure to ensure that all teacher education candidates are ready, willing, and able to use technology to enhance teaching and learning when they graduate from our 15 public teacher education programs.

A major focus of NC Catalyst is helping university faculty and cooperating teachers develop the knowledge, skills, and dispositions they need to integrate technology into their teacher education programs and field experiences. To accomplish this goal, each of the teacher education programs in the University of North Carolina system provide professional development opportunities for their faculty and cooperating teachers.

SAS inSchool has partnered with NC Catalyst in this important undertaking. As part of the partnership, SAS inSchool provides each teacher education program in the University of North Carolina system with an annual license to all of its curriculum software for secondary students as well as to Curriculum Pathways™ a curriculum resource for secondary teachers that provides quick and easy access to high quality, standards-based lesson plans, teaching ideas, and web resources.

Through the NC Catalyst/SAS inSchool partnership, we are helping university faculty and cooperating teachers meet the challenge of preparing the next generation of secondary teachers for our state’s public schools. In this panel presentation, we will present NC Catalyst from four perspectives: that of the system-level grant coordinator, university faculty member, a cooperating teacher, and a business partner.

We will:

- provide an overview of NC Catalyst professional development efforts and related evaluation data to-date
- present an overview of SAS inSchool products and describe our unique, problem-based, collaborative approach to professional development
- share examples of how university faculty and cooperating teachers are using SAS inSchool products in teacher education programs and field experiences
- present and discuss the lessons we’ve learned about how universities, public schools, and business can work together to achieve mutually beneficial goals
Never Bowling Alone: Building Social Capital and Professional Knowledge Through Educational Technology

John J. Sweeder, Ed. D

bednar@lasalle.edu

Abstract: This paper maintains that teacher educators who infuse a multi-layered reciprocal cognitive apprentice "idea technology" (Ryan, Sweeder & Bednar, 2002) into teacher preparation programs will build social capital (Putnam, 2000) and enhance professional knowledge among graduate preservice teachers, teaching assistants, novice and veteran certified teachers, and university faculty. These 5 groups participated in a two-week summer immersion teaching practicum that included 63 middle-school children. A quantitative and qualitative survey was distributed to all pre- and in-service teachers as well as university faculty. Each questionnaire was analyzed systematically to determine the extent to which social capital had been built using the aforementioned idea technology. Results suggest that study participants formed strong bonds across both horizontal and vertical social networks (Driscoll & Kershner, 1989), bonds that, in turn, fostered professional development with respect to technology usage, leadership skill, collegiality, and personal reflection.

Introduction

A well-connected individual in a poorly connected society is not as productive as a well-connected individual in a well-connected society. – from Bowling Alone by Robert Putnam (2000)

Our paper argues that teacher educators who incorporate a multi-layered reciprocal cognitive apprenticeship model, an idea technology (Ryan, Sweeder & Bednar, 2002), into their pre-service teacher preparation programs, build social capital and enhance professional knowledge in a variety of powerful ways. "Social capital refers to connections among individuals – social networks and the norms of reciprocity and trustworthiness that arise from them" (Putnam, 2000, p. 19); likewise, social trust, an element of social capital, not only "promote[s] productive behavior," but also serves as "the cornerstone of reciprocal action..." (Coleman, 1988, as cited in Smylie & Hart, 1999, p. 423). Social capital comprises good will, fellowship, sympathy, and social intercourse among individuals who make up a collective unit. When pre-service and in-service teachers have opportunities to make connections with all parties involved in a professional development school (Mittleton, 2000) or in an immersion program such as a six-week summer practicum (Sweeder & Bednar, 2001), they are more likely to refine their professional decision-making abilities dealing with issues such as classroom management, lesson planning, and technology use (Wilen, Ishler, Hutchison, & Kindsvatter, 2000).

In our secondary education graduate immersion program, educational technology is deployed using an specifically-tailored cognitive apprenticeship model (Woolfolk, 2001) with five distinct, yet interrelated groups: graduate pre-service teachers, a graduate teaching assistant, newly certified secondary teachers, veteran certified secondary teachers, and university faculty. Our multi-level apprenticeship model was
created to support the preservice teachers in their initial endeavors, to provide additional learning opportunities for the newly certified teachers, and to offer renewal opportunities for the veteran teachers involved.

Eleven graduate students, who possessed little, if any, classroom teaching experience, matriculated into our two-course, six-week integrated summer practicum. They were each responsible for creating and teaching a unit of study to classes of middle-school students who attended the enrichment program component of the practicum. One graduate assistant, who had successfully completed the summer practicum the previous year, served in a support role to the graduate students. Three newly certified teachers, our curriculum assistants, served collectively as a technology support system for the practicum. Three veteran teachers, our university supervisors, served as pedagogical content knowledge experts (Shulman, 1987) and provided midlevel supervision for the graduate students as they developed and taught their daily classes. Two university faculty served not only as experts in technology, adjustment, and instructional methodology, but also as universal problem solvers across all five apprenticeship levels.

At the conclusion of the practicum experience, all participants completed a “Building Social Capital” survey wherein they reflected upon the degree to which they had established connections or bonds with each other during the six-week program. The anonymous survey included two different types of questions: ones requiring Likert-type responses and ones requiring brief narratives.

Results

Table 1 presents the participants' mean responses (M) to the Likert-type questions, with respect to their perceived growth in social capital, “the construct being measured” (Mason & Bramble, 1997, p. 309). The pre- and in-service teachers and university faculty were required to circle Likert-like ratings in response to a series of statements. (For example: “In my estimation, I have built social capital with the university supervisors: to a great extent, somewhat, not sure, a little, or not at all.”) After the surveys were collected, the five Likert ratings were numerically converted. For instance, “to a great extent” was converted to a 4, “somewhat” was given a 3 rating, “not sure” was awarded a 2, “a little” was deemed a 1, and “not at all” received a zero.

The following question stem was used in prompting the participants as they crafted five, short-answer narratives: “To what extent, if any, have you benefited personally and/or professionally from the connections or bonds you established with the” graduate assistant, curriculum assistants, fellow graduate pre-service teachers, university supervisor, and university faculty. All written responses were reviewed to identify common themes or “thought units” (Glaser & Strauss, 1967). “Thought units” were then analyzed, and subsequently categorized using a systematic cognitive framework (Sweeder & Bednar, 2001, October).

Discussion

We believe that the multi-layered reciprocal cognitive apprenticeship model is a particularly effective mechanism to enhance professional development, because it fosters not only horizontal but also vertical social networks amongst the various groups (Putnam, 1993, as cited in Driscoll & Kerchner, 1999). To illustrate this point, the mean social capital ratings for each group reported strong connections with members within their respective groups. For instance, one horizontal network, graduate students with graduate students, produced a 3.88 mean rating. Another horizontal network, curriculum assistants with their fellow curriculum assistants, established strong relationships ($M = 3.66$). Several groups, however, indicated that they believed that they had built similarly strong connections with other participants along vertical networks (Driscoll & Kerchner, 1999). For example, the curriculum assistants indicated that they each had built social capital with the university supervisors ($M = 4.0$) and the university faculty ($M = 4.0$), while the university supervisors indicated similar 4.0 mean ratings with the curriculum assistants, the graduate assistant, and the university faculty.

Social capital was not as strong between two distinct groups: the graduate students with the curriculum assistants ($M = 1.88$), and the graduate assistant with the curriculum assistants ($M = 1.00$). The curriculum assistants had very specific technology roles during the practicum experience, and even though they spent a portion of their time assisting technology-related issues in the graduate students’ classrooms, they spent a
more substantial period of time assisting technology issues related to the overall practicum. This may
limited the number of opportunities to develop connections with the graduate students and the graduate
assistant. In addition, the graduate students and graduate assistant may have viewed the curriculum
assistants with their newly earned undergraduate degree as having less legitimate power (Wilen et al.,
2000).

In light of our findings, we believe, as do Etcheverry, Clifton, and Roberts (2001) that "because students
are strongly influenced by their interactions with each other, it is important for university professors to
attend to the social structural characteristics of the educational environment vis-à-vis students' interactions
in their classrooms” (p. 36). Extending their findings using an undergraduate population, we found that our
graduate students, as well as the supporting in-service teachers, were similarly influenced by their
interactions with others; hence, we put our emphasis upon establishing a multi-layered apprenticeship
model so that each of our participants had multiple and varied opportunities to build social capital within
our specific educational environment.

Our multi-layer, reciprocal model provided ample opportunities for all of the participants to refine their
professional decision-making skills. This is supported by both the quantity and quality of the “thought
units” elicited from their written comments. For example, the pre-service graduate students indicated that
they believed that they had extensive opportunities to observe experts model (see Feature 1., Table 2) a
practice, procedure, or attitude. The graduate students defined expert along both vertical and horizontal
relationships associated with the building of social capital. Several indicated that they viewed the lone
graduate assistant as an expert because “ she went through the practicum the previous summer” and, thus,
they valued what she had to say. As one would expect, graduate students pointed to both the university
supervisors and the university faculty as experts, e.g. “I benefited from their example and leadership.”

There was strong recognition of the external support made available through coaching and scaffolding
(Features 2. and 3.) by the different participants. The graduate students, for instance, indicated that they felt
highly supported by one another. One commented, “We shared ideas and brought materials for each other”;
while another wrote, “I was inspired by the variety of teaching methods [I observed].” The graduate
students also indicated that he university supervisors were instrumental in supporting them through
mentoring. “The focused feedback was what I really needed and I got it from each of the supervisors
differently,” stated one graduate student. The university supervisors commented about the individualized
and contextualized scaffolding they received by the university faculty members. In turn, the university
supervisors mentored both the graduate students as well as the curriculum assistants. This mentoring was
reciprocated when the curriculum assistants taught the university supervisors about the newer product
technologies they used during the program (e.g., Sony Mavica Digital Still Cameras and Sony Digital 8
Camcorders).

The graduate students indicated that they felt they had ample opportunities to articulate (Feature 4.) their
knowledge both formally and informally. Six of them specifically stated that they valued the “lunch and
free periods” where they were able to discuss events that occurred in their classrooms. Others indicated that
their journals, as well as their interactions with the graduate assistant, the university supervisors, and the
university faculty were all critical in helping them to reflect on their progress (Feature 5.). Finally, the
university faculty enhanced their professional knowledge. One commented that it was “professionally and
personally invigorating to watch the ‘little Sweeders’ [a sobriquet that the graduate students invented for
the curriculum assistants]. I caught their wave and am exploring new ideas for next year” (Feature 6.).

At the conclusion of the enrichment program we produced two multimedia presentations highlighting the
middle-school students’ experiences during the practicum. The first, an electronic slide show, was created
using PowerPoint; the other, an edited video production, was created using a Sony Digital 8 camcorder and
MGI’s popular Video Wave III, a piece of inexpensive, nonlinear editing software. Both productions were
projected onto a theater-sized screen and amplified by “surround sound” for added emotional impact. Not
only were these productions warmly received by the middle schoolers, but the shows also spawned a
multimedia parody that the curriculum assistants spontaneously (and surreptitiously) created. Featuring
adults only -- the graduate students, the graduate assistants, university supervisors, and university faculty --
this lampoon provided a further example of the social capital built amongst all of the participants.
Conclusion

We believe that teaching, like the sport of bowling, is seldom as engaging — or productive — when performed alone. To paraphrase Robert Putnam, "A well-connected [teacher] in a poorly connected [school] is not as productive as a well-connected [teacher] in a well-connected [school]." Thus, during our summer practicum experience, we created a school community (a microcosm of our larger society) where mutual trust and reciprocity helped to de-isolate our novice teachers and lubricate the social intercourse amongst the pre-service and in-service teachers as well the university faculty. No one in our summer enrichment program "bowled alone."

Collaborating Across Boundaries to Form Technology-infused Learning Communities

Kathe Taylor, The Evergreen State College, US

The term, "learning community" has many meanings and is often used in a general way to describe any community of learners. Our PT3 catalyst grant adopted a definition of learning communities that was very specific and consistent with a curricular approach common to The Evergreen State College. We asked faculty in teacher education courses to create technology-infused learning communities by purposefully restructuring curriculum to link together courses and create an interdisciplinary experience for students that faculty would collaboratively plan and perhaps team teach. Technology would be an integral part of the community.

How technology was integrated into the learning community experience was left in part to the discretion and creativity of the faculty. We did specify two requirements, however. One stipulated that students would have opportunities to participate in an electronic learning forum. The second asked the faculty to create opportunities for preservice students and Generation www.Y students to work together on technology-related projects. Generation www.Y is a program designed to train K-12 students with the technology, collaborative and pedagogical skills necessary to help teachers integrate technology into learning.

Fundamental assumptions of this project were that it would be beneficial for students aspiring to be teachers to 1) experience learning that was collaborative, authentic and integrated; 2) view K-12 students as sources of knowledge, particularly in the areas of technology and learning; and 3) acquire and apply technology skills in context.

Nine colleges of teacher education and 16 K-12 schools were part of the consortium that tested these assumptions. And, as might be expected, nine different learning community models emerged. The story of each learning community is not one we can tell in an hour-long presentation. But stories told from different perspectives might offer a glimpse into the benefits and challenges a technology-infused learning community can present. A panel will also model the very nature of the collaboration that this project has been about.

In this panel presentation, five individuals—two teacher education faculty members, a Generation www.Y teacher, a teacher education student, and a Generation www. Y student—will discuss the following questions:

1. How was technology integrated into this learning experience, and what were the benefits and challenges of teaching and learning about technology in this way?
2. How did you participate in this learning experience both as a learner and as a teacher?
3. From your perspective, how can this type of learning experience contribute to the education of a teacher?
4. What role did technology play in building community?

Each participant will preface his or her remarks with a brief description of the learning community he or she has been associated with.
Building Successful School and University Partnerships: "Finding the Fit"

Dr. Nancy Todd, Professor, Eastern Washington University
Dr. Linda Kieffer, Associate Professor, Eastern Washington University
Patti Dean, Technology, Director, Cheney School District

The PT3 partnership between Eastern Washington University (EWU) and the Cheney School District (CSD) has emerged as being exceptionally collegial and productive. The partnership has been a catalyst for systemic change in the district beginning with the entire curriculum being re-examined and developed with a base of technology integrated in all areas.

Key district personnel readily attribute the new focus on change to the opportunities provided by the Preparing Tomorrow's Teachers for Technology program. As stated by the Technology Coordinator, "Cheney School District teachers need help with integrating technology across the K-12 curriculum. EWU teacher candidates are providing a significant amount of help to our teachers."

Like other universities, Eastern Washington University (EWU) has worked with many school districts in Washington State, as well as with the Cheney School District with varying levels of commitment over the years. The CSD of 3500 students surrounds this regional university in a small town of about 8000 permanent residents. We asked ourselves, is there anything about this partnership that would be applicable to other partnerships? What are the unique features of this partnership?

In thinking about these questions, we kept returning to the concept of "finding a fit" among school district personnel, education faculty, and teacher candidates. Questions such as "What is it you need? How do our institutional goals work together? How can we help?" have been continually asked by all parties.

We found that there were some key elements that help find the fit, such as administrative commitment, accountability, and communication.

Administrative Commitment.

While the university and school district have been close neighbors for over 100 years, cooperation between the two institutions was not always fruitful. About two years ago, we had the convergence of a new university president and college of education dean who are both committed to working closely with the local school district.

At the district level, the superintendent has also committed to work closely with the university. Because of the size of the district, it has little hierarchy. A superintendent, assistant superintendent, technology coordinator and curriculum coordinator make up the district level administrative "team." The partnership has been so successful that this group has designated the district technology coordinator to spend 50% of her time working on integration of technology in school district classrooms in which teacher education candidates have field experiences. All teachers have direct access to the Technology Coordinator.

Mutual Accountability

Cheney School District will be implementing new technology student learning targets in the fall, 2002. Teachers will be expected to demonstrate proficiency in the learning targets that are scheduled for mastery as their respective grade level. In addition, teachers will be evaluated on the presentation of a technology-integrated unit of instruction. "Classroom teachers hold the key to the effective use of technology to improve learning. But if teachers don't understand how-to-employ technology effectively to promote student learning, the billions of dollars being invested in educational technology initiatives will be wasted." (NCATE)

Cheney teachers are developing skills in technology integrations in two ways: 1) They have the opportunity to participate in the Intel Teach to the Future program where they receive 40 hours of free technology training. 2) Teachers may participate in the PT3 grant which partners an EWU teacher candidate
with a classroom teacher to create and deliver a technology-integrated unit of instruction meeting technology standards (ISTE). After jointly delivering a module of instruction, they will evaluate the positive impact on student learning. An extra pair of hands for planning and implementing has been an asset for many teachers. The district technology coordinator assists with planning for all teacher candidate placements that relate to technology initiatives, as well as evaluating results of each of the projects. Results are communicated to the candidate’s professors.

Working with teachers and technology together, EWU candidates are gaining experience and insight into how classrooms work when technology is infused. These experiences are the "laboratory" for what is discussed in teacher education courses. Teacher candidates are better prepared to use technologies in classrooms. Schoolteachers and education faculty are more willing to try technology with an extra pair of hands. Being able to assist classroom teachers integrate technology has been valuable in being able to have these hands-on experiences, rather than, say, develop theoretical lesson plans one might use "someday." As a growth opportunity it helps students stretch in a professional environment by trying out new technology activities with kids to find what works and what does not.

Continuous Communication

Communication of successes is an important element. A professional video was produced that consists of interviews with Cheney teachers and pupils. The video portrayed successful projects that we facilitated by teachers and teacher candidates working together. The video was used in October 2001 at faculty meetings in each of the district schools to sell PT3 partnerships with teachers who had not yet participated with EWU candidates helping with technology in their classrooms. Hearing testimonials of fellow teachers, who admitted on tape to being technophobes, many teachers responded, "If so and so can do that with an extra set of hands, I might be able, too." Seeing local success was inspirational to teachers and encouraged them to give technology a try. It was well worth the production cost of the video.

Continual communication is necessary between key players from both university and school (i.e., CSD Technology Coordinator and PT3 Project Directors), to clarify, re-examine, track progress, and make recommendations. How are we affecting the K-12 pupils? The district teachers? The EWU teacher candidates? In particular, the university personnel look for ways the university candidates can fit in and enhance the CSD technology goals. CSD personnel are also committed to providing teacher candidates with quality classroom experiences. And, importantly, neither institution is being prescriptive to the other. This mutual respect is an underlying aspect of "finding the fit."

PT3: Connecting Educational Technology Integrated Curriculum in Higher Education with K-12 Schools

Robert Z. Zheng, Ed.D.
Educational Studies Division
Marian College, USA.
rzheng@mariancollege.edu

Abstract: The teacher education in schools, colleges and departments of education (SCDEs) faces the challenge of how to prepare future teachers to teach competently in a digital age. An important question has been raised: how to prepare preservice teachers to transfer their tech-rich experience in higher education to K-12 settings? This paper will address the issue by examining the ways to (1) redesign teacher education programs, (2) improve pre-service teachers' use of the technology through a K-16 networked learning environment, (3) establish partnership with local schools. The notion of "Virtual K-12 Classrooms" will be introduced and the way of how such classrooms can be used to establish a K-16 networked learning environment will be discussed.

Introduction

In less than a decade there will be over two million new teachers entering the educational arena. How do schools, colleges and departments of education (SCDEs) meet this new challenge? How do SCDEs prepare the future preservice teachers to teach competently in a digital age? The existing teacher education programs in many SCDEs do not seem to have answers. Yet as a way of meeting the imminent challenges ahead, the teacher education programs in SCDEs have begun to offer computer specific courses as a tentative solution to the problem. However, such an approach does not change the already aggravated situation: the limited exposure to appropriate models of computer use in the classroom prevents the preservice teachers from effectively integrating modern educational technologies into K-12 classrooms (Vannatta & Beyerbach, 2000).

Although huge efforts have been made to improve the status quo of using technology in teaching and learning, approximately $70 million per year has been spent in Wisconsin in the area of professional development for use of instructional technology, the results have not been satisfactory. A recent survey made jointly by Wisconsin DPI and Cooperative Educational Service Agencies (CESAs) indicates that 15.6% of teachers do not know how to use modern learning technologies in their classrooms, 6.8% of teachers have used technologies which have little or no relevance to the individual teacher's operational curriculum, 42% of teachers employed technology either as extension activities or as enrichment exercises to the instructional program. The survey shows that only 18.8 percent of teachers are able to integrate educational technology into their curriculum to some extent with an emphasis on higher levels of cognitive processing. Only 16.9% teachers can integrate technology into their curriculum at various levels from mechanical to routine (Lohr, 2000).

To face the challenges and prepare future teachers to become technologically competent to teach in the 21st century, Marian College proposed a systemic change in undergraduate teacher education by aligning technology integrated curricula in higher education with K-12 schools and establishing a K-16 networked learning environment that enables preservice teachers to teach effectively in a tech-rich setting. The project was supported by the Preparing Tomorrow's Teachers to Use Technology (PT3) Grant from the U.S. Department of Education. The purpose of this project is to bring a systemic and fundamental change in teacher education.

The Study

Starting from mid 1990s, Marian College began to embrace the idea of using technology in undergraduate teaching. It worked closely with K-12 schools to substantiate a change in the use of technology in K-12 classrooms. This effort was supported by an earlier federal grant Goals2000 which resulted in some positive changes in terms of technology use at Marian and its partner schools. However, like other SCDEs the undergraduate program at Marian College offers technology-specific courses as a remedy for the lack of technology proficiency in students. Such an
approach may develop basic computer skills in pre-service teachers who may become "aware of the impending use of technology in their future classrooms, but they were unsure of how technology could be used" (Vannatta & Beyerbach, 2000, p.144). Moreover, our recent alumni survey suggested that Marian graduates were not quite prepared to use technology in a variety of instructional settings. We believe that such a problem originated in large part from the existing curricula in SCDEs. Being fully aware of the seriousness of the problem in K-12 education, Marian College therefore, proposes that:

1. There must be a fundamental change in the teacher education curricula.
2. Educational technology must be fully integrated into every education course.
3. Partnerships with K-12 schools must be established so that pre-service teachers can be exposed to various technology uses in K-12 schools.

How to start and what change must be made to trigger a paradigm shift in teacher education in terms of technology integration? First, we examined the difference between the existing and the new approaches in the use of technology; Secondly, we looked at the strategies that will trigger a paradigm shift in technology integration; Thirdly, we created ten virtual K-12 classrooms in which pre-service teachers would engage in various learning activities as the K-12 students do and transfer what they learn in virtual K-12 classrooms to real K-12 classrooms.

Existing Approach vs. New Approach. Analyses were done to distinguish the existing use of technology in teacher education from the new approach in terms of the role, function, curriculum, and collaboration of technology in classrooms and schools. The following diagram shows the differences:

**A Paradigm Shift in Technology Infusion**

<table>
<thead>
<tr>
<th>Role</th>
<th>An extension, add-on</th>
<th>Integral part of instruction, related to learning objectives</th>

<td>Focus on systemic change in teacher education</td>
</tr>
<tr>
<td>Collaboration</td>
<td>Occasional, sporadic collaboration with K-12 schools</td>
<td>Sustained efforts to build K-16 learning environment</td>
</tr>
</tbody>
</table>

The paradigm shift in technology integration in undergraduate teacher education is defined by the changes needed and strategies for such changes. As has been discussed above, the areas need changing are the role, function, curriculum, and collaboration of using technology in schools. To make sure such changes occur in teacher education, we develop strategies in each needed area: we developed a logical model that identifies the resources, the technology activities, the customers impacted, the short-term, mid-term, and long-term outcomes for the changes. In curriculum renovation, we develop a technology renovation road map that indicates the steps from simple application to effective technology integration in teaching. We also developed an assessment model that monitors the steps of technology integration. In partnership, we tried to establish a K-16 networked learning environment by working closely with our partner teachers in K-12 schools.
Virtual K12 Classrooms. Part of this project is to establish ten virtual K-12 classrooms. Instead of placing preservice teachers in the computer labs - a common practice that prevails in most traditional SCDE curricula - the preservice teachers will learn how to integrate educational technology into content area in a regular classroom equipped with high-end computers. Such technology-rich classrooms will simulate the ideal K-12 classroom learning environment in which preservice teachers will engage in various learning activities as the K-12 students do.

Partnership with K12 Schools. In addition to learning in a virtual K-12 classroom, the preservice teachers will have the opportunity to practice technology integration in real K-12 classrooms through partnership programs. The pre-service teachers will use technology to teach their clinicals and participate in various K-12 related courses and practicums, including students teaching. In so doing, Marian College and its partners will create a K-16 networked learning environment in which the preservice teachers will be fully exposed to various modern learning technologies and will learn how to infuse those new technologies into teaching and learning. The preservice teachers who are merged in this K-16 networked learning environment will develop a better understanding of the use of various technologies in K-12 schools, and hence will effectively integrate educational technology into subject areas.

Findings and Conclusions

This project is still in its trial stage. Five undergraduate faculty were involved. Seven courses have been revamped for technology and curriculum integration. The change affected 115 pre-service teachers. Four partner school teachers joined the seamless curriculum development between higher education and K-12 schools. The initial implementation indicates that (1) the project has profoundly changed teachers’ and students’ perception of the use of technology in classrooms, (2) technology is no longer regarded as an add-on or extension to teaching and learning, (3) more and more teachers and students use technology as a cognitive tool to engage in higher level thinking rather than something as electronic paper and pencil, and (4) preservice teachers know better how to integrate technology into various learning settings. Both the college faculty and cooperating teachers commented that there has been a great improvement in the quality of the lesson plan developed by pre-service teachers and the teaching they did in K-12 schools.

Our study shows that offering computer specific courses does not solve the problem in existing undergraduate teacher education, particularly in technology integration. A fundamental and thorough way for the change is to revamp the existing curricula, redefine the role and function of technology, and establish partnership with local schools as a path for educational renewal (Goodlad, 1984). In order to reduce the gap between higher education and the K-12 schools in terms of technology integration, a seamless curriculum between the two ends needs to be created so a transfer of learning experience and knowledge between both settings can be realized.

Models of Teacher Development for ICTs Integration: Examples from the 2001 SITE Proceedings

Peter Albion
Department of Curriculum and Instruction, Purdue University, USA, palbion@purdue.edu

Avril Loveless
School of Education, University of Brighton, UK, A.M.Loveless@brighton.ac.uk

Abstract: This paper identifies papers from the 2001 SITE conference which may serve as examples of strategies described in a forthcoming report on Models of Teacher Development for the Integration of ICTs in the Classroom. It provides convenient means of amplifying understanding of the models and obtaining guidance for future implementation. In addition it makes recommendations for presentation of future work in the field.

Background

The need to prepare teachers for integrating Information and Communications Technologies (ICTs) is widely recognized and much can be learned from considering various initiatives already undertaken around the world. It was in that context that Professional Group 5.2 met at the IFIP World Conference on Computers in Education 2001 in Copenhagen, to consider the topic, Models of Teacher Development for the Integration of ICTs in the Classroom. A report of those discussions will be published early in 2002 (Downes et al., 2002).

A key task undertaken by PG 5.2 was to identify models of teacher development for ICTs integration in pre-service teacher education and continuing professional development programs. For those charged with preparing teachers to integrate ICTs, the value of the list of models would be increased if they could easily locate examples of the models in use. Tables listing the models in the report are supplemented by illustrative examples, but space did not permit a comprehensive list of examples. Hence there is a need for a more extensive list of examples.

The annual conference of the Society for Information Technology in Teacher Education (SITE) is a large meeting with a focus on ICTs in teacher education. Although the majority of participants at SITE are from the USA, there is a significant and growing international attendance. Many of the hundreds of presentations at SITE conferences report on practices for preparing teachers to integrate ICTs. Hence, the SITE proceedings should be a rich source from which examples of the PG 5.2 models might be identified. This study sought to examine the proceedings of the 2001 SITE conference (Price, Willis, Davis, & Willis, 2001) with a view to assessing whether they include examples of the pre-service teacher education models listed in the PG 5.2 report (Downes et al., 2002).

Method and Results

The 2001 SITE Proceedings (Price et al., 2001) totaled 3175 pages comprising over 700 papers and were published on CD-ROM as PDF files. Searches of the full text of the proceedings were conducted using the search facility in Adobe Acrobat Reader with search terms selected from the proposed models (Downes et al., 2002) and, where such terms proved unsuccessful, selected synonyms. As terms were located, the papers were scanned for relevance and, where appropriate, noted for closer examination. In selecting papers for consideration, preference was given to those that included a thorough description of practices corresponding to the models. Table 1 matches papers with models. To conserve space, the papers are identified using the first author and page number from the SITE proceedings.

On examining the selected papers, it was evident that programs commonly included multiple models and the list of papers was progressively reduced to form a minimal set of 11 papers that included all 15 models. There is no implication that the papers identified herein are the best or only papers that exemplify particular models listed in the...
PG 5.2 report. Some models were notably less common and the papers identified for some had little useful detail. For example, online collaboration with students in schools was the subject of a roundtable at the conference (Goldman 2965) but, although it is mentioned in a section summary, there is no paper in the proceedings.

| Models for pre-service teacher development in ICT integration (Downes et al., 2002) |

| N Flexible delivery, student-centered approaches to teaching and learning | X | X | X | X | X | X | X | X | X | X | X | X |
| O Partnerships with industry: curriculum/software development programs | X | X | X | X | X | X | X | X | X | X | X | X |

Table 1: Models of preparation for ICT integration in pre-service teacher education (Downes et al., 2002)

Conclusions

Based on the contents of Table 1, it seems fair to conclude that the 2001 SITE proceedings include all of the models identified by PG 5.2 for pre-service preparation of teachers for integrating ICTs. However, it seems that many teacher education programs use combinations of the models, presumably because they offer different benefits.

The search for papers matching the PG 5.2 models was sometimes hampered by differences in terminology. For example, PG 5.2 used “professional experience” in reference to pre-service teachers but the only use found in the SITE proceedings was to the experience of professionals. The nearest equivalent appeared to be “field experience”. Such instances suggest that the usefulness of the SITE proceedings would be enhanced by the adoption of an agreed vocabulary of keywords. Such an addition would be worthy of consideration for future SITE conferences.

This initial review of one conference community's proceedings is part of a wider ranging review of examples to support the report, Models of Teacher Development for the Integration of ICTs in the Classroom. This will inform and raise issues for future evaluations of the experiences of teacher development with ICT.

Abstract: This paper reports on one specific Portuguese university's student teachers' opinions, experiences, perspectives and expectations regarding Internet usage. Data was collected using a questionnaire which was anonymously answered by 189 student teachers from 9 different preservice programs. Some differences were found between males and females and between the diverse program groups concerning opinions about the Internet and how they use it and expect to use it in the future. Some reflections are made about the effectiveness of our students' technological preparation.

Introduction

The growth of the new information technologies and their spreading uses in education have been enormous. Educators' concern with mathematics teacher education (Grouws and Schultz, 1996) along with the increasing availability of both virtual information and modes of communication (Hughes and Hewson, 1998) led us to rethink mathematics teachers' pre-service education. Furthermore, as collaborative work (Wallace, Cederberg and Allen, 1994) as well as the use of technology (Balacheff and Kaput, 1996) have long become two of the focuses of the recommendations for mathematics teachers preparation and professional development, we cannot but envision its context within a framework of new information technologies. The avalanche of available resources on the Internet as well as one's access to it, is rapidly changing both one's views of a worldwide community and one's conceptions of Internet usage (Schrum and Lamb, 1997).

Making changes and breaking barriers require courage and creativity. This seems particularly true for the people responsible for teacher's in-service and pre-service education. The Internet seems to be the answer to the problem of finding and giving information, because it is easy and fast. However the large amount of available information brings new demands on the teachers for whom being able to select what is relevant becomes critical. Therefore the intervening agents in the teacher education process must contribute to open up perspectives so that students take advantage of all the information that is available, both in their lives and in their careers. In Portugal there has been research on the Internet usage in the context of both the mathematics classroom (Morais et al., 1999; Almeida et al., 2000; Ponte et al., 2001) and the professional development of teachers of mathematics (Ponte et al., 2001; Ponte, 2000; Miranda et al., 2001; Almeida et al., 2001; Almeida et al., 1999). However more has to be known about our students' Internet experiences and how they may influence their perspectives and expectations. Only with this knowledge may we seek further action into creating new learning communities as well as helping our prospective teachers to fully integrate them.

In this paper we will talk about one specific Portuguese university's student-teachers' experiences, perspectives and expectations on Internet usage.

Sample and Data Collection

Our data stem from a questionnaire for which there were 189 anonymous responses from our 2000/2001 academic year 360 entire student-teachers population. The sample's ages range from 22 to 44
with mean 24.74, mode and median both 23, and the third quartile 25. There were 159 females and 30 males distributed by a total of 9 pre-service education programs. Only 29 of the respondents reported having had previous teaching experience. From a total of 181 who reported having a computer at home, 92 say that they are connected to the Internet. Most schools where the student teachers do their teaching practice have computers and Internet which can both be used by teachers and students. Table 1 shows the distribution of students by pre-service programs and sex. There is 1 missing answer from a female student.

Table 1: Distribution of student teachers by pre-service programs and sex

During their 5-year pre-service education programs all prospective teachers have the same general education courses, along with courses specific to each program: History and Philosophy of Education in 1st year; Psychology of Education and Pedagogical Practicum I (Teacher-pupil interaction analysis) in 2nd year; Educational Sociology, Curriculum Development and Teaching Models and Pedagogical Practicum II (Technology) in 3rd year; School Organization and Administration in 4th year. As far as technology preparation is concerned, only the Mathematics and the Physics/Chemistry students have more than just the Pedagogical Practicum II (Technology): Physics and Chemistry students also have an Introduction to Informatics course in their 1st year; the Mathematics Education students have an Introduction to Programming course in 1st year and Informatics in Teaching in 4th year. In their 4th year all students have a didactics course specific to their area.

What student teachers think and feel about the Internet

The student teachers answered a nine-item semantic questionnaire. In each item they were to indicate, on a five-point scale, their inclination (or neutrality) towards one of two opposite adjectives. For analysis purposes, items were code so that in each of them 1 is the most negative opinion and 5 the most positive opinion. Table 2 summarizes the results for the entire sample.

Table 2: Summary of all student teachers answers to the semantic questionnaire

It can be seen that, in general, student teachers characterize positively the Internet in all items considered.
Differences between males and females

Lack of homogeneity of variance (found by Levene's statistics) induced us to use chi-square tests to find differences between males and females in each of the 9 items of the semantic questionnaire. However, care must be taken as there were cells with expected values less than 5. Males and Females generally agree that the Internet is useful, interesting, important, beneficial and motivating. But males seem to find it funnier, easier, simpler, and clearer than their female counterparts do. Figure 1 shows differences between males and females.

![Graph showing differences between males and females.]

Figure 1: Differences between males and females

Further investigation into this matter shows that, when asked to indicate simple words to describe advantages, disadvantages, and difficulties, females' answers are more consistent than those of males. Furthermore, they refer more frequently to the ease of access to information and of communication as advantages of the Internet, while being costly (not being for everybody) and giving access to obscene information are indicated as disadvantages. Too much information, assessing/selecting the right information not being so easy, lack of information in Portuguese, and technical issues (like software installation and working with chat and e-mail) were the difficulties most referred specially by females. As far as these female-male differences are concerned, we hypothesize that causes may be socially bound.

Differences between education program groups of student teachers

For the semantic questionnaire and the education programs, it was found that the degree of heterogeneity was not significant in any of the cells at the .05 level. Therefore, a one-way analysis of variance was used to find whether student teachers from different programs had different views of the Internet regarding the nine items of the semantic questionnaire. There were significant differences only in the Complex - Simple ($F=3.499, p<0.001$), and Confusing - Clear ($F=2.365, p<0.019$) items. Some differences were also observed in item Hard - Easy, although significance was not clear ($F=1.799, p<0.80$). Figure 2 shows the means plots for these three items.

BEST COPY AVAILABLE
Internet usage by student teachers: perspectives and expectations

From the other items of our questionnaire we can see that these student teachers’ global usage of the Internet seems to have increased from the 1st to the 5th year. One factor which cannot be ignored is the growth of computer and Internet facilities in our campus. More and more the Internet is being used as a means of communication even at the official level. Students now also have to enroll for the exams on the university web page.

In their answers to the questionnaire most student teachers reported never having used the Internet to chat, to construct a WWW page, to communicate with colleagues from other schools. Most also admitted having seldom discussed with their colleagues about Internet applications in teaching. Most also denied ever having used the Internet in someway by suggestion or requirement from the part of their school or university supervisors. In general it seems that the Internet was not a very frequent presence in the student teachers’ lives. However they expressed the idea that in the future they will frequently use the Internet: mostly to search for bibliography and for information about their field of work, and to find ideas for their teaching. They also think that they may quite often show things from the Internet and suggest sites to their students. It is revealing that the Internet is not yet used by student teachers as a potentially fast and efficient means of communication, but that they expect to use it in their future professional lives. However to construct web pages does not seem to be in their future perspectives.

Conclusions

From our investigation we can infer that in general the university’s student teachers have high expectations and quite favorable opinions about their Internet future usage. It can be seen from our data that a high percentage of students with a computer at home are connected to the Internet. However they report a very limited actual use of the Internet as a means of communication and interaction in their academic activities.

Surprisingly for us mathematics educators, this is also true for our mathematics student teachers. Considering the contents of the mathematics education program, we would expect the mathematics student teachers to be better acquainted and to feel more comfortable with computers and particularly with the Internet. Therefore we should reflect on the weak effect technology courses seem to have on students and on what the causes of found differences may be. Also we should not forget that there is a longer history of computer usage in mathematics education than in any other field. This fact had previously led us to expect
that the mathematics student teachers would feel more at ease with computers and with the Internet than students from other programs. But such does not seem to happen. Why? Might there be too much pressure on the mathematics student teachers? Knowing mathematics, knowing about calculators and about computers, dealing with kids’ negative attitudes towards mathematics in their teaching practice, and a lot more, all seem to take too much time and energy to leave any room for new cyber discoveries. Might there be also a reflection of faculties’ own ideas and expectations about the Internet? These are questions that we cannot answer now.

Abstract: Written Lesson Plans with the National Educational Technology Standards: Professors, Pre-service Teachers, and K-6 Teachers Worked Together to Perfect Lessons that Work in Schools with Children from Ethnically Diverse Backgrounds Technology enhanced K-6 lessons are now available, “hot off the press,” at this session. They are engaging, creative, focus on critical thinking, and contribute new knowledge to the field of technology in teacher education. Eight subject area teams spent a year using technology in their classrooms. The teams included Reading/Language Arts, Math, Science, Social Studies, English as a Second Language, Exceptional Student Education, Curriculum, and General Methods. After a year of research in the field of technology in the classroom, the team members began to write content area lessons based on the National Educational Technology Standards. Selected pre-service teachers and professors cooperatively wrote the lessons. The lessons were sent through an outside peer review process. K-6 teachers in several public and private schools in South Florida field-tested the lessons. Tried and true, these lessons will spark your interest in using technology in teacher education.

History of the Project

The main goal was to infuse technology into all aspects of pre-service teacher education training. We have set out to accomplish this by professional development and team accountability. Each of the eight teams was assembled with pre-service teachers, professors, and K-6 teachers. They have received at least 50 hours of professional development related to technology in their subject area. They have also been working
together in their online team area to reflect on the practical use of technology in their classes. The number of postings per group were tabulated and viewed over time. The actual postings for each group are included as documentation of the thoughtful reflection that each team has participated in.

On-Line Presence

Information about our project may be viewed at: http://garnet.fgcu.edu. To view these discussions, one may register for the PT3 Fall and/or spring courses and create an identity. Once this is done, posting will be enabled for the viewer. Our website also contains information that documents our workshop activities with our partners. Our website is located at: http://coe.fgcu.edu/PT3/home.htm.

Interdisciplinary Partnerships

We have fostered relationships among other departments by recruiting professors from other disciplines to be participants on the subject area teams. We began with professors from Communication, Guidance and Counseling, Math, Science, and English. Several of the professors we originally recruited have resigned due to the differences between their professional fields and teacher education at the elementary level. We have, however, retained a few professors from other departments.

K-6 Teachers Relate with Professors and Pre-Service Teachers

We have addressed the need for collaboration with K-12 teachers by placing eighteen K-6 teachers from five elementary schools on the subject area teams. This has been an essential part of our project as professors and pre-service teachers relate with classroom teachers on a regular basis. Four of these K-12 teachers serve as team leaders.

Journey to Technology Integration and Meaningful On-Line Communication

We began the project in early fall. We scheduled two orientations, one at STU and one at FGCU so that all participants would know what they were required to do for the year. It was presented, but after a few weeks it was apparent that some of the participants were not posting weekly in their online team areas as they were supposed to. Because we had two separate orientations, many of the team members never did get a chance to meet. In order to get the participants to post in their team area, we first tried sending them many reminders. That worked with some people, but not all. Another problem we had was that the reflective postings were not quality postings. Some team members would cut and paste information from other sources or just refer the team to a website without any reflection on how that site could be used in their classroom. In order to get some quality control, we defined what we believed to be a "substantive posting." We told the participants that it was: "A substantive posting requires content that reflects participant’s actual understanding or use of technology in the classroom. This awareness grows out of the participant’s direct experiences with the literature, professional development experiences, personal experience, or direct responses to other substantive postings."
After this, the quality of the postings improved significantly. We also changed the weekly posting requirement to 14 substantive postings per semester. This enabled the participants to "catch up" if they were behind. It quantified our requirements. Our next step was to issue contracts to all our participants, which we should have done at the outset.

Another barrier was the distance between STU and FGCU. One is on the east coast of Florida and one is on the west coast. During the second semester, we initiated team leader on-line chats. Those chats were helpful in bringing the team leaders together. Individual teams also decided to have on-line chats. We also had a team leader meeting in person. It was the best thing for us. We were all able to talk about our goals for next year and come to an agreement on the contracts we will offer the participants year 2. Team leaders will meet monthly next year, alternating between on-line chats and in person meetings. All the participants will meet together at the beginning of year 2. There was resistance to bringing all the parties together from FGCU, but it is needed and will be done.

ESTABLISHING A MINOR IN INFORMATION TECHNOLOGY FOR PRESERVICE EDUCATION

Gouri Banerjee, Department of Instructional Technology
Emmanuel College, Boston, Ma., USA
banerjee@emmanuel.edu

Abstract: Increasing reliance on computers for teaching and learning places many additional demands on providers of preservice education. For small schools the challenges are particularly daunting. This paper briefly describes how a minor in information technology was conceptualized and offered. The minor has a strong hands-on focus, is flexible in sequencing, and allows students to choose where and when they take IT courses. In a very brief span of three years this minor has become very popular and appears to provide the educational and professional needs of a growing population of education majors.

The growing reliance on computers for both teaching and learning in the classroom has challenged the training of preservice education providers. A hotly debated issue on campuses today is what specific kinds of training in the field of information technology (IT) do preservice student's need?

Almost every institution and individual engaged in preparing teachers has asked questions about how to train adequately in a rapidly changing IT environment. For smaller schools, in particular, providing IT training to preservice students has been a significant challenge. This paper describes some major issues that arise and presents the outcomes of the introduction of a new program called the minor in information technology.

Since 1919 Emmanuel College, a Catholic institution in Boston, has prepared pre and post-service teachers for positions in suburban and city schools. Students are given a strong theoretical base in the liberal arts upon which their practicum experiences are built. This helps students develop those skills necessary to manage a sound, organized, and creative learning environment. Preservice undergraduate students are encouraged to develop a philosophy of education uniquely their own. At the same time students need a strong foundation in technology to better prepare them for teaching in the Internet linked, hardware and software rich computerized classroom.

Early in the process of designing the minor in IT in 1999, we conducted a college-wide survey aimed mostly at sophomores and juniors. We asked whether students preferred courses in IT or whether they would choose to take a more formal minor in IT. The survey indicated nearly equal interest in both. The department of instructional technology decided to offer a minor in IT starting in the fall of 1999. They developed a course structure which would prepare students to work directly after graduation by having a significant hands-on component. It was clear that if there was sufficient interest in the minor more courses could be added later on, but at the outset, the identification of a group of core courses was critical. In addition, it was felt that a minor in IT would attract varied interests, not just majors in the filed of education, and students needed a range of IT courses and choices to support their interest.

Our concern was to design a minor where all streams of students, with varying levels of preparation, would receive strong conceptual knowledge of, and, sound skills in computing. We designed a minor that was broad in scope, focused on hands-on skills, and flexible in sequencing. Students, engaged in the four-year bachelors program were required to choose five or six semester-long courses, each offering 4 credits. These courses included: a course called 1) computers for the liberal arts, and a course in 2) spreadsheets (freshman year); 3) communicating and problem solving with computers, 4) design and development of databases, 5) tools and techniques for using the Internet for research, 6) learning and leading with technology in education.
and the business environment (sophomore and junior years); 7) social and ethical issues in the use of technology and 8) information systems in the workplace (junior and senior years). A few students also chose to do individualized courses.

Our goals in designing this eclectic selection of courses included:

- A felt need to introduce the preservice education major to a wide range of computer concepts and related skills considered critical and essential for their work as classroom teachers and as IT skilled educators. Thus the first course, computers for the liberal arts, was a required course. Students were assessed in computer skills and a few, very few, tested out of this course. It introduced students to basic software skills in word processing, spreadsheets, presentation software, using email and web searching. It also provided a foundation in computer concepts related to hardware, software, networking and ethical issues in IT environments. For those wanting more skills in computing, the spreadsheet course offered greater depth in using formulas, functions and charting.

- To develop skills and attitudes in students appropriate for self-learning and exploration. Students could take courses flexibly during their sophomore, junior and senior years. They could also take courses at other colleges within a consortium without incurring additional fees. Online courses at their own expense were also permitted.

- To ensure that at all times the acquisition of these skills are seen by the students as relevant to the liberal arts education which they were concurrently receiving, courses in the minor were reviewed and evaluated each semester and adjustments made to reflect changes in the field of IT and state mandates for teachers.

- To allow students to gain a sufficiently deep understanding of emerging IT issues and to permit further specialization at the post service level.

In a brief three-year span, the minor in IT has become extremely popular. It offers in-depth IT instruction, significant time and energy invested in advising, and a careful selection of courses within a fairly small rotation of annual course offerings. Instruction in information technology continues to be very challenging due to numerous constraints: the availability of trained faculty, small budgets, classroom space issues, equipment maintenance, IT helpdesk support, overloaded computer networks and network security and management issues. Change and evaluation is ongoing, and an important component. For a small urban college this has been particularly hard given the limited resources available, and the high expectations set by larger institutions. Needed courses were introduced without total replacement of the existing programs in education. Numbers show that the minor in information technology, one of the most popular minors in the college today, clearly filled a much-needed educational and professional void and was successful in meeting preservice educational objectives.
Models for Collaboration for Pre-Service Teacher Education Programs

Adis Beesting, Florida International University, US
M.O. Thirunarayanan, Florida International University, US

Within the last few years, national standards and guidelines have been created to ensure that tomorrow's teachers are prepared to address the challenges and expectations of a technological society that requires a seamless union between traditional core competencies and new information environments. Teacher education programs are able to address these needs by creating innovative programs and new partnerships that integrate technology within the context of the educational objectives of the teacher certification program. At Florida International University, successful partnerships have been created which address these issues by creating hands on learning experiences that reinforce the learning outcomes developed in the Information Literacy Initiative and the instructional objectives of the teacher education program.

The FIU Information Literacy Initiative seeks to partner librarians and faculty to prepare students to think critically and use information in ways that will enhance their academic, professional and personal lives. Librarians assist the students in the identification of information sources and the retrieval and selection of information; the faculty member creates assignments that require students to use both technology and critical thinking as they evaluate and use information available in print and electronic formats. The intent is to foster information literate individuals who understand the complexity of the information environment and can use the skills they have mastered as a means toward continued development.

The College of Education and the Education Librarian have built a close relationship that has resulted in the creation of library instruction sessions targeted specifically toward future teachers. When Information Literacy objectives are paired with the educational requirements of teacher certification programs, the resulting partnership can yield fulfilling results. One example of a successful affiliation takes place with the "Introduction to Educational Technology" course. Students attend library instruction sessions to research a topic related to technology in the classroom, which is then used as a basis to create a presentation on their topic in PowerPoint format. Students are encouraged to consult with faculty and librarians as they complete their project.
Perceptions of Technology in Preservice Education Courses

Abstract: This study examined preservice teachers and their instructors’ perceptions of the use of technology in their education courses. The current research was part of a larger evaluation project that examined the impact of the first year of Project THREAD (Technology Helping restructure Educational Access and Delivery), a U.S. Department of Education “Preparing Tomorrow’s Teachers to Use Technology” (PT3) grant implemented in a large southwestern university. Participants (preservice teachers, N=273, instructors, N=12) completed a survey designed to measure perceptions of technology. Classroom observations and instructor interviews were used as well. Results indicate that instructors who implemented a high degree of technology in their classrooms and created more constructivist learning environments had significantly more positive student perceptions in terms of technology and its usefulness in educational settings.

Introduction

Preparing future teachers for rapid advancements in technology within our culture and the classroom is on the minds of many involved in teacher preparation programs (Becker, 1996; Garner & Gilligham, 1996). Much of the discussion surrounding this daunting task focuses on teacher knowledge and beliefs about teaching and learning. One definition of this states that, A flexible and adaptive use of technology also implies knowledge, skill, and dispositions beyond simple functional and procedural applications and toward the incorporation of technology in the very fabric of everyday teaching and learning (Gillingham & Topper, 1999, p. 305). How teacher preparation programs are taking up this challenge and affecting change is an important consideration for research.

This study examined preservice teachers and instructors’ perceptions of the use of technology in their education courses. The teacher preparation courses in question are part of a College of Education that is making strides to incorporate technology standards such as ISTE (International Society for Technology in Education) into their programs. ISTE standards relate to the integration of technology into teacher education programs. These standards call for teacher candidates to demonstrate a sound understanding of technology operations and concepts as well as the ability to plan and design effective learning environments and experiences supported by technology (ISTE, 2000). In support of this goal, the current research was part of a larger evaluation project that examined the impact of the first year of Project THREAD (Technology Helping Restructure Educational Access and Delivery), a U.S. Department of Education “Preparing Tomorrow’s Teachers to Use Technology” (PT3) grant that was implemented.

The purpose of the current study was to gather information regarding the self-reported views of technology and its use by students and instructors involved in a teacher preparation program. We expected that the more and varied technology implemented in preservice teachers’ courses the more positive attitudes (both students and instructors) would be regarding the use of technology and its implications for learning.

Method

As was stated previously, this study was part of a larger evaluation project that examined a PT3 grant implemented in a large southwestern university. Participants (preservice teachers, N=273, instructors, N=12) completed a survey designed to measure their perceptions of technology adapted from a measure developed by Knesek, Christiansen, Miyashita, & Ropp (2000). The items were organized into five subsections that included questions relating to the concepts of: 1) Experiences with specific technologies in class (e.g., “Experiences with e-mail.”), 2) Technology topics addressed in class (e.g., “Using technology to assess student learning of subject matter.”), 3) Attitudes toward computers in education (e.g., “Computers can help me learn.”), 4) Attitudes toward student use of computers in education”), and 5) Attitudes toward information technology (e.g., “To me, electronic mail is important.”).

In addition to the survey, classroom observations and instructor interviews relating to technology use were used as data sources. Observations took place during regular class time and during times when technology assignments were occurring. Faculty interviews were conducted face-to-face or via e-mail and consisted of five questions relating to teaching philosophy in general and the use of technology within the classroom. Observations and interviews were transcribed for subsequent analyses.
Results

Two levels of analyses were completed.

Level 1

To examine if individual instructors varied in terms of their students’ overall perception of technology, a One-Way Analysis of Variance (ANOVA) was run. This Overall composite score was obtained by collapsing the five subscores of the survey. This analysis showed a significant difference between the instructors on the Overall variable, $F(11,195) = 9.71$, $p < .001$. Post-Hoc Tukey comparisons of individual means showed that two of the twelve instructors had significantly higher, more positive, means than their colleagues.

Level 2

To gather information regarding the classroom environments and instructors involved, classroom observations and interviews were analyzed. More specifically, we were interested in why these two instructors stood out in terms of their students’ more positive perceptions of technology found in Level 1 of the analyses. Thematic analyses (Bogdan & Biklen, 1998) of both the classroom observations and the interviews revealed interesting results. Varying degrees of technology use were found within the classrooms. Classroom use of technology in both instructor use and students use varied from very minimal use (e.g., using WebCT as a discussion tool only) to several instances of modeling and required student use of technology (e.g., using imaging devices and editing software). In addition to differences in technology use, our observation and interview data indicated that classrooms varied in terms of the learning environments created. For instance, a small number of classrooms kept a traditional format (i.e., frequent instructor lectures, little discussion, and multiple-choice exams) while others came across as being quite student-centered and constructivist in nature (i.e., frequent discussions and reflection tasks). Differences in class size were also noted.

In summary, what is important to note is that the two instructors who significantly differed from the rest of the group statistically (Level 1 analyses) also differed in the classroom environments they created. Along with several of the other instructors both of the instructors who stood out had technology incorporated into many phases of their course. Interestingly, where the instructors differed the most was in their approach to learning. Based on the data, both of the classrooms were more constructivist in nature than the rest of the group. More instances of opportunities for critical thinking and decision making were evident not only in technology infused situations but in these classrooms in general. In other words, along with increased technology use in the classroom a more student-centered, constructivist learning environment was required to obtain significantly more positive student perceptions of technology.

Discussion

Our results are consistent with previous theory and research indicating that technology use both by instructors and preservice teachers within the classroom is important in encouraging more positive perceptions of technology and its usefulness in educational settings (Carlson & Gooden, 1999). An additional and very important implication of our research indicates that not only is technology training necessary but a constructivist learning environment conducive to student involvement in technology is crucial (Jonassen, Peck, & Wilson, 1999; Scardamalia & Bereiter, 1996) as well.

References

Abstract: Creating a First Day of School can be scary, confusing, and exhausting, but also exhilarating, energizing and satisfying. Because so many disparate and unknown components must be imagined, reflected upon, planned and organized, many new teachers often wonder, “Where do I begin? How do I even think about what is needed on the First Day of school?”

In response to student teachers’ requests, and recognizing a need for information in this area, the College of Education and University Media Services at California State University, Sacramento, undertook the development of what began as a single videotape, the goal of which was to provide new teachers with an opportunity to learn from, and adapt, “first day” experiences of veteran teachers.

Production Overview

In the course of the production, a diverse group of six elementary classroom teachers, all teaching in multicultural/multilingual classrooms, were interviewed and three of them were followed while undergoing a first day of school. The wealth of material that was acquired during the production process lead to a series of six subject specific learning modules, all demonstrating how these teachers - diverse in ethnicity, age, experience, and teaching style - think about and implement the first day. Designed to accentuate the feelings and attitudes of the first day as well as to provide concrete activities and address the nitty-gritty details, the series shows intelligent, articulate teachers who share similar aims, but manifest them differently.

The video series has been field-tested with CSUS student teachers, teacher interns, and experienced teachers. The response in every venue has been overwhelmingly positive! Comments have included: “I feel inspired,” and “I feel affirmed as a teacher.”

“The First Day: Teachers’ Ideas and Experiences”, with accompanying Facilitator’s Guide, is being distributed at cost as a public service to the field of Teacher Education.
Video Series Module Synopses

Module #1  Preview: Meet the Teachers
Module #1 functions as a preview to the entire series. First, we meet the six teachers, and then through excerpts from each module, we experience the flavor of the series, as well as intriguing examples of what's to come.

Module #2  Planning and Preparation
In Module #2 the teachers articulate their aims and how they plan for the first day. This module considers particulars such as arranging the classroom, offering choices to their students, developing guidelines for their groups, and connecting with families. It also shows a range of first day activities. Underlying all of the planning and doing is attention to taking account of students' needs and interests.

Module #3  First Steps Toward Building a Community of Caring Learners
Teachers know that communities are made, not born. As they aim to draw their students together into a learning community, the teachers pay attention to ways of communicating and building relationships with students and their families. In Module #3 the teachers talk about and we see first day activities that value the common needs and interests of children.

Module #4  Assessment and Reflection
With information gleaned from a balance of ongoing assessment and reflection, teachers come to understand individual students and the whole class, which leads to adjustments in their teaching. Module #4 emphasizes the value of embedding informal assessment and reflection in every aspect of teaching and learning. Formal assessments, which can provide useful information, are an accompaniment to this.

Module #5  Problem Solving: The Expected and the Unexpected
The First Day is a magnet for interruptions, only some of which can be foreseen. In Module #5, the teachers confront a range of typical intrusions, e.g. late students, and crying children. Then, one teacher deals creatively with some surprising events, including a beguiling bee and a hurting heart; while another responds to a student who needed her continual care and attention all day.

Module #6  Working with English Learners: The Story of Lyudmila and Julie
Module #6 differs from the first five in that its form is chronological. We follow the progression of a Ukranian girl who arrives at Kindergarten with her mother. Both do not speak English. Julie, her teacher, strives to create a safe, comforting space for Lyudmila, while providing for the needs of the whole class. We see a range of strategies and activities that support and include English learners, but also we see a compassionate teacher who builds on the Lyudmila's strengths. Initially worried and anxious as she enters Kindergarten, Lyudmila gradually, and dramatically, shifts across three hours toward finding her way into the group.

Acknowledgements

Any worthy production of this magnitude is built out of the many who contributed significantly in great and small ways. The idea to create a video about the first day of school was the brainchild of Marie Gallegos, a Phase I student teacher at the time. She collaborated as a full, equal partner in the entire endeavor, as did Richard Osborn, our director, who wrought his magic on the strings of video segments, which we brought to him. Foremost, we value the courage of the teachers and their students and their willingness to allow us to tape. We thank CSUS University Media Services and their staff, who not only funded and supported the project, but also believed in its value and importance. We are grateful also to our Special Sponsors for additional funding. Throughout the project colleagues, teachers, student teachers, and friends have given valuable time and feedback to us through field-testing and previews, as well as sustained support and encouragement.
ITPS: A Performance Based Assessment of Instructional Technology Competencies

Joseph Braun, Department of Curriculum and Instruction - Illinois State University, US
Rhea Walker, Department of Curriculum and Instruction - Illinois State University, US
Brent Simonds, Department of Communication - Illinois State University, US
Carl Wenning, Department of Physics - Illinois State University, US
Jill Thomas, Department of Geography - Illinois State University, US
beverly rich, Illinois State University, US

Illinois State University’s Technology Learning Circle (TLC), a group formed in 2000 as part of a federal grant, developed an Instructional Technology Passport System (ITPS) designed to ensure that graduating teacher candidates are able to use instructional technology in ethical and effective ways, in compliance with national, state, and institutional standards, e.g. National Council for Accreditation of Teacher Education (NCATE, 2001) or Illinois State Board of Education (ISBE, 1999). The introduction of the standards afforded the faculty an excellent opportunity to develop a system of teacher education performance assessment that can help ensure that teacher candidates graduating from Illinois State University do so with the ability to meet technology standards in preparation for their work in schools.

This paper will describe the unique composition of the TLC, highlight the core beliefs and values that guided their work, and provide an overview of the design and development of the ITPS to date. While significant progress is being made in implementing the ITPS, the reader should note that this is considered a work still in progress. Thus, the paper concludes with a look at the next steps to be undertaken by the TLC in implementing the system to ensure that graduating students from Illinois State University as teachers in the nation’s schools will be able to meet the standards for using instructional technology.

TECHNOLOGY COMPETENCIES IN TEACHER EDUCATION AND PERFORMANCE BASED ASSESSMENT

The composition of the TLC reflected a collaboration among various departments in Arts and Sciences with a role in teacher education, e.g, Physics, Geography, and Communication, together with Curriculum and Instruction faculty as they developed the ITPS. As part of its role in the federal grant that underwrote the work of the TLC, the committee was charged with the task of “examining and implementing technology-related issues with regard to both K-12 educational settings and college teacher preparation programs.” The Technology Learning Circle has created a project to implement a standard set of instructional technology tasks that will serve as a basis of authentic performance-based assessments that all teacher candidates must complete successfully prior to graduation from Illinois State University.

Based in part upon committee expertise, review of the literature, and experiences at Alverno College – an institution recognized for its “Student Assessment-as-Learning” principle (Alverno College Institute, 1994) – the following core beliefs and values were adopted by the Technology Learning Circle and served as the basis for much of its work.

- Assessments must judge actual performance, not merely intellectual knowledge.
- Assessments can and should be an opportunity for learning.
- Assessments must include “corrective feedback” to the student.
- Assessments represent the learning outcomes of the teacher education unit.
- Assessments, because they represent a minimum of what all teacher candidates should be able to do, must be satisfied at the 100% level.
- Teacher candidates should be proficient in demonstrating their use of instructional technology.
- University faculty will provide a basic introduction to the various performance tasks, but students will be responsible for obtaining in-depth training as necessary.
- Learning is best when there are examples of expected outcomes and public criteria for performance.
- Development of the ability to self-assess is essential to becoming a lifelong learner.
The TLC examined both internal and external technology standards, i.e. university-wide standards for students in regards to technology as well as the International Society for Technology in Education. From this examination were derived twelve consolidated indicators that, as integrated tasks, address the multitude of elements presented in the various standards. These indicators were reviewed by a panel of K-12 teachers as part of the development process. The consolidated indicators are general in nature, and relate what all teacher candidates should be able to do at a minimum under authentic teaching conditions. Arguably, any student who completes all twelve assessments encountered in ITPS rightfully can be said to have demonstrated the competencies required by the University and external accrediting agencies. The consolidated performance indicators are as follows:

1. The teacher candidate demonstrates knowledge of ethical standards in the use of technology.
2. The teacher candidate demonstrates the ability to use technology to work effectively and equitably with students challenged by a variety of physical disabilities (including the scanning of text, OCR, text-to-speech applications, image resizing, etc.).
3. The teacher candidate demonstrates an understanding of basic computer terminology and concepts, including fundamental understanding of basic computer operations and an ability to perform simple trouble-shooting tasks.
4. The teacher candidate demonstrates an ability to use a variety of instructional media effectively (e.g., DVD player, CD-recorder, laser disk player, VCR, digital still camera, digital video camera, smart board, document camera, and video projector).
5. The teacher candidate demonstrates the ability to use telecommunications effectively (e.g., e-mail, discussion groups, list servers, instant messaging, etc.).
6. The teacher candidate demonstrates the ability to create and edit the content of web pages, including the posting of the web pages to the World Wide Web (e.g., presupposes ability to use FrontPage, PageMill, DreamWeaver, or Netscape Composer, and inclusion of digital images obtained from a digital camera, etc.).
7. The teacher candidate demonstrates an ability to effectively use web browsers, including the utilization of search engines.
8. The teacher candidate demonstrates the ability to use presentation authoring tools (e.g., PowerPoint, Hyperstudio, etc.).
9. The teacher candidate demonstrates the ability to use idea development software (e.g., Inspiration, etc.).
10. The teacher candidate demonstrates the ability to use spreadsheets (e.g., Excel, etc.).
11. The teacher candidate demonstrates the ability to use database management software (e.g., FileMaker Pro, Access, AppleWorks, etc.).
12. The teacher candidate demonstrates the ability to perform desktop publishing (e.g., In Design, Word, etc.).

It was agreed that these consolidated performance indicators are subject to periodic review and editing in order to take into account the very significant ongoing changes in the field of instructional technology.

Associated with each of these consolidated indicators is an authentic performance-based assessment task that examines student performance and ensures program compliance with adopted standards. This system stipulates that all teacher candidates must demonstrate certain competencies, e.g. designing and manipulating a database to retrieve information or using a desktop publishing program to produce a class newsletter, at various institutional gateways, i.e. beginning of professional studies, student teaching, and graduation.

Students may acquire the knowledge of skills associated with any individual performer at different points in their teacher preparation beginning with their initial undergraduate coursework as freshmen. The TLC decided, however, that the first four performance indicators would be assessed prior to beginning professional studies and such assessment would be conducted at a center dedicated to the work of the TLC. This work includes not only conducting the performance assessments for the first four indicators, it also would be a source of training and retraining for those not successful in their completion of the assessment task. As students successfully complete the tasks at the various gateways described above, progress is posted to their electronic record for which we adopted the metaphor of a passport. That progress could be
achieved through continuing assessment of performance based on indicators five through twelve which could take place within the context of a course assignment or through the proposed center.

**NEXT STEPS**

The next steps for implementing the ITPS include several critical elements for making the system workable. First, the process of faculty involvement in the curriculum mapping of where the indicators will be mastered is underway. This means that the Curriculum and Instruction program faculty in teacher education, i.e. early childhood, elementary, middle school, and secondary, will have to come to consensus regarding in which courses a particular indicator should be targeted. Upon completion of this curriculum mapping, the process will be repeated for other programs, such as those included in special education.

Along with the curriculum mapping of the indicators, the faculty in the various programs will have to be adequately prepared to use and model instructional technology in relation to the indicators that are identified within courses they are teaching. The university already has a staff development opportunities in place but these will need to be tailored somewhat to meet the particular needs of faculty. For example, it would not be assumed that early childhood faculty would use the same database or graphing program as would a secondary faculty member. While we would expect all faculty to develop the same proficiencies as expected of the students through the ITPS, in the short term we know the busy schedules of university faculty preclude everyone gaining such proficiencies at the same rate. Nonetheless, vital to the success of ITPS is an effective staff development program, as well as on-going technology support for the faculty.

Finally, the performance assessments need to be developed and refined. This step will involve development of authentic assessments by the TLC and, as with the development of the indicators, K-12 teachers will be included in a review process prior to implementation. The assessments must result in products or performances that can be used to document how students actually achieve the indicators as part of the NCATE re-accreditation process that will begin next fall.

Once in place, the model will serve teacher education students well. We believe that our approach is constructivist in nature, which is consistent with our philosophy of teacher education at ISU. It incorporates best practices in assessment and is consistent with the changes in accreditation developed by NCATE as we approach our re-accreditation. Finally, the process has involved faculty in such a way that a feeling of ownership for this curriculum development effort has developed beyond those of just the committee who created it. In general the faculty has readily embraced our work and to date there has been very little resistance. The committee eagerly looks forward to completing the above mentioned work.

Successful Infusion Of Technology Throughout A Teacher Licensure Program

Dr. Gary Breegle, Department of Education, Belmont University, USA, breegleg@mail.belmont.edu
Dr. James Stamper, Department of Education, Belmont University, USA, stamperj@mail.belmont.edu

Abstract: For the past two years Belmont University’s Department of Education faculty has infused 28 technology competencies throughout its pre-service teacher preparation program. These competencies are the competencies required for teacher licensure by the State of Tennessee. The technology course that pre-service teachers and interns were required to complete in the past is no longer offered. Now pre-service teachers and interns develop these competencies and demonstrate them by completing the technology tasks that are embedded into course assignments and into the internship. This paper describes the process we used to infuse technology throughout our licensure courses, and lists recommendations for strengthening the infusion based upon a survey of Belmont’s pre-service teachers, interns and faculty.

Introduction

Some teacher preparation institutions have successfully infused technology into their programs (Cooper, et. al., 2000; Woodruff et. al., 1998). And yet, while incentives and resources to train faculty to infuse technology are available (Niederhauser, 2001), researchers continue to report that education professors do not model the use of technology in teaching their courses (Deal, 1999). The purpose of this paper is to encourage more teacher preparation institutions to follow Belmont’s lead and successfully infuse technology throughout their teacher licensure programs.

Our Infusion Process

In 1999-2000, Belmont participated with Nashville Metropolitan Public Schools and another local university in a PT3 catalyst grant (U.S. Department of Education, 2000). The grant specified that the Belmont faculty use an online self-assessment tool to rate their own technology skills. During a private interview, each professor (1) developed a list of personal technology strengths and weaknesses based upon the self-assessment results, (2) determined which technology skills were already included or taught in the professor’s courses, (3) developed strategies to infuse (or further infuse) technology into the professor’s courses and (4) identified special training and/or resources the professor needed to successfully infuse the technology. Belmont faculty subsequently approved a course matrix of infused technology competencies. Our education technology professor then coordinated the infusion and team-taught the competencies with the faculty in their courses, and moved the technology assignments in selected courses online using WebCT. Pre-service teachers were then required to access and to complete selected technology tasks online in WebCT in the first core licensure course (Foundations of Education), and in the Professional Development Site (PDS) 15 credit hour Methods Block course. Interns in Belmont’s 15 month Internship program used WebCT to record daily journals, submit unit and lesson plans, and to complete other assignments for review and comment by Belmont faculty and PDS mentor faculty. They also completed a technology workshop in WebCT that taught them how to construct a web page for their students to use in the classroom, and how to use Microsoft’s free software (NetMeeting) to videoconference their classrooms with other classrooms.

Assessment Of The Infusion Effort

In the fall 2001 semester, our pre-service teachers, interns and faculty completed a survey to help determine the extent to which infusion provided opportunities to develop technology skills, and how the infusion can
be improved. Based upon the survey results, the following recommendations were submitted to the Belmont faculty:

- Since Belmont now has a new computer proficiency course that all entering students must complete during their first semester, infused competencies that are taught and/or verified in the proficiency course should not be taught in the licensure courses. However, skills that are required by the state of Tennessee and that are not taught in the proficiency course should be taught throughout the licensure courses, especially in the methods block course and the Internship,
- In the first core course, Foundations of Education, students should be introduced to WebCT because they will need to use it as they move through other licensure courses,
- Pre-service teachers and interns should be required to systematically demonstrate competencies in a broad range of assignments and practicums throughout their courses,
- Bi-weekly technology sessions should be conducted on site at the PDS schools. These sessions should include instruction on how to infuse technology into the curriculum, how to construct and maintain a teacher web site, and how to use a variety of technology resources.
- Since interns complete core courses during the summer before they begin their internships in the schools, these courses should include additional introductions to technology resources (e.g., computer projector, digital camera, videoconference software and hardware) and additional opportunities to construct lesson plans that include the use of technology resources.

Conclusions

At Belmont we believe that the following are necessary for successful infusion:

- First and foremost, a faculty committed to infusion as evidenced by its willingness to develop personal technology knowledge and skills, and to model the use of technology in their courses,
- Second, clear explanations by administrators and faculty to students about the infusion plan and why students are no longer required to take a stand-alone education technology course,
- Third, an understanding of and approval of the new role of the faculty member who teaches education technology as evidenced by an assigned workload, which includes time to plan and time to team-teach with other faculty members, and
- Fourth, a commitment to regular and systematic assessment of the infusion effort

Simple and Effective – Teacher Roles Remain a Powerful Framework to Embed ICT Within the Practice of Teaching

Dr Christine Anne Brown
Faculty of Education
University of Wollongong
Australia
christine_brown@uow.edu.au

Abstract: Teacher roles of learner, manager, designer and researcher provide a simple framework to embed ICT within the practice of teaching. They have been used to convey the impact of information and communication technology within compulsory ICT subjects in the Faculty of Education at the University of Wollongong for five years. The roles have been adapted to suit students studying ICT on campus without simultaneous classroom access (Example A), to frame ICT on practicum (Example B), and to structure video vignettes of local teachers working with ICT (Example C). Each examples is explored in relation to the sequence or clustering of roles, their dependence on context, their relationship to an electronic portfolio, and the degree of support required. These fundamental roles facilitate communication among pre-service teachers, new graduates and experienced colleagues to enable professional development for all teachers.

Introduction

The integration of information and communication technology (ICT) in teaching practice provides a challenge for pre-service educators. If you maintain a separate focus on ICT you can be lured into emphasis on a skill set; embed ICT within all subjects and you run the risk of assuming “someone else has covered that.” Couple with that simplistic dichotomy a range of interpretations of “integration” and you have a complex problem for pre-service educators who require not only big picture thinking of leadership, but also faculty wide support.

In its most basic form, integration can be met by development of student skills with ICT tools and these skills can simply be mapped across subjects in a degree program. Other more pedagogical interpretations of integration require substantial alterations to tertiary teaching practice, either through emphasis on student-centered activity design, the development of high quality on-line resources and interactive learning experiences, or whole program re-structuring as a consequence of use of ICT. Theory and practice can be linked through communication tools and communities established in a virtual environment that is capable of bridging the pre-service to school divide.

Within such complexity, it is often simple structures or ideas that resonate with different groups. In this case it is the anchor point of fundamental teaching roles – learner, manager, designer and researcher. The temporary separation of these four teaching roles permits a closer examination of associated skills, processes and ways of thinking. The teacher as learner must be a sophisticated and technologically literate information processor, with a considerable degree of self-regulation, internal motivation and a lifelong approach to learning. It is easy to see how this role instantly addresses student attainment of core ICT skills. The teacher as manager must be highly organized and logical, capable of great attention to detail with personal and teaching resources, student work, classroom layout and management and reporting of student capabilities. Since many capable learners struggle to organize or archive their own work and fail to see the virtue of developing a personal information management system that outlives short-term needs, the transition to managing the additional work of a class is far from minor. The teacher as designer must be able to creatively design student activities to meet a range of learner and system needs in a given environment. Activity design is problem-solving that draws on learning theory, on management experience and on interpersonal skills. The more a teacher moves from a didactic to a facilitator approach, the more flexible they must become as problem-solvers who are required to “think on their feet”. The teacher as researcher must monitor practice, maintain a focus on professional development, collaborate with teaching
peers and reflectively improve their practice. This demands feedback from students and fellow teachers and a willingness to accept constructive criticism.

Classroom reality weaves multiple teaching roles together in ways that are highly context specific. Since evaluation is an integral component of any teaching role, and assessment drives much of what is learned in schools today, assessment and evaluation are embedded within the roles. The four teaching roles of learner, manager, designer and researcher have been used as the framework for conveying the impact of information and communication technology within compulsory ICT subjects in the Faculty of Education at the University of Wollongong for the last five years. They have been adapted to suit students studying ICT on campus without simultaneous classroom access (Example A), to frame ICT use on practicum (Example B), and to structure video vignettes of local teachers working with ICT (Example C). Each of these examples is now explored in relation to the sequence or clustering of roles, their dependency on context, their relationship to an electronic portfolio structure, and the degree and nature of teaching support required (see Tab. 1).

Table 1: Relationship of teacher roles for ICT integration to context, electronic portfolios and student support

Example A: Students studying ICT on campus without classroom access

The core compulsory first-year ICT subject for all pre-service teachers in our Primary (elementary), Early childhood or secondary PE/Health program has changed dramatically over the last few years. The 1997 subject re-modeling of “Information Technology for Learning” geared to the state ministerial guidelines for the integration of ICT into classroom practice. Skills and pedagogy were translated into basic skill tests, design of lesson activities incorporating ICT, exam testing of concepts and resource support through a textbook and web site. Although the themes of learner, manager, designer and researcher were embedded in the lecture structure, it was not until the 2000 subject revision that these teacher roles became explicit.

In 2000 skill tests were replaced by paired student activities (database, multimedia presentation and web-based activity), the exam questions were unfolded weekly via asynchronous discussion so students could develop and share ideas, and a process oriented electronic portfolio was introduced. The aim was to
functionally anchor skill development, allow students to develop file management skills within a designated folder structure, model the organization and collection of electronic student work, and allow students to choose a cluster of activities that suited their interest and degree. The choice of portfolio activities in the 2000 subject offering is presented in Tab.2, accompanied by the number of students who chose each option, and the subsequent options offered in 2001. Students were asked to choose one activity from each category.

Table 2: Portfolio options offered in 2000 and 2001 in “Information Technology for Learning”

Subject re-vision for 2001 was once again substantial. Lectures provided information, introduced themes, explored and modeled resources and allowed a core team of three lecturers to weave together coherent but diverse approaches to ICT integration. The exam was replaced by an online discussion activity that required students to contribute at least two substantial entries to the question of their choice, summarize and reference the work/comments of their peers, then draw some conclusions. The process of analyzing themes produced much deeper student processing of the pedagogy of ICT integration than previous exam answers, allowed students to identify many writing styles, use a powerful cognitive tool, and research and present data. Educational software review was re-introduced within tutorials, permitting groups of students to experience the technical issues of software installation, review the pedagogy and discuss classroom application. The electronic portfolio for 2001 remained anchored to the four roles, but options were reduced to two within each category on the strength of the popular choices made by students the previous year (see Tab.2). In addition, CDs of sample student work from 2000 were supplied within tutorials to help frame expectations and reduce over-reliance on any single example.

One constant from 1997-2001 is the sequence of unpacking teacher roles—begin with the learner (where they are at), follow with the manager (relate to practical issues in the classroom), progress to designer (creative application of pedagogy) and cap off with reflective and organized researcher. These four roles can be used to illustrate some of the diverse ways a teacher must think and operate (reduce initial complexity), and to allow pre-service teachers to accept that they may not be equally comfortable or proficient at all teaching roles. This provides a strong rationale for teaching as a team enterprise, particularly in an ICT-rich environment, given the potential complexity of the technology.

Students study this subject in the second session of their first year of a three or four year program, hence their school practicum experience is limited and they may not be fluent flipping between teacher and learner hats. Introducing the teacher as learner permits them to step straight into the teacher role as a novice, and models the idea of lifelong learning and professional development.
The four roles become explicit within the electronic portfolio, where the key emphasis is on assisting students to develop ongoing electronic information management skills that will permit them in their later years to take a product approach to portfolios for assessment and ultimately presentation to potential employers (Brown 2002). Students are asked to construct four folders to contain work related to teacher roles (see Tab.2).

The support students require has shifted progressively from the development of application skills to the pedagogical application of those skills, largely due to increased acceptance of the role of ICT rather than increased skill base. Peer tutoring is critical, and the use of fourth year students as demonstrators has been mutually beneficial. Surprisingly, basic computer skills are the most lacking - many students are highly competent using specific applications on their home machine, but have no understanding of how to transfer documents using portable media. The typical requests for a print copy or electronic submission through web-based course support systems bypass such file transfer and can mask inability to complete simple movement of documents in a non-networked environment such as might still exist within their first school placement. Emotional support is critical in this subject, particularly for both ends of the experience spectrum. Those with little past experience feel intimidated, while those with sophisticated skills in a limited range of applications may initially fail to realize their role is to help others learn to use ICT for learning in addition to maintaining and expanding their skill base.

Example B: students using ICT on practicum

The one-year Graduate Diploma of Education (GDE) program began incorporating a specific focus on ICT in 1997, when a 9-week series of lectures and tutorials was placed at the end of the annual subject “Pedagogy”. In the following three years (1998-2000) a 6-8 week block of Pedagogy early in the year was allocated to ICT integration to allow for skill development throughout the year. The 2001 iteration adopted an extended approach to ICT as a stepping-stone to course redesign with an ICT backbone in 2002. Although the lecture series was placed in session one of the year, the bulk of student assignment work was due in second session, permitting a focus on ICT use within the major mid-year practicum. Lectures and tutorials were merely the source of resources, ideas and support for subsequent application in the classroom context. The four teacher roles were made explicit through the electronic portfolio as they relate to the teaching cycle. Students first research their school ICT environment, design activities with their supervising teacher, manage those activities and finally evaluate what they have learned (based on observations, supervisor feedback and collections of student work).

The brief nature of the GDE program relative to Example A, coupled with the ability to anchor ICT experience within the practicum necessitates that students jump straight into the teaching sequence. The electronic portfolio requires them to stitch their experience together in a structured report (product), accompanied by electronic folders containing resources, activities and student work they can archive for subsequent access (part of the ongoing process). The request for students to note all available resources means they have a record for future use, and the request for samples of student work models the need to look at student work to make a meaningful self-assessment of their performance. The key time students need support is during and after their practicum, so future plans to "backbone" ICT activities throughout the year seem highly appropriate.

Example C: video vignettes of local teachers working with ICT

The lectures and tutorials in Examples A and B do not occur at a time when students have access to the classroom. They often have trouble relating to the classroom context, and frequently question the expertise of a university lecturer relative to the school classroom context. One solution (tried 1998-2000) was to involve a range of classroom teachers as guest lecturers. Considering the diversity of courses in either of these subjects, it is very difficult to balance the range of needs against the internal coherence of a lecture set. The pair of lecturers in 2001 provided internal consistency - for classroom links in the future, we are pursuing the collection of video cases from local schools.

The four roles are aligned to link pre-service and practicing teachers. The learner and manager focus on the teacher. The aim is to tap into the thought processes and reflections of the classroom teacher about ICT integration and the management issues involved in planning, monitoring and collating student electronic work. The designer and researcher relate to the interaction between teacher and students. What
kind of activities do teachers design that seamlessly integrate ICT? Can we hear the teacher's reflections on what happened? How do students work with ICT? A case may represent one teacher, or a school group. Video vignettes feature teacher reflections on the use of ICT in the classroom (learner); equipment, layout and management of student work (manager); student activities with before and after thoughts of the teacher (designer); students engaged with ICT in individual and group work (researcher).

Every teacher and classroom is unique. This process begins a video vignette collection that can grow and be used flexibly for professional development of teachers generally (see Tab. 3):

<table>
<thead>
<tr>
<th>Learner</th>
<th>Teacher A</th>
<th>Teacher B</th>
<th>Teacher C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manager</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Designer</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Researcher</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 3: Potential combination of video vignettes as the basis of many class activities

One collection of vignettes could be the profile of a particular teacher, such as "Teacher A" (Tab. 3). Alternately, the manager theme could be explored for comparison and contrast of a range of classroom environments with respect to technical infrastructure and resources. The value of the vignette structure lies in the re-usable nature of the individual elements that might find their way into web pages, onto a DVD or projected for discussion within a tutorial. They rely on the creativity of the activity designer to "come alive" from multiple perspectives for many educational issues. The teachers at the heart of the case studies are gaining valuable resources for their professional portfolio. This process also models the benefits to be gained from close observation and analysis of your own teaching. Monitoring and sharing cases provides many starting points for great professional development. Video production requires significant support to ensure high quality. The video editing and processing are complex, but may also be the most valuable part for either students or teachers. Alternately, students could capture the case studies.

Conclusions

If our goal is to support the prime endeavor of learning that is active, constructive, collaborative and intentional through transparent use of ICT, then we have to look at the fundamentals of teaching and transcend the particulars of technology. Teacher as lifelong learner, teacher as manager, teacher as creative designer and teacher as reflective practitioner appear to offer some promise. These roles may facilitate clear communication among pre-service teachers, new graduates and their experienced colleagues to allow for the concept of professional development for all teachers. Teaching in an ICT-rich environment tips the load for teachers and demands teamwork (Jones 2001). These roles provide a simple means of teachers dividing the labor, acknowledging that as classroom generalists we are naturally better at some things than others. The roles also provide a team structure for targeted professional development activities within a school. All teachers present a unique profile of proficiency with ICT. The real challenge may be to deal with the emotional issues surrounding effective teamwork (Luca and Tarricone 2001).

The Design of a Computer-Based Review for the ExCET

Douglas Bump, Houston Community College, US

To be certified as a teacher in the state of Texas a candidate must pass the Examination for the Certification of Educators in Texas (ExCET). Students today spend four years or more in education programs taking courses intended to prepare them to become teachers. At the end of the program students must pass a test such as the ExCET that is a prerequisite for becoming a teacher.

Texas is now holding the teacher education program responsible for the success of teacher candidates on certification examinations (Hernandez, 1999). Universities may lose their teacher certification programs if their students do not pass the certification tests. Because of these consequences, colleges of education are beginning to prescreen students who desire to enter their teacher preparation programs, requiring students to meet specific GPA and basic skills standards before being admitted to the programs (Hernandez, 1999). There is currently a shortage of certified teachers in Texas and prescreening students who desire to become teachers has the potential effect of eliminating some people who could become very good teachers. There is a need to develop a computer-based examination, that can be used to prepare students for the ExCET and to study the effect of this computer-based examination on their ExCET scores.

Books and Manuals do not provide enough interactive preparation for the ExCET. Most ExCET preparation manuals today include examples of ExCET tests. These tests encourage students to take the whole test first and then check their answers. These manuals provide detailed written explanations of the answers at the end of the test. In an inefficient manner, students must turn back and forth in these books if they want to check their answers.

Computers-based education allows students to quickly compare their responses to the correct answers. Computers do not ridicule student’s answers, and students can work at their own pace at each concept before they advance to the next. Computers can provide students instant feedback that can tell the student why their answer is right or wrong.

The purpose of the study was to design, develop, and evaluate a computer-based test that provides teacher education students with a review for the ExCET. The design and development process for the test was defined by a group of stakeholders that included the designer/programmer, teacher educators, an author of a print-based ExCET review, and teacher education students. This study provided information regarding the following concerns evolving throughout the development cycle: (1) content; (2) screen design; (3) feedback; and (4) evaluation.

The focus of this study was in four distinct areas: test design, test development, implementation of the test in an authentic context, and evaluation from students and faculty. The results are reported in both quantitative and qualitative measures that reflect feedback from surveys and test results. Constructivism was the foundation for both the design and development of the test, and participatory design guided the process.

The overarching principles of reflection and recursion were critical for this design model. Recursion provides the opportunity for stakeholders to revisit and rethink the
materials in a cyclical method throughout the development of the software. Reflection provides the opportunity for all of the stakeholders to think about and reflect on the design and development decisions that have been made and change them when needed.

The idea for the program originated as the competencies and domains were introduced to teacher educators. The teacher educators noticed a need for software that would help students prepare for the ExCET. The development of the program incorporated the suggestions, propositions, and plans of teacher educators making these contributors an important part of the project. The teacher educators grew from being contributors to become stakeholders in the project. Students who participated in the trials made many suggestions as part of a formative evaluation. These suggestions made many improvements to the program which made the stakeholders feel that the program was their program. Finally when one stakeholder suggested that the future version incorporate video, ownership was divided evenly by all the stakeholders. The project is now a very important part of the ExCET review.
Using Problem Based Learning to Prepare Students for IT Leadership Positions in Schools

Dianne Chambers
Science & Mathematics Education, Faculty of Education
The University of Melbourne, Australia
d.chambers@unimelb.edu.au

Abstract
Teachers take on a wide range of roles in a school, yet most teacher education courses prepare students for only the role of classroom teacher. A problem based learning approach to teaching and learning and IT-based resources in a technology-rich learning environment are combined to provide undergraduate education students with an exciting and innovative way to learn about IT in schools. This paper explores how problem based learning and technologies are utilized to provide powerful opportunities for learning about IT in schools through: solving authentic tasks; taking on leadership roles; working as a team; and collaborating on solutions to authentic ill-structured problems. Students taking this subject have reported over a three-fold increase in confidence in tackling IT problems in a school, in addition to development of content knowledge and transferable leadership skills.

Introduction
The roles of a teacher include not only teaching and classroom activities, but also many other roles such as curriculum planner, decision maker, human resources manager, technology manager, team member, and team leader. A problem based learning (PBL) approach is used in the subject Information Technology (IT) in Primary Schools at the University of Melbourne. This approach enables us to project undergraduate students into their future role as teachers, to enhance their learning, and to prepare them for the varied roles of a teacher through authentic tasks and scenarios. The subject is supported by a website that includes a rich description of a fictional primary school [named ‘Federation Primary School’ in honor of Australia’s centenary of federation in 2001] and its inhabitants in which the problems are set, and the subject is conducted in a technology-rich teaching space (see Arnold & Gruba, undated, for a description of the teaching space and the resources available in it). Although the teaching space was very well-equipped, this level of technology is not considered to be vital to running a program such as that described here.

This subject is part of the Bachelor of Education (Primary) [B.Ed.(Primary)] degree, which is a four year course of study and the principal vehicle for the education of primary (elementary/K-6) teachers at the University of Melbourne, a research intensive university in Melbourne, Australia. During the third and fourth years of the B.Ed. (Primary) degree students select one optional subject each year, allowing students flexibility to strengthen an area of interest or to broaden their knowledge. IT in Primary Schools is an optional subjects and runs over two semesters with a two-hour block each week. The tasks students undertake are designed to develop their content knowledge about IT and its uses in a school, to give students experience of working as a team, and to develop skills and knowledge about being a leader in the context of decision-making about IT issues in a school. It is considered that the leadership skills developed will be transferable to other roles of leadership in schools and elsewhere.

Using a PBL approach for this subject (first taught in 2001) was examined for a number of reasons — new graduates told us that in their first years of teaching they were made members of the Information Technology Committee (or equivalent) at their school (a big role for a new graduate!) and PBL appeared to be an excellent means of facilitating the transition of our students from the role of a student to that of a education professional. Thus, this subject gives our students experience in tackling the kinds of IT issues that they are likely to encounter when a teacher and to experience the roles of committee member and chair of a committee with responsibilities for developing a report with recommendations for a School Council or the principal. PBL allows students to develop both the content knowledge and the transferable skills required for the many roles of a teacher, with this subject having a particular focus on leadership roles.
Using PBL to Support Learning

Finkle and Torp (1995) describe problem based learning (PBL) as:

"a curriculum development and instructional system that simultaneously develops both problem solving strategies and disciplinary knowledge bases and skills by placing students in the active role of problem solvers confronted with an ill-structured problem that mirrors real-world problems".

Finkle & Torp (1995)

The subject employs a problem based learning approach (see also Stover, 1998; Stepien & Gallagher, 1993) and each problem is explored in a four week cycle (see Table 1). The students work in teams of four students and tackle four problems involving IT in a fictional primary (K-6) school over the course of the academic year (two semesters). The problems are: Integrating IT into the Curriculum; Developing a Three year IT Budget; Developing an IT Professional Development Plan; and, Developing a Three year IT Strategic Plan. For each problem the team prepares a written report that are the recommendations to the School Council and the team presents their proposal, as if to the School Council.

The role of the team is that of the school’s IT Committee that respond to briefs developed by the principal or School Council. The team leader is in the role of committee chair and the team members act as committee members. Teams meet in scheduled class times once each week and may also meet – electronically or in person – outside scheduled classes. Students used telephones, email and short messaging system (SMS, on mobile telephones) extensively to communicate outside class times. As the year progressed scheduled classes were reduced.

The subject had no lectures or formal workshops about any of the content areas. The first two sessions of the subject were used for the class to discuss issues that would prepare students for this mode of learning, as this was the first subject the students had undertaken using a PBL approach. Discussions included how the subject would operate and students were directed to resources about problem based learning and the roles of team members and team leaders were discussed extensively and students defined the characteristics of a good leader and team member. These introductory sessions were time well invested and made explicit to all students what their colleagues saw as good team behaviors.

The class met for a two hour block each week with staff only addressing the whole group at the start of each problem (week 1) to raise general issues about the topic and field questions and in the class that teams presented their recommendations (week 4) staff chaired the session and managed the discussion and the students critiquing of presentations.

---

**Week 1 (of 4 week cycle)**
- An introduction to the problem & a discussion that raises general issues related to the topic. This is supported on the subject's web site with notes, links to useful sites and articles, and supporting artifacts about the scenario for the problem.

**Weeks 2 & 3 (of 4 week cycle)**
- Teams work on the problem, with staff available to mentor the teams. Staff & experts (principals, teachers, and others) are available (via email) to team leaders.

**Week 4 (of 4 week cycle)**
- Teams present their recommendations to the group, the style is similar to a School Council meeting and students critique and discuss the recommendations of each team.

---

**Table 1. Activities during the four week cycle of each problem.**

---

**Development of Leadership Skills**

Students are assigned to the role of team leader on a rotating basis and are responsible for compiling and submitting the report and coordinating their team’s presentation. This allows students to gain experience in working as a team and in leading and coordinating a team to meet a deadline. These are highly valued transferable skills for students to gain, in addition to the content knowledge developed. In the first sessions of the subject students, as a group, described the characteristics of a ‘good leader’ and the sorts of behaviors a good leader would have. Characteristics and behaviors of good team members were also described and discussed. This discussion was quite extensive with students drawing on both their positive and negative experiences of working with teams. Students were also encouraged to engage with literature about team leadership skills, team management and team participation via links on the subject’s website.

During the course of the subject each student was team leader for one problem and the role was taken seriously by students and staff. At the conclusion of each problem students were required to reflect on a number of aspects of the problem including on how the team process had worked and how they would have handled the team had they been team leader. This reflection enabled students to consider how well the team leader had managed the group and to consider alternative ways the process could have been handled. The reflective process as part of the cycle is an important aspect of
PBL (Holen, 2000). Thus, although each student was team leader for only one problem, they had many opportunities for critiquing the leadership of others and projecting themselves into the role of team leader.

The following quote from a student at the end of the subject exemplifies some of the learning students had about working in a team and in leading a team.

*The subject has many strengths, these included working in a team and having team-leaders. Having experienced four different teams, it was clear to see when a team had a leader with the right qualities. For successful leadership, organization, initiative, vision and negotiation is needed. At times the leader has to be frank and direct and keep things moving along. In successful team work, there has to be balance of roles and work load, there has to be sharing of ideas and there has to be a willingness to help out each other and be honest to each other about concerns that might be facing the team.*

**Development of Content Knowledge**

In this subject there were many aspects of knowledge development. Some of these are:

- Students developing a knowledge of the body of literature relating to IT in schools. For example, students investigated the research basis of different models of professional development when designing a professional development program for teachers in the school and had to investigate theories of learning when planning the integration of IT into classroom activities.

Although no 'content' was taught in this subjects it is believed that students' learning in this area was enhanced because the students themselves determined what they needed to know for each problem. Another powerful learning outcome was students developing the skills of finding and making sense of reliable information and applying it to a problem at hand.

- Students becoming conversant with currently used software and hardware and educationally sound ways these can be used in the primary classroom and becoming experts on current government Education Department policies and requirements regarding IT in schools.

It is acknowledged that the details of these are only ephemeral, but the skills in finding and evaluating this type of information are of ongoing value.

- The information literacy skills of students were greatly enhanced during the subject as students were given links to only basic sources.

As the year progressed the information literacy skills of the students blossomed, as did their confidence and autonomy in taking control of their learning. Students also developed a rich knowledge of useful and reliable sources of information about matters relating to IT in schools.

- Students developing a rich understanding of working in a team and in leading a team.

It must be acknowledged that not all team work was 'plain sailing' and for some groups difficulties did occur. These were viewed as learning opportunities and students involved were encouraged and supported in sorting out any difficulties as they arose.

- The richness of description of the fictional school, and the authenticity of the characters of the school meant that students developed some understanding of the complexity of working in a school and understanding the political and personal minefield that getting staff to use IT in their teaching can be!

Some staff members of the fictional were deliberately 'awkward', such as the teacher who saw herself as an IT leader in the school (because she had been an early adopter of IT), but had not changed her classroom practice in 15 years!

*It must be noted that none of the content was 'taught' to the students — that is, there were no lectures or tutorials in which staff did traditional teaching about these content areas. Students developed their own knowledge in the various aspects of implementing IT to support teaching and learning in a school as it was required for each problem, which highlights the importance of well-designed problems. As the students defined what they needed to know to work through the problem they were in an optimal state for learning.*

When students approached staff with questions about finding information or how they might tackle a problem, staff did not take on a didactic role at any stage and did not tell students where to find information or what the next step might be. If the problem was informational, staff modeled to students how they might go about finding out such information (but did not give the information to the student) or bounced questions back to the students to get them to find the next step. This methodology of scaffolding students worked extremely well. As the year progressed the scaffolding was progressively withdrawn as students developed skills and no longer required support to tackle the problems. By the final problem the class did not meet between weeks 1 and 4 of the problem (a staff member was available in his office if any help was required — it wasn't!) and teams worked on their own on the final problem. This is pleasing as these were final year students who will be practicing teachers within months of completing this subject.
Student Responses to the Subject

The subject was offered for the first time in 2001 (February to October 2001). Students responded very positively to this style of learning and developed skills and understandings not developed elsewhere in their studies. The first semester (February to June) feedback from students in the University's 'Quality of Teaching' survey (University of Melbourne, 2001) was excellent — average scores for the questions ranged from 4.4 to 4.9 out of a possible 5. These are substantially higher than the University averages. The results from the second semester of the year-long subject were even higher, with a 'perfect five' scored on four of the nine questions — this indicates that all students surveyed gave the highest rating for that question. Averages of other questions ranged from 4.6 to 4.9 — which are well above the university averages. That the response to the statement 'The subject was taught well' scored 4.6 in semester 1 and 4.9 in semester 2 is both pleasing and interesting, as there was no 'teaching' (but lots of learning!) in the subject. Student satisfaction with the subject is also suggested by an almost doubling of enrolments in the subject for 2002 as positive 'word of mouth' about the subject was passed onto the students of the following year.

The effectiveness of this approach to teaching and learning is indicated by the following quote, which is from a reflective piece from a student in the subject:

I had to think about the school's philosophy and charter, as well as think about what the teachers hope to achieve and what learning environment they want. These were not easy, they took strategic thinking — hence a strategic plan — I was constantly asking myself, is this really achievable? Is this realistic?

The following quotes from students indicate the immense value that they found in this style of learning:

This is an amazing subject that has taught me an unbelievable amount of knowledge. When reflecting back on the year, I can see that I have grown personally, academically and professionally.

Through this subject, I have been prepared to face the challenges that come with including IT in a school's curriculum in a direct hands-on fashion, in that I was forced to think of the problems in a realistic manner, and solve it in a practical and sensible way that would work in a real school.

One of the things I really enjoyed was the problem based nature of the course. It gave me a sense of empowerment to know that we were directing our learning and were in control of it. That is how it really works from now on for us — that is, we need to have the skills to be able to go out and find things for ourselves.

These comments from students' reflective writing indicate the very powerful possibilities of using PBL as part of the learning process.

Pilot Evaluation of the Subject

At the conclusion of the subject, as a pilot evaluation of the subject and the students' learning, a subset of students were asked to complete a series of simple questions (Table 2). This was undertaken both to inform us of students' perceptions of their own progress and to direct them in reflecting about their own learning. [As only twelve students were asked to complete these questions it is acknowledged that these data are preliminary and form part of a pilot study of the subject and its outcomes]. As can be seen (Figure 1) both the confidence and the content knowledge of the students surveyed increased substantially over the duration of the subject. Although these data are from a pilot study with a small number of students and are not suitable for statistical analysis or the drawing of major conclusions, data suggest that this subject has made a large impact on the students surveyed and, for these students, has contributed in their development as a professional and as a useful and valuable member of a school community. Thus, it appears that PBL can provide a rich learning experience for students developing both content knowledge of implementation of IT across a school and the transferable skills and knowledge for them to take up leadership positions in schools. [Further investigation of confidence in leadership roles will be made with currently practicing teachers and with other final year students.]
Questions

At the beginning of this subject my confidence level in taking on position on a school IT committee was ____ out of 10.
Now my confidence level in taking on position on a school IT committee is ____ out of 10.

At the beginning of this subject my confidence level in taking on a leadership role in a school was ____ out of 10.
Now my confidence level in taking on a leadership role in a school is ____ out of 10.

At the beginning of this subject my knowledge about issues a school IT committee would consider was ____ out of 10.
Now my knowledge about issues a school IT committee would consider is ____ out of 10.

At the beginning of this subject my knowledge about issues a leader in IT in a schools would need to consider was ____ out of 10.
Now my knowledge about issues a leader in IT in a school would need to consider is ____ out of 10.

Table 2: Questions from a pilot evaluation of students' perception of changes in their confidence and content knowledge

Figure 1: Students scores (averages) of their confidence and content knowledge before and after having completed this subject (N=12). [See Table 2 for the questions].

Conclusions

The resources and style of teaching used in this subject for undergraduate teacher education at the University of Melbourne allowed our students to investigate authentic issues involving IT in a school and to develop recommendations for a school. These experiences in working as a team member and being relied on to contribute, in leading a team and coordinating the process and the outcomes, and in presenting the findings to peers and staff give the students valuable opportunities to develop knowledge and skills in a way quite different to traditional university teaching styles. PBL, supported by appropriate technology and experts, has allowed our students to analyze authentic situations in a fictional school and consider alternative solutions or paths of action while working in a team. An element that strongly influenced students' experiences and learning is that students did not work on these materials alone, but rather discussed their findings with colleagues and worked as a team to arrive at conclusions. The need to reflect on observations and share with others and develop the skills required in being a successful team member will, we believe, serve our students well in becoming leaders in the rapidly changing environment of schools of the twenty first century.

Education Technology Training Center, Albany State University, USA
gburgess@asurams.edu

A curriculum based on handheld and mobile technology called PalmTech is under development to prepare preservice teachers as well as inservice teachers to use handheld technology in the classroom. Currently all preservice teachers at Albany State University must complete a technology curriculum called InTech before graduation to master their technology skills. This new PalmTech curriculum is being developed to complement and extend InTech in areas not being covered by InTech. PalmTech, despite its limitations, has the advantage of short training time, easy to use, low cost, and taping into the emerging technology. PalmTech is mainly designed to explore areas of teaching strategies not easily implemented by the traditional desktop technology.

One of the major missions of the SOWEGA PT3 Project at Albany State University, besides technology infusion in the classroom and faculty development, is to train student teachers how to integrate technology into curriculum that they are using during the student teaching period and in the future classroom. The SOWEGA PT3 project partners with the Education Technology Training Center (ETTC) of Georgia State Data and Research Center on campus to provide every student teacher on campus intensive technology training through a vigorous program called Integrating Technology (InTech). InTech is a 50-hour course originally designed for Georgia K-12 Teachers by Georgia Department of Education to retrain inservice teachers in technology skills. The SOWEGA PT3-ETTC partnership helps modify the InTech curriculum to suit the needs of student teachers in the region. In the program, student teachers apply basic technology skills into K-5, Middle, or High-School curriculum according to their specializations.

To demonstrate their competence, each student at the end of the training must produce a CD-ROM and a Website that features everything that they have done for the InTech course. Practically, the student produces an electronic portfolio that can either be carried in his/her own pocket as a business card (actually a cd-rom in the size of a business card) or can be distributed as Web pages. The e-portfolio is not part of the requirement of the original InTech curriculum; but it is becoming a standard for the pre-service students because of the collaboration. In fact, it has become a requirement for all student teachers to complete InTech training before they are eligible for graduation since the partnership started two years ago.

InTech at Albany State University was launched in 1997, since then the technology has changed rapidly; inevitably the InTech curriculum has to be modified on yearly basis to reflect the change. But the
change is still largely surrounding the desktop and its peripheral technology. The recent rapid growth in handheld technology that demonstrates tremendous potential in preparing tomorrow's teachers to use the technology effectively has largely been ignored. The SOWEGA PT3 project and the ETTC Center have decided to launch a new initiative to expand the InTech curriculum to include handheld technology for training preservice teachers. Since then a curriculum called PalmTech has been developed as an attachment unit to the InTech program. Now students not only are capable of producing an e-portfolio on the Web and on cd-rom; they are also capable utilizing the information technology via handheld computing devices such as Palms and other Pocket-PCs in the classroom to enhance their teaching.

In the presentation, both InTech and PalmTech curriculum will be shared interactively. A model e-portfolio and the power of PalmTech will be showcased by one of the student teachers who has participated in one of the InTech-PalmTech courses. The potential of PalmTech will be discussed and demonstrated through interactive activities. An assessment of the student's performance and reactions to new the PalmTech curriculum will be presented.
Moving Beyond Make Believe: On-Line Lesson Plan Collaborations

Abstract: Brunswick County Public Schools (Virginia) has partnered with Old Dominion University on a collaboration project aimed at bridging the gap between pre-service university methods courses and authentic classroom environments. Instead of merely writing theoretical lesson plans, based on make-believe scenarios, individual or small teams of pre-service students from ODU are paired with a teacher in Brunswick County from a similar grade/subject level. These partners are encouraged to write a technology infused lesson plan addressing Virginia Standards of Learning. Participants communicate through an online interactive message board that is supplemented by emails and other electronic message systems. The use of electronic communications allows the site administrators and methods faculty to observe and archive the communication flow and facilitate the collaborative process.

Introduction

In the field of education and technology, on-line collaborations are increasingly influencing instructional strategies. Through interactive web pages and e-mail, classrooms from different parts of the world can communicate with each other, work in unison on projects, and compare the results. Websites, such as iEARN (www.iearn.org), provide platforms, facilitating these inter-classroom collaborations—linking far-flung classrooms.  

Teacher-to-teacher collaborations have also become prevalent components of the Internet. Early on, teachers were quick to see the value of sharing their lesson plans with others. An almost overwhelming variety of lesson plan pages have cropped up to meet the large demand of teachers (www.lessonplanz.com). List serves, such as the Teachnet site (www.teachnet.com/t2t), have become useful tools linking teachers together and allowing them to share their ideas.  

In addition to list serves, e-mail, and teacher web pages, new platforms for on-line collaborations have emerged to facilitate actual asynchronous collaborations among different people. These sites allow
participants to communicate in “rooms” designed for their group. In higher education, university classes use these on-line communication platforms to collaborate on course assignments.

The Project

The current project is a unique use of on-line communication platforms, in an effort to link pre-service student teachers with in-service teachers. It responds to the trend of methods classes requiring students to write lesson plans without a particular school, class, or student population in mind. Instead of merely writing theoretical lesson plans, based on make-believe scenarios, students write lessons for a specific classroom and teacher. These lesson plans are submitted to a pre-service teacher, who actually teaches the lesson. The project uses an on-line interaction platform to facilitate communication between collaborators and encourage the use of technology.

In this collaboration, methods students from Old Dominion University are paired with a teacher in Brunswick County from a similar grade/subject level. Pre-service and in-service teachers share information on the dynamics of the in-service teacher’s classroom and the two work toward a mutual lesson plan. The pre-service student submits a lesson plan to meet the needs of the students in that individual classroom. Before being passed on to the in-service teacher, the plan is checked for technology integration by the site administrators. The in-service teacher receives the lesson plan, along with any supplementary resources, and videotapes it while being taught. Afterwards, the in-service teacher uses a rubric to evaluate the performance of the lesson plan.

Copies of the video and the comments of the in-service teacher are delivered to the methods teachers, who share them with their students. Once the pre-service teacher sees the video of their lesson being taught, they evaluate their lesson according to a rubric that assesses its strengths and weaknesses.

Faculty members are free to use the tapes as they choose. Some simply hand out their videos. Others watch them in class and conduct group assessments. One, in particular, handed out the videos to their students and asked them to pick out a five-minute portion of it to share with the class. The videos are archived in the College of Education’s Resource Library and may be used with future methods classes.

Results

Fall semester 2001 was the first trial run of this project. Although it was something completely new to ODU methods faculty, students, and Brunswick teachers, it achieved an encouraging amount of success. Out of the 60 pairs of collaborators, only a few lessons did not get taught.

Methods faculty were initially somewhat apprehensive about the project. By the conclusion of the fall semester, they were overwhelmingly supportive. Aware of their role as the last trainers of these future teachers, the methods faculty were excited about the authenticity of the learning experiences. Students were exposed to a technology rich school division and a myriad of technology resources. They were mentored by veteran teachers and asked to plan with a specific audience in mind.

One problem teachers and students reported revolved around communication. Some found the message board and on-line communication too impersonal and preferred communicating over the phone. This issue is being addressed during the spring semester through an increased effort to prepare students and teachers to use the on-line communication platform.

Conclusions

The project provides a mutually beneficial relationship for both higher education and K-12 education. Old Dominion methods courses achieve a greater depth and purpose to their lesson planning activities. Old Dominion students have reported higher levels of technology usage. Students must regularly check messages from their collaborating teacher on-line and teachers expect technology to be infused in the lesson planning process. Pre-service students get additional ‘real world’ mentoring. Brunswick Schools benefit from the influx of new ideas that current pre-service teachers provide through their on-line interactions and lesson plans. armed with improved strategies and the experience of the fall semester, the lesson plan collaboration project expects to continually see more positive results, as it tries to bridge the gap between pre-service studies and in-service teaching.
Educational Endeavors for PreK-12 Instructional Design: NASA Partnership Opportunities

Caroline M. Crawford
University of Houston-Clear Lake
United States of America
crawford@cl.uh.edu

Chris Chilelli
NASA Johnson Space Center
United States of America
chris.chilelli1@jsc.nasa.gov

Abstract: National Aeronautics and Space Administration (NASA) offers educational opportunities throughout the nation and maintains educational endeavors for PreK-12 learners as well as teacher education coursework in real-world environments so as to aid the university methods faculty in the real-world uses of NASA-related subject matter and focus.

Introduction

The integration of the National Aeronautics and Space Administration’s (NASA’s) real-world data and educational environments makes the curricular planning and implementation less focused upon purely theoretical matter and further focused upon the actual day-to-day understanding of difficult conceptual underpinnings of subject matter. This is of primary importance to teacher candidates, who must have such educational endeavors modeled to them as they move through the teacher education curriculum of study and before they are expected to develop curricular scope and sequences on their own.

Modeling is of primary importance within coursework, especially methods coursework for teacher candidates, as many instructors teach as they have been taught; the innovations available within today’s educational arena must be focused upon in order to break free of the educational ineptitudes of years past and to refocus today’s learners upon the importance of understanding theoretical matter within an environment of real-world, data-driven information environments. It is no longer a viable option to have theories available and memorized by learners; today’s environment stresses the use and integration of information into understandable units that can be manipulated to glean the aspects of necessity and importance. Therefore, NASA partnership opportunities offer the real-world environment through which to maintain theoretical grounding of knowledge while reaching towards higher order thinking skills that are necessary within today’s world. Teacher candidates must have opportunities to integrate the real-world data and information available through NASA into the instructional design process, so as to design and develop appropriate and successful lessons for their future learners.

Cross-Curricular Ventures

Within the educational environment of today’s PreK-12 schools, there has been a growing emphasis upon cross-curricular activities. The theoretical underpinnings that emphasize such a learning opportunity is the clear understanding that all knowledge should be introduced to the learner as a whole, instead of offering “bits and pieces” of important information that the learner must understand and integrate into the “whole” on his or her own. Further, the cross-curricular learning opportunities emphasize the appropriate and successful development of the learner’s conceptual framework of understanding, which is based upon the theory of cognitive flexibility and the learning opportunities available within a cross-curricular venue. Spiro and Jeng state that, “By cognitive flexibility, we mean the ability to spontaneously restructure one’s knowledge, in many ways, in adaptive response to radically changing situational demands…. This is a function of both the way knowledge is represented (e.g., along multiple rather single conceptual dimensions) and the processes that operate on those mental representations (e.g., processes of schema assembly rather than intact schema retrieval)” (1990, page 165). Additionally, cognitive flexibility “is
largely concerned with transfer of knowledge and skills beyond their initial learning situation” (Kearsley, http://tip.psychology.org/spiro.html, paragraph 2).

As such, NASA’s engagement within the PreK-12 educational realm supports cognitive flexibility as well as the cross-curricular development of a learner’s conceptual framework. The real-world opportunities that NASA offers to the learners is envisioned as supporting mathematics, science, history, English and language arts, geography as well as numerous other subject areas of emphasis, while supporting the hands-on research of the learners. The integration of technology at every conceivable point is also a supported venture, as technology has the ability to offer real-world data sets, streaming audio and video, graphic elements, Web sites presenting useful information and other interesting aspects that were previously unavailable.

NASA Educational World Wide Web Sites

Numerous Web sites are available through NASA’s support of educational ventures within the PreK-12 arena. Such support of the young people is an area that NASA and the professionals associated with NASA have taken as their own personal opportunity to support the educational endeavors of the professional educators of the world’s young people, as well as enrich the learning environments with the real-world learning opportunities that not only entertain but also meet important learning objectives. Following are merely a few of the numerous Web sites that support NASA’s interest in PreK-12 education. As expected, there is a significant bent towards mathematics and science; however, other disciplines are also valuable and are integrated whenever feasible.

- Practical Uses of Math and Science: The On-line Journal of Math and Science Examples for Pre-College Education
  http://pumas.inl.nasa.gov/
- InfoUse’s PlaneMath
  http://www.planemath.com/
- NASA Spacelink
  http://spacelink.nasa.gov/index.html
  - Spacelink: Mission Mathematics
- The Space Place
  http://spaceplace.ipl.nasa.gov/teachers_page.htm
- NASA Human Space Flight Metric Converter
- NASA-AMATYC-NSF Mathematics Explorations I and II
  http://mathema.com/nasa/ta/
- NASA KIDS
  http://kids.msfc.nasa.gov/
  - How Much Would You Weigh on Another Planet?
    http://kids.msfc.nasa.gov/Puzzles/Weight.asp
  - How Old Would You Be on Another Planet?
    http://kids.msfc.nasa.gov/Puzzles/Age.asp
- LTP Glenn Learning Technologies Project
  http://www.grc.nasa.gov/WWW/K-12/airplane/index.html
- Space Science Data Operations Office of NASA/Goddard Space Flight Center: Space Science Education
  http://ssdoo.gsfc.nasa.gov/education/education_home.html
- NASA -JSC Distance Learning Outpost
  http://learningoutpost.jsc.nasa.gov/

Engineers and scientists in the field do not only support the availability of curricular experience; the inclusion and support of professional classroom educators is also an important element within each of the Web sites noted. The desire to enrich the learning experiences available within today’s learning environment, as well as heightening the level of interest of young people within the fields of mathematics and science, are important elements towards the success of these programs.

Interactive Learning Opportunities

NASA and their affiliates offer numerous interactive elements through which to enliven the learning environment of the PreK-12 classroom environment, as well as higher education endeavors at the community
college and university levels. The availability of such simplistic information as a lesson plan with integrated activities, through the time-delineated interactive activities with professionals working directly with the learners are available. Following is a short explanation of merely a few opportunities available.

**World Wide Web Sites**

Web sites developed by NASA and partnering affiliates emphasize numerous points of information as well as interactive elements. For example, PUMAS (http://pumas.jpl.nasa.gov/) "is a collection of one-page examples of how math and science topics taught in K-12 classes can be used in interesting settings, including everyday life" (Kahn, paragraph 1). This site emphasizes the design and development of examples that are primarily written by scientists and engineers, so as to make available peer refereed lesson opportunities to the education profession. It is noted by Kahn that "NASA program directors and other leading representatives of the scientific community have been asking working scientists to contribute to science education" and goes on to write that "part of the motivation for these requests is to encourage and train future scientists, the emphasis has been on helping teach basic 'science literacy' to all students" (http://pumas.jpl.nasa.gov/Short_Intro.html, paragraph 4). Some examples offered in the PUMAS Web site are as follows:

- Coastal Threat: A Story in Unit Conversions
- How Now, Pythagoras?
- Just what is a logarithm, anyway?
- Square Roots Using a Carpenter’s Square
  (http://pumas.jpl.nasa.gov/examples/titlefl0_1_1_1.htm)

For each of the activities available, the appropriate grade level(s), curricular benchmarks, and subject keywords are available, as well as the peer review timeline to ensure appropriate review of the subject matter and educational viability are met.

As well, simulation learning opportunities are available through NASA sites. One example of an innovative design is InfoUse's PlaneMath (http://www.planemath.com/), which is developed by InfoUse in cooperation with NASA. The PlaneMath Web site offers an interactive opportunity to learn mathematics and aeronautics, with an emphasis placed upon real-world style simulation activities. There is an opportunity for the students to work within the simulation atmospheres associated with the following topics:

- Applying Flying
- Pioneer Plane
- PlaneMath Enterprises

Further, the professional educator or parent has the opportunity to register their class at the Web site. Following are the opportunities available to the professional educator or parent:

- Activities for Students
- Help Me Get Started
- Links to Other Sites
- Parent/Teacher Info

Therefore, there is adequate support available through the NASA and NASA-affiliated Web sites to ensure an appropriate and successful learning opportunity.

**Real-World Data Sets**

Real-world data sets are available through different venues associated with NASA. Such real-world data sets make available opportunities for learners to take theoretical models and formulas that are usually conjecture and may be perceived as having nothing to do with the daily world of a learner’s reality, and move towards a cognitively viable conceptual framework of understanding. One Web site that offers real-world data sets is the NASA-AMATYC-NSF Mathematics Explorations I and II (Capital Community College, 2000) Web site. This site is
maintained for educational purposes and states "The first Project emerged from a desire to create exciting mathematics classroom materials based on NASA space activities" (Capital Community College, 2000, http://cctc.commenet.edu/lta/history.htm, paragraph 1). The original idea was to focus the project towards two-year community college courses; however, this information is just as valuable and viable within secondary classroom learning environments.

**Streaming Video and Instructional Television Interactive Sessions**

There are numerous venues through which to actively interact through interactive sessions, such as streaming video, instructional television, and videoconferencing. For example, Spacelink (http://spacelink.nasa.gov/) offers annual series of television broadcasts and streaming video broadcasts free to all educational parties. The series integrates mathematics, science and technology through educational distance learning opportunities, with grade-specific subject matter. Distance Learning Outpost, through videoconferencing, allows students to interact with NASA personal through integrated Expeditions and Challenges. Following are a few of the opportunities available, by grade range:

- **NASA CONNECT**  
  Grades: 6-8  
  Subject Matter: Mathematics, Science, Technology  

- **NASA-JSC Distance Learning Outpost**  
  Grades: K-12  
  Subject Matter: Mathematics, Science, Engineering, Geography, and Technology  
  [http://learningoutpost.jsc.nasa.gov/](http://learningoutpost.jsc.nasa.gov/)

- **NASA Why Files**  
  Grades: 3-5  
  Subject Matter: None Specified  

- **NASA Optics**  
  Grades: K-12  
  Subject Matter: Science, Math  

- **Taking the Measure of the Universe**  
  Grades: 6-12  
  Subject Matter: Measurement and Computation in Mathematics  

The above-mentioned Web sites are merely a few of the numerous opportunities that NASA and NASA collaborations have made possible to the education profession. Along with the broadcast element, there are also additional flyers, lesson guides and Web activities available for each session. Reviews of the available interactive sessions easily meet course objectives. As well, NASA educational endeavors can also be requested specifically for a classroom's activities and objectives.

**Meeting National Standards**

Each discipline is supported by national organizations that emphasize the importance of standards at the national level. Through the association's development of national standards, there is a clear vision as to the importance of subject matter taught to teacher candidates as well as emphasized within the PreK-12 curriculum at specific levels through out the learner's progress. As an example, the National Council of Teachers of Mathematics (NCTM) has developed Professional Standards for Teaching Mathematics (NCTM, 1991) as well as Principles and Standards for School Mathematics (NCTM, 2000). Within each of these standards, at both the teacher candidate and PreK-12 learner levels, technology is a supporting factor towards the success of educational endeavors.
The "Technology Principle" is one of six principles that the National Council of Teachers of Mathematics (NCTM) designate as imperative for all teacher candidates to master (NCTM, 2000). The "Technology Principle" states that "Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning" (NCTM, http://www.nctm.org/standards/principles.htm, paragraph 28). However, it is ultimately the mathematics teachers, not the technological tools that have the ability to support the educational goals of each endeavor integrated into the curricular scope and sequence, that is the key to the success of the mathematical learning environment (Garofalo, Drier, Harper, Timmerman & Shockey, 1991; Kaput, 1992; NCTM 1991, 2000). The National Aeronautics and Space Administration (NASA) offers technological opportunities towards the support of educational endeavors and the ability to meld numerous subjects into innovative, real-world, interesting lesson opportunities for PreK-12 learners. Further, the support of NASA offers the teacher candidates opportunities towards successfully meeting NCTM's "Technology Principle" (NCTM, 2000).

Conclusion

The integration of the National Aeronautics and Space Administration's (NASA's) real-world data and educational environments makes the curricular planning and implementation less focused upon purely theoretical matter and further focused upon the real-world understanding of difficult conceptual subject matter underpinnings. Emphasis must be placed upon links between theory and practice within all specialization areas; further, the desire to develop cross-curricular endeavors is also extremely important. NASA and their affiliates should be commended for their efforts, as well as further integration of the available resources should be implemented within teacher education coursework, PreK-12 curriculum, and higher education curriculum.

References

Centuries ago, Archimedes recognized technology's power to both initiate and facilitate world altering change. Although his enduring metaphor places appropriate emphasis on the role technology plays in the change process, Archimedes' illustration fails to acknowledge that several important factors influence the speed, direction, and magnitude of efforts to bring about change.

At present, computer-based technology, is the lever of choice for many proponents of educational change. Research on efforts to improve teaching and learning with technology has revealed that several factors influence technology-driven educational change. Early research in the 1980s on the implementation of technology for the purpose of enhancing teaching and learning revealed that limited access to appropriate and adequate equipment was largely to blame for the failure of change efforts. Once these problems were addressed, researchers turned their focus to other problems. In the late 1980s and early 1990s, researchers focused on problems stemming from teachers' need for basic technical skills and various kinds of support (administrative, community, technical). Now that efforts have been made to address these aforementioned concerns, current research in the field revolves primarily around problems emanating from teachers' lack of knowledge about appropriate integration of technology. The research trend that emerges from examination patterns during the last twenty years is a movement from the investigation of technical and organizational forces influencing change to those more professional and personal forces (in humans) influencing change. If the trend continues, one might anticipate that the next realm of research will study the most fundamental human characteristics influencing efforts to change—individual beliefs and attitudes.

In other areas of educational research, teachers' beliefs and attitudes have been identified as factors critical to the success or failure of reform efforts (Fullan, 1991; Elmore, Peterson, & McCarthy, 1996; Tyack & Cuban, 1993). Although the research literature on teacher beliefs and attitudes toward innovations affecting such professional concerns as content area instruction (Battista, 1992), instructional reform (Holland, 1998), and multicultural education (Shaw, 1993) has grown dramatically in the last ten years (Richardson, 1996), a body of research investigating the effect of teachers' beliefs and attitudes on efforts to change teaching and learning using technology has not yet been developed. Information regarding the nature of teachers' attitudes in regard to their relationship with technology and their beliefs about the relationship of technology and learning could be important for a variety of reasons.

This paper reports on a study exploring teachers' attitudes toward and their beliefs about the relationship between instructional technology and learning. It shares the information gained from an investigation conducted with some 26 preservice teachers participating in a semester-long technology infusion project. Teachers were asked to share their personal relationship with technology and their belief about the relationship of technology and learning using the poetic conventions of either similies or metaphors.

Information generated from this investigation revealed that teachers' attitudes toward and relationships with educational technology vary considerably. It communicates that these beliefs and attitudes are able to be influenced by participation in academic coursework and field experiences geared toward the integration of technology with instruction.

The study suggests that teachers' beliefs and attitudes play a critical role in the speed, direction, and magnitude of efforts to integrate technology with instruction. It identifies concerns that might be addressed when attempting to facilitate teachers' adoption of technology in the classroom. Finally, it suggests that use of poetic convention was an effective method of inquiry for investigating teachers' beliefs and attitudes that might be used in future research projects.

Perspectives

Humans use poetic convention to explain objects, ideas, and relationships that often defy explanation in more simple terms. Metaphors and similes can be more economical than other manners of expression—using fewer words to paint a better picture. They enable the expression of feelings, thoughts, things, and experiences for which there are no easy words. And they are generous to readers and listeners as they encourage interpretation and further exploration.

In this study, preservice teachers were asked to use the poetic convention of similes and metaphors to describe their attitudes and beliefs about technology. This approach was employed because the researcher believed that the qualities of poetic convention mentioned above would aid teachers in recognizing their own views and sharing them with others. It was presumed that teachers might feel more comfortable using similes and metaphors than simple expression. It was also believed that teachers, who are known for their ability to be creative, might enjoy this creative approach and share more information about themselves if given the option to use descriptive language.
Methods and modes of inquiry

26 third-year preservice teachers from a large state school in the northeast participated in this study during the spring of 2001. The preservice teachers had recently completed basic undergraduate coursework in the arts and sciences and some foundational courses in the field of education. These preservice teachers varied in their amount of experience with technology but had no formal training to help them develop specific skills for using technology nor experiences teaching them how to integrate technology with instruction prior to this study. Preservice teachers participated in a pre-practicum placement taking place in an elementary school classroom (grades 1-5) that was located in one of four school districts (representing rural, suburban, and urban school settings). In these placements, they were matched with an experienced teacher (with a minimum of 3 years experience) who was considered a novice with technology. The preservice teachers spent two, 6-hour, school days during a 14 week semester in their placement.

During the semester when the study was conducted, the preservice teachers participated in a two credit course called "Technology as a Tool for Instruction" offered as part of their formal courses concurrent with the pre-practicum experience. In this course, students developed skills necessary for using three popular software programs - a multimedia program called Kid Pix, a spreadsheet program called Excel, and a semantic mapping program called Kidspiration. They also received instruction helping them develop an understanding of how technology might be integrated with instruction. This instruction included opportunities to write lesson plans in which behavioral objectives were considered a condition for learning, student interaction with technology was required, and where the technological resources utilized were limited to those found in their pre-practicum classroom.

As part of their experience in this course, preservice teachers were expected to share the skills and knowledge they gained as part of the technology course with teachers in their prepracticum placements. The preservice teachers completed assignments that required them to discuss their beliefs about teaching and learning, their experiences with technology, and their understanding of technology's instructional role with the teachers with whom they worked. In addition, preservice teachers were asked to plan at least one technology integrated lesson with their partner teacher and reflect on it during the course of the semester.

The preservice and inservice teachers were brought together once at the beginning and end of the semester for brief meetings. During these meetings, all were introduced to the project, expectations for the semester, and the idea of using poetic convention to describe the power of technology. The definition of two specific poetic conventions - similes and metaphors - were shared with the group. In addition, a quotation from Archimedes using a metaphor and other examples were shared. All of the teachers were given paper and asked to develop two comparisons (either a simile or a metaphor) describing their personal relationship with technology and their perception of the relationship between teaching and learning. Teachers were then asked to share their ideas with others.

Data was analyzed using a variation of the constant comparative method (Guba & Lincoln, 1989; Strauss, 1989). After being compiled following the two meetings, it was grouped into exclusive categories that were representative of emergent themes represented by all data in each category.

Data sources or evidence

Some 50 similes and metaphors were collected at the beginning of the semester from 23 preservice teacher participants. An additional 55 were collected at the end of the semester from 24 preservice teacher participants. In addition to grouping the data by category, analysis was conducted to determine whether preservice teachers attitudes and beliefs were influenced over the course of the semester. An open-ended questionnaire administered to preservice teachers at the final project meeting added data to the researcher's analysis that was used for verification purposes. Students metaphors were member-checked and the categorization of data using the constant comparative method was checked by a colleague who was not involved in the project.

Results and Conclusions

Eight themes were generated to reflect the perception that students had of their relationship with technology. The preservice teachers described their relationships as variable, unpredictable, evolving negative, difficult but promising, overwhelming, optional, and transformational. Seven themes were generated to describe students' perception of the relationships between technology and learning. These themes reflected students' perception that: 1) technology should be an essential part of the learning process, 2) that technology merely enhanced learning, 3) technology had specific and particular roles to fill in the learning process, 4) technology should be used as a reward, 5) experiences using technology were addictive for students, 6) technology was useful in learning but not a personal preference, and 7) technology leads to learning. When metaphors created at the beginning of the semester were compared with those created at the end of the semester, some evidence of change in students over the course of the semester was present. This raised interest in future research to determine the source of this change.

Educational importance of the study

Efforts that focus on encouraging teachers to use technology in their classroom are more likely to succeed if teachers' beliefs and attitudes are taken into consideration. This study would suggest that preservice teachers beliefs and attitudes regarding technology can be influenced by experiences they have as part of their professional preparation. This study reports on one such model for integrating technology into professional preparation that might be of use to other institutions preparing teachers. In addition, this study reveals specific attitudes and beliefs preservice teachers possess in relation to educational technology. If taken into consideration during the design of technology infusion projects, the beliefs and attitudes shared here might improve such efforts.

Abstract: This paper is a report of the findings of a study conducted to determine if the use of the Collins-Brown-Newman (1989) Cognitive Apprenticeship model in an instructional technology course based on the Integrating Technology for Inquiry (NteQ) model (Morrison & Lowther, 2002) would positively affect the pre-service teacher's: (1) beliefs/concerns about using the computer as a tool to enhance student learning, (2) perceived ability to use technology and integrate it into the curriculum in an appropriate manner, and (3) ability to effectively design lessons that integrate technology into the elementary school classroom. Findings indicate that this approach positively affects the pre-service teacher. At the end of the study, participants indicated that they felt confident in their overall ability to (1) use and effectively integrate technology into the elementary classroom, (2) use, teach basic skills, and design a lesson that included meaningful use of database, spreadsheet, Internet, and desktop publishing, and (3) manage a learning environment, which includes multiple computers.

Introduction

Newly certified teachers are often faced with a variety of expectations with regard to technology when entering their first teaching assignments. For example, school administrators may require them to integrate technology into instruction, parents and community members may expect them to have students use technology as it is used in the workplace, and students expect computer use to be part of their classroom activities. In order to make effective use of this technology, these beginning teachers must have the ability to use the technology resources that will be available. They must be able to design lessons that include meaningful student use of these resources, and be able to manage a learning environment that includes multiple computers. If new teachers are to meet these expectations and succeed in a technology-enhanced environment, it is imperative that they have the knowledge and skills needed to effectively use technology in an instructional setting and that they have the belief that using technology will be beneficial.

Although most teacher education programs now have at least one required course that focuses on technology, recent studies suggest that many of these courses have not been successful in preparing pre-service teachers to effectively use technology in the classroom (NCATE, 1997, Milken Exchange on Teacher Education, 1998). This lack of success is often attributed to courses that place a greater emphasis on the technology itself rather than how to use technology to enhance learning.

The current, most common model is Computer Literacy, which is more traditional and is based on a formal approach in which pre-service teachers learn to use the computer through a series of lessons and activities focused on the basics of hardware and software technology. The primary goal of this model is to produce computer literate teachers. It is assumed that once these skills have been developed, the pre-service
teacher will have the competence and confidence to integrate technology into their instruction.

Unfortunately, this model does not provide pre-service teachers opportunities to see instructors modeling the use of technology like it should be used in K-12 classroom. Nor does it provide instructional strategies for the integration of technology into the curriculum, opportunities to observe technology being used by students in technology classrooms or opportunities to practice teach with technology.

As noted in the International Society for Technology in Education (ISTE) National Technological Education Standards (NETS) for Teachers (2000), graduates of teacher education programs are expected to possess a degree of instructional knowledge and skills that encompass both computer literacy and the effective integration of technology into the curriculum. The Computer Literacy model does not appear to provide the content and experience necessary for pre-service teachers to effectively use instructional technology in the classroom. Therefore, the problem becomes more of how do teacher education programs prepare teachers who can meet the growing expectations with regard to technology use in the classroom? In other words, how can the instructional technology course meet the ISTE NETS for Teachers (2000) within the current educational environment?

The Study

The purpose of this study was to determine if the use of the Collins-Brown-Newman (1989) Cognitive Apprenticeship (CA) model in an instructional technology course based on the NTeQ model (Morrison & Lowther, 2002) would positively affect the pre-service teacher’s: (1) beliefs/concerns about using the computer-as-a-tool to enhance student learning, (2) perceived ability to use technology and integrate it into the curriculum in an appropriate manner, and (3) ability to effectively design lessons that integrate technology into the elementary school curriculum. The Cognitive Apprenticeship model was based on the incorporation of modeling, coaching, scaffolding, articulation, reflection and exploration into an instructional technology course. This study used these approaches in the context of effective technology integration that focused on the pre-service teacher’s use of the computer to locate, process, and present information.

If the Cognitive Apprenticeship model was to prove successful in a pre-service instructional technology course, other factors needed to be considered, as suggested by the “knowledge and skills” portion of the NETS for teachers (2000). This knowledge base includes: basic computer technology operations, personal and professional use of technology, and the application of technology in instruction. In this study, the approach taken to address these competencies was the Integrating Technology for Inquiry (NTeQ) model (Morrison & Lowther, 2002). This model aligns with the Cognitive Apprenticeship model and fulfills the NETS for teachers. With regard to the use of the Cognitive Apprenticeship model in an instructional technology course, the NTeQ model provides a realistic context for learning and encourages the use of the computer-as-a-tool. Pre-service teachers learn the same computer skills that teachers are expected to use in the classroom and apply these skills to real-world activities similar to those found in a typical technology classroom.

Method

The participants for this study were seventy-six education majors enrolled in a required undergraduate instructional technology course. The course included the following components: (1) supervised practice to learn and refine basic computer skills, (2) participation in simulated computer-based lessons where the pre-service teachers take on the role of elementary school students and the instructor models the role of the classroom teacher, (3) assisting elementary students as they use computers, and (4) collaborative and independent development of computer-based lesson plans and related student products. The course covered a broad range of computer applications: email, word processing, database, spreadsheet, Internet, desktop publishing, and multimedia presentations.

This study included one treatment (36 participants) group and one comparison (40 participants) group. Two course sections were randomly assigned to the treatment group and two were randomly assigned to the comparison group. A full cognitive apprenticeship approach, based on the Collins-Brown-Newman (1989) model, was used with the treatment group. This approach provided participants with real tasks that were typical of the
conditions and contexts of a technology classroom. This group participated in three model integration lessons taught by the instructor, and a series of field experiences which included: (1) observing an elementary classroom teacher teach a technology-based lesson in a technology classroom, (2) interviewing an elementary classroom teacher who regularly integrates student use of computers into her/his instruction, (3) participating in two instructor facilitated model lessons with small groups of elementary school students, and (4) observing the implementation of a treatment group-created technology based lesson plan into an elementary school classroom.

The comparison group received a limited cognitive apprenticeship approach. Although both groups covered the same course materials and prepared the same final products, the comparison group sections were taught in a more traditional manner that involved reading about and discussing what happens in a classroom that integrates technology rather than experiencing what actually happens.

The measures for this study consisted of: (1) Pre-and Post-Stages of Concern (SoC) questionnaires, (2) Pre- and Post-Technology Needs Assessment (TNA) surveys, and a Final Lesson Plan Rubric. The SoC questionnaire is a 35-item instrument used to identify the seven stages of concern through which teachers pass when they are introduced to an innovation, such as integrating technology into the curriculum: awareness, informational, personal, management, consequence, collaboration, and refocusing. Participants rated the degree to which each item reflected her/his current concerns/beliefs using an eight-point Likert-type scale that ranged from (0) not relevant to me now to (7) very true of me now.

The TNA survey addressed the following topics: (1) background information, (2) overall level of computer ability, and (3) level of computer ability as an educator. The participants used a five-point Likert-type scale to rate her/his perceived level of computer proficiency from low (1) to high (5).

The participants were given an NTeQ (Morrison & Lowther, 2002) Final Lesson Plan template on the last day of the semester and they were instructed to design a lesson that appropriately integrated technology into the elementary school curriculum. This lesson plan was evaluated using a two-part Final Lesson Plan Rubric. The first part consisted of evaluation criteria for each of the NTeQ lesson plan components. Each lesson plan criteria was evaluated using a rating scale, (1) did not meet expectations to (5) highly exceeded expectations. The second part of the rubric assessed the overall quality of the lesson with a five-point assessment scale that ranged from (1) Poor to (5) Excellent.

Results

To determine if the use of a cognitive apprenticeship model in an instructional technology course affected the pre-service teacher's beliefs/concerns about using the computer as a tool to enhance learning, a 2 x 2 repeated measure (Treatment vs. Comparison) analysis of variance (ANOVA) procedure was performed to compare the results of the Pre- and Post- Stages of Concern Questionnaires. The results revealed a significant difference between the treatment and comparison group's mean percentile scores for the following stages of concern: awareness and informational at a significance level of p<.05.

To determine if the use of a cognitive apprenticeship model in an instructional technology course affected the pre-service teacher's perceived ability to use technology and integrate it into the curriculum in an appropriate way, a 2 x 2 repeated measures (Treatment vs. Comparison) ANOVA procedure was used to compare the results of the Pre- and Post-Technology Needs Assessment Surveys. No significance was found. Both groups' mean scores increased from pre to post in all areas.

To determine if the use of a cognitive apprenticeship model in an instructional technology course affected the pre-service teacher's ability to effectively design lessons that integrated technology into the elementary school curriculum, independent t-tests using a between subjects design were calculated for each final lesson plan component criteria and the Overall Lesson Plan Rubric. The results revealed a significant difference between the treatment and comparison group's Final Lesson Plan Rubric scores for the following lesson plan component criteria and the Overall Lesson Rubric at a significance level of p<.05: (1) matching computer functions to learning objectives, (2) specifying computer application function(s) and their required manipulations, (3) describing specific computer tasks, and (4) developing evaluations that reflected the learning objectives, as well as overall quality of the lesson.
Discussion and Conclusions

The conclusions of the study will be presented by discussing each component of the research question: Does use of the Cognitive Apprenticeship model in an instructional technology course based on the NTeQ model positively affect the pre-service teacher's:

**Beliefs/concerns about using the computer-as-a tool to enhance student learning**

At the beginning of the semester, self-concerns (awareness, informational, and personal) that dealt with the pre-service teacher's perceived ability to integrate technology into the curriculum were high for both groups. Task (management) and impact (consequence, collaboration, and refocusing) concerns were less evident. High self-concerns at the beginning of the semester are typical for nonusers who are just becoming aware of an innovation and therefore want more information about it and its consequences for them.

At the end of the semester, the treatment and comparison groups continued to have high self-concerns regarding management and impact, although the treatment group's concerns were significantly lower than the comparison group's. These results indicate that treatment group felt more comfortable in their perceived ability to integrate technology into the curriculum. Impact concerns increased for both groups suggesting that participants from both groups were becoming interested in how the use of technology in the classroom impacts students and in working with others.

**Perceived ability to use technology and integrate it into the curriculum in an appropriate manner**

The Technology Needs Assessment (TNA) Survey was given to the participants on the first and last day of the semester to assess their perceived ability to use technology and integrate it into the classroom. No significant differences were found between the treatment and comparison group's Pre- or Post-TNA mean scores, indicating that participants entered and exited the course at similar levels, however, both group's mean scores had increased in all areas from pre to post assessment. At the end of the study, the participants felt confident in their overall ability to: (1) use and effectively integrate technology into the elementary school classroom, (2) use, teach basic skills, and design a lesson that includes meaningful student use of database, spreadsheet, Internet, and desktop publishing, and (3) manage a learning environment, which includes multiple computers.

**Ability to effectively design lessons that integrate technology into the elementary school curriculum**

The results revealed a significant difference between the treatment and comparison group's ability to effectively design specific lesson plan component as well as develop an overall lesson plan that successfully integrates technology. These lesson components were: (1) matching computer functions to learning objectives, (2) specifying computer applications and their required manipulations, (3) describing specific computer tasks and, (4) developing evaluations that reflected the learning objectives.

The treatment group, in contrast to the comparison group, developed lesson plans that were more well thought out, cohesive, and based upon a meaningful and interesting problem. The learning activities within these lesson plans were age-appropriate, engaging and required multiple applications of critical thinking skills. These lessons required students to use a variety of computer applications to process data. Forms of authentic assessment were used to assess students.

Incorporating NETS Standards into an Elementary Certification Program

Kenneth Clark, Georgia Southern University, US
Alice Hosticka, Georgia Southern University, US

This paper will present the design of a teacher certification program at Georgia Southern University that meets the NETS standards (the basis for the Georgia Technology Standards) for teacher certification. After an initial course that presents introductory knowledge and skills related to technology, the program area integrates into their courses applications of instructional technology. These applications include projects that:

- integrate commercial software into a classroom activity.
- use commercial software as a vehicle for total classroom problem solving in a one-computer classroom.
- use spreadsheets and software to develop mathematically sound graphs for use in the classroom.
- use digital images and presentation software programs.
- use probe ware in science instruction.
- create classroom materials stored on a CDR.
- download and store materials from the WWW for classroom instruction.
- deliver instructional units/lessons that use a variety of software, hardware and learning to support instruction.
- implement lesson that build student content knowledge and skills with the use of a variety of modern technologies.

The details of the projects and how they relate to the general content needs for certification, as well as, how they help the student meet the technology standards required for certification will be illustrated.
Teacher Created Data Bases that Foster Scientific Literacy

Kenneth Clark, Georgia Southern University, US
Marti Schriver, Georgia Southern University, US
Alice Hosticka, Georgia Southern University, US
Jackie Bedell, Georgia Southern University, US

This paper will present the value of using a database to developing scientific literacy in an inquiry-based learning situation. The emphasis will be on presenting a model for developing databases for use in a K-12 classroom. Aspects of the presentation will include:

I. Science that can be developed using databases
   - Help teachers provide an inquiry-based science program for their students
   - Help teachers provide a classroom setting that will have the teacher as a guide and facilitator of student learning by providing the resource and questions
   - The unifying concepts and Processes of Systems
   - Content of life science: the characteristics of organisms; life cycles of organisms; organisms and their environments; populations and ecosystems; diversity and adaptations of organisms; behavior of organisms
   - Show Students the abilities of technological design in scientific investigations
   - Provide an understanding about science and technology

II. Considerations necessary for designing a database
   - What information do you want to store
   - What format you will retrieve information in
   - Sorting features
   - What population will be entering data and sorting
   - Type of data, e.g. text, numerical, graphic, video, sound
   - Organization of data

III. Classroom applications of databases
   - Information retrieval
   - Recognition of patterns and trends
   - Analysis of relationships
   - Testing of hypotheses
   - Interpretation of data
   - Critical thinking

The above issues will be illustrated with an in-depth look at eight data bases developed for use in a middle school science methods course. The content of the databases presented are: birds; plants; trees; animals; insects; fungus and marine organisms. Elements of design and classroom activities for pre- and in-service science teachers will be presented. The use of these databases in such a matter help certified teachers and public school students meet the appropriate NETS standards in a pedagogically sound manner.
Approaching Authentic Assessment: Two professors share their methodologies.

Brenda Dressler, Ph.D., Joanne Clemente, M.S.
Teacher Education Department
New York Institute of Technology
United States
bdressle@nyit.edu, jclemente@nyit.edu

Abstract: Two professors share their methods of authentically assessing pre-service teachers. Instead of traditional midterm and end term exams, students in their classes must prove competence in real-world situations. In one class, Educational Foundations, pre-service teacher candidates participate in a simulated interview for a teaching position in which the interviewee must respond to questions and propose strategies to address current educational issues. Questions such as these are the basis for competitive interviews in New York State’s school districts. In the second class, pre-service teachers (Tech Ambassadors) are partnered with F-12 teachers and must deliver researched, technology-integrated lessons to elementary students in their classrooms under faculty supervision.

Dr. Brenda Dressler: “Interviews with depth”

Teacher education programs have always viewed assessment as significant in the training of pre-service teacher education candidates. New accreditation standards are driving the teacher education program’s assessment practices to focus on what its candidates can do in terms of standards and performance. According to NCATE’s Program Standards for Elementary Teacher Preparation (1999) candidates need to be evaluated by traditional assessment instruments and performance assessment instruments that are integral to instruction and aligned with the standards. Data generated can then be used to assist the individual candidate and to improve the teacher education program.

Traditionally, except for student teaching, assessment in education courses consists of tests, quizzes and research papers. Prospective teachers are now expected to implement multiple assessment measurements in their classrooms. In this paper, I share a performance assessment method, “the interview” used with pre-service teacher education candidates in Educational Foundations.

A good assessment instrument must be congruent with reality (Wiggins, 1993; McClelland, 1973). Performance assessments are regarded as more realistic because they measure higher-order thinking skills rather than just accumulating knowledge (Tuchman, 1993) The pre-service teacher candidates in my class will be asked questions on the performance assessment measurement that are often asked at an interview for a teaching position. The interview performance assessment used in Educational Foundations meets many of the characteristics of an effective assessment instrument.

The following items adapted from Margaret Jorgansen, in Reflections of Learning (1992) indicate that an effective performance assessment instrument should: reflect ideal instructional practices; involve the teacher as participant-observer; require collaboration; allow investigation; are motivational; facilitate response preferences; allow multiple strategies; have multiple solutions; integrate knowledge and processes; have relevance; have topic currency; have an appropriate level of difficulty; are feasible; are cost effective and tap higher order thinking skills.

The interview process provides candidates with additional modalities to explain what they have learned (Gardner, 1991). Throughout the semester, candidates write papers on educational and philosophical issues, field experiences, critique journal articles, present oral reports and have traditional paper-and pencil midterm and final essay exams (Part II). The interview process included in the final exam (Part I) provides an opportunity for candidates to develop a plan of action when faced with a new situation. In this assessment measurement, the interviewer poses a “what if...scenario” and the interviewee must respond with a plan of action. This is a change in the methodology of learning from memorization of content to the potential to apply and understand knowledge and it a characteristic of an effective performance assessment (Jorgansen, 1992)
The interview performance assessment exam was developed in response to several needs: new accreditation standards in teacher education programs require that multiple methods of assessment be used (NCATE, 1999); to create a final exam congruent with current educational issues and strategies studied in the course; to determine whether knowledge of issues and strategies can be adapted to other situations; to create a venue for pre-service teacher candidates to demonstrate orally and visually their knowledge, skills and their impact on the learning of students in their future classroom; to create a performance exam that engages pre-service teachers to reflect on realistic, significant problems faced in the classroom and to design innovative solutions; and to prepare pre-service teachers for an interview for a teaching position and to prepare for the video tape teaching performance assessment required for permanent certification.

The Model:

Educational Foundations, a study of major educational factors that impact on the schools is the first course in the program taken by pre-service teachers during their junior year. The topics emphasized are social issues, school governance and finance, cultural diversity, diverse learners and learning styles, inclusion, curriculum and instruction, legal issues, global education and technology integration in the classroom. Classroom observations and attendance at a school board meeting are required. During the semester, pre-service teacher candidates are assessed using traditional and alternative assessments.

The interview questions on the performance assessment measure are congruent with the topics studied in the course. Pre-service teacher candidates are given the interview questions and the rubrics for an oral presentation seven to ten days before the scheduled exam. To prepare for this interview, candidates engage in inquiry and problem solving and then develop strategies for responses. Examples of questions posed are:

1. What if...? (I create the scenario and then you plan how it would be resolved)
2. What are your weaknesses? (2) (Pick one weakness and explain how you would turn this around to work for you)
3. How would you handle discipline/ school violence/ conflict resolution in your classroom? (3 strategies)
4. What strategies (4) would you use to involve ESL students in your class?
5. Describe in detail a lesson that you observed indicating the objective(s), activities addressing different learning styles and evaluation.
6. What strategies (4) did you observe or would you use to teach respect for diversity?
7. Give examples (2) of how you would integrate technology into the curriculum.

The pre-service teachers are informed that they will be asked three questions and that they can select the fourth question. All pre-service teacher candidates are asked the “what if” question and needed to respond with an analysis of the situation and a solution. The researcher designs a variety of situations such as “What would you do if a student arrives late to class?” or “What would you do if the student did not participate in discussions?” Candidates complete an evaluation form on the interview process. After the exam is completed, the tapes are duplicated and the pre-service teacher candidate receives the original tape which can then be used for reflection and self-evaluation along with the rubric.

In summary, the interview performance assessment measurement has been administered for two semesters. The classroom settings were very different for each semester. In the first semester, two separate classes received the interview assessment with the instructor present. In the second semester, the class was located in three distance learning rooms on three different campuses with three different people administering the exams. The instructor interacted with the candidates and sometimes asked additional questions. The other proctors did not interact with the candidates in this way. Most candidates performed very well although some were uncomfortable with being filmed. In conclusion, the interview performance assessment measurement needs to generate more data to be evaluated.

Joanne Clemente: TechAmbassadors – Authentic Assessment of Teaching Abilities

"Few teachers (20%) report feeling well prepared to integrate educational technology into classroom instruction." Thus states a report by the Department of Education entitled, Teacher Quality: A Report on the Preparation and Qualifications of Public School Teachers. Additional study by the Milliken Exchange shows that "Most institutions report that IT is available in the K-12 classrooms where student teachers get their field experience; however, most student teachers do not routinely use technology during field experience and do not work under master teachers and supervisors who can advise them on IT use." It further concludes that, "the most important finding of the survey is that formal stand-alone IT coursework does not correlate well with scores on items dealing with technology skills and the ability to integrate IT into teaching." The report recommends:

- "Student teachers need more opportunities to apply IT during field experiences under qualified supervision"
- "In order to provide models for change, researchers, professional societies, and education agencies should-on an ongoing basis-identify, study and disseminate examples of effective technology integration that reflect the current needs in both teacher education and K-12 schools." (Moursund, 1998)

In addition, a 1997 NCATE task force on technology in teacher education report found that "teachers-in-training are provided instruction in 'computer literacy' and are shown examples of computer software, but they rarely are required to apply technology in their courses..." (NCATE, 1997.) Some schools such as Southwest Texas State University have initiated programs that require assessment of pre-service teachers in the use of technology in their field based experiences in public schools. The initiative I describe, the TechAmbassador program, is the first step toward providing such experiences in the undergraduate teacher training program at New York Institute of Technology.

The Model

This paper is a report from the field to describe the outcomes of a second semester of the TechAmbassador Project. In the first year of the project, pre-service teachers were placed in several P-12 school districts in partnership with in-service teachers for the purpose of technology integration in the partner’s classroom. Pre-service teachers attended a class on the college campus entitled, “Curriculum Articulation and Multi-Media” for which 20 hours of field experience was required. The initiative was enthusiastically received and executed, and further development was a natural consequence. In the second iteration, it was decided to limit the placement of pre-service teachers to one school and to convene the undergraduate class at the school itself (field-based methods course). More control over the environment, more convenient supervision and a closer relationship with in-service teachers was anticipated. However, permission to relocate the undergraduate class was not received from the college in time for the beginning of the semester. Adjustments were then made to conduct the college class on campus, as usual, and allow each student to complete their field experience at the selected school at a time when both in-service and pre-service teachers were available for collaboration.

At the start of the semester, as the professor teaching the course, I introduced the project to in-service teachers at the elementary school and explained the collaborative process. Teachers were enthusiastic about receiving TechAmbassadors, and enrollment had to be limited. However, there were some underlying issues that both helped and hindered this pilot project throughout the study that bear mentioning. While the computer lab in this school was brand new, the computers and the Internet connection were not. They were ported from an old location in the school and not well tested with the installed software. This network setup had not been used very much for the two previous years, since the district made the unpopular decision.
to eliminate the only "Tech Teacher" position. In retaliation, the teachers at this school had been boycotting the lab. The principal at this school was instrumental in convincing the teachers that this TechAmbassador initiative would provide assistance for teachers while allowing them to maintain their position to district administrators that a "Tech Teacher" was an essential component for technology integration. Putting pre-service teachers into this troubled situation to "teach with technology" and assit these teachers thus became more challenging than anticipated for all concerned. First, the in-service teachers had very high expectations. They believed that since our college was an Institute of Technology, our pre-service teachers would be technology "experts" and able to trouble-shoot any hardware/software problems that arose. Some in-service teachers even expected the pre-service teachers to take students into the lab weekly. While our students may have had more experience than most college students, they were still only "students" and as such, needed more training in pedagogy, technology integration and classroom management. The purpose of this initiative was to enable a partnership that would provide such training for both student and teacher. In the end, the pre-service teachers were indeed very proud of themselves. They had been placed in "real" situations, faced with political, technological and pedagogical challenges, and rose nicely to the occasion. This was not a sterile, "college classroom" environment; rather, it was a real world experience with real problems, curricula and students to reconcile.

Some students had a difficult time with this format. Two students stand out in particular. One of these started out enthusiastically, feeling overly confident in her abilities to manage a class and integrate technology. This student did not prove to have the follow-through to carry lessons to completion and finished with poor evaluations. On the other hand, a student who started his observations rather late in the semester was threatened with being dropped from the course. Not only did he rally and truly commit himself to deliver exemplary lessons, he later wrote in his research paper, "This was a wonderful experience for me and I learned so much about getting ready to teach a lesson. I can now see that teaching does not just end in the classroom. Some lessons take lots of prep work before it can be taught. This class really showed me that teaching is what I truly love, and I can’t wait to one day have my own class." This student was later asked by the principal to submit a resume for a future position. Another student produced two exemplary lessons, using Internet research and cooperative learning groups. What distinguished her work was her ability to calm the teacher who became frazzled when the computers were not functioning properly and later, her ability to refocus her lesson within ten minutes when her partner teacher did not have the class learn the appropriate background material as previously promised. Some students and teachers worked so well together. One teacher, in particular, gave students curricular material with which to work. This material happened to have contained web site suggestions, upon which my TechAmbassador built a lesson. She writes, "Research is the key aspect in writing a lesson. If the research is off, the lesson has the opportunity to fall apart." Since this in-service teacher was being treated for cancer and was absent more than once a week, the two partners developed a reciprocal and mutually beneficial relationship. The TechAmbassador says in her paper, "She has such great rapport with the students, they respond, respect and listen to her with their ears and minds wide open. Being in her class, I have learned so much. Everything she does with the students, she explains to me, how and why she did what she did. Seeing her teach makes me even more eager than I already am to become a teacher. I hope I am half as good as she is and that I can inspire someone like she has inspired me."

Within the course, I attempted to follow a pre-determined protocol. First, the pre-service teachers were sent to observe teachers in their normal environments. Each TechAmbassador had a partner teacher and visited the classroom for a least one hour a week to observe, participate, or assist as deemed appropriate by the host teachers. As mentioned above, each partnership took on different characteristics and some flexibility was needed. Some students merely observed quietly, while others attempted to take classes into the lab at the teachers’ requests. Each week, in the college classroom, these students would discuss their experiences, learn how to develop technology-enriched lessons, practice new technology skills and prepare their upcoming lessons. Two "delivered" lessons were required in this course; one at mid semester and the other at the end of the term. Each lesson needed to be discussed in class, researched, planned using the NTEQ format developed by Morrison and Lowther. Through observations, assisting, researching and practicing, pre-service teachers prepared throughout the semester for these two benchmark performances. The purpose of such planning was not only to deliver technology enriched curriculum-based lessons, but to provide the in-service teachers with two well-documented, turn-key lesson plans for later use. This collaboration not only served as professional development inside the classroom but it allowed pre-service teachers to be authentically assessed by college faculty as to their understanding of and competence in
meeting curricular needs. So, in this project, instead of taking midterms or end terms, students (pre-service teachers) received performance assessments of the lessons delivered in "host" classrooms (lab).

A rubric was developed by students together with me, the professor, to evaluate the performance of their two technology-enriched lessons. These rubrics were then used by students for developing their lessons, self-evaluations and professor-evaluations. Grades were based on adherence to the rubric criteria, taking into consideration any circumstances beyond the students' control, i.e. lab inconsistencies. Criteria for evaluation included preparedness, enthusiasm, content knowledge, use of technology, classroom management, attire, speaking and listening skills, grammar and clarity, teacher interaction, and the quality and thoroughness of the lesson plan. These are criteria expected of a true professional. The rubric allowed students to think of themselves and their planned lessons in the light of professional performance, in terms that ranged from speaking skills and attire to technological and pedagogical competence. Lessons delivered that exemplified the integration of technology included: map skills using the Internet for research and Kid Pix for re-creation of map highlights; continent study utilizing Hyperstudio to create a multi-media slide show; document based questions (on the Internet) used to study Native American culture; and Point of View writing using an Internet-based scenario and the Student Writing Center.

Flexibility often became a hallmark of this initiative. Students were challenged by circumstances and sometimes even the most practiced lesson did not proceed precisely as planned due to network configuration problems. At mid-term time, I was willing to participate in the lesson, helping the TechAmbassador to deliver a lesson; at end-term time, however, I participated to a much lesser extent and was less lenient on evaluation. While my objective was to fairly evaluate my students' performances, as a professional, I believed it was also essential to prioritize P12 student learning. Thus, if P12 students needed assistance, I provided it within reasonable parameters. Most P12 students were actively and consistently engaged in the technology enriched lessons and looked forward to their computer lab time.

Pre-service teachers were also asked to submit several papers throughout the semester. From the first day, I referred to them as colleagues, as teachers with responsibilities to me, their partner teacher and to the P-12 students. They were initiated into the teaching profession by having to lead a class discussion on an assigned book chapter. They were evaluated on their summary of the content as well as their development of open-ended discussion questions based on the chapter readings. I was encouraging them to take a leadership role. In addition, they were asked to document their observations in their partner teachers' classrooms, reviewing teaching styles, students' behaviors and curricular goals. A journal of their weekly experiences was also collected for evaluation. These are perhaps traditional evaluations by college course standards. What distinguished the measure of their true learning as teachers was the authentic assessment of their teaching ability. This was done through the use of the rubric to evaluate the technology-enriched mid-term and end-term lessons.

In summary, pre-service teachers were provided an opportunity to enter a real classroom setting and integrate technology into the curriculum through well prepared, researched and delivered lessons. They not only experienced students behaviors but teacher conflicts and technology lab inconsistencies. I don't believe I could have provided a more realistic setting for authentic assessment of their abilities.

Abstract

Views about constructivism in the classroom are varied and at times misleading. Ideas about integrating technology into the curriculum are also varied and at times misleading. The authors present a clearer vision of the use of constructivism in the English, Math, Science, and Social Studies classroom by meshing Vygotsky's ideas about constructivism with the use of technology as a tool for learning.

Technology and Constructivism

Views of constructivism in the classroom are varied and at times misleading. Ideas about integrating technology into the curriculum are also varied and at times misleading. A clearer vision of the use of constructivism in the classroom by meshing Vygotsky's ideas about constructivism with the use of technology as a tool for learning is needed.

There are various views of constructivism, including: trivial, radical, socio/cultural, critical, and constructionism. The aspects of socio/cultural constructivism as seen through the writings of Lev Vygotsky will be addressed in this paper. The authors believe that by studying constructivism from this viewpoint the reader will get a clear view of one perspective as it relates to the use of technology across the curriculum. The authors have future plans to study and report on other views of constructivism in relation to the use of technology in the learning environment.

The ideas presented in this paper reflect the use of technology to "infomate" not "automate" the learning process, such as: concept mapping, problem-based learning (including webquests), asynchronous communication (including email, discussion boards, and collaborative writing), selected database and spreadsheet activities, desktop publishing opportunities, and the use of the internet. Ideas for integration of constructivist technological learning environments in the English, Math and Social Studies classroom will constitute the remainder of this paper. Examples of these ideas, as well as those for the Science classroom will be an integral part of the poster session.

The Social Studies Constructivist Classroom

A marriage of socio-cultural view of constructivism with technology opens up myriad opportunities for students to develop ideas and construct meaning through social interaction facilitated by technology. In the absence of such a theory of learning, teachers often rely solely on textbooks to provide information, which has been processed, for students. Students are not constructing the knowledge for themselves.

Technology-mediated learning, however, offers opportunities far beyond the classroom walls for communication, collaboration, research, and publishing. With the textbook and curriculum guide as resources, a teacher can facilitate the learning process, which might begin with exploration of a topic and end with creation of a product, perhaps a web site or PowerPoint presentation. In the process, students guide their own learning, working their way through various internet sites that afford opportunities for interaction with actual social scientists (i.e. Africaquest, Greecequest, etc.), on-line discussion, problem-solving situations, virtual tours of places throughout the world, access to on-line libraries and data-bases,
and even competitions and quizzes. Three of the many web sites offering incredibly diverse on-line projects are www.classroom.com, www.exeepc.com and www.cssjournal.com. With imagination and desire, a teacher can whet the learning appetite of students who have previously been fed only dry textbook food.

The Mathematics Constructivist Classroom

Opportunities exist in mathematics for young children to discover important mathematics ideas using technology, in the context of shared experiences and development of terminology. LOGO, the programming language for creating designs using geometric transformations, can be the medium by which elementary children discover these transformations and use them to create tessellations. Children can also explore combining two or more transformations of one variety that accomplish the work of one transformation of another variety. Such activity can be used later as a model for composition of functions. Students can be encouraged to name the different transformations and to attempt to identify and name the types of tessellations that can be created.

Opportunities exist for secondary mathematics students to discover how “parent” functions are affected by systematic modifications in values of x before substitution, and modifications in values of the function after substitution. Using a graphing calculator, students can discover systematic effects of these modifications, and can learn to describe and classify them using terminology not normally associated with mathematics. The process can be reversed, with each student posing a graph for other students in a small group, and other students attempting to describe the equation of the given graph, by first describing parent-function modifications with the agreed-on terminology.

The English/Language Arts Constructivist Classroom

Vocabulary development is a central objective in every language arts classroom, K-12. Traditionally, students read and listen to words and definitions selected and provided by their teachers. In a social-constructivist classroom where the teacher has infused technology into the teaching and learning environment, students collectively identify words they consider important and relevant from within their own life experience. These words may emerge from a number of sources, such as live conversation, television (video), movies, video games, web sites, e-mail, and a variety of print media. Then students construct an understanding of each word’s meaning and appropriate use beginning by discussing what they already know about the words and the context within which they have encountered the words before. Students then mediate their personal understanding of these words by investigating ways the words are used and defined by others. This often begins by comparing published definitions from a variety of sources, including electronic databases. Students then seek a broader understanding about how the words might be used. One approach to understanding how words are used outside the students’ daily discourse is the “find” function found in most text readers and editors. Students participate in an ongoing collaborative negotiation of meaning, sharing and challenging each other’s understanding of the words as they emerge and evolve. Students then demonstrate an understanding of the words in authentic contexts, both spoken and written. This demonstration may be facilitated by technology in the form of electronic presentation, word processing, communication, and publishing. Students learn not only vocabulary in this process. They concurrently negotiate the value and use of various information and communication technologies. Technology is made available as a resource (much like dictionaries, textbooks, and the chalk board) to be used by the students as they solve problems, seek information and understanding, and find ways to apply what they have learned in ways that are both personally and socially meaningful. Teachers in such a classroom act as coaches and guides — mediating disputes, giving approval, and establishing the social framework within which the learning occurs.

Lev Vygotsky forwarded the notion that higher mental functions (the way we understand things — all things) are mediated (modified, limited, or enabled) by language. Thus it behooves students to work to construct their learning in a socio-cultural environment. The authors believe that this environment needs to be infused with the use of technology as a tool to help construct that learning.
Examining the Value of Technology in Creating and Assessing Narrative Pedagogy in Teacher Education

Marvin Cohen, Bank Street College, US
Helen Freidus, Bank Street College of Education, US

Abstract

This panel presents a set of practices which can be described as "technology enhanced narrative pedagogy". The presentations explore the ways in which combining technology with narrative practices in teaching and teacher education has proven valuable in helping:

- preservice and inservice teachers to identify, share, and extend their understanding of teaching and learning
- teacher educators to evaluate their practice and develop increasingly effective ways of meeting the needs of diverse learners

The practices will be described in sufficient detail so that others can participate in judging their validity for educating both pre-service and in-service teachers, as well as for self-study.

The presentations thus address two important issues:

- ways in which to create effective "technology - enhanced narrative teaching practices" that are useful in teaching and teacher education
- ways in which to create forums in which such practices can be rigorously interrogated for their value as well as their validity in the professional education of teachers and the self-study of teacher educators

Educational Importance

The use of technology enhanced narrative practice provides many as yet untapped opportunities for the conduct of research that is deeply relevant to teaching and teacher education. It provides access to diverse contexts and insight into the ways in which teaching and teacher education is situated in these contexts (Putnam & Borko, 2000). In this way, it facilitates the sharing of experiences and development of common understanding.

Narrative teaching practices have advanced because of the careful scrutiny and self-study of practitioners. New technologies can support and document such scrutiny.

The technology enhanced practices documented by these presenters and the dialogue generated by the presentations will create new forums for understanding and defining effective practices in teaching and teacher education.

Format: Interactive Panel

This interactive panel will be comprised of a series of presentations by teacher educators in the fields of special education, early childhood and elementary education, bilingual education, educational leadership, and reading and literacy. These presentations will describe the process and outcomes of a project designed to foster increased use of technology by and for teachers and teacher educators. Particular emphasis is paid to diverse uses of "technology enhanced narrative pedagogy" including: digital video case materials, e-mail journaling, web based discussion forums and digital portfolio. Each presentation will address a common set of questions:

- How did the use of technology facilitate the implementation of narrative research and/or narrative teaching?
- How did technology support the learning process of the teachers and teacher educators involved?
- What unexpected problems surfaced?

After a brief presentation by each participant, the discussion will be opened to the floor. The audience will be encouraged to comment on the practices described and/or share their own experiences. Dialogue will focus on the validity and usefulness of technology enhanced narrative practice in teacher education and professional development.

Presentations

Increasing the Use of Technology in Teaching and Teacher Education
Our programs in teacher education and leadership have been working since 1997 to integrate new technologies and pedagogy in ways that prepare teachers to work in diverse and inclusive classrooms. To do this, teacher educators, themselves, needed to become more comfortable with the possibilities technology offered for extending teaching and learning. With support from private funders (Project EXPERT) and the federal government (Project DEEP), a program of technology based professional development for teacher educators was developed. Approximately 85% of our faculty now use new technologies in their work at the college, and 35 of our teacher education courses have had their syllabi, assignments and readings infused with technology-rich resources.

While this work has been very successful it has not been without significant resistance. In this presentation, we will examine to what degree faculty participation in the projects has nurtured interest, overcome resistance, and led to achievement of both individual goals and projects goals. Data collected from peer review discussions, observations, and final project reports suggest that 2 factors have been central to the project's success:

- A carefully constructed cultural match - The identification of relevant connections between the uses of technology enhanced pedagogy and the institution's core values
- The role of the outside evaluators - "Critical friends" who helped shape the project by listening to and questioning both project leaders and project participants.

Using Digital Video as a Tool for Advising and Rethinking the Teacher/Adviser (Supervisor)/Researcher Relationship

This paper presents a year-long study in which nine teachers from West Harlem in New York City were videotaped as part of a federally funded grant designed to prepare general education teachers serve the needs of English Language Learners. Digital video was used as a tool to help teachers narrate and reflect on their practices. In this presentation, we ask the question: Is technology-enhanced narrative pedagogy a feasible tool for stimulating teacher growth?

E-Journaling: Examining Intensity and Efficacy in Advisement (Supervision)Relationships

The reflective journal - sometimes expanded to "dialogue journal" - is a time-honored practice of educators who value student voice and increased student-teacher interaction. This presentation will report on how Journaling through e-mail has significantly altered the nature of many of those interactions. The ease and immediacy of narrative reporting - and response - bring the potential of far greater intensity and efficacy to the dialogues -- and the possibility of substantial distortion as well.

Web Based Discussion Groups: A New Lens for Examining Practice

This presentation will focus on the experience of one teacher educator as she engaged in a two year process of learning to use web-based discussion groups in graduate courses and staff development. Particular attention will be paid to the impact of this experience on the teaching of a graduate course in child development. Information that surfaced from the discussion groups led to changes in the content and structure of course assignments.

Digital Portfolio: Teachers and Teacher Educators Learning Together

This presentation reports on the collaboration of a teacher educator and an educational technologist in advising a graduate student in the process of constructing a digital portfolio that narrates her understanding of and competency in teacher education. Particular attention is paid to the ways in which each participant learned from the others throughout the process.

The many drafts of artifacts and captions replete with comments that led to the construction of the portfolio which can be viewed at http://www.edc.org/CCT/BSC/work-bin/suesse/pmap.htm provide a rich data source.

Evaluators as "Critical Friends": Identifying and Supporting Promising Practices

This presentation will identify the ways in which the role of "Outside Evaluator" informed both the practice of those being evaluated and that of the evaluator herself. By extending the dialogue around the "narrative teaching practices", both insiders and outsiders were able to raise questions of the value and validity that surround these practices. These questions include:

- Are these technology enhanced narrative practices congruent with philosophy and practices across the institution?
- In what ways does the presence or absence of congruence impact on the value of the practice?
- What implications does the congruence have for replicating these practices in diverse contexts?
The Teaching Observatory Concept: Embedding Zones of Interactive Technology into Teacher Education & Research Programmes

Do Coyle, Centre for Research into Second and Foreign Language Pedagogy, School of Education, University of Nottingham, UK. Email: do.coyle@nottingham.ac.uk

Abstract

This short paper presents research in progress into the concept of a Teaching Observatory (TO) currently linking two sites but soon to expand to a national network. The TO set out to create a flexible multi-modal and multi-purpose interactive training tool for a post-graduate teacher education course (PGCE). The university site and sites in 'beacon' secondary schools are linked via a 6 ISDN large screen video facility with pan/zoom cameras and interactive whiteboards. Funded through the national Training School Initiative (DfES 2000), the TO project initially aimed to explore how an interactive training tool might be used effectively to enhance learning and teaching at different levels. It was soon evident that the TO offered many more inter-connected opportunities for pre- and in-service education and research than had originally been conceived. Set within a sociocultural framework, this case study explores and evaluates how different strands (zones) of the research can be woven together to inform the dynamic of an emerging TO concept.

Introduction to and uses of the Teaching Observatory

The TO concept had its origins in a pragmatic need for over 60 trainee teachers specialising in immersion/bilingual education (geography, history and science through French/German) and modern languages (especially German, Japanese and Russian) to have school-based experiences which could not be provided within the locality of the university of Nottingham, UK. It also intended to involve trainees in statutory ICT applications through the authentic use of technologies to enhance their own training experiences and thus prepare them well for incorporating a range of new technologies into their future teaching repertoire. In the initial phase of the project the university site, along with a beacon secondary school with a section bilingue near London, were equipped according to defined specifications (in consultation with Promethean, UK). During the initial experimental phase of the project, the TO has been/is being used for non-intrusive lesson observations in real time of expert teachers in their classes by large groups of trainee teachers; individual remote support by tutors and observations of lessons taught by trainees during their teaching practice; sharing interactive whiteboard applications between the two sites eg trainees creating electronic teaching materials; trainees experimenting with and teaching lessons to school students at a distance; interactions with learners and teachers by the trainees to discuss lessons and issues; teachers participating in mentor training via the TO; meetings between teachers, tutors and technicians; observation and research into strategic classrooms focussing on a target class of French learners and a similar class for German; using video recorded lessons to create training materials; observation and analysis of the use of the TO by a team of researchers investigating Fitness-for-Purpose for the Information Society Technologies Programme Eye-to-Eye project; exploring the use of activote machines by students to encourage the development of thinking skills as well as experimenting with interactive whiteboards to enhance literacy awareness.

Adopting a theoretical framework for investigating the Teaching Observatory

In order to classify and organise the different uses of the TO into a coherent research context, a sociocultural framework was adopted. Sociocultural theory supports a context-based communicative perspective on learning and teaching which foregrounds two crucial elements: learning though communication and the need for scaffolded environments to assist in co-constructing and negotiating meaning (McLoughlin & Oliver 1998). For technology to encourage and support interaction – a concept central to the TO – then building on the notion of collaborative learning and co-constructed understanding elevates the zone of proximal development (ZPD) to a pivotal position (Vygotsky 1978). The ZPD suggests that learning (through, with and from the TO) is a co-ordinated activity with all participants (expert and novice) responsible for solving problems. However, in this context it could also be argued that in some TO activities all participants are relatively novice since the TO constantly presents them with situations and problems never previously encountered. In other TO activity the roles of expert and novice are more
clearly defined. The multifaceted nature of the TO therefore suggests that there are several sub-zones or strands which interrelate and interact to co-construct a cohesive ZPD. Common to all strands is the TO technology and its evaluation in terms of possibilities and limitations as a tool as well as a contributor to the scaffolded collaborative context it helps create. The strands are identified as follows: strand 1 - trainees and trainer/tutors; strand 2 - trainees and teachers in school; strand 3 - teachers and trainer/tutors; strand 4 - trainees and students in school; strand 5 - researchers and trainer/tutors; strand 6 - technicians/technology suppliers and trainer/tutors. The concept of the TO is thus being researched through the six component strands of its ZPD.

Case studies: researching six ZPD strands in the Teaching Observatory

The complexity of different strands and ensuing research demands lends the current work to a case study approach (Cohen, Manion & Morrison 2000). The table sets out parameters of the case study research:

<table>
<thead>
<tr>
<th>Strand</th>
<th>Activity/Interaction in ZPD</th>
<th>Case Study Focus: Use of Technology in...</th>
<th>Data Collection Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>1: Trainees/Trainers</td>
<td>Observations lessons by tutor of trainee teaching face to face Creating lesson plans and materials</td>
<td>Effectiveness of lesson observation at a distance including pre and post lesson discussion/analysis Creating and evaluating electronic resources</td>
<td>Video recordings/ Analysis Tutor field notes/diary Trainee focus groups</td>
</tr>
<tr>
<td>2. Trainees/Teachers</td>
<td>Observations of expert lessons, post-lesson discussion Trainees teaching at a distance</td>
<td>Developing observation, analytical and reflective skills Awareness raising of skills needed to be effective 'distance' teacher Evaluating the distance teaching experience</td>
<td>Video recordings/ Analysis/ Field notes Trainee Focus groups Collating/evaluating materials</td>

<td>Technological development/support</td>
<td>Monitoring/evaluating whiteboard Enhancing targeted sound (for group/pair work) and use of activote</td>
<td>Field notes/ virtual meetings/training sessions/reports</td>
</tr>
</tbody>
</table>

Interim reflections

The data collected so far is rich and complex - it touches on a variety of paradigms and methods. Whilst it is too early to publish outcomes, results thus far indicate that different uses of the TO will meet with differing degrees of success (Crook 1994, Heamshaw 2000). All those involved are inextricably engaged in learning and reflection in the ZPD, since the nature of the work has provided all players with new experiences including the highs of innovation and the lows of frustration or disappointment. What is certain is that the TO is opening up complex new ways of re-conceptualising teacher education by extending its potential ZPD through the use of technology which supports quality interaction and collaborative learning (Jacobs & Rodgers 1997, Laurillard 1993).

Views From Within an Online Learning Environment: Perceptions and Practices in a Teacher Education Course

Dorothy Valcarcel Craig, EdD
Department of Educational Leadership
Middle Tennessee State University
Murfreesboro TN
United States
dvcraig@mtsu.edu

Abstract: This paper presents findings of a study conducted on a graduate level Teacher Education course. Perceptions and practices within an online environment were explored and examined. Using a framework focusing on issues and trends in public education, graduate students engaged in online dialog, action research, and teleresearch. Findings indicate that the patterns of online use and teleresearch among participants encouraged the same practices in the K-12 environment and provided a model for technology use for teachers and students.

Introduction

Due to the demands of a dynamic, digitalsavvy student body, the average teacher employed by a U.S. school system in many cases is required to infuse technology into classroom instruction. The average teacher educator typically is not required to take advantage of available technology. This can be somewhat attributed to the concept of academic freedom and in part to the fact that—although working within the teacher preparation environment—many university professors view the process of teaching and learning much differently than the K-12 teacher. Therefore in many cases unless the teacher educator is technology-oriented and forward thinking, technology is not fully utilized in typical classroom sessions. Jackson (1995) suggests that this is due to the fact that many university professors conceive of teaching as a well-organized syllabus supported by clear, logical, teacher-directed presentations. Educators at any level must remember, however, that teaching has value only if it promotes student learning. This learning must include conceptual growth, working collaboratively, and communicating. In addition, the main focus of teaching and learning must shift from content presentation to a combined, dynamic focus of how students approach learning, multiple styles of delivery, and ongoing inquiry (Jackson and Prosser, 1989; Ramsden, 1992).

Just as public school teachers must become conscious of: a) the technologically-literate student body, b) the intricate process of teaching and learning, c) the diverse learning needs of students, and d) multiple methods of delivery, the university professor preparing future teachers must also consider these factors when designing learning experiences. In the forward to The National Educational Technology Standards for Teachers (NETS, ISTE, 2000), the authors state that the educational system in the United States must produce technology capable kids—those who can live, learn, and work successfully in an increasingly complex and information-rich society. To do this, all educators must themselves be:

1. Capable information technology users,
2. Information seekers, analyzers, and evaluators,
3. Problem solvers and decision makers,
4. Creative and effective users of productivity tools,
5. Communicators, collaborators, publishers, and producers, and
6. Informed, responsible, and contributing citizens.

The NETS (2000) publication suggests that certain conditions must be present in order for the goals to be met. Included in the general preparation of teachers, university leaders must share a vision
for technology use in all appropriate preservice and content courses. They must have access to current technologies—including software and telecommunications networks. Teacher education faculty members must engage in interactive sessions with colleagues to discuss, model, and design appropriate uses for technology. Last, teacher educators must incorporate student-centered approaches to learning and assessment. While technology is rapidly opening up more and more possibilities for students entering the education profession, little research has been conducted on the benefits of online learning and the development and effectiveness of the online university environment. Examining the work of Papert (1996) and Tapscott (1998) regarding technology utilization within the K-12 environment, prior research generates several questions regarding online learning within the teacher preparation environment such as: a) would the learning styles and preferences enrolled in a graduate level teacher education course be met via an online version of the course, b) would the environment invite and nurture in-depth discussion and inquiry typically part of an education issues course, c) would K-12 classroom technology experience assist with completing course assignments and requirements, and d) would technological literacy—if any—gained from the experience assist the classroom teacher as well as the future teacher in better utilizing the resources and technology for their own students’ inquiry and learning experiences?

Project Description and Methodology

The study utilized these initial questions to examine, document, and provide a thick and dense description of how graduate students—both licensed teachers and future teachers—operated within an inquiry-based, technology-infused online learning environment via a course designed and offered using the CourseInfo online development program. Using a qualitative approach outlined by Bogdan and Biklen (1992), the researcher became a participant observer in conducting eight case studies consisting of students enrolled in a core education course and who were seeking either state licensure and/or the Masters of Education degree in Curriculum and Instruction. The self-selected sample represented those teaching in rural, urban, and suburban environments, those who were substitute teachers in local public schools, and those who were not yet teaching in a professional education environment. Each individual student completed inquiry-based readings and assignments, engaged in online discussions with each other, and conducted action research at local public schools by utilizing the components available through CourseInfo. These components included: a) Announcements Board, b) Course Documents which included handouts, articles, and online resources, c) Assignments Board, d) Online Discussion Board, e) Student Tools which included email links, online grade access and Student Drop Box, and f) External Links—additional Internet links to supplement textbook reading assignments.

Data sets were collected through student products; coded virtual field notes gleaned from student email, student-generated questions regarding selected topics in education, and asynchronous online discussion board postings; results and findings from individual action research projects; research papers; and online course evaluation forms. The researcher engaged in prolonged engagement over a one-semester period during a spring semester. In addition to data collected by the researcher, the CourseInfo package provided additional information by way of generated reports to chart frequency of use, number of accesses per day/time/hour, and frequency and number of responses to Discussion Board topics. The study was driven by the following questions, which provided a framework for data collection in addition to providing the researcher with a set of overarching inquiry themes:

1. Would levels of technological literacy hinder or assist students in completing assignments, participating in asynchronous discussions, accessing documents, utilizing Internet resources, and exchanging products with the instructor and with each other and would these levels become evident in the patterns of student use and preferences that may emerge throughout the study?
2. Will inquiry-based action research assignments and requirements assist students in making connections between course content, relevant education issues, technology utilization, and their own immediate or future classroom teaching?
3. Would the online environment provided by CourseInfo compliment course content while providing an alternative learning environment for students and how will the findings from the study impact future course development and current practices in teacher preparation?
4. How will participation in the online course and technological literacy gained from the experience impact and assist the classroom teacher as well as the future teacher in utilizing resources and technology for their own students' inquiry and learning experiences?

Findings and Conclusions

Egon Guba (1978) describes qualitative research as a “discovery-oriented” process that minimizes investigator manipulation of data and setting and which places no prior constraints on what the outcomes of the research will be. This description became evident on the first of two on-site meetings held for orientation purposes in order to acquaint participants with CourseInfo online software and its components. It was during the first on-site meeting that participants expressed a strong desire to explore the online learning environment as an alternative to typical on-site graduate education, seminar-based courses. At the beginning of the semester, a total of ten students were registered for the course. The ten enrollees attended the first orientation meeting. However, after approximately one hour, two of the original ten decided that they did not possess a level of technological literacy they felt would be required to complete assignments. Ultimately, the two participants dropped the course opting to take it during a semester when it would be offered in a traditional manner. This focus on technological literacy and prior “computer-based” experience continued throughout the study and was often a source of participant-to-participant discussion.

In an attempt to offer insights into the milieu, general findings are presented in the chronological order in which they occurred. Data collection began at the initial orientation meeting where participants completed a demographic survey. This information enabled the researcher to begin building a “participant profile” of each student enrolled in the course. Data gleaned from the survey provided a brief explanation of where the participant was employed, what type of school system—if any—each taught in, years of experience, available technology, and the approximate physical distance from campus that participants would be working from (Table 1).

In addition to the demographic survey, sample products were gathered on a weekly basis. Assignments, informational handouts, related readings, Internet resources, and themes for discussion were posted each Tuesday and were due on the following Tuesday. Assignments consisted of approximately three to four research-related mini papers, bi-monthly action research projects, reflections of weekly readings, and Discussion Board postings. Discussion Board postings were checked by the researcher on a daily basis. Participant postings and responses were printed and coded. Results from all action research projects were printed, copied, and summarized. Themes corresponded to weekly readings and enabled participants to further explore topics and exchange multiple perspectives with each other. Each participant selected an education issue to explore throughout the course of the semester. Three assignments related to the theme were due on the last day of the semester. The assignments consisted of: a) research paper, b) presentation of findings, and c) annotated bibliography. Study participants completed a summative Online Course Evaluation, which focused on their perceptions of the online learning environment, course content and assignments, and instructor-as-mediator effectiveness. Evaluation responses were examined, analyzed, and summarized. To further substantiate findings, reports were generated using CourseInfo Course Statistics to chart user preferences, frequency, and total number of accesses per participant and per component.

As participants worked through course assignments, it became evident that several of the education issues and themes were of high importance while others were of little or no importance. For example, Discussion Board postings focusing on equity and/or disparity in public school funding across the state as well as the nation ranked as most important with a total of 83 postings—including initial and follow-up responses. Throughout this particular discussion, participants referenced current problems that they were personally facing with regard to funding as well as the funding issue currently in debate within the state. Online discussion focusing on school integration issues was of equal importance to students. Participant #3, who at the time was employed by a large urban school system, related what was happening with school integration, problems with the magnet program, and school bussing issues which further provided a relevant description of urban problems to those participants teaching in rural areas. The experiences brought to the online Discussion Board assisted in connecting the reading assignments to current problems in public schools. The board postings also provided a non-threatening open-ended arena for exploration. Figure 1 provides an example of discussion.

**Current Forum: Integration Issues**
**Author:** Participant #3  
**Subject:** Task 4.1

I teach a self-contained class of 20 first graders.
African Americans = 19 students  
African American/White = 1  
Females = 12  
Males = 8

The racial population of my class is typical of the rest of the school. I have more females in my class than many of the other classes. My school has been rezoned as of this year. I don’t anticipate any changes in our population unless we are given the needed funds to enhance our school as a Design Center and attract a more diverse group of students. The students are still bussed, but results remain the same.

**Current Forum: Integration Issues – Response to Questions**
**Author:** Participant #6  
**Subject:** Re: Task 4.1

Dear Participant #3,
How much rezoning can take place when the white population of Metro is so small? There aren’t enough white students to go around. The only solution to integration is to integrate the entire student population of Davidson County. Is integration the answer to the learning problems of students in Metro? Or must Metro look into other ways to improve the education of inner-city students? It might be the case that separate but equal will become the norm again. However, this "equal" will mean equal learning opportunities, but separate in inner-city schools.

**Figure 1:** Example of Discussion Board Dialog
Responses gathered from the summative evaluation indicate that all participants viewed web-related teleresearch assignments as most relevant and significantly useful. In addition, utilization of additional materials—web-related documents posted in Course Documents and online articles—were perceived as significantly useful in completing future graduate courses. Although the action research projects were cited as the assignments that assisted in connecting the content with real-world education issues, only five of the eight participants cited these projects as most useful to them in their current teaching situation. The five who cited the projects as most useful were already teaching in a public school.

The study offered students an opportunity to experience an alternative to typical on-site teacher education courses. The online learning environment matched course content, action research, and Internet utilization while empowering teachers and future teachers to take charge of their own learning via self-pacing and preferences. Referring back to the overarching questions, the level of technological literacy that each participant possessed at the onset of the project seemed to provide the self-confidence needed to successfully complete the course. Based on responses, the inquiry-based design of the course matched with the online components assisted students in making a connection between textbook material, classroom experiences, and relevant issues currently of importance to public school educators. Although products, postings, and related assignments indicate that participants displayed a broad knowledge-base regarding issues relevant to education, it seems as though the design of the assignments and the nature of the action research process provided a means for increasing this depth. Responses from on-site as well as individual email inquiries to the instructor reveal that the inquiry-based nature of the assignments broadened knowledge and that the online environment provided a scaffold for increasing this knowledge. As participants accessed their assignments from their own classrooms, the process acted as a catalyst for public school students' discussions regarding online learning. The success of the online course prompted a further investigation of other courses contained in the departmental Masters' programs as possible courses for online development.

If educators must meet the needs of their digital-savvy students in the K-12 classroom setting, they must be able to utilize technology in a meaningful, relevant manner. The challenge of training and nurturing highly qualified, technologically literate teachers falls on the shoulders of teacher educators. If they do not embrace the challenge, the education system will continue to fall short in meeting the needs of a dynamic student body. By incorporating inquiry-based tasks, ongoing discussion and dialog, teleresearch, and classroom action research into the online learning environment, the teacher educator can create an enriching alternative to typical coursework.

The Design of a Supportive Faculty Development Model: 
The Integration of Technology Within the University Faculty’s Teacher Candidate Coursework

Caroline M. Crawford  
University of Houston-Clear Lake  
United States of America  
crawford@cl.uh.edu

Abstract: The desire to integrate technology within the PreK-12 educational environment is a noble endeavor and may lead to the enhancement of student achievement. Teacher candidates are constantly striving to understand the learning environment and to meet these expectations, but do not have models from which they may glean appropriate knowledge, conceptual and instructional frameworiking. The integration of instructional technology within the methods coursework aids the teacher candidates through a model of appropriate technology integration within a classroom environment, as well as further enhances their own achievement.

Introduction

The integration of technology within a learning environment, especially significant within a methods course for teacher candidates, emphasizes the significance of a student-centered focus. However, many methods university faculty have not had the opportunity to research the integration of technology at any significant length. This session offers methods faculty the opportunity to work with an instructional technologist who specializes in the integration of technology within a learning environment, to discuss and analyze significant elements associated with the integration of technology within a learning environment, and to critically consider the beginnings of a technology integration action plan for teacher candidate methods courses.

Information Versus Instruction

Information is a term referenced when discussing the knowledge communicated or received concerning a particular fact or situation; however, instruction is a term referenced when discussing the particular, deliberate composition of learning situation and environment that have been specifically formulated to support the realization of the learning objective or goal. Through this clearly delineated formulation towards the support of instruction is the opportunity towards the integration of instructional technology as a tool towards this instructional accomplishment.

Instructional Technology: A Definition

Instructional technology has been defined numerous ways, but the final delineation of instructional technology is towards the successful support of the learning goals for each delineated lesson. The Association for Educational Communications and Technology (AECT) has adopted the following definition of instructional technology: “Instructional Technology is the theory and practice of design, development, utilization, management and evaluation of processes and resources for learning” (Seels & Richey, 1994). Through consideration of this definition, a clear understanding of the roles and processes pertaining to instructional technology can and may appropriately occur within an educational environment.

Teacher-Centered Versus Learner-Centered Learning Environments

Models of instruction are important elements towards a clear understanding of the philosophical and conceptual theoretical underpinnings within the learning environment. For this reason two main emphases, related to the structure of the learning environment and the information interrelated to such an arrangement is situated within such an environment, are noted: the teacher-centered model of instruction and the student-centered model of instruction. Below is a graphic clearly delineating the two significant models of instruction.
As both models of instruction are imperative towards successful learning environments, the significant shift between the two is of a philosophical nature. Instructional technology is an important element within both learning environments, as the interactive element of the technology may be integrated in a teacher-centered or a student-centered situation.

Levels of World Wide Web Integration

As the World Wide Web (Web) becomes a more important element towards the creation and manipulation of learning environments, it follows that the Web will be integrated into the learning environment at numerous levels. Following are ten levels of Web integration:

Level 1: Marketing/Syllabi via the Web
Level 2: Student Exploration of Web Resources
Level 3: Student Generated Resources Published on Web
Level 4: Course Resources on Web
Level 5: Substantive and Graded Web Activities
Level 6: Electronic Conferencing Course Activities Extending Beyond Class
Level 7: Repurpose Web Resources
Level 8: Web as an Alternative Delivery System for Resident Students
Level 9: Entire Course on the Web for Students Located Anywhere
Level 10: Course Fits Within Larger Programmatic Web Initiative

(Bonk, Cummings, Hara, Fischler & Lee, 2001)

Each level delineates the level of integration of Web resources, which in turn impacts the learning environment and the model of instruction implemented within the learning environment.

Professional Development Opportunities Model

An appropriate model towards the appropriate and successful implementation of professional development opportunities for university faculty must be delineated so as to support the university faculty's efforts towards the integration of instructional technology into the university coursework. Further, teacher candidates must have instructional technology appropriately modeled for them within their methods courses so as to develop a conceptual framework of understanding within specific specialization areas. As such, the following model for professional development opportunities is offered.
Each professional development opportunity follows the model graphically delineated above. An introductory, basic workshop is offered to university faculty that is based upon a specific subject. Once the attendees have attended the basic workshop, then they have the option to attend a novice workshop that is actually the basic workshop in a smaller group setting, or an advanced workshop that delves further into the subject matter from the basic workshop opportunity. Additional support is necessary through one-on-one, face-to-face support meetings, as well as hardware and software troubleshooting training and support. While each of the professional development opportunities are occurring there is a level of online support that should remain an undercurrent, consistently available to the university faculty, that consists of tutorials, subject matter experts that are available for support and information, as well as discussion lists wherein the university faculty can discuss issues from the professional development opportunities and to develop a sense of community. That the university faculty are not, in fact, alone trying to integrate the instructional technology into their courses. Additionally, the online support further enables the conceptual framework development of the university faculty.

Learning Environment Interactive Activities

As university faculty delve further into the integration of instructional technology within the teacher candidate coursework, there are specific aspects that must be considered within the learning environments. The following interactive activities are important within any learning environment, whether it be face-to-face, Web-enhanced or Web-based:

- Learner – Content
- Learner – Interface
- Learner – Instructor
- Learner – Learner
- Learner – Self
- Learner – Community
- Instructor – Community
- Instructor – Content
- Instructor – Interface
- Instructor – Self

Each of the interactive activities should be carefully considered throughout the instructional design of the coursework and appropriately integrated so as to ensure the successful and appropriate attainment of the course, as well as unit objectives.

Faculty Resistance

University faculty have time-honored traditions associated with their instructional practices and there is the possibility that faculty may not find the technological innovations to be appropriate within their course learning environment. However, there is the possibility that university faculty may find it an uncomfortable proposition to consider the introduction of instructional technology into their coursework’s instructional design. Fear factors are apparent and real for numerous persons who have the opportunity to integrate technology into their instruction. For example, the following factors may have an impact upon the integration of instructional technology. The fears associated with:

- change
- time commitment
- appearing incompetent
- inadequate instructional technology knowledge base
- technological lingo
- technological failure
- not knowing where to begin
- having to move backward to go forward
- reprisals (Rutherford & Grana, 1995)
are real and clear for numerous university faculty. These can not be overemphasized and must be carefully and delicately managed so as to ensure the university faculty will consider further implementation of instructional technology into the teacher candidate’s methods coursework.

Faculty Implementation Barriers

As is well known, opportunities towards professional development opportunities have at least a few implementation barriers. Following are a few university faculty implementation barriers that offer obstacles for consideration.

- Specialization more important than technology
- Lack of knowledge and support personnel
  - Hardware
  - Software
- Time commitment
- Difficulty maintaining subject matter currency
- Technology integration viewed as risky
- Frustration surrounding technology use (Roberts & Ferris, 1994)

Each of these implementation barriers should be considered before professional development opportunities are offered, as the significant impact each aspect offers can not be overemphasized.

Reward Faculty Efforts

Rewarding university faculty efforts towards the integration of instructional technology into the teacher candidate methods coursework so as to model the appropriate and successful implementation of instructional technology into the specialization areas takes time and effort on the part of the faculty. Therefore, consideration towards faculty efforts and reward structures may be appropriate. Following are some areas of consideration:

- Displays of Admiration for Innovative Efforts
- Time Drain Compensation
- Positive Tenure Review Impact
- Incentive Programs
  - Interest
  - Motivation
- Financial Support
  - Hardware
  - Software
  - Course Buy-Out

The element of time is an important aspect for all university faculty due to the teaching, research and service triad of obligation and interest for each university faculty member. There are four main groups of university faculty who must be addressed through out the integration of instructional technology into the university coursework venture. The groups of faculty to address are:

- Early Innovators
- Cautious Innovators
- Hangers-On
- Negative Nay Sayers

Acknowledgement of the university faculty member’s efforts also impacts not only the faculty implementing the instructional technology efforts within the methods coursework, but also the university faculty who are carefully considering the time and efforts towards integrating instructional technology into their courses. Positive efforts should be admired and rewarded at every opportunity.

Conclusion

The design, development and implementation of a supportive faculty development model is of utmost importance to the teacher candidates graduating from each teacher preparation unit. The integration of technology within the university faculty’s teacher candidate coursework should be carefully considered and implemented with a clear understanding of goals and expected outcomes over a series of supportive professional development
opportunities. The longitudinal study of university faculty progress is of utmost importance towards the further understanding and consideration of instructional technology, its integration and implementation within the teacher candidate’s plan of study.

Abstract: Both teachers and principals act as critical decision-makers as to whether or not computer technology is implemented in classroom learning. Yet, there is a limited amount of literature that examines, concurrently, teachers’ and principals’ frequency of use and confidence levels for a given productivity software, as well as their expectations for the integration of that software into classroom learning. This pilot study is an initial attempt to focus upon the above criteria to sketch a baseline profile for both teacher credential candidates and prospective principals to delineate the following: 1) to the extent that frequency of use of a given productivity software influences personal confidence level when using that software, 2) to the extent that a teacher’s personal confidence level influences the probability that a given productivity software will be utilized in classroom learning, and 3) to the extent that a principal’s personal confidence level influences a professional expectation of teachers to use a given productivity software in classroom instruction.
Using TrackStar to create standards-based modules

Anne Daugherty, University of Kansas, US
James Daugherty, University of Kansas, US

Dimensions of electronic learning for enhancing choral music rehearsals and choral music education courses include web-based rehearsal notes and links, web forms, electronic portfolio assessment, audio and video files, discussion boards, and electronic collaboration.

For the past three years, (fall 1999, 2000, and 2001) pre-service teachers in a choral music methods class at the University of Kansas engaged in a project designed to ascertain the feasibility of teaching teachers to develop electronic learning resources. A particular focus of the project was to design electronic learning experiences in conjunction with the National Standards for Music Education and specific examples of choral literature suitable for school choral ensembles. Specifically, the project sought to gauge the effectiveness of using models or templates that could readily be adapted for use with various real-life contexts and objectives.

In total, six fifty-minute class periods were devoted to the project, including brainstorming ideas, constructing the modules, and sharing the finished products. In 2001, "TrackStar" was used for the first time. Developed by HPR-TEC, TrackStar is a tool that assists users to create a "track," a composite work based on other people's original online creations. Benefits of using TrackStar include its ease of use--users can create a track in approximately 20 minutes. The design of TrackStar is such that users can access the material online, or via a convenient printable format. Further, TrackStar includes an automated link-checker that periodically checks Track links and e-mails authors with a list of broken links.

The purpose of the current project, then, is to evaluate the benefits of using a pre-programmed tool to assist students in developing their standards-based modules to ascertain if the tool further aids students to feel comfortable with designing their web-based work.
Integrating Technology into the Study of Teaching and Learning

Heather A. Davis, PhD., Department of Educational Psychology
Gail Ring, & Richard E. Ferdig, PhD., Department of Educational Technology
1422 Norman Hall, Box 117047, University of Florida, Gainesville, FL 32611

Introduction:
In a report released September 1998, the US Department of Education reported, “Only one in five teachers... felt ‘very well’ prepared to work in a modern classroom. Specifically only about 20% said they were confident using modern technology or in working with students from diverse background.” The focus of this study was to attempt to integrate technology into the study of Human Learning and Development. Data were collected across three semesters and at three separate university settings. As part of their course in Learning and Development, students explored the application of learning developmental theories to assessment of students’ cognitive, social, emotional, and motivational needs as well as individual differences in learning. Furthermore, throughout the course pre-service teachers had opportunities to practice evaluating and developing instructional methods and materials to meet the group and individual needs of their students. The purpose of this paper is to describe attempts by the first author to:

1) Integrate technology-based instructional strategies into a pre-service teacher education course on educational psychology and child development,
2) To explore from a psychological perspective students’ resistance to change in attitudes and behaviors toward technology,
3) To describe the impact of integrating technology, specifically on-line dialogue, on pre-service teachers’ beliefs about technology, their interest and engagement in the course, and their mastery of course material.

It is important to note that my experience and knowledge of how to integrate educational technology is limited to my understanding of potential social and cognitive factors that may underlie technology use (Eagley & Chaikin, 1993; Pintrich & Schunk, 1996; Guzzetti & Hynd, 1998). As a researcher of motivation and social relationships in the classroom, I have often observed teachers using videos, computers in their classroom, or computer lab-time as motivational rewards. Held over students like a carrots, teachers would grant or deny access to technology in order to encourage different social and intellectual behaviors in the classroom. As with most reward structures, students responded to the reinforcement but with certain costs to their motivation to learn and their relationship with their teacher (Kohn, 1993; Pintrich & Schunk, 1996). In my own classroom, I hoped to provide my pre-service teaching students with an alternative model for how to used technology in their classrooms. Specifically, I incorporated media into instructional presentations, utilized computer resources to increase access to course information and to design presentation tools, and integrated journaling activities with the electronic bulletin board (WEBCT) hoping to create an extended dialogue about and critique of the material. From a pedagogical perspective, I was the most interested in the on-line dialogue because I believed it would provide students with opportunities to engage in the co-construction of knowledge about learning and development.

Preliminary Findings:
As we suspected, students who became actively engaged in the on-line dialogue, posting and reading frequently, tended to report increased interest and knowledge of educational psychology, increased mastery of concepts, and tended to exhibit higher performance on the test. If you consider the frequency of reading and posting a reflection of students’ engagement in the on-line dialogue, we found students who attended class regularly were the most engaged in the on-line dialogue. Furthermore, students who frequently read their classmates’ submissions were more likely to continue to be engaged throughout the end of the semester. In additionally, we found frequent reading at the midterm was the best predictor of students’ final examination grade and final grade in the course. What is interesting is that students’ frequency of posting on-line did not predict performance on either exam. Regarding students’ perceptions of the WEBCT at the midterm and end of semester, we found students’ who perceived the WEBCT as helpful were more likely to report increased interest in the course, increased knowledge of educational psychology, and were more likely to be engaged in the online dialogue (both reading and posting). Furthermore, students who actively read their classmates’ ideas, were more likely to report increased interest in the course and increased knowledge about the material. Lastly, students who frequently posted and read items on the WEBCT reported the activity helped them to master concepts in the class. To our disappointment, however, analysis of students’ self-evaluations revealed students who held negative views of technology (low efficacy, low value) resisted becoming engaged in the dialogue more than was “required.” Additionally, while many students saw “value” to the activity conducted on-line (journals), they did not see the value of the communication and co-

1 “I” refers to the first author.
2 Correlations were statistically significant and in the moderate ($r_{(66)}=.30-.35$) range.
construction of knowledge that occurred as a result of public discourse, nor did engagement with technology shape their views about effective means of teaching and learning.

**Discussion:**

These findings parallel those of Shallert, Reed, Dodson, Benton, Boardman, Amador, Coward, and Beth, (2001) as well as Burniske & Monke (2001). Across both programs of research, findings suggest the implementation of technology (e.g. using an on-line dialogue) is not enough to encourage meaningful engagement with and integration of technology in the classroom. Likewise, findings suggest students exhibit resistance towards change in their beliefs about and usage of technology. Findings across the Shallert et al. (2001), Burniske and Monke (2001), and my own data led us to ask: What factors shape psychological engagement in technology (Ferdig & Weiland, under review)? How can we get students to become invested, or committed to technologies used in the classroom that encourage public discourse (e.g. on-line discussions, electronic portfolios) (Burniske & Monke, 2001; Pintrich & Schunk, 2001)? How do we encourage lasting change in beliefs about the use, utility, and value of technology for the teaching and learning (Eagley & Chaiken, 1993; Guzzetti & Hynd, 1998)? The purpose of this paper will be to synthesize data across three semesters of technology implementation in a pre-service teacher-education course, to look across findings and examine sources of students’ “resistance” to become engaged in on-line dialogue from a psychological perspective, and to describe the impact of technology implementation on pre-service teachers’ achievement, engagement, and mastery of course material.

Using Computer Based Modules to Prepare Pre-service Teachers for Future Learning in the School Classroom

Chrystal Dean, Lori Tyler, and Paul Cobb
Mathematics Education
Vanderbilt University

chrystal.dean@vanderbilt.edu

Abstract: In the context of computer based modular design, we are currently investigating ways to bridge the gap between the university and the school classroom for pre-service elementary teachers. We have developed two authentic web-based cases in which pre-service teachers can investigate the process of supporting students' learning of significant mathematical ideas. In this paper we report on the results from our first pilot of the web-based modules in a master's level advanced teaching of elementary mathematics methodology course.

Mathematics methods courses should do more than try to inform future teachers about content and pedagogy. As teacher educators, we have a responsibility to prepare pre-service teachers for a career of future learning as classroom teachers. In the context of computer based modular design (Brophy, 2000), we are currently investigating ways to bridge this gap between the university and the school classroom.

In order to support the development of our students’ identities as teachers whose focus is on the challenges they will encounter in school classrooms rather than as university students whose primary concern is to achieve adequate grades, we delineated four overarching goals for our pre-service elementary mathematics methods course. The first of these goals is that pre-service teachers will learn to make pedagogical decisions that are justified by focusing on students’ thinking. In other words, students’ reasoning should be at the center of teachers’ decision making. The second goal is for the pre-service teachers to reconceptualize content of the elementary mathematics curriculum in terms of relationships between quantities. This goal is important as the future teachers have developed the belief that mathematics consists of rules for manipulating symbols as a consequence of their own experiences as students in school and in university mathematics courses. In contrast, we want them to come to view numbers not as mere symbols but as measures of an amount of some quantity. The third goal is for the pre-service teachers to both appreciate the importance of and learn to use coherent curricula composed of long-term instructional sequences that aim at significant mathematical ideas. The fourth goal is for the pre-service teachers to perceive teaching as a knowledge generating activity where they adapt, test, and refine instructional ideas and innovations that have been developed by others and have proven effective elsewhere. We attempt to achieve these goals by using what might be termed an emergent approach to teacher education (cf. Gravemeijer et al., 2000). In this approach, we develop conjectures about the pre-service teachers’ interpretations, arguments, and strategies when we design instructional activities with the intention of building on their contributions to achieve the goals of the course.

The technological tools we have developed to support the future teachers’ learning consist of two authentic web-based cases in which they can investigate the process of supporting students’ learning of significant mathematical ideas. These modules each comprise a series of challenges for future teachers to explore. The Patterning and Partitioning module focuses on an instructional sequence that was taught in a first grade classroom over a five-week period and includes video-recordings of classroom episodes and of pre- and post-interviews conducted with the students. The goal of instruction in these lessons was to enable the students to develop a relatively deep understanding of elementary number concepts, with an emphasis on relationships between numbers up to 20. The second module, Investigations in Teaching Geometry, covers a three-day instructional sequence taught in a fifth grade classroom that focuses on informal explorations of volume. The challenges in this module allow future teachers to investigate both the various ways in which the fifth graders interpreted and solved the problems posed, and the role of the teacher in
supporting and guiding her students’ mathematical development. In the course, we coordinated the use of these modules with message board discussions (Bringelson and Carey, 2000). The use of the message board allowed the students to continue discussions initiated in class sessions as well as to debate new ideas that emerged.

The design of these modules is founded on a “challenge based” learning environment (Bransford, Brown, and Cocking, 1999; Brophy, 2000; Schwarz, Brophy, Lin, and Bransford, 1999; Schwartz, Lin, Brophy, and Bransford, 1999). Brophy (2000) defines modules as the combination of challenges and learning activities.

A course using modular design divides up its content into learning activities that target specific concepts germane to that domain. Based on cognitive research, one effective instructional method is to anchor specific domain content around challenges that exemplify the utility of that content. The challenges will be the entry point into a series of learning activities designed to help students explore the concepts related to that challenge (p. 2).

Each of the modules begins with a brief overview to give the future teachers an idea of the mathematical topic being addressed together with background information about the students and the instructional setting. In the first challenge, we ask the pre-service teachers to identify essential aspects of the mathematical concepts being addressed and to speculate about what they think students will already know and what they can learn about the concept. By asking the pre-service teachers to make their thinking explicit, we gain insight into their suppositions and assumptions about learning and teaching in this particular content area. In addition, the pre-service teachers’ initial thoughts serve as a benchmark that can support reflection and self-assessment (Schwartz, Brophy, Lin, & Bransford, 1999). Against this background, the pre-service teachers then tackle challenges based on short video-clips taken from classroom episodes or student interviews. In the Patterns and Partitioning module, for example, they compare representative excerpts from pre- and post-interviews of the same children. As the shift in the students’ thinking is quite significant, they are intrigued about what brought about this change. This interest serves to motivate their engagement in the major challenge of the module in which they work in groups to investigate different aspects of the classroom during the five weeks of instruction. These aspects include mathematical tasks, classroom discourse, the role of mathematical tools, classroom norms, students’ thinking, planning for instruction, and role of the teacher. For each aspect, the students have access to resources to support their investigation, assess their progress, and publish their final analysis online. Each group also presents its findings during a class session as preparation for the final challenge of the module in which the future teachers step back to investigate how the various aspects of the classroom that they have investigated relate to each other. In this challenge, the papers that they have published serve as the primary resource.

We have recently finished our first pilot of the web-based modules in a master’s level advanced teaching of elementary mathematics methodology course. Overall, the feedback that we received from the future teachers in the form of surveys, message board postings, and class discussions has been positive and informative. Many of the future teachers indicated that they were initially skeptical about the value of the message board but came to appreciate this additional forum for discussion. After the completion of each module, the future teachers completed a survey to help us improve the modules and message board. The surveys asked the future teachers to focus on the modules as a means of supporting their learning and included the following questions:

1. As you have completed the challenges and engaged in the associated discussions on the message board, what are the most important things you have learned?
2. What problems and issues relating to the teaching of mathematics became important to you as you completed the challenges?
3. How could the Patterning and Partitioning/Investigations in Teaching Geometry module or the way that it was used in this class be improved?
4. To what extent did you find either set of modules to be repetitious after completing each? (This question was included on the second questionnaire.)

The issues that emerged from the surveys, message board discussions, and in-class feedback were relatively consistent. The future teachers commented that they were able to gain a relatively cohesive sense of how to sequence instructional activities. Equally importantly, they reported developing an appreciation
for the importance of conceptualizing content in terms of quantities and their relationships, how to understand, assess, and support students’ learning, being able to recognize in action the contrast between instrumental and relational understanding, and simply, making mathematics meaningful for all students.

The following two observations are representative of the general thrust of the future teachers’ comments:

“The most value [to me] was the concrete set of lesson sequences which we went through in the class. Most of my other teaching and learning classes seemed to have glossed over the actual content and methods of teaching. This class gave me a good understanding of how to understand and teach numeracy, place value, geometry, and fractions.” (J.D.)

“The modules [specifically, geometry] provided a model teacher who was able to learn what students were thinking by asking the simple question, why? She explored the rationale behind both correct and incorrect answers, which helped her know their understandings, and sent a message to the students that everyone’s thoughts were valued, not just students’ right answers. Through asking about student thinking, the teacher also discovered that students took alternative paths to the right answer. As the teacher gained a better understanding of the students’ thinking, she was then able to tailor her future instruction.” (E.M.)

The future teachers also commented on the usefulness of the message board to continue discussions that would otherwise have been curtailed due to the time constraints of class sessions. As we have noted, the message board was used not only to continue in-class discussions, but also as a location for posting initial thoughts and assignments within the modules. The future teachers indicated that they felt comfortable communicating with fellow students on the message board. In addition, they appreciated knowing that their peers were dealing with similar issues as this made it easier for them to verbalize their thoughts about topics and concerns that arose from in-class discussions, readings, and assignments. It would therefore appear that the platform of the message board was relatively unobtrusive in allowing the future teachers to pose questions and receive constructive comments from one another between class sessions. These exchanges were also valuable to us in that they enabled us to develop insights regarding the future teachers’ understandings as we monitored our progress in achieving the goals we had established for the course. We were able to document the extent to which they were developing an increased awareness of a teacher’s ongoing decision making, ways of adjusting lessons, and the diversity of students’ thinking and the process of their learning. Chat room facilities were included with the message board, but the future teachers did not take advantage of this opportunity. However, several commented that they wished the instructors had encouraged them to use this resource for communicating with each other more strongly.

The feedback we received about ways to improve the modules and how they could be used in future courses was substantial and constructive. A number of the students commented on the technical difficulties that they encountered, especially when attempting to access the modules from off campus locations. This was due to the limited bandwidth that some of them used to access the large amount of video included as a resource on each module. We made efforts to eliminate such technical problems during the course by providing each future teacher a CD ROM of each module so that they could view the video without accessing the website.

In addition to commenting on these technical difficulties, a significant number of future teachers indicated that they would have increased both the frequency and length of in-class discussions of their responses to the challenges. This suggests that the supplemental message board discussions were not, by themselves, adequate. Several of the future teachers also made observations about what they regarded as the limited range of video available as a resource. They wanted additional video-clips that captured the students’ and teacher’s perspectives on classroom events, as well as more examples of students’ activity in the classroom. In regards to the last survey question that asked them about repetition between the two modules, the future teachers stated that they felt that several topics of discussion did overlap and that the major challenges in the two modules should be adjusted accordingly. The majority of the future teachers also volunteered that they had experienced difficulties in writing a group paper. However, from our perspective, this group challenge is justified with the reality of writing and publishing in any field, especially teaching. The future teachers’ feedback therefore indicates that we need to consider developing additional resources to support collaborative writing.
Finally, several of the future teachers suggested reversing the order of the modules. We introduced *Patterning and Partitioning* before *Investigations in Teaching Geometry* due to grade level considerations. However, the future teachers said that both the shorter length of the instructional sequence covered in *Geometry* module and its mathematical content would have made their introduction to the use of modules and to instruction that focuses on students’ thinking easier.

As is the case in any innovation or design change, we have developed conjectures about ways to improve or adjust the sequencing of instructional activities. As we reflect upon the course and revisit both the nature of the instructional activities and their sequencing, we have many changes to consider. As a consequence of using the modules, we found it impossible to focus on the specifics of teaching in as many mathematical contact areas as when we have previously taught the course. However, this limitation is, in our judgment, more than counterbalanced by a number of positive developments that we observed earlier in the semester than in previous iterations of the course. In particular, the students seemed to approach the activities in the course as future teachers rather than university students far earlier than we had witnessed previously. In addition, they moved quickly beyond the discovery/direct teaching dichotomy and developed a shared agenda that involved a strong sense of themselves as change agents. Our students, or rather, our future teachers, also appeared to develop an initial understanding of the subtleties and complexities of teaching mathematics early in the semester as they completed challenges in the *Patterns and Partitioning* module. This, in turn, led to an awareness that they needed to deepen their own mathematical understanding if they were to be effective teachers. These emerging interests and motivations enabled us to focus explicitly on important aspects of our instructional agenda as teacher educators relatively early in the course. As a consequence of using the modular web-based cases, we were therefore able to address more specific goals and objectives of the course in greater depth than had previously been the case.

Preservice Teachers and Multimedia Design: A Portfolio of Projects

Thomas A. Drazdowski, Ph.D.
Director, Teacher Technology Center
King's College
United States
tadrazdo@kings.edu

Abstract: This paper will review the evolution of our “Multimedia Design” course for preservice teachers since its beginning in the Spring of 1996 and will highlight some of the 300 plus multimedia projects developed by our students to date for use in their clinical experiences, in particular their student teaching practicum. Attendees of this session will receive a CD-ROM of sample multimedia projects.

“It was the best of times, it was the worst of times.” I think the author may have been describing life as a technology professor in a preservice teacher education program. My initial experiences with trying to integrate technology into a teaching curriculum dates back to the early 80’s (Drazdowski, 1985) when I was the seventh grade language arts teacher on a middle school teaching team in Juneau, Alaska. Although the technology has evolved dramatically since the days of the old Apple Ile, the concept of infusing technology throughout the curriculum is still very pertinent to teacher education programs today. It has now been five years since the education division at my college began the metamorphosis of its traditional “Methods of Instructional Design” to a course in “Multimedia Design” (Drazdowski, 1997). What a strange, fine trip it’s been. It has certainly made coming to work each day exciting, unpredictable, and for the most part fun for the instructor and students alike.

Although the education division continues to face many of the same barriers to implementing technology that are often cited in many national reports (CEO Forum, 1999; Milken Exchange, 1999), the division continues to make successful strides forwards. Students are using our portable wireless laptop lab of iBooks to create iMovies of public service announcements in their “Foundations of Education” course (Dills & Ayre, 2001), to create concept maps using Inspiration software in “Educational Psychology,” and to investigate websites and webquests in their math and science methods courses. Electronic portfolios are on the near horizon. All education majors are also required to take a “Computer Applications for Educators” course that is closely aligned with NCATE and ISTE (2000) technology standards for beginning teachers. And students in the “Multimedia Design” course have designed and created some 300 multimedia projects for use in their various clinical experiences.

Below is a brief summary of some lessons learned through our technology efforts over the past decade: a.) a combination of required technology courses and infusion of technology throughout the entire teacher education curriculum is most effective (Duran, 2001); b.) sustained administrative support for experimentation and vision is critical (Mehlinger & Powers, 2001); c.) risk takers and change agents among the faculty are needed (Strudler, 1991); d.) effectively using technology in specific courses and throughout the curriculum gives professors the opportunity to model concepts from constructivism (Jonassen, Peck, & Wilson, 1999; Sprague & Dede, 1999; Ferguson, 2001), problem-based learning (Boud & Feletti, 1991; Lieux, 1996), and collaborative and cooperative learning; e.) students need access to technology in their field settings and need to be placed with technology using cooperating teachers; f.) your students will always make you look good.

The multimedia projects created to date are as varied, complex, and creative as the students themselves. Since early childhood, elementary education, secondary education, and special education majors are all required to take the “Multimedia Design” course as part of their “Professional Semester,” the topics can range from healthy teeth to Hamlet, from the ABC’s to American literature, from a simple addition game to geometry theorems, or from parts of a plant to genetic crosses. As students present their
various projects to the class each semester, lesson "f" is continually reinforced: “Your students will always make you look good!”

judyl@purdue.edu

Abstract: Given the difficulty involved in trying to arrange successful classroom technology experiences for preservice teachers, this study was designed to examine whether electronic models of exemplary technology-using teachers, presented via CD-ROM, could provide a viable alternative for developing ideas about, and self-efficacy for, technology integration. Sixty-nine students enrolled in a one-credit technology course completed demographic and online survey instruments before and after interacting with a CD-ROM that featured six teachers' classroom technology beliefs and practices. Results suggest that electronic models can significantly increase preservice teachers' ideas about and self-efficacy for technology integration. Furthermore, students' found the examples of teachers included on the CD-ROM to be both realistic and relevant. Implications are discussed as well as suggestions for future research.

Theoretical Framework

New teachers today, despite possessing adequate technical skills and a strong desire to use computers in their classrooms, still report not feeling well prepared to teach with technology (NCES, 2000). Clearly, the growing increase in teachers' technical skills is insufficient to guarantee the effective use of technology in the classroom. In order to translate skills into practice, teachers need specific ideas about how to use these skills to achieve meaningful learning outcomes. While today's teachers are expected to leverage the full potential of powerful conceptual technology tools to meet the changing needs of their students, they have been given few, if any, opportunities to develop their own visions for, or ideas about, meaningful technology use. As Dexter, Anderson, and Becker (1999) explained, "For teachers to implement any new instructional strategy, they must acquire new knowledge about it and then weave this together with the demands of the curriculum classroom management, and existing instructional skills" (p. 223). Teachers need information about how, as well as why, to use technology in meaningful ways. Lack of knowledge regarding either element can significantly decrease the potential impact that these powerful resources might have on student learning.

Yet even the best ideas about technology use will go unused unless teachers believe that they are capable of implementing them in the classroom. In particular, teachers' beliefs about their ability to use computers in instruction may be key, given the role self-efficacy is proposed to play in determining behavior. Self-efficacy refers to personal beliefs about one's capability to learn or perform actions at designated levels (Bandura, 1997). According to Bandura, "beliefs of personal efficacy constitute the key factor of human agency" (p. 3). Thus, teachers who have high levels of efficacy for teaching with technology are more likely to participate more eagerly, expend more effort, and persist longer on technology tasks than teachers with low levels of efficacy.

Researchers in the area of self-efficacy describe four primary sources of information that can influence
judgments of efficacy: personal mastery (successful task completion), vicarious experiences (observing models), social persuasion ("I know you can do this"!), and physiological indicators (emotional arousal, relaxation). Next to personal mastery, vicarious experience provides the most valid information for assessing efficacy (Schunk, 2000). According to Olivier and Shapiro (1993), "vicarious experiences with the computer increase one's feelings of control and confidence" (p. 83). Given the logistical difficulties involved in providing preservice teachers with enactive experiences related to successful technology integration, teacher educators have turned to modeling as a feasible, yet powerful, method for increasing teachers' ideas about and self-efficacy for technology integration (Schrum, 1999). Not only can models provide information about how to enact meaningful technology use but they can increase observers' confidence for generating the same behaviors (Schunk, 2000).

Many factors have been shown to influence observers' responses to models including the prestige and competence of the models, consequences experienced by the models, perceived similarity of the models to the learners, as well as learners' own self-efficacy for performing the behaviors (Schunk, 2000). However, research has yet to establish whether models, presented electronically, can be used to achieve results similar to those achieved with live models. Will learners perceive themselves as similar to models that are presented electronically? Will they regard the models as both realistic and relevant? Given the increasing potential to present models of exemplary technology use via multimedia technologies, it is important to determine the extent to which pre- and inservice teachers can benefit from observing these types of electronic models.

**Purpose of the Study**

This study was designed to examine the effects of electronic models on preservice teachers' perceived ideas about, and self-efficacy for, technology integration. Specifically, exemplary technology-using teachers were presented via a CD-ROM teacher development tool, called VisionQuest (VQ). VisionQuest features the classroom practices of six k-12 teachers and is designed to support users' reflections on both the underlying beliefs and classroom strategies that enable exemplary technology use. Given the few opportunities preservice teachers have to observe exemplary technology use in actual classrooms during student teaching or observation sessions (Vannatta & Reinhart, 1999), VisionQuest was developed to provide these opportunities. Specifically, the research questions were:

- What effect does observing exemplary technology-using teachers, presented electronically, have on preservice teachers' perceptions of ideas about technology integration?
- What effect does observing exemplary technology-using teachers, presented electronically, have on preservice teachers' perceptions of self-efficacy for technology integration?
- What are students' perceptions of the use of electronic models for learning about technology integration?

**Research Design**

A pretest-posttest research design was used to examine increases in preservice teachers' ideas about, and self-efficacy for, technology integration following two 50-minute class sessions in which students used VisionQuest. Of the 103 students enrolled in six sections of an undergraduate educational technology course, 69 students signed a consent form and completed all three data collection measures needed for the study. Participants ranged in age from 18-34 years (M = 20). The majority of the students were female (65%), sophomores or juniors (71%), and majoring in Elementary Education (60%). When asked to rate current levels of computer skills, 75% of the students rated their skills at an intermediate level while 9% rated themselves as beginners; 16% rated themselves as advanced. None of the students rated themselves as novice users.

**Methods**

Demographic information was collected during the first class session of the semester. During weeks 10 and 11, as part of their normal class activities, all students worked with VisionQuest, completing two different tasks.
During the tenth week, students evaluated VisionQuest as an example of professional development software. Students focused on content the following week when they used VisionQuest as a modeling tool to examine the beliefs and classroom practices of the teachers included on the CD-ROM. Students were asked to describe how the different teachers prepared their classrooms for technology use, how they used various grouping strategies to manage their rooms, how they managed classroom "chaos," and so on.

At the beginning of the tenth class session, prior to evaluating VQ, students completed an online survey designed to collect three types of information. First, information was collected regarding students' computer ownership, current use, and perceptions of skills and comfort using computers (e.g., "I enjoy working with computers." "When using computers, I can deal with most difficulties I encounter."). Eight items comprised this initial section. The second section included seven items regarding students' ideas for technology use (e.g., "I have ideas about how to use one computer effectively during large group instruction."). Items were presented in a Likert-style format; students were asked to rate their level of agreement (from 1-strongly disagree to 5-strongly agree) with statements related to the possession of specific ideas regarding technology use. The third section used the same seven items but with an emphasis on the possession of confidence rather than ideas (e.g., "I am confident I can use one computer effectively during large group instruction."). Students used the same rating scale to record their levels of confidence. Students' responses to the online surveys, prior to using VQ, comprised pretest measures of students' perceived ideas about, and self-efficacy for, technology integration.

At the end of the eleventh class session, after students had explored the ideas presented by the models on VQ, students completed the second and third parts of the online survey again. These measurements served as posttest indices of students' perceived ideas about, and self-efficacy for technology integration. In addition, four items were included to explore students' perceptions of using VQ as a modeling tool (e.g., "I can relate to the examples of teachers shown in VQ." "I can relate to the examples of technology shown in VQ.").

During both class sessions in which students interacted with VQ, one or two researchers were in attendance, making observations of students' engagement with the software. Observations provided evidence of the "holding" quality of the software and also provided useful information for the selection of interviewees. Students were purposefully selected for interviews (one or two per section) based on noted levels of interest, with an attempt to choose one highly- and one less-engaged student from each section. Interviews were scheduled at a time convenient to each participant and were audiotaped and transcribed by the interviewer. Interviews focused on identifying specific ideas (about classroom organization, assessment practices, etc.) that students gained from VisionQuest and the extent to which they thought they would use these ideas in their classrooms. We were particularly interested in knowing whether students regarded the VQ models as "real" and whether they believed that they had learned from them, just as they might learn from live models.

Results and Discussion

Students' Perceptions of Ideas and Self-Efficacy for Technology Integration

A two-tailed paired t-test (df = 68) indicated a significant increase in students' ratings of perceived ideas about technology integration (t = 8.85; p < .0000) from pre- to post survey. A two-tailed paired t-test (df = 68) also indicated a significant increase in students' ratings of perceived self-efficacy for technology integration (t = 3.46; p < .000) from pre to post survey.

Based on a critical r value (df = 66) of .35 (p = .0005), correlations among demographic characteristics and pre- and post- ideas and self-efficacy indicated no significant relationships among age, gender, or year in school (freshman, sophomore, etc.) and ratings of computer skills, ideas, or self-efficacy. Although one might expect advanced college students (e.g., juniors and seniors) to have more skills, ideas, or confidence, this was not the case here. Furthermore, there were no significant relationships between gender and any variables examined in this study.

Significant correlations were found between students' perceptions of their ideas for technology integration, before and after using VisionQuest (r = .61); similarly students' perceptions of self-efficacy for technology integration (r = .50) were significantly correlated before and after using VisionQuest. Additionally, perceptions of ideas and perceptions of confidence were significantly correlated. Students who began with greater perceptions of ideas, also tended to have higher levels of confidence (r = .72). This relationship was even
stronger at the time of the posttest \( (r = .84) \). That is, the more ideas students had about technology integration, the stronger their beliefs that they can be successful integrating technology into the classroom. As ideas increased, so, too, did confidence for implementing the ideas.

Interestingly, judgments of computer competency (skills) were not highly correlated with either ideas or confidence for technology integration. This supports earlier research findings (Yildirim, 2000) that suggest that simple skills training is insufficient to prepare students to use technology in the classroom. In fact, students' perceptions of the direct usefulness of their skills may have decreased after seeing how the teachers on VisionQuest were not dependent on high skill levels, although this conjecture requires further examination. Furthermore, skill competency did not seem to translate into confidence for achieving integration either pre- or post-VQ \( (r = .18 \) and \( .26 \) respectively). Just because students know how to use word-processing, email, and the Internet, does not mean that they know how to use these skills within classroom instruction or that they are confident trying to do so.

Based on the correlations obtained, providing preservice teachers with specific integration ideas (e.g., how to organize a classroom that uses technology, how to assess student technology products) via electronic observations of technology-using teachers may be more effective than skills training for increasing their self-efficacy for technology integration. Furthermore, by increasing future teachers' self-efficacy, we increase the probability that these behaviors will be implemented in their future classrooms. According to Olivier and Shapiro (1993), "Self-efficacy has been shown to be an excellent predictor of behavior. Individuals with a low sense of self-efficacy will, more often than not, shy away from the best alternative, and, instead, choose an alternative that they believe they can handle" (p. 84). Even when practicum and student teachers possess "positive dispositions towards computer use," they often lack confidence in their ability to teach successfully with computers (Albion, 1999). This lack of confidence for teaching with computers has been shown to influence the levels of computer use by student and beginning teachers.

**Students Perceptions' of Learning from Electronic Models**

Interviews with 10 students, as well as data obtained through four post-survey items and two software evaluation questions, were used to answer our research question regarding students' perceptions of using electronic models to learn about technology integration. Interviewees were representative of the students enrolled in the class; interviewees included both male and female students who ranged in age from 18-34 years and in skill levels from beginner to advanced.

Two questions on the software evaluation form asked students to rate the relevance of the activities and models observed on VQ. On a scale from 1 (strongly disagree) to 5 (strongly agree), students agreed to strongly agreed that "activities regarding the use of technology were realistic" (mean = 4.46) and that "the video cases of teacher interviews and class activities were relevant" (mean = 4.31). Four similar questions included on the post survey averaged a 3.96 rating indicating that students' perceived the VQ models to be both realistic and relevant.

Although students had suggestions for improving the software (particularly in terms of navigation, which was unfinished at the time), interview comments were overwhelmingly positive. Students viewed the models as realistic, indicating that they felt as though they were in the classrooms with the teachers. Students described the "life-like" quality of the videos and how they felt that the teachers were talking directly to them (S: I felt like they were talking to me as a teacher and not as a student). As an example, one student stated:

I liked it. I liked how I got involved when it showed you (the clips) and you felt like you were right there in the classroom with the students watching them. It's like you're in a movie theater almost because they have such good (videos)... and it shows the students and it shows the teachers – and you feel like you're right there in it.

Based on these results it appears as though students both enjoyed and benefited from observing the electronic models provided on VisionQuest. Interview comments suggest that preservice teachers perceived that the use of electronic models was a positive approach that provided "life-like" learning experiences.
Educational Implications

Data from this study support our hypotheses that electronic models can be used to increase preservice teachers' ideas about and self-efficacy for technology integration. Even though students used VisionQuest for a relatively short period of time over the course of two class sessions (approximately 90 minutes total) and were unable to explore the entire content of the CD-ROM, students showed significant increases in both their perceived ideas about and self-efficacy for technology integration. Interview and software evaluation comments indicated that students found the models to be both realistic and relevant. Students described a number of specific ideas that they gained from the models and furthermore, described their intent to apply these ideas within their future classrooms.

Students' pre- and post- ratings of their ideas and confidence were not significantly correlated with their judgments of skill levels, suggesting that computer skill competency does not translate directly into ideas or confidence for classroom technology use. However, there were significant correlations between students' perceived ideas and confidence, especially at the time of the posttest suggesting that as students see new ways to use technology and develop new ideas about technology integration, they develop higher levels of confidence about their ability to use technology in a variety of ways.

The results of this study suggest that preservice teachers can benefit from observing teacher models presented via multimedia case examples, such as those featured on VisionQuest. Whether delivered via the Web or CD-ROM, multimedia models are becoming more readily available for use by teacher educators. These types of examples can be incorporated into an educational environment for self-paced exploration, as a small group reflection tool, or as an instructor-led activity. From an instructor's perspective, electronic models can positively impact the authentic nature of a course and simultaneously increase the confidence and integration beliefs of students. This type of modeling can help preservice teachers develop a vision for what technology integration looks like in real classroom as well as strategies for implementing those visions.

How and when do students become “invested” in online collaboration?

Richard Ferdig, University of Florida, US
Heather A. Davis, University of Florida, US

Teacher candidates often express concern with the conventional pedagogy of their methods classes, complaining of a need to see challenging, reform-oriented teaching in action (Ferdig, Hughes, Packard, & Pearson, 1998; Hughes, Packard, & Pearson, 2000). They describe instruction that is limited to articles, books and lectures about methods of teaching reading and writing (Ferdig et al., 1998). Most universities have responded to this call, supplementing students’ in-class experiences with classroom observations and internships. However, even when provided with these opportunities to ‘watch’ pedagogy in action, pre-service teachers often fail to see (or are failed to be provided with) teaching models that align with the focus of university pre-service preparation programs (Kinzer & Risko, 1998).

Educational researchers have responded to this problem by introducing web-based learning environments that attempt to supplement preservice teacher education through technologies such as web-based learning environments (Ferdig, Roehler, & Pearson, 2001). Research in this area provides evidence that this form of instruction and electronic medium can be successful. In one study, Ferdig, Roehler, and Pearson (2001) found evidence that students who participated in the electronic forum were more likely to demonstrate a deeper understanding of pedagogical diversity as well as a more complete approach to the teaching and learning of literacy. In a different study, students who posted more frequently to an electronic discussion forum (and thus participated most in the assigned classroom activities) reported both increased interest in the course and mastery of the material (as evidenced by their self-evaluations and class journals) (Davis & Ferdig, 2001). In both cases, students had the opportunity to become meta-analytic and meta-cognitive about their participation and journey towards becoming fully enculturated into the community of practice known as teaching.

Unfortunately, in both cases, researchers reported data suggesting these claims were substantiated only when students became “invested” in the technology. In other words, gains and successes were measured only when students fully participated in the electronic activity. Neither case reported the process in which students became invested, nor did they describe the characteristics or context under which students became emotional, intellectually, and behaviorally involved in the activity. In both cases, authors called for future research to examine and define exact contexts in which students would become invested in both the classroom integration and the new technology.

The purpose of this paper is to discuss, from a psychological perspective, ways in which several preservice teachers became invested in electronic innovation. We describe how supplemental discussion forums were used in preservice education courses to further students’ a) skills and abilities in working with diverse populations of students; b) knowledge and adoption of psychological and developmental theory; and c) ability to integrate cutting-edge technology innovations into their instructional design. Most importantly, we describe characteristics of electronic learning contexts in which students are most likely to become invested emotional, intellectually, and behaviorally.

References

Teacher candidates often express concern with the conventional pedagogy of their methods classes, complaining of a need to see challenging, reform-oriented teaching in action (Ferdig, Hughes, Packard, & Pearson, 1998; Hughes, Packard, & Pearson, 2000). They describe instruction that is limited to articles, books and lectures about methods of teaching reading and writing (Ferdig et al., 1998). Most universities have responded to this call, supplementing students’ in-class experiences with classroom observations and internships. However, even when provided with these opportunities to 'watch' pedagogy in action, pre-service teachers often fail to see (or are failed to be provided with) teaching models that align with the focus of university pre-service preparation programs (Kinzer & Risko, 1998).

In response to these concerns, we developed the Reading Classroom Explorer (RCE). Originally a CD-ROM product for the Macintosh, the current iteration of RCE is a web-based learning environment for pre-service teachers studying literacy instruction. The goal of RCE is to provide multiple opportunities for teacher candidates to develop rich understandings about teaching and learning in classrooms where diversity of pedagogical approaches and diversity of student populations are evident (Ferdig, Roehler, & Pearson, 2001). An RCE user logging into the system is provided with an opportunity to search over 300 movie clips using four different search mechanisms.

First, they may decide to search by school or “case.” RCE contains movies from ten major elementary school ‘cases’ from throughout the United States (i.e. Hawaii, San Antonio, Harlem, and Lansing). Students may choose to watch the entire video from a case (~45-60 minutes), or they can select specific components within that full case. A second option is to select movie clips by choosing a Theme. Much like a table of contents, the themes are broad categories divided by “Teacher”, “Student”, “Curriculum”, and “Context.” Examples of themes include “Assessment”, “Planning”, and “Management Strategies.” Users might want to search more specifically, and thus they would choose the third option of searching by Keyword. If the themes are like a table of contents, then the keywords are the index for that book. Keywords are much more specifically designated, and include words like “book clubs” and “decoding.” A fourth and final way to search is to use a free-form text search, referencing text that is either in the transcripts or the general description of a clip.

Once a movie clip is selected and the title is clicked, the user is sent to a webpage that contains the video and any related information for the clip. Using Real Player, a user only has to wait 3-4 seconds for the video to begin playing—one of the major benefits of a web-based system. The transcript, related keywords and themes, links to artifacts that may appear in the clip (e.g., pictures of students’ work shown in the clip), and any other related information also appear on the page. In order to stimulate further thought on the video, questions—and a notepad to save responses into—are provided for each individual clip.

One of the problems with a CD-ROM based product is that interaction between students is limited to those students working together, or a “share-time” provided by the teacher after using the tool. Since RCE has moved to the web, we are now able to provide students with scaffolding through social interaction. For instance, if a user wishes to see what others thought about the movie clip, he or she merely has to click on a button and anonymous responses (provided the user has granted permission) pop-up in a new window. Or, if a user has a specific question, they can go to the “RCE Discussion Forum”, where messages are hierarchically saved in either a “General Room” or a room designated specifically for that students’ class (provided they are part of a class). At any point in time, a student has access to all of their notes, which is important if a student decides to write and/or submit a paper online. RCE provides the opportunity for students to write papers that include links to specific movie clips discussed in their paper, and then electronically publish that paper to their teacher, their classmates, or RCE users as a whole.
Up until now, we have basically described the user side. RCE also has a “teacher” side. The teacher can log-in at any time to read student papers and to answer questions from their students. They can also go to their own discussion forum to discuss ideas (i.e. collaboration) with other RCE instructors. Finally, RCE instructors can create, save, and search saved lesson plans regarding implementing RCE into the curriculum.

In recent studies, data has been collected that suggests RCE is beneficial to instruction in a number of ways. For instance, evidence suggests that students using RCE, and specifically the discussion forum in RCE, are more likely to demonstrate a deeper understanding of teaching and learning (Ferdig, Roehler, & Pearson, 2001). They are also able to relate what they have learned to experiences outside of the RCE learning environment (their internship, other classes, etc.). Research is currently being conducted that explores issues of diversity, as well as dispositions and skills related to literacy instruction before and after the use of the Reading Classroom Explorer.

The purpose of this interactive session is to present audience members with a new web-based learning environment for preservice education. Audience members, specifically those who teach preservice methods classes, will be invited to use the web-based learning environment in their own classroom. More importantly, they will also be invited to join the RCE research team in exploring innovative ways to teach preservice teachers about pedagogical and student diversity. Novice and expert technology users are invited to attend, as minimal technology expertise is required. Specific objectives of this presentation include:

1. exploring an innovative web-based learning approach to preservice education
2. discussing new integrations for teacher education that highlight pedagogical and student diversity
3. discussing research techniques and possibilities for innovative learning technologies

Distributed Learners – Motivated Classrooms
Building Class Knowledge

adharkar@macromedia.com

Abstract: Using technology requires wide expertise. Teachers need expertise for everything from troubleshooting everyday hardware and software problems to helping students keep up with the latest technology. This need for expertise can place a large strain on the teacher as the sole provider of information. One method that can be modeled in teacher education programs and in the classroom to alleviate this strain and model professional work practices is to distribute some of the knowledge and responsibility among students. In professional work teams one person is rarely the expert on all topics, so the team shares information to accomplish team goals. Similarly, students can become experts in some areas and share their expertise with their class. Small student groups can be formed where each group has two main roles. In the first role, the group helps with general tech support for the classroom. If a question comes up in the classroom about using the scanner, a student group would use class reference materials to find a solution before approaching the teacher. Students gradually learn how to handle more basic tech support issues on their own. The second role of the group is to bring new knowledge into the classroom. Each week a student group researches technology innovations relevant to class work or background information on a class technology topic. They present this research to the class to share their new knowledge. In this model students are in charge of seeking knowledge and helping to build collective classroom knowledge. This yields empowerment for the student, ownership over their learning, and a model for bringing in new information to the classroom.

With the advent of technology standards and a greater need for students to be prepared for a technologically complex world, teachers are required to gain greater technological expertise. Coupled with the need for technology expertise is the need to be prepared for new forms of changing and advancing technologies. Technology integration results in a classroom that requires constant upkeep and updating of that technological knowledge. Although professional development workshops exist to help teachers “catch-up” with new technology and technology implementation methods, how can teachers learn about new technologies while being able to support present technology in the classroom? This dual problem can be addressed by modeling class management methods in teacher education classes that can be transferred to student classrooms. Distributing the learning process for understanding implemented technology and for incorporating new technology can help teachers survive the changing environment that results from technology integration while helping them stay updated on current technology.

Tech Support Teams
One method to help support present technology use in the classroom without deep expertise would be to engage the help of students in technical support. For example, students can volunteer or be placed in small teams in charge of technical support for the class. These teams are asked to use the Internet, help manuals, and software support books for find answers to basic software issues before approaching the instructor in the class. This management method helps students learn details about the software while alleviating the need for the instructor to be a software expert. This method will also help students learn different pathways for help support systems. In professional work environments, there is rarely one person who knows how to solve all the technical
problems and therefore solving these problems requires team members to seek out answers. Students learn the various ways that professionals use to seek out answers. Although students may not always solve the technical problem, they will learn to use the resources available before approaching the instructor. If the students are unable to uncover the answer, the instructor can address questions that cannot be answered from this pathway. Students become more self sufficient in organizing methods to help themselves and others. Teacher education or professional development workshops that model finding help support and building the help support pathway, will help teachers learn to deal better with technology problems that arise in the classroom, without losing time and attention with students. This action also prepares the teacher to become more of a facilitator in the classroom rather then the pinnacle of knowledge for students. Teacher become better able to adapt to new versions of existing technology, since they are prepared to answer questions or help students understand how to answer new questions without spending large amounts of time becoming experts in that technology.

New Technology Research Teams
Technology is dynamic and new forms of technology emerge daily. When using technology in the classroom, instructors need to be prepared and keep their students apprised of any new developments in this field. How can instructors keep up with the newest technologies as well as how these technologies impact the future of the field? One method is to have an ongoing seminar series where small groups of students are designated “research teams.” These teams are responsible for introducing new technology topics to the class. Students not only model professional practice, but also become proactive about their learning. Similar to professionals who must always stay apprised of the most current technologies and trends, students will contribute to the class ability to be aware of the most current technologies and trends. The class builds its own knowledge and sets up a model for keeping up with technology. The instructor re-asserts the role of the facilitator instead the sole provider of knowledge.

Conclusion
Distributing tasks among students helps the instructor manage technology issues in the classroom. Students are responsible for learning pathways that seek help, while supporting and improving collective knowledge by bringing new information into the classroom. Modeling this methodology helps future teachers empower students to become proactive in their education while utilizing professional practice, which gives more validity to their work and supports the idea of an instructor as a facilitator. The main benefits for teachers are the following:

- Teachers can concentrate on the content of the project or unit
- Processes of thinking, and problem solving are emphasized
- Students have ownership of both content and process
- Learning is natural and student-centered

Systematic Observation of Student Teaching Episodes

Warren Gamas, Minot State University, US
Kevin Prusak, Minot State University, US

Introduction
Our question was simple. What can we do to best prepare preservice teachers for the rigor of their first year of teaching. We believe that good teaching behaviors are quantifiable, transferable, and masterable. Good teaching behaviors can be observed and measured, they can be learned by observation and practice, and they can, with practice, become a natural part of a person's teaching presence. Our response was to focus on developing a Pedagogy Lab; a high-tech facility for video viewing, editing, and recording designed for student use in documenting their own teaching episodes. This short paper reports on the system implemented within the Pedagogy Lab including the hardware selected, student process developed, and lessons learned in the course of the first year of the Pedagogy Lab.

The Pedagogy Lab
The Pedagogy Lab is a technology lab designed to facilitate student learning in identifying, learning, practicing, and mastering specific teaching behaviors. To do this, we have created a facility to that allows students to observe and document teaching behaviors using real world examples as well as requiring students to record, edit, and assess examples of their own teaching episodes.

Key Features of Pedagogy Lab
Key features for our Pedagogy Lab include digital video viewing station, digital video editing stations, and digital video authoring stations. Each of these stations fits within one or more of the activities that are in our good teaching cycle.

Viewing Stations
The digital video viewing station allows students to focus on viewing example or their own videos of teaching and quickly documenting specific teacher behaviors. This includes a custom computer program designed to assist students in systematically recording, coding and reporting observed teacher behaviors.

Editing Stations
The digital editing stations use Apple's iMovie for the clipping, titling and output to quicktime for students as they identify and document specific teaching behaviors from their own teaching opportunities. Our custom computer program for recording, coding and reporting observed teaching behaviors will allow students to improve their self assessment of their teacher behaviors.

Authoring Station
The authoring station utilizes Apple's iDVD, students will create final products that document their skills in the teaching environment. DVD output allows students to create feature rich long videos of their teaching performance.

Process
1) Classroom instruction on systematic observation focuses on teaching students to identify specific teaching behaviors.
2) Students review and practice their systematic observation skills by observing non-specific lessons which students will code using the systematic observation computer program within the pedagogy lab.
3) Students record and review their own teaching episodes within the Pedagogy lab utilizing the systematic observation system to identify their own abilities and deficiencies.
4) Make and implement a plan for improvements, further teaching and lab time to assess improvements on specific behaviors.
5) Students may create final products that contain exemplar episodes of their own teaching.

Presentation Outline
If accepted, we will share the development of our systematic observation system, example video episodes, and lessons learned in the first year of our implementation schedule. We will also bring a complete student presentation documenting one student's journey from classroom instruction to completed final product.
A Web-based Solution for Integrating Technology into Teacher Education Courses

Marsha A. Gladhart
College of Education
Wichita State University
Wichita, KS USA
marsha.gladhart@wichita.edu

Abstract. The purpose of this study was to research, develop, and validate a product to assist faculty in meeting accreditation standards for integrating technology into teacher education programs. The design used in this study included three phases of research and development. Phase one used an online survey to determine if teacher educators perceived a need for assistance in meeting technology standards. A prototype of a Website interface to relational databases of information on technology tools and standards was then designed to meet those needs. Phase two involved evaluation and modification of the prototype using focus groups and feedback through an online questionnaire. The third phase involved a field test by teacher educators from two institutions preparing for NCATE review.

Introduction

Even though computer technology and Internet access have become more available in public PreK-12 schools throughout the United States (NCES 2000), teachers have not been prepared to integrate the technology into instruction (Resnick 1999; Trotter 1999; NCES 1999). As a result, teacher education programs have been challenged to better prepare teachers to integrate technology to meet content standards (CEO Forum, 1999). Unfortunately, teacher educators are not always prepared to provide effective models of technology integration (Glennan & Melmed 1996; NCATE 1997; Queitzsch 1997). They lack models and experience with technology, receive few rewards and incentives to integrate technology into their own classes, and do not have adequate professional development and support to develop their own skills (Green 2000).

In addition to increased public pressure to better train teacher candidates to integrate technology, teacher educators are also faced with increasing numbers of standards to be met, both in their content areas and in broader areas of education. NCATE has recently revised accreditation standards to include outcomes-based criteria (Wise 2000). The NCATE standards are broad in scope and are supported by more specific standards developed by professional organizations such as ISTE (NCATE 2000; ISTE 2000). Both sets of standards are new to teacher educators and require new thinking in terms of course goals and objectives.

Integration of technology into instruction requires training in the technology but training alone has not resulted in integration (Barron & Goldman 1994; Cravener 1999; Gilbert 1995; Gillespie; Matthew et al. 1998; NCATE 1997; Rogers 2000; Taylor & Little 1996). Professional development in higher education has been based on the traditional workshop model (Calves 1999; Gillespie 1998; Lieberman 1995). The workshop model has not been as effective by itself as it is when combined with other professional development strategies such as one-on-one mentoring, action research, and more collaborative models (Apple Computer 1995; Darling-Hammond & McLaughlin 1995; Eiser & Salpeter 1992; Howey 1994; Johnson, Johnson & Smith 1991; Valli & Cooper 1999; Webb 1996). Effective training in technology integration involves a constructivist learning environment, situated staff development, time for reflection, team planning for implementation, and ongoing dialog (Apple Computer 1995). Collaboration (Dede 2000; Ringstaff, Yocam, & Marsh 1996), any time, anywhere support (Gilbert 1996), inspiration and excitement (Milone 1999; Rogers 2000), and variety (Milone) also contribute to the success of professional development in technology integration.

Methodology

A research and development model was used to develop the product in this study. Three phases of development included a needs assessment, the evaluation of a prototype based on the results of the needs assessment, and a field test by teacher educators who used the product to identify technology integration...
tools and activities for their own courses. Online questionnaires, focus groups, peer evaluation, and a field study were used to gather feedback and draw conclusions during the phases of development.

Each phase used participants from different populations. The first phase surveyed members of the ISTE NETS*T writing team to determine if there was a need for a product to assist teacher educators with integrating technology. Participants from 11 states responded to the survey. The second phase utilized 2 focus groups in the development of a prototype and an online survey administered to directors of PT3 grants to evaluate the resulting product. The third phase involved 8 teacher educators from 2 Midwestern universities in a field test of the product. The participants represented both elementary and secondary fields in teacher education as well as a diversity of technology background and expertise.

Conclusions and Implications

Phase One

The results of the needs survey in phase one resulted in the most intriguing information of any of the surveys in the study. The results indicated that a majority of the participants in the needs survey believed teacher educators do need assistance in integrating technology. Respondents viewed colleagues in their teacher education program as having more skills than sufficient knowledge to integrate technology. This response may indicate that participants perceived their colleagues as knowing more about how to use technology than how to teach with it. Integrating technology is a multi-layered process. It requires a new or revised pedagogy as well as new technical skills. Teacher educators must rethink how they teach and how the content is conveyed with few models and little experience of their own. They may know how to use the technology for their own productivity without having integrated it into their instruction.

Participants also reported their colleagues were not familiar with NCATE and ISTE standards yet nearly half reported that course syllabi in their programs identified ISTE standards and over half reported indicators of technology skills and concepts were included in their programs. This discrepancy may be a result of technology being taught in computer courses rather than being integrated into curriculum and instruction courses or methods courses. When technology is taught as a separate course, the teacher educators may consider it someone else's responsibility to teach their students how to use technology in instruction. Unless teacher educators were involved in the field of technology it is possible that they would be unfamiliar with technology standards unless they had a technology leader in their midst or were preparing for an NCATE accreditation visit and were held accountable for knowing the standards.

Responses to the question on accountability may explain why programs and syllabi identify technology standards and outcomes but faculty are judged lacking in knowledge and require assistance to integrate technology. Almost three-fourths of the respondents reported that teacher educators were not held accountable for integrating technology. This lack of incentive may account for the lack of actual technology integration.

Because any time, anywhere support is so widely sought, the lack of interest in CD-ROM delivery was surprising. Even paper manuals received a higher ranking than did CD-ROM delivery, either as a manual or in an interactive format. Since paper manuals have the same static content available as CDs, the technology involved in CDs may be the factor. CDs and paper manuals need to be stored and retrieved requiring extra steps for the user while the Web is omnipresent on networked computers. It is possible that faculty are uncomfortable with the installation necessary on some CDs or that they find navigation on the Web more familiar than varying metaphors and navigation on CDs. The Web does have the advantage of being updated as technology and strategies change. However, the Internet can go down and is notoriously slow on some overworked campus networks. The reasons behind the reported preferences, especially for the high ranking of the paper manual, should be clarified by further study.

Phase Two

The positive responses to the feedback form in phase two showed that the prototype of the Web interface was workable but needed improvement. The layout of the integrated lessons was designed by members of a focus group who desired a simple one-page format but wanted to be able to connect to more
information if desired. This feature was easy to accommodate with related databases. Reviewers responded favorably to the primary colors of the Web site and to the metaphor of the robot as their assistant. They judged the content to be accurate, useful, and appreciated being able to browse through the hypermedia environment of the Web.

One of the most interesting comments in the feedback at this point was the comment made by one evaluator that the product appeared to assume that the users had the necessary knowledge to use the technology and only needed to be nudged. Even though the needs survey indicated that the participants in that phase viewed their colleagues as having the necessary skills, this respondent did not think her colleagues knew enough to use the technology. Her experience may be more common than those of teacher educators involved in technology grants and initiatives. To accommodate for this need, more tutorials were added to the technology tools section.

Phase Three

The teacher educators who field-tested Integration Assistant were very positive in their responses about the ease of use and content. Most of the participants found the Web site easy to navigate but several made comments that indicated that they could not find what they were looking for even though the material was there. These comments may reflect a lack of understanding of how relational databases fit together, lack of knowledge about how to conduct a search, or need for better organization of the Web site.

Most comments in phase 3 focused on the content in the databases. Two users asked for more specific examples in their content areas. Another participant asked for more examples in the tour to help search the databases more effectively. In general, the participants were satisfied with the content and found it useful. When asked to identify the least helpful section, several of them responded that none of the sections were "least helpful" and went on to describe what they liked about the product.

Users were invited to enter an activity or technology tool in the Integration Assistant databases. Three of the participants in phase three did enter integrated lessons. The Web interface did not allow as complete an entry as did Instant Web publishing or direct access to FileMaker®. One participant asked to be allowed to enter the activities directly into the Instant Web publishing interface to the database rather than try to fit into the fields allowed in the Integration Assistant interface. Her request pointed out the wide variance in users' skill levels. Other participants in the evaluation stage did not even realize that they were working with a database. Further development of the Web interface could facilitate entry of data by novice users.

Conclusions and Recommendations

The feedback in all three phases of this study indicates that teacher educators do need assistance with integrating technology into their courses. Respondents to the needs survey reported a variety of support was available to their faculty, that faculty had technology skills, and that their programs did specify technology outcomes. In spite of the presence of such support and knowledge, faculty did not have the knowledge necessary to integrate the technology. This discrepancy raises questions related to integration and knowledge of technology. What factors have inhibited acquisition of the necessary knowledge if most of the teacher educators have the necessary skills? Do the rankings of the respondents represent an accurate perception of teacher educators' knowledge? Would the teacher educators rate themselves the same way the participants did?

The efforts of initiatives such as the U.S. Department of Education PT3 grant program should continue to focus on integration strategies in teacher education programs to better encourage teacher educators to model technology integration. If it can be determined that teacher educators actually do have the necessary skills but do not integrate technology, then professional development in SCDEs should focus more on integration strategies and less on skill training. Furthermore, teacher education programs should establish clear measures to hold faculty accountable for meeting standards identified in course syllabi and program documents.

The preference for a Web-based mode of delivery expressed by the respondents to the needs survey should be considered as teacher education programs develop support and training for faculty to meet accreditation guidelines. The Web-based product, Integration Assistant, provided helpful content and a
convenient format for the participants in the study. Feedback indicated that teacher educators wanted more information for themselves and for their students and liked the easy access through the related databases. Textbook publishers and instructional design teams should continue to explore and develop the use of databases and Web sites to share current information on rapidly changing technologies and instructional strategies. Further study on the use of interactive materials in comparison to the use of textbooks and static print materials should be conducted to determine which mode of delivery best meets the needs of teacher educators.

One of the difficulties in designing a Web interface to relational databases is how to organize the information so that it takes few clicks for the users to find the necessary information. While the designer is very familiar with the data and how it is organized, the user does not share that same frame of reference. Further study on human factors that influence the ability to find information would provide useful information for Web developers. The development process of this product raised several questions for study. Does understanding the technology make the search for content easier? How much does technical background affect the user's ability to search and find content? What key factors determine a user's ability to find the desired information? How much and what kind of assistance is helpful in a tour?

Relational databases provide easy access to information and provide an interactive interface between the user and the data. Continual updating of data adds to the timeliness of the information that cannot be reproduced in paper manuals. The technology involved in a Web interface to relational databases requires the developer have the support of a Web designer and a network administrator, have fairly sophisticated skills in developing and using FileMaker©, and have knowledge of how to write scripts for the Web interface. Providing and updating the content is time consuming because the developer must keep current with new resources and continually analyze and enter new information into the databases. Writing descriptions for users with different backgrounds and keeping up with changing technology also requires experience in instructional design as well as a background in technology support. Any further development of Integration Assistant or a similar product would be best accomplished by a team with expertise in Web development and relational databases or by a publishing company.

Integrating Technology Experience into Student Teaching: A Model for Preservice Teachers’ Technology Education

Yi Gong

College of Education, Indiana University of Pennsylvania
Indiana, PA 15701

Abstract: Effective integration of technology into curriculum and instruction has received much attention in education, and teacher education programs are expected to equip the preservice teachers with both technology literacy and teaching methods with technology. In most of the teacher training programs, the common practice is to insert technology-related courses as required courses into teacher education curricula. But it is not a practicable solution to the problem, which is the lack of effective use of technology by new teachers in school settings (Bruder, 1991).

In this study, a new model of integration of technology into preservice teacher technology education is explored. The study is conducted in an elementary class setting through a webpage building project. The participants are student teacher, classroom teacher, college technology staff, and students. Before the study, both student teacher and classroom teacher are new to the webpage design. An interview with the student teacher is conducted regarding his technology literacy, proficiency, and attitude toward technology use in teaching. During the process, the student teacher acts both as trainee...
and trainer. As the project proceeds, the role of the student teacher focused more, until totally, on a trainer. The webpage of the class is well designed and uploaded as a result of the cooperation of the student teacher, classroom teacher, college technology staff, and the students. An after-project interview is also conducted with the student teacher. Results show that such an on-site technology experience contributes significantly to preservice teacher’s technology competence and increasing his attitude positively toward using technology in their future teaching.

Learning to See, Learning to Teach: Developing Video Case Studies From One’s Own Practice

Elizabeth L. Haslam, Ph.D.
School of Education
Drexel University
United States
elizabeth.haslam@drexel.edu

Abstract: This paper describes a case study approach in a field seminar for pre-service teachers. Building on the focus of reflective practice, students develop a video segment from a videotaped teaching scenario into a case study format. In the seminar discussions, students present their own case studies to other students, cooperating teachers (who are part of the seminar) and university faculty. The goals of this authentic assessment are to (1) inquire into specific teaching practices pre-service teachers experience through individual ways of knowing; (2) use multimedia tools as partners in inquiry and meaning-making; (3) connect teaching performance, best practice standards and reflective assessment; and (4) use mediated learning in a more conscious and empowering context for continuous learning, research and reflection. The paper includes assessment criteria, examples of the student video cases and implications for pre-service education.

Introduction

During their field placements in student teaching or graduate field experience, Drexel University pre-service teachers participate in a collaborative weekly seminar, reflecting on their field journal entries and learning more about best practices based in constructivist theories (Wilson, 1996). Participants in the seminar include the pre-service teachers (student teachers and graduate field experience students), cooperating teachers who serve as clinical adjunct instructors, and university faculty. In addition, students’ videotapes are studied and analyzed at the beginning and end of their placements. The videos, however, seemed loosely connected to their overall performance goals. What would happen if the students were asked to develop their own video cases in the context of best practice, selecting a focus that had relevance and meaning for them? Would learning to see help them learn to teach? Students were asked to select a segment from a videotaped session that had presented a teaching/learning example in the context of best practice. Next, the student was to write a case description of the background context, why they selected this focus, what the audience should look for, and what they planned to do next. They presented their video cases during the seminar meetings.

Video Case Features

The video case assignment is regarded as an authentic assessment that would “challenge students to apply new academic information and skills to a real situation for significant purpose (Johnson, 2002, p. 165). This approach develops the students’ abilities and learning in several important ways. First, inquiry into one’s own practice is at the heart of making sense and meaning out of one’s individual experience and helps students find their own creative and unique solutions in a collaborative context. Second, students use multimedia tools, such as video, as partners in their inquiry. Through video, a holistic scenario unfolds that facilitates learning on cognitive, sensory and emotional levels (Laurel, 1993). So much of what we learn as teachers is learned through our thought, senses, and feelings together. Using video also allows students to “leave a pre-conceived role and to take chances while constructing and deconstructing knowledges through the use of technological partners” (Goldman-Segall, p. 65). Third, developing the video case connected and aligned performance, best practice standards and reflective assessment. Students were now making the
connection among the theories and their teaching performance through reflecting on real situations in a critical stance. Fourth, by consciously selecting and developing a video case, students are empowered in their own ways of learning and knowing as reflective practitioners.

**Student Cases**

This past fall term, students presented their video cases in the seminar. Several cases were memorable. A physics graduate student discovered how important it was for him to design engaging hands-on experiments and then make adjustments, rather than focus first on controlling disruptive behavior. His video excerpt showed students working on a project at various stages of collaboration. Another graduate student, biology major, showed a video in which students conducted a role-play as an iodine or starch particle in diffusion. As someone who had only lectured before, he was obviously pleased that the students not only enjoyed the activity, but also understood the concepts of diffusion, particle size and weight, and cellular bonding. And finally, a former computer programmer who now teaches computer skills to high school juniors, showed how an emphasis on quality instead of speed was reflected in the students’ purposeful work as they moved among their stations. Her follow up plan was to gradually lessen the amount of structure she provided and increase the amount of collaboration. When she presented her video, she was the most relaxed and engaged I had seen her all term.

**Implications for Pre-service Education**

Ann Berthoff stated “pedagogy always echoes epistemology; the way we teach reflects the conception we have of what knowledge is and does (1981, p. 11). For pre-service teachers, this gap between pedagogy and a critical examination of one’s practice is often tacit and unexplored. It may appear insignificant, but this disconnection often leads new teachers to experience burnout or quit the profession. According to Schon (1987), the prevailing conceptions of many teacher education programs of professional knowledge may not match the actual competencies required of practitioners in the field. He emphasized that prospective teachers must untangle situations that are complex and undefined and impose a coherence of their own making. As educators, we need to give pre-service teachers the time, space and medium for them to investigate their practice intentionally, for the student “has to see on his own behalf and in his own way the relations between means and methods employed and results achieved” (Dewey, 1974, p. 151). Developing a video case study is a dynamic way into reflective practice.

Practical Experiences: Teaching Preservice Teachers Using Technology

Tina Heafner, University of North Carolina at Greensboro, US

A. Objectives or Purposes

A pressing need exists for preservice teachers to become proficient in using technology. Many states have implemented technology standards that identify the skills young teachers need. However, there is no consensus on how these skills should be taught in the university setting. At a public university in North Carolina, a cohort group of interns were exposed to an education course in which instruction was delivered online. The purpose of this study was to evaluate preservice teachers’ views toward using technology in this technology rich education course. The course topic was Seminar: A Focus on Exceptional Children. Elementary education majors took the course online and meet once a month to discuss topics of study and to reflect on their experiences during the semester.

B. Perspectives or Theoretical Framework

Much has been written about the infusion of technology into academic life. Schools are moving at different paces at integrating technology. Varying beliefs about the effectiveness of technology has attributed to the inconsistency in implementing a technologically based curriculum. Concern about the social consequences of technology have driven some to suggest de-emphasizing technology in education (Stoll, 1999), while others have argued that effective instruction, particularly in social studies education, must include a range of computer technology skills (Martorella, 1997). Research studies describe an intensive computing environment as a positive influence on academics (Corwin & Marcinkiewicz, 1998; Geissler & Horridge, 1998; Walters & Necessary 1996). Brown (1999) suggests that technology is an integral part of education in the 21st century.

In a statewide study of the impact of technology, Dirksen, Bauer, Coifland, and Naylor (1998) identified that the computer is an adaptable and versatile tool. They continued by stating that when used appropriately, technology can be a very effective tool. Technology as a tool does not change basic learning processes, but instead it transforms how these processes are developed. To infuse computers in the curriculum, teachers need to be more technology-literate. Teachers’ beliefs about technology are often hindered by teachers’ lack of technological skills. Difficulty in locating resources and ineffective use of software can inhibit teachers’ decisions to integrate technology. Teachers should not only know how to use technology, but they must also know how to effectively integrate technology in their teaching practice and to engage their students in active learning and research (Pan, 1998). Mason et al. (2000), in Guidelines for Using Technology to Prepare Social Studies Teachers, suggest that teachers need to learn how to successfully integrate technology to make their teaching better than it would be without it. They emphasize the need for teachers to develop technical skills not just for simply acquiring these skills, but to make them proficient at using technology.

Pan (1998) suggests that in order to infuse computers in the curriculum, teachers should know not just how to use computers themselves, but also how to engage their students in active learning with computers. It is not enough for teachers to allow students to employ technology; they must network with their students and teach them how to effectively apply technology. Trentin (1999) emphasizes along with many others that teachers need specialized technical skills to apply the most appropriate network-based teaching and learning strategies, which usually involve cooperation, sharing, organizing work and study groups, and searching the network to locate significant resources for the educational process.

C. Methodology

At the end of the semester, students enrolled in the seminar were asked to complete a survey identifying their perceptions of their technology use in the course. The survey was posted online (with a CGI script to encode responses in a text file) and an email message was sent to all students enrolled in the seminar encouraging them to follow the included link and complete the survey. After one week, a reminder email was sent. The survey consisted of 29 questions that were divided into the following categories: Collaboration and Communication, Content Knowledge, Individualized Tasks, Frequency of Use, and Ability Rating. Responses were reported using a Likert scale.

D. Results

In the area of Collaboration and Communication, students compared this online course to more traditional educational courses that rely primarily on face-to-face instruction. 56% of the students reported that they were somewhat more likely to actively participate in scheduled discussions about the course material, such as a threaded discussion posted on a discussion board. 67% of the students were somewhat more likely to ask for clarification when they did not understand assignments or content and to discuss the ideas and concepts taught in this course with the instructor. 89% of the students stated that they would tell the instructor when they had a complaint or suggestion about the course. 67% of the students reported that they worked on an assignment for this course with a group of other students three or more times during the semester. 78% remarked that they discussed with other students the comments they made on one or more of their assignments or examinations for this course three or more times during the semester. 44% of the students reported feelings of isolation from other students due to the structure of the course.

Content Knowledge was evaluated by looking at the effort required by students to complete tasks and the perceived quality of those assignments. 56% of the students stated that they spent more time studying. 56% of the students felt that they put more thought into their comments. 89% reported that the technology used in this course was appropriate for performing the tasks required. 78% of the students stated that thought the use of technology in this course, they were acquiring skills that will be useful to them as
teachers. All students stated that they discussed the ideas and concepts taught in this course with other students three or more times during the semester.

Individualization of the tasks of the course is a major advantage of an online course. 89% of the students stated that taking this course online strongly valued the ability to work though the course materials at their own pace and to complete tasks at times that were convenient for them. 89% reported that they were better able to juggle their course work with work and/or home responsibilities. 89% of the students stated that using technology enabled them to earn at their own pace. All of the students agreed that a benefit of the online course was the ability to see the results of their work almost immediately.

The survey was used to identify how often students were using technology due to the nature of this course. Students were asked to approximate how much time they spent during a typical semester on various activities. 56% reported that they spent ten or more hours per week working on assignments, projects, quizzes or examinations on a computer-based, self-paced instructional program. 67% spent three to five hours per week interacting with their instructor or other students at their institution by way of email or other "time-delayed" electronic communication, such as bulletin boards or discussion lists.

Students were asked to rate their technological ability. Responses were reported using a scale of one to five. One represented a self-efficacy rating of no knowledge or technological ability and five identification of one’s ability as an expert technology user. All students rated their abilities as a four or greater. 56% reported a self-efficacy rating of expert. No students reported feeling at a disadvantage, because they did not possess adequate computer skills.

E. Implications

The use of technology in teacher education has a positive effect on preservice teachers' learning. Information technology empowers interns to learn more easily, enjoyably, and successfully due to the individualization of tasks. Appropriate experience with instructional technology promotes improved cognitive understanding, content knowledge, problem-solving skills, and basic academic skills (Mayer, et. al., 1999, Soloway, et. al., 1999).

Pedagogy affects teachers’ motivations for using computers. Sadera and Hargrave (1998) identified that teachers' epistemological beliefs affect their instructional practices and their conceptions of the role of the computer in learning and teaching. Technology engenders an environment that promotes cooperation and collaboration among students; more in-depth conversations among teachers and students and among students themselves; encourages constructivist classroom instruction; a more equitable distribution of power between the teacher and his/her students; increases both written and oral communication (McGrath, 1998).

Computer experience fosters positive attitudes toward computers (Sadera & Hargrave, 1998). Galloway (1997) conducted a study of teachers to determine their use of technology and how teachers learn to use technology. The results revealed that educators learn to use computers primarily on their own and that it is unlikely that teachers will integrate computer technology into classroom instruction without the inclusion of personal and professional usage. Teachers' motivations for integrating technology into the curriculum, as identified in this article, are dependent upon teachers' experiences with technology and their technical skills. A study by Janice Mitchell and Susan Williams (1993) evaluated the effect of teacher knowledge of technology in the classroom. They categorized teachers into two groups: novice and expert. Their study revealed that experts promoted the use of technology and exhibited a greater confidence in the implementation of technology. Novice teachers did not emphasize the use of technology. The technological knowledge of students depends on the technical savvy of the teacher. Teacher technological literacy is essential in the integration of technology into the curriculum.

Teachers' self-efficacy is defined as teachers' knowledge that they can successfully integrate technology within their curriculum. Teachers' self-efficacy related to instructional computer use fosters flexibility, experimentation, and multiple approaches to using computers in instruction (Dawson, 1998). There is a positive correlation between teachers' technical savvy and teachers' self-efficacy in computer use (Sadera & Hargrave, 1998). Teachers' self-efficacy about their technical expertise will have an effect on whether or not and how they integrate technology in their curriculum Lanich and Meyer (2000). Kurkjian and Sponder (1998) identified attitudinal objectives for effectively integrating technology: teacher motivation to use technology and motivation to develop their skills. Helping teachers enhance their attitudes toward technology involves developing teachers' self-efficacy by transforming their self-perceptions as non-tekkies. If teachers have a high self-perception of their technological abilities, they will be more effective at integrating technology.

Getting beyond the preconception of teacher as technology expert

Belinda Hill, Saint Martin's College, US

The Field Based Program at Saint Martin’s College has been working with two grants that promote changing the learning environment with technology. The ST2EP grant, is a PT3 catalyst grant, that focuses on creating a learning community that includes pre-service teachers, a team of college faculty, and K-12 students. The Intel grant involves a curriculum for pre-service teachers that encourages the use of technology to include more critical thinking tasks. The grants work together, the ST2EP grant provides an opportunity for our pre-service teachers to work with K-12 students using and learning with technology, while the Intel grant provides support for creating curriculum that includes K-12 students use of technology.

In order to help our pre-service teachers understand how technology can change the way K-12 students learn they need to see and work with those students. Contact with the students, will allow us to test to see if the ideas put forward in either grant can be implemented. Will the pre-service teachers be able to see the advantages of working with K-12 students as the technology experts and themselves as guides to learning. This session will report the findings of this study.
Preparing Pre-service Teachers in Technology: How Far Should We Go?

Mark Hofer
Steve Whitaker
Center for Technology and Teacher Education
University of Virginia
United States
mhofer@virginia.edu
whitaker@virginia.edu

Abstract: This paper examines the challenge of determining how colleges of education should prepare pre-service teachers to enhance teaching and learning with technology. With so many different types of software, emerging technologies, and the constraints of the typical K-12 classroom, it is difficult to determine the best content for the "technology course" in a teacher education program. This paper will examine some of these new trends and offer a framework to assist teacher preparation programs in determining the content of the educational technology course. A discussion of how different technologies fit into the framework and how a teacher preparation program's values can help guide the answer to the question: how far should we go?

Introduction

As NCATE, ISTE, and other national organizations issue the call to teacher education programs to prepare teachers to teach with technology, a new question has arisen: how far should we go? Even as colleges of education work to integrate technology throughout the teacher preparation program, the educational technology course retains the potential to lay the foundation for technology as the students move into their methods and education foundation courses. While the typical educational technology class deals mostly with productivity tools, several new initiatives have developed in K-12 schools that are expanding the use of technology to enhance teaching and learning. These new initiatives are stretching the types of technology tools used and their application in the classroom.

While these new initiatives are exciting, they pose a challenge for colleges of education. With the wide range of options available for integrating technology, teacher preparation programs must make several choices in determining what technologies/applications should be included in the educational technology. Should the focus be on technology as a productivity tool, a medium to foster creativity, or as a catalyst for change? Further, should the emphasis of the program be on preparing teachers for the practical reality of today’s classroom or expanding their horizons to prepare them for the potential of tomorrow’s classroom?

Current Trends

Some students in K-12 classrooms are creating web pages, animation with Flash, digital video, and even claymation films. They are using PDA’s, probes, digital microscopes, and digital imaging to enhance learning. For students in other classrooms, work with any type of technology is measured in minutes per week. OTEA reports that while the connectivity of US classrooms is increasing, student access is limited. This wide range of access and current use makes a "typical" technology program and infrastructure in a school elusive. This lack of continuity begs the question, “what should we prepare our teachers for?”

The typical “technology course” in a teacher preparation program is often focused on productivity tools. Leh (1999) reports that most courses typically require facility with word processing, databases, and spreadsheets. Many also include work with multimedia presentation software and webpage design. Other courses incorporate digital video editing and production, curriculum integration, and hardware and software maintenance and
troubleshooting. With the wide range of capacity and use in K-12 schools, and the varied approaches to technology integration in teacher preparation programs, how can an instructor decide how to best prepare her students for an uncertain future?

A Framework for Discussion

In order to answer the question of how far we should go, it is fundamental to examine the different focuses of technology and schooling and the different vision and mission of teacher preparation programs. Only then can we begin to determine the content of the “technology course.” Different schools and districts have different visions of the purpose of technology and learning. In the current climate, many schools have a keen focus on standards and how to use technology to increase student learning in measurable ways. Other schools see technology as a means to increase the depth of the curriculum and to provide students with an outlet for creative expression. Still others see technology as a way to transform education to be more project-based and learner driven. While all of these approaches are valuable, they have distinctly different views of technology and the learning process. In the same way, the vision and missions of the colleges of education can widely differ. Some programs may put the premium on practical preparation. The goal would be to provide them with the skills, strategies, and methods that will be immediately useful for them as teachers. Other programs may value innovative approaches to schooling within the current school framework. Still others desire to prepare teachers for the classroom of the future.

The choices one makes in these categories greatly impacts what should be taught in the technology course. The chart below offers some suggested course content within each of the criterion cells described above. For example, a teacher education program that values innovation with partner schools who see technology as a way to provide depth into the curriculum might stress the use of mindtools such as databases and spreadsheets to allow students to ask and answer inquiry-based questions.

Conclusions and Recommendations

While the framework above is merely a starting point of a discussion, it is important that the content of the technology course is carefully considered. In order to make these decisions, it is important to define the values and focus of both the college of education and its partner schools. This can be accomplished by talking with university faculty (methods faculty in particular), teachers, administrators, students, and parents from local schools, and by surveying partner schools on technology capacity and current use. While these conversations can help one arrive at a focus for the technology course, it is probably best to incorporate activities that have a primary focus on a particular area of the chart, while also touching on activities in other areas.

A difficult question like this requires ongoing discussion and different perspectives. To facilitate this discussion, a discussion board has been set up in the Electronic Learning Community section of the PT3 website (http://www.pt3.org/) to provide a forum to discuss these issues.

Using Formative Evaluation in Teacher Designed Multimedia Courseware

Chun Hu
National Institute of Education
Singapore

Abstract

This paper describes an experience of pre-service teachers using formative evaluation in courseware design. In the module “Learning, Thinking and Instructional Technologies”, trainee teachers learned to use PowerPoint to produce multimedia courseware. In the process, they learned basic strategies of formative evaluation and applied them to the improvement of courseware design. The trainee teachers had three weeks to finish their products. By the end of the second week, they tested their courseware on respective target learners. Subsequently, the courseware was revised to incorporate the feedback obtained. Some trainee teachers managed to do the second testing before the final submission. The experience helped the trainee teachers learn the importance of formative evaluation in instructional courseware development, one of the least-well-done parts of multimedia design.
Using the internet to link preservice teachers to the state and national standards

Elaine Hutchinson, University of Wisconsin-Stevens Point, US
Sandra Madison, University of Wisconsin-Stevens Point, US

As a portal website, IDEAS provides Wisconsin’s educational professionals a starting point in their search for resources and materials that have been evaluated for quality and align with the Wisconsin Model Academic and the National Standards.

All the websites have been reviewed by a team of researchers including teachers and university personnel. A rubric was developed by the team to evaluate all resources. After resources have passed this test, they are tested in the classroom and feedback is provided from these field studies. All the resources are linked to the Wisconsin and National Standards so that a teacher may choose a content area, a grade level and the standards he/she wishes to teach.

Elaine Hutchinson was a part of the initial researcher team in the mathematics area. This presentation will share the rubric and the development of the IDEAS website and use examples of the resources included in the mathematics area.
Children of the 21st Century have issued this demand: Give us teachers who know how to use technology in the classroom. Are we prepared to meet the challenge?

Gerrie Johnson, Southeastern Oklahoma State University, US

Objective of the Presentation:
The objective of the presentation is to inform teacher educators of the importance of preparing technology proficient teachers who are able to integrate emerging and existing technology into the pre-K through 12th grade classroom curriculum. To accomplish this task, all teacher educators must be involved. Simply taking an educational technology is not enough.

Interactive of the Audience:
Participants will have an opportunity to share their experiences and the policies of the colleges or schools of education in terms of preparing technology proficient new teachers.

Abstract:
Educational systems within our society are experiencing fundamental changes directly linked to emerging technologies and improvements in existing technologies (Matthews, 1998). According to Schank (2000) “Technology is on the verge of fundamentally reshaping the American education system” (p. 43). Colleges and schools of education have a responsibility to prepare a new generation of technologically proficient educators (Krebs, 98). This responsibility was addressed in the 1987 landmark study entitled A Nation Prepared: Teachers for the 21st Century, conducted by the Carnegie Corporation, which proposed reforming the current education system in order to provide opportunities for professional development for teachers, especially the use of technology and the promise it holds for developing new approaches to classroom instruction (Krebs, 98).

Research indicates that teachers teach the way they were taught (Goodlad, 1994). If integration of technology is to occur in education systems, the change must occur within teacher preparation programs, not on an in-service basis once teachers are out in the public schools (Dolly, 1995). The need for training teachers to integrate educational technology into the curriculum is highlighted in virtually all major reports analyzing technology-based instruction (Krebs, 98). Colleges of education must take a leadership role to guarantee that teacher education students experience a full range of the use and application of educational technology. Teacher education students should be required to apply technology to a variety of settings, not just in the context of an educational technology course. They would leave college better prepared to utilize technology in the K-12 environment if they were required to use and integrate technology in a number of
course assignments (Dolly, 1995). It is in this manner that the students will realize how the use of technology can be effective for conveying appropriate content and knowledge to students in the classroom (Knupfer and Zollman (1994).

Development of CD-ROM Course Materials: Demonstration of Toolbook Assistant

Lewis R. Johnson  
Department of Specialized Education Services  
University of North Carolina Greensboro  
United States  
Lew Johnson@uncg.edu

Abstract: In this interactive session, a short application will be built to demonstrate the power of the multimedia authoring program Toolbook Assistant 8.1 for creating tutorials and case-based simulation instructional materials. This PC-based authoring program was selected as the authoring tool for our university’s online learning initiative due to its power as an authoring tool and its ease of use. Toolbook has a drag-and-drop interface that is easy for subject matter experts to use to create high-quality e-Learning content, and comes complete with a wide selection of ready-made templates similar to PowerPoint templates to get a new author preparing instructional materials quickly. The program can make a log of user data that is saved to a disk for verification of learner performance or research.

Introduction

As teacher educators, we are faced with a daunting task: to prepare special education teachers who have the professional knowledge, skills, and dispositions to meet the challenge presented by the new accountability measures of teacher education and the challenge of working with children of increasingly complex disabilities in the classroom. The teachers of today must pass an application-oriented national licensure exam and be well trained to develop high levels of professional self-efficacy to withstand the demands of the profession, which can result in their retention in the field. Further, from a university perspective, the national report card on university teacher education programs will publish the pass rates for all programs. To meet these multiple challenges, the teacher education faculty in special education must revise its programs to meet the new licensure standards and provide instruction in a way that the pre-service teachers acquire the skills for teaching not at the knowledge level but at the performance level. In redesigning our instruction for the teacher education program, we focused on adding tutorials and case-based simulations on CD-ROM to our web-supported, and our online courses.

Including Multimedia in the Design of the Courses

Courses were designed using a textbook or a collection of readings as a core knowledge base. Course objectives and resulting content were examined for forms of knowledge (factual to strategies), and intended levels of performance, such as knowledge of higher-order learning skills such as evaluation and synthesis. There was a strong mandate to avoid focusing on knowledge acquisition in the classroom so time could be devoted to developing higher-order skills. Instructors were already using Blackboard a teaching and learning environment that could be used to organize instructional materials, provide forums for discussion and assessments. However, Blackboard-based courses lack the hypertext and media capabilities unless these materials are externally linked to the course interface.

Multimedia materials such as Functional Behavioral Assessments (Liapsin, Scott, & Nelson, 2000), a $79.00 program published by Sopris West were included in the in-class instruction. However, this program required two hours of class time to present and proved to be too expensive to require students to purchase for use outside of class. The cost-benefit of using multimedia programs in our instruction became a critical question to resolve when courses were being developed to be taught online. Once we began designing courses we realized that to match the quality of the courses in which multimedia was presented to the class and to accomplish the ambitious learning objectives needed by our students, tutorials and authentic case-based examples and simulations were needed. This choice of adding multimedia tutorials was validated by Welch and Brownell (2000) who recently developed a CD-
ROM multimedia instructional program and evaluated its use with undergraduate and graduate students. They found significant differences between pre-and posttest scores on content knowledge.

The Solution: Hypermedia Authoring

The university’s technology-based courses were comprised of MS Word documents, web pages and some audio-visual PowerPoint slide presentations. These solutions were not able to match the interactivity standards established by the commercial materials. With a clear understanding of our instructional objectives and very positive experiences with commercial multimedia instructional materials, the course development team examined its course development options. It became clear that to move the course development to the next level, multimedia authoring needed to be part of the course development process. Multimedia authoring involves structuring content in a manner that is consistent with the instructional design: sequential in tutorial direct instruction model applications, and open-structured in constructivist model applications. In the tutorial applications, the metaphor of a book with chapters works well in developing a mental model of the instructional program (Lehner, 1987). Also, in the case-based authentic learning model advocated by Herrington and Oliver (1999) for teacher education there is a need to develop non-linear hypertext learning environments.

In examining the multimedia programs that are used in the classes, the tool used to develop the commercial materials was either Macromedia’s Authorware or Director (Macromedia.com). Several of the multimedia programs our faculty found useful were developed as part of federal grant projects supported with hundreds of thousand of dollars in the budget. Additionally, university instructional support professionals did not have the expertise to create multimedia using these programs and certainly it was beyond the expertise the faculty. A problem with university course development is that faculty members are content experts not multimedia authors who work within limited budgets, so the search for an alternative authoring tool using product reviews (White, 1997) led the instructional technology support staff and faculty to Toolbook, a multimedia authoring tool.

Toolbook Assistant

ToolBook Assistant (Click2Learn.com), a PC-based program, was selected as the authoring tool for this program redesign initiative due to its power as an authoring tool and its ease of use. Toolbook uses the metaphor of a book with chapters, table of contents, glossary and pages of content to ease the developer into the process of building multimedia instructional material. The program has a drag-and-drop interface that is easy for subject matter experts can create high-quality e-Learning content. ToolBook comes complete with a wide selection of ready-made templates similar to PowerPoint templates which facilitates a new author in preparing instructional materials quickly. The program contains a catalog of authoring objects (icons) to build your interactive content-assessment objects, media players, navigation panels, and other interactive objects, many with predefined behavior that you can customize. With its WYSIWIG page development, and the ability to toggle from author level to reader level with one click of a key, Toolbook provides immediate feedback to the developer.

From a student accountability and research perspective, Toolbook has a feature equivalent to the Authorware data tracking feature. The program can make a record or log of user data that is saved to a disk. This data tracking information can be used for verification of learner performance or as research data.

The development of multimedia incorporates the five-stage process as outlined by Jerram and Gosney (1995) which end with authoring. The technology used for authoring will in part creates a context to define the parameters of the final project, but does not control or drive the project. For example, once the authoring stage begins for a basic tutorial the faculty member:

- selects a template and a background which is similar to PowerPoint.
- creates or copies page layouts for text and media
- pastes text content into text boxes, and adds audio and video as it is needed to support the instruction
- makes hyperlinks to other pages, or pop up notes
- inserts question objects.

Many of these actions are easily accomplished by dragging preprogrammed objects from a convenient catalog onto the work space as shown in Figure 1. Immediate feedback to the student is accomplished by adding to quiz items. Context-based assistance is accomplished by using branching user paths which can lead to reteaching or additional examples can be placed into the program by answering questions in dialog boxes as the questions are created. The final product can be “packaged” for distribution as read-only files for Windows PC CD-ROM.
or converted to web pages for cross-platform accessibility through a process managed by an autopackaging feature. This process "collects" all of the media and support files, creates folders and places it neatly in a folder that includes an install/setup file and a reader file.

Conclusions

Toolbook Assistant offers the instructor who has both the content knowledge and interest in working with technology the opportunity to develop multimedia instructional programs for use by students online or from CD-ROM. The data tracking-log file function that makes a recording in the form of a text file on a floppy disk that can be submitted to the instructor via e-mail is especially valuable to faculty who wish to conduct research into learner performance and navigational patterns. The programs developed are easily edited and updated so a small project can be expanded and become more elaborate as formative feedback is received from students. In course evaluations from courses that have included multimedia materials as part of the instructional delivery, the student feedback has been quite positive. Therefore, if instructors wish to go beyond the use of web pages in a Blackboard-like teaching and learning environment and animated audio narrated PowerPoint presentations, consideration should be given to including multimedia authoring tools as an option for instructional material development (Mitchell, 1999).

Meeting the Challenge of Teacher Education
Through a Technology-enhanced Program of Studies

Lewis R. Johnson
Department of Specialized Education Services
University of North Carolina Greensboro
United States
Lew_Johnson@uncg.edu

Abstract: Special education is one of the most challenging specialties within teaching. It provides an excellent opportunity to test the promise of technology to enhance teacher education. As teacher educators, we are faced with a daunting task: to prepare teachers who have the professional knowledge, skills, and dispositions to meet the challenge presented by the special education classroom. To meet this challenge, the special education preparation at Arkansas State University redesigned its instructional design so that it makes full use of instructional technology options for teacher education.

Introduction

First year teachers have report that their teacher preparation courses do not sufficiently prepare them for the realities of the classroom. Moreover, recent changes in the performance-based teacher examinations have placed more emphasis on application of the knowledge and analysis of situations. As teacher educators, we must find ways to present information and encourage students to process that information prior to coming to class, so class time can be spent on actively making connections between the course content and field experience. The program of studies and courses in special education described in this case study of Arkansas State University accomplished this task and led to increased student learning, satisfaction, and sense of professional efficacy.

Program and Course Design

The work on program revision began with examining each course for content type according to Gagne’s forms of knowledge and Bloom’s Taxonomy. Courses that were heavily loaded in content were supplemented with text study guides, PowerPoint presentations that were accessible for review on the web before class meetings. Also, provided were tutorials designed from a direct instruction model that included many instructional supports, such as explicit help in organizing information through content maps, coaching, summaries and immediate feedback on comprehension questions. Due to the extensive knowledge base needed by students as a foundation for engaging in higher order learning, the critical need emerged to “package” content in a manner that would make it available for students to study outside of class. For topics such as Direct Instruction and collaborative consultation CD-ROM hypermedia tutorials were created that had the capability of recording on a student disk the “path” of the student through the tutorial and recording student performance on assessments. Through the use of these tutorials, especially the Direct Instruction tutorial, presentation of content and the demonstration of skills could be accomplished outside of class, so class time was used for viewing teaching clips and engaging in analysis of lesson plans and teacher behaviors.

Courses that involved application, analysis, and synthesis of information to solve problems included case-based situated learning materials. Situated learning incorporates into the learning environment: authentic contexts, authentic activities or problems, multiple perspectives, expert opinion, and opportunities for collaboration and reflection. This instructional design feature is ideally suited for preparing special education teachers, who are learning a body of knowledge and skills that must be applied in a simulated meaningful, complex context, such as a classroom. This situation reflects the context in which the information will be used in real life. These authentic contexts for learning anchored the instruction in reality which facilitated retention and application of the instruction. Langone, Malone and Clinton (1999) compared test scores of preservice teachers taught using either anchored or nonanchored instruction, a form of situated learning. The nonanchored instruction consisted of traditional lectures while the anchored instruction used video-based case studies. While no difference in test scores were noted between
groups on tests administered immediately following the instruction, test scores of those receiving anchored instruction given eight weeks later were significantly higher than the nonanchored group. The authors concluded that retention of content was better for the anchored instruction group. The Teacher Problem Solving Skills (TPSS) (Fitzgerald, Semrau, Johnson, Kraus, Nichols, & Standifer, 1996) series of multimedia programs developed and used at Arkansas State University are integral components of the preservice preparation program.

Given this research, the Arkansas State University special education preparation program moved from an information dissemination model with assessments of low-level learning toward a model of instruction focused on higher-order learning and thinking. That is, it shifted from a Reductionist orientation to a Constructivist orientation as the student progressed to more advanced courses within the program (Herrington & Standen, 2000). This made course design very important. Careful consideration was given to the instructional design of courses, activities within courses, and the instructional conceptual framework. The Instructional Events Model (IEM) (Rosenshine & Stevens, 1986) was selected to guide our development process. IEM consists of nine elements: a) gaining the learners' attention, b) stating learning objectives, c) guiding the learners through learning activities, d) presenting information, e) coaching through learning exercises, f) facilitating interactions between learners, g) providing constructive feedback, h) assessing learners' performance, and i) promoting transfer of skills to new situations. This selection was validated by research conducted by Welch and Brownell (2000) who recently developed a CD-ROM multimedia instructional program based on IEM design principles and evaluated its use with undergraduate and graduate students. They found significant differences between pre-and posttest scores on content knowledge.

The following components were included in our technology-enhanced courses:
1. a comprehensive listing of specific knowledge and skill objectives to establish the expectations for the learning outcomes;
2. an instructor authored commentary for each module and each chapter which serves to alert the student to important aspects of the chapter and provide motivation;
3. multimedia presentations or tutorials of chapter content that include audio and video material to serve as introductions to the chapter before arriving in class;
4. reading study guides which help the student focus on important content;
5. case examples which serve to anchor the information in real-life situations and provide a common experience for discussion and analysis;
6. authentic activities to provide practice;
7. opportunities for in-class and online synchronous discussion using virtual class software;
8. a discussion web to provide a forum for sharing views and publicly reflecting on what is learned and experienced; and
9. on-line quizzes so the student can check his/her comprehension of the content.

Conclusion

It was the intention of this short paper to expand the notion of the technology-enhanced program and course from a web-based correspondence course to a carefully planned series of web-supported courses containing interactive CD-ROM multimedia tutorials and authentic case-based learning exercises. Consideration should be given to including technology resources beyond PowerPoint lectures and web links to improve student outcomes.

Intergenerational Learning: A Model for Teacher Preparation

Deborah Jolly, Texas A&M University, US
Frank Clark, Texas A&M University, US

With funding from the Preparing Tomorrow's Teachers to Use Technology initiative a consortium of seven rural school districts along with Texas A&M University has designed an innovative approach for integrating technology into teacher preparation programs that allows thousands of minority, language minority, children of poverty and geographic isolation to access teachers that are better prepared to teach in their increasingly high tech classrooms. Through the use of an intergenerational mentoring program, pre-service teachers, university faculty, and K-12 teachers interact with one another to learn best practice and technology integration skills.

The need for institutions of higher learning to prepare students for a technological world is self-evident and is striking in an area that is geographically isolated such as East Texas. Here not only school districts struggle to get qualified technologically savvy teachers to fill classrooms but the university also struggles to provide the technical assistance and ongoing support to a faculty that is just now beginning to embrace technology. Finding technical support and training opportunities in the business world has proved expensive and non-existent when indeed the answer to the dilemma was immediately evident: use the existing pre-service teachers now in the College of Education to provide the assistance to faculty.

Why use a technical assistance group that ranges in age from about 18 to 24 years of age? First we know that this age group is made up of predominately the Net Generation (sometimes called Generation Y). The Net Generation, having grown up with the new technologies, enters our institutions of higher education with a much better comfort level for technology than the existing university faculty who grew up with television and radio. Consequently an "Intergenerational Digital Divide" exists. To compound the problem, a second divide exists in our state: that is, the technology infrastructure gap between public schools and higher education teacher preparation programs in Texas.

Texas schools have experienced substantial technology infrastructure changes over the past few years. Colleges of Education, however, are limited in their ability to provide substantial pre-service training in Internet-based technologies so that beginning teachers may take advantage of this increased infrastructure. Rather than presenting exemplary models of technology-enhanced instruction to pre-service teachers, most Texas institutions of higher education are struggling with integrating technology into courses and content areas and in offering of on-line courses.

The design of this PT3 initiative, funded in the first round of funding in 1999, is to address the need for increased faculty proficiency in technology while recognizing the challenge and the potential of the disparity between faculty and students in technology skills. The goals of the project were to facilitate faculty development through both approaches: building capacity and providing tech support. We did this by: 1) developing proficiency of the faculty in the TAMU COE in the use of various instructional and communication technologies (building capacity); 2) developing capacity within the TAMU COE in digital media that supports the NCATE standards and the International Society for Technology in Education (ISTE) (building capacity); and 3) providing support to faculty transitioning to the new teacher training program by providing support in the area of technology support and infusion into the curriculum and coursework (providing tech support).

Program Description

The Technology Mentor Fellowship Program (TMFP) draws upon successful strategies evolving from programs funded by the Technology Literacy Challenge, specifically the Generation www y program, Gen Y Challenge Grant-Olympia, Washington) and the Profiler and Trackstar tools developed in a partnership with the current High Plains Regional Technology in Education Consortia. Training materials supplied through a partnership with Intel and Microsoft (Gates Foundation) through the Intel Teach to the Future initiative provided additional training and support.

The scope of work for the TMFP is to: 1) Provide teacher education faculty (campus based faculty, cooperating teachers, early experience supervisors) a system for technology training that:

- Provides intensive mentoring and support to faculty, and cooperating teachers in the field from pre-service teachers experienced in the process of integrating technology into instruction at the K-12 level,
• Identifies the growing knowledge base within college and school organizations, among students and faculty, and supports the sharing of both skills and knowledge through collaboration and the development of specific, skill related instructional objects;
• Provides continuous assessment of competence for college and school teacher education faculty, in the area of integration of technology into instruction;
• Provides professional development activities tailored to the particular needs identified by teacher education faculty regarding technology skills/processes for technology integration.

2) Provide teacher education faculty and pre-service teachers access to a repository of instructional objects designed to:
• Develop and use basic technology skills, skills in the instructional application of technology;
• Use technology-congruent pedagogy, such as project based learning and continuous skills assessment;
• Be searchable by their application to specific issues related to the integration of technology into instruction across grade levels, content areas, and national standards.

3) Provide opportunities to organize instructional objects into web-based courses.

Outcomes
The redesigned elementary and secondary teacher preparation programs became fully operational as field based programs during this TMFP initiative. The elementary program has 12 Professional Development Schools (PDS) and 10 Integrated Methods Schools (IMS) that support the preparation of approximately 430 teaching candidates each semester. IMS are pairs of schools that support the field-based teacher preparation programs. All methods classes are conducted on site at the schools. The department head of teacher education has worked closely with the TMFP project staff to provide the equipment and infrastructure to support technology integration throughout the teacher preparation curricula. To example, four “smart carts” have been placed at PDS/IMS schools to enable greater technology integration into the field experiences for our teaching candidates. The smart carts consist of a large heavy-duty movable cart equipped with a laptop computer with Internet card, a digital projector, a VCR, a digital camera, and a PolyComm (2-way audio-video communication system). In turn, TMFP project staff assigned a team of technology fellows (pre-service teachers) to assist the faculty in developing instructional objects for the methods classes and classroom activities in the school. This collaboration will be very significant in sustaining the goals of the TMFP initiative once the funding has been completed.

Early on in the project, logistical challenges became daunting for tracking the large number of technology fellows. Anticipating these challenges, project staff developed an Electronic Management System to track various forms of information and to aide in the data collection. The management system uses the Internet to address challenges associated with multiple levels of communications, project management and monitoring of electronic instructional object development. Profiler has been used to assess and monitor the ongoing progress of all project participants.

One key aspect of the program is the joint-creation of learning objects by faculty and their student mentor, as we believe this provides for support and builds capacity. It is clear that a large number of electronic objects have been created across a wide range of content areas for learners from kindergarten through graduate school. Of the electronic products created, three are directly associated with an online asynchronous course that was offered during the year.

The initiative offers an extensive professional development program to enable all teacher educators to develop and assess their own changing skill levels for developing synchronous and asynchronous distributed learning systems. It also provides a vehicle for teacher education faculty to develop and demonstrate innovative learning resources, such as web-based learning environments, on-line forums, multimedia project-based learning activities for all components of their teacher preparation programs, and where appropriate, allows for the organization of related digital instructional objects into web-based courses. Findings from this study also address issues related to intergenerational learning and cross-age teamwork.
Trainee Teachers Experiences of Using Information and Communication Technologies.

Institute for Research into Learning and Teaching in Higher Education (IRLTHE)
Centre for Teaching Enhancement
University of Nottingham, UK
Gordon.Joyes@nottingham.ac.uk

Abstract: This article describes the ways new entrants to science teaching on a one year post graduate training course in a UK university develop the skills necessary to embed Information and Communication Technologies (ICT) into their teaching. This is set within a framework of national personal and professional standards which all trainees have to achieve. The complex process described involves an initial audit of their confidence in a wide range of ICT skills from e-mail to spreadsheets, the use of an ICT in science education portfolio to set targets and monitor achievements, the use of university based and school based tasks and the role of written reflections/assignments. In order to develop a greater understanding of the students' experience of, and attitudes towards, using ICT in the classroom; the students discourses as revealed through their written work have been analyzed and this approach is discussed.

Background:
In the UK, the notion of initial teacher education has been replaced by initial teacher training as signaled by having a Teacher Training Agency centrally involved with its administration and inspection. This work-place learning approach or apprenticeship model is reflected in the requirement that student teacher trainees now spend large amounts of their time working in schools. The school based element for a post graduate teacher on a 36 week course leading to Qualified Teacher Status (QTS) is 24 weeks. In the past few years UK Government initiatives have placed ICT at the centre of a skills focused drive within the curriculum (DfEE, 1997c). Minimum standards for ICT in schools have been set by the Government requiring: improvements in resourcing (a computer to pupil ratio of 1:7 for secondary schools; that all schools have ICT curriculum plans; that schools are internet connected with 20% via broadband). In addition individual funding has been provided for all teachers to receive ICT training in order to reach national standards by 2002. Alongside this there is the important notion that student teachers should be ICT competent in the classroom (Davis, 1992) and in 1998 the UK Government's Department for Education and Employment issued the 'Initial Teacher Training National Curriculum for ICT in Subject Teaching' (DfEE,1998). This ICT National Curriculum for student teachers is a very prescriptive document and is essentially the same as the standards required for all UK teachers by 2002. It contains 118 separate requirements and is organized into two sections. Section A is 'effective teaching and assessment methods' and section B is 'trainees knowledge and understanding of, and competence with, information and communications technology'. Thus section A is to do with classroom pedagogy or professional development and section B is to do with the student teachers' own ICT competence or personal development.

The concern over the past two years of implementation of this curriculum is that the classroom teachers and the mentors with whom the student teachers would be working for the majority of their time would in most cases only be beginning to explore effective pedagogy themselves (Bell & Biott, 1997; DfEE, 1997a; Galanouli & McNair, 2001; Goldstein, 1997) and that an adequate level of resourcing would not as yet be in place (DfEE, 97b). Indeed often schools look to students and newly qualified teachers to invigorate the use of ICT within the subject area (Fisher, 1996). A UK Government survey (DfEE, 2001) indicates an improving teacher confidence and competence, and improvements in aspects of resourcing, but the reality is that the indicators used do not relate to the actual pedagogic impact in classrooms and provide limited descriptive statistics. What is of direct relevance to this paper is that the survey revealed that 51% of the science teachers in the 67% of schools that responded saw ICT as having little or no benefit. This finding is supported by the more general Ofsted report on ICT, which indicated that the general improvements in teacher confidence had not translated into effective pedagogic practice (Ofsted, 2000a) and that ICT was a common omission in science department planning at lower secondary level (Ofsted, 2000b).

The rest of this paper describes the ways this ICT National Curriculum has been implemented within the one year PGCE course at the University of Nottingham in the UK in ways that recognize the varied
experiences and opportunities students teachers may have in school. It then explores their understanding of the use of ICT in classrooms by analyzing the ways they describe its use.

The Framework for Development

Whilst the UK Government imposes rigorous and detailed standards, the ITT providers' agenda of developing reflective, principled and critical practitioners has continued. Support for student teachers in taking ownership of their own personal and professional development has been the general principle underlying the pedagogy used by UK HE institutions. The approach used at the University of Nottingham, which follows a reflective practitioner model (Schön 1987, 1991), recognizes the varying pre-course experiences of the students, the varying range of ICT skills and the differing school cultures in which they carry out their practice. It does this through an auditing process, which involves the ongoing setting of and the monitoring of individual targets supported by the use of a student completed ICT in science education portfolio. However, in order to support the development of effective pedagogic skills, taught sessions and reflective assignments based on observed classroom practice of science teachers, as well as of their own practice, are used.

This process is embedded within a wider approach, which has at its centre a Record of Professional Development (RoPD) of which the ICT in science education portfolio fulfils one small part in supporting student teachers in monitoring their performance. This approach is taken for all the areas of personal and professional development within the wider national framework of teaching standards throughout the course. For science student teachers there are over 400 separate standards for which there must be evidence of achievement to achieve QTS status. These standards are described within the areas of Knowledge and Understanding; Planning, Teaching and Class Management; Monitoring, Assessment, Recording, Reporting, and Accountability; Other Professional Requirements; ICT; Communication (spelling, punctuation and grammar); Numeracy (mental/general arithmetic, applications of measurement, basic algebra, using statistical information).

The RoPD contains all of the targets the student teacher has set through the course within the areas above, together with evidence of their achievement. The process has as its basis SWOT analysis and a SMART target setting cycles which are carried out at regular intervals during the course and are supported by group and individual tutorial sessions. What on the surface may appear to be a burdensome administrative task is critical as the means of raising student, tutor and the supporting teachers in schools’ awareness of the student teachers’ professional development needs. This information is used in the weekly discussions of student progress with the school mentor whilst the student is in school and is a means of focusing the student on the wide range of ICT and other skills they need to develop.

The ICT Activities

The framework consists of the components or activities which are carried out in a sequential manner and these are set out in figure 1.

Evaluation of Personal and Professional Competence

The evaluation of personal competence is achieved through the on-line student teacher completed rating of confidence in personal ICT skills. This measure of their confidence in their use of the wide range of ICT applications available is clearly related to their competence to use these in the classroom. Analysis of the confidence ratings reveals that for most student teachers, competence can be associated with a limited number of applications, e.g. word processing, spreadsheets, email (Fisher, 1998). Experience of data logging or using modeling or simulation software is not widely spread amongst the science group and some mature students have had little experience of anything except word processing. Thus the prospect of having to achieve the standards for ICT which include professional (classroom) practice can be a little daunting for some.

The evaluation of the student teacher’s professional competence is on the surface unproblematic. They must go through the process outlined above providing evidence for the achievement of the standards. However what is of real interest is not what they have achieved in terms of the number of ICT lessons taught or how widely read they are in this area, but how they value the role of ICT in the science classroom at the end of their training. It is this that one suspects will be a key factor in their wish to continue to develop this aspect of their teaching. The components in figure 1 provide written examples of their explorations in this area and an analysis

---

1 SWOT analysis is the process of identifying Strengths, Weaknesses, Opportunities and Threats as part of the process of setting targets
2 SMART targets are Specific, Manageable, Achievable, Relevant and Time-related
of the discourses that these students use to describe what is happening in the classroom form the focus of an ongoing study and a discussion of the approach and some initial findings form the basis of the rest of this paper.

Figure 1: The ICT components (All tasks are monitored and feedback is provided. Those components marked with an asterisk are formally assessed.)

Analysis of Student Teacher Discourse about ICT in the Science Classroom

The approach taken initially has been to focus on a sample of nine student teachers and analyze their written assignments that relate to their own classroom practice, components 5 & 6 (see figure 1), in order to understand the ways they perceive the value of ICT. Component 5, ‘Teaching using ICT’, is a student evaluation of their experiences of teaching two lessons that incorporate the use of ICT within them, whereas component 6, ‘Commentary on the use of ICT in the classroom’, is broader and involves a reflection on science classroom practice with reference to relevant literature. The researcher was their university tutor and thus had extensive professional knowledge of each of them and also of the schools in which they were based and this supported the
analysis in validating what the students had written. In fact the researcher had observed all of the student teachers in the sample using ICT in the classroom. Discursive psychologists (Wetherall, 2001) claim that people use language to create the objects of which they speak, to position themselves and others, and to make some ideas seem more natural and right and others unthinkable. In this light what student teachers express about their classroom practice in the language they choose reveals their constructed perspective.

Results Overview

The analysis revealed the issues raised by students and these provided an operational perspective, i.e. they were describing their actual practice in school rather than theorizing about it. However the ‘Commentary on the use of ICT in the classroom’ did reveal the ways theory was viewed in relation to their classroom practice. The analysis revealed a set of paradigms for use of ICT in the science classroom and these are set out in figure 2.

<table>
<thead>
<tr>
<th>Focus</th>
<th>The rationale for the use of ICT</th>
</tr>
</thead>
</table>
| Curriculum (Knowledge and understanding) | **The instructional paradigm** (Drill & practice, tutorial). Reference was made to the ways pupils were motivated to repeat on-line quizzes in order to improve their performance.  
**The revelatory paradigm** (Simulations).  
**The conjectural paradigm** (Modeling). Reference was made to the use of spreadsheets and the ways pupils could make predictions and test these out easily.  
**The emancipatory paradigm** (Labor saving/allowing time for higher order thinking). The use of data logging was referred to in that automatic graph plotting allowed more time for interpretation.  
**The modernist paradigm** (modern, authentic, contemporary). This refers to the ways the Internet (and the use of hand-held data loggers) were viewed as being ‘modern’. This carried with it the implication that Internet resources were more up to date than text books and potentially more authentic and real. An attractive notion of science and of scientists could be presented, rather than the traditional ‘old fashioned’ image. (Driver et al., 1996) |
| Curriculum (Process skills)        | **The experiential paradigm** (Development of ICT skills including information processing and data handling skills, e.g. selecting & summarizing information). This was expressed as providing opportunities for pupils to gain hands on experience of using new learning technologies and developing new skills with minimal teacher intervention. |
| Pupil (Generic skills)             | **The empowerment paradigm** (Giving ownership of the resource and learning to the pupil). This was expressed as a desire to provide pupils with opportunities to own the resources they selected, to give them a sense of discovery and of bringing something new into the classroom as well as raising pupils’ self-esteem.  
**The professional paradigm** (Allowing pupils to work like professionals, drafting and then producing high quality/professional looking output). This covered the use of presentation packages, such as word processing, paint, spreadsheet and PowerPoint etc. Student teachers valued the fact that pupils were able to work in professional ways producing professional looking outcomes, by drafting and redrafting, using spell checks etc. raising self-esteem.  
**The pragmatic paradigm** (Choice of use based on practical planning needs). For example, the need for a variety of teaching and learning approaches, the lack of equipment available to teach a topic, the need to make a boring topic interesting, the need to increase the variety of resources available etc.  
**The impersonal paradigm** (Sensitive topics can be accessed ‘privately’ by pupils) Coverage of sex education through an Internet site, that provided a range of resources, an animation and an on-line quiz, stimulated a wide range of questions which they were keen to share (confidently) with the teacher. The impersonal nature of the resource was planned to help develop pupil confidence as there was less opportunity for teasing or for feeling embarrassed.  
**The motivational paradigm** (Teachers recognise that ICT can motivate pupils) The student teachers’ all assumed that pupils would find the use of ICT in the classroom a motivating experience. |
| Teacher (Classroom management and organization) |                                                                                                                                                                                                                               |

Those in italics were first put forward by Kemmes and reported in Wellington (2000)

Figure 2: The rationale for use of ICT in the science classroom
Conclusions

The analysis of the student teacher's written reflections revealed interesting differences between their perspectives of the use of ICT in classrooms. Most focused on the set of teacher and pupil paradigms as described in figure 2. For them, ICT was perceived as just another tool to be used within the classroom. It was most often valued in pragmatic and motivational terms rather than being selected, because it was able to deliver the curriculum in a 'better' or value added way. However, this value added perspective predominates the literature in terms of justifying the use of ICT in classrooms. Interestingly, those students who made particular reference to the curriculum focused paradigms seemed to consider the use of ICT in classrooms as something 'extra' of 'bolt on'. Their rationale for use was not described in terms of their more general values and beliefs about teaching and learning, whereas for those who made reference to the pupil focused paradigms this link was explicit. A teacher who awaits the ideal curriculum opportunity for using ICT will not be exploiting its use as widely as the teacher who is taking a more holistic teaching and learning perspective for their rationale for use. Perhaps there is a need for a shift in focus from the curriculum, particularly the knowledge and understanding perspective, to a more holistic teaching and learning perspective when considering the value of ICT in the classroom. This would encourage student teachers to view their use of ICT in the classroom in terms of their own developing models of teaching and learning. A useful tool in this process would be their reflections on their own use early on in their course in that this would reveal the wide range of paradigms set out in this paper; a powerful way of exploring with them the ways ICT fits into their developing understanding of effective pedagogy. Perhaps if serving teachers could explore their notions of effective teaching and learning and how ICT could be used to support this, there would be fewer thinking that ICT brings little or no benefit to the science classroom.

NEW! ISTE NETS Resources for Preparing Teachers to Use Technology

Peggy Kelly, California State University, San Marcos, US
Lajeane Thomas, Louisana Tech University, US

DESCRIPTION: Session includes samples from NETS for Teachers: Preparing Teachers to Use Technology integrating ISTE NETS in teacher preparation foundations, methods, student teaching, and classroom instruction.

SUMMARY: Dr. Peggy Kelly, Co-Director of the ISTE NETS for Teachers Project and Document Development Director with Lajeane Thomas, ISTE NETS Project Director will present sample learning activities from the newly released NETS for Teachers: Preparing Teachers to Use Technology book. The document includes standards-based lessons for preparing teachers or teacher candidates to use technology effectively to support learning in mathematics, science, social studies, and the English language arts. Additionally, activities applying technology to support communications, research, problems-solving, concept mapping and other applications cutting across subject areas will be included. The session will consist of an overview of the resources included in the document including specific examples and Web locations where the contents of the document can be located.

The purpose of the session is to reveal model lesson resources based on both the National Educational Technology Standards (NETS) for Teachers and subject area standards. The lessons will illustrate how teaching activities for each content area can be supported by technology thus addressing both the content standards and technology standards within the same learning activity sequence. The underlying goal of the session activities is to provide a framework for establishing new learning environments supported by technology and guided by the national standards of the professional societies. These new learning environments rely on integration of research-based learning theory and on technology as a catalyst for promoting these learning strategies in classroom practice.

Participants will leave with an understanding of the NETS for Teachers and how those standards can be addressed in programs for preparing teachers to use technology. They will receive examples of the learning activities, the Web address where all of the lessons and resources can be found on the Internet, and will be provided with insights regarding how the standards and resource materials can be used to prepare both preservice and inservice teachers to meet the ISTE NETS for Teachers as well as subject area standards.

Removing the Walls: Creating a Virtual Classroom to Link Theory and Practice in Teacher Education

Susan J. Kiger
School of Education
Indiana State University, USA
Email: eskiger@isugw.indstate.edu

Abstract: This short paper describes the outcomes of an effort to link field-based practitioners with teacher education students both virtually in the campus-based portion of a course as well as physically in the field-based portion of the course. The objective of the project was to structure an ongoing, substantive, theory/practice-based discussion.

Project Background

At Indiana State University an upper-division blocked content literacy and general teaching methods course is conducted on campus. This on-campus course also has a lengthy early field experience (EFE) carried out in public high schools as preparation for student teaching. On campus, students are introduced to various theoretical frameworks that are to "guide" their thinking and action as they plan for, render, assess, re-mediate and reflect on instruction delivered during the field experience. As always, one of the primary challenges is supporting movement beyond Lortie's (1975) "apprenticeship of observation" so that pre-service teachers reflectively address student need rather than simply reproducing the practices learned through their twelve-plus years as public school students. In response to this challenge, our efforts focus on "grounding" these pre-service teachers in relevant theoretical frameworks so that as they move into the field experience, they are better able to respond to the diverse needs of the public school students they encounter. Of course, reflection about the link between theory and success in practice (i.e., careful application of a particular learning theory for a given group of students actually does support student achievement) is critical to the ability and propensity to move beyond an "apprenticeship of observation."

Schon (1987) established the centrality of the role of reflection in such professional development. In the context of this course, Zeichner and Liston's (1987) Reflective Teaching Index provides a framework and process that challenges students to thoughtfully connect theory with practice. However, given the centrality of dialogue between pre-service teachers and practitioners as they confront the complexities of practice during the EFE, and the somewhat peripheral role of the university professor during that time, various means of enhancing, or grounding, that conversation to create the reflection required were considered.

As I considered this dilemma, the parameters for its resolution became quite clear. I needed to create a time and space for the reflective dialogue needed, and I needed a way to involve practitioners in my course so that the theoretical frameworks and language used could become common to all. In short, I needed to remove the walls between the campus-based component of the course and the field, and between the professor and the practitioners. My solution, I believed, was in cyberspace; I would create a virtual classroom.

Primarily, the software available on campus, Blackboard's CourseInfo, drove the selection of the environment for my virtual classroom. That environment would not only allow students and practitioners alike access to the required reading materials, but would also provide an electronic forum for discussion accessible only to those enrolled in the course. Because electronic forums are increasingly becoming a viable alternative for supporting reflection (Burley et al., 2001; Kerka, 1998), and this environment allowed the discussion to be fostered in close virtual proximity to relevant theory, it seemed the most appropriate solution for the grounded reflection sought.

Findings

In terms of usability, participants reported that the password-protected environment was easy to navigate and felt that, because of password protection, the electronic forum was a "safe" and private environment for
open discussion. Additionally, having the discussion based on the web rather than "distributed" to participants not only prevented mailbox "clutter," it also provided an environment where a number of topical forums could be established within which a number of related threads would support conversations. Discussants reported that because discussion threads were topically sorted, particular conversations were easy to follow and participation was encouraged.

Preparing participants to enter and dialogue in cyberspace presented differing demands for pre-service and practicing teachers. Pre-service teachers had been engaged in listserv conversations for at least the year prior because of program course requirements. These individuals had been given direction and appropriate feedback concerning online professional discussions. Practitioners were also supplied with the same basic information, though in a manner consistent with their professional stature. Both groups were given direct instruction on the “mechanics” of use of the forum. In terms of transitioning to conversations among participants in cyberspace, there had been face-to-face dialogue between most of the students in the course and the practitioners, and many of the practitioners knew each other professionally. Of course, some of the pre-service teachers and practitioners had never had a face-to-face meeting, but this did not influence online conversations according to participants.

Equipment proved the most daunting challenge. Because of the demands of this course, pre-service teachers had few problems because they had been challenged to locate and keep accessible the necessary equipment. Also, because computer use is such an integral part of completing assignments for most college courses, this was not much of an obstacle. Students reported that the extensive use of the software prior to engaging in the electronic forum helped them feel comfortable with negotiating its use. Practitioners faced more challenges, however. For many, available equipment at the school was not "fast" enough to make communicating with it an efficient use of their limited time. Time limits, once home where more appropriate equipment was available, prevented practitioners from participating more. While a listserv might have addressed some of the access issues, it would not address the privacy issues and would not have provided the organization necessary to make sense of the wide range of topics over which conversations convened.

Nonetheless, substantive conversations did occur. Even with relatively little preparation for conversing, practitioners were astute in finding and addressing pre-service teachers’ concerns. Apparently, they are masters of understanding the sub-text, even in cyberspace. Among others, discussion topics included management issues; interface with parents and the community; current trends in curricular approaches; recruitment of students to content areas; career education; supporting “at-risk” students; influences of student’s home life on teachers’ instructional strategies; homework; graduation testing; tips on effective use of particular instructional strategies within various disciplines; safety in instructional areas; establishing relationships with students; infusion of multiculturalism; infusion of technology; service learning; licensing and re-licensing; sharing of professional information; marginalization of particular disciplines; funding; assessment strategies; teaching across disciplines, etc. In terms of frequency, the “bulk” of conversations occurred during the early field experience (EFE). Post-EFE conversations were few and primarily considered issues of time management, seemingly reflective of students’ projections (or concerns) for student teaching. Unfortunately, use of theoretical frameworks and language from the course, the prime reason for establishing the forum, was not supported. Practitioners did not read the course materials primarily because of time factors. However, some of the desired theory was discussed, but the language did not directly reflect that used during the campus-based portion of the course.

Connecting Curriculum and Technology: The Integration of Theory and Practice in Civic Education

Miri Kim
Department of Curriculum and Instruction
Indiana University
United States
mirikim@indiana.edu

This presentation will report the results of a research study conducted during the 2000-2001 school year in a midwest middle and high school. One of the central arguments in civic education is how we can make social studies curriculum work well in a real context: the seamless integration of theory and practice. Web-based instruction (WBI) can help to solve this explosion of problems. In this presentation, I will demonstrate that the best approach to effective civic curriculum development is to synthesize knowledge and skills with actual practice. Guidelines for designing civic education programs using WBI will be explained. Also, detailed methodological issues regarding WBI for civic education will be mentioned. Based on the findings of the research, I will address several future research questions in the last part of the presentation.

Design and Practice of the Technology Integrated Teacher Education Program for Parental Engagement

Miri Kim
Department of Curriculum and Instruction
Indiana University
United States
mirikim@indiana.edu

This paper is to design and implement a technology integrated social studies methods course in order for preservice teachers to have a better understanding for engaging parents into their children's education. The schools are social systems that include parent, communities, and school professional reinforcing each other's efforts to keep students in schools. Especially parents working with schools and community are vital to the improvement of schools and neighborhoods. In this paper, several obstacles in participating in their children's education are discussed. Further, it is argued that these problems are not about knowledge but about institutional settings, social structures, values, goals of the school, and life style. We need to develop a program with an effective communication tool to improve the communication between teacher and parents in a real setting. If the teacher education program does not implement this new method, our future teachers will be limited in their communication skills with all parents. In this paper, a program for preservice teachers is explained.

Abstract: The field-based undergraduate teacher education program at Midwestern State University has been designed using TxBESS standards (PathWise, FrameWorks for Teaching). We are using Palm computers to collect data based on these standards. Data are collected in the field setting, using spreadsheets, word processing or Learner Profile software (Sunburst). The data are used during post-conferences with student teachers or interns to help in their continual development as teachers. The data will also be used as an assessment of the university's curriculum.

Our undergraduate teacher education program is based on the work of Charlotte Danielson, as presented in Frameworks for Teaching and her work at ETS's PathWise. The state of Texas has also adopted these standards for first year teacher support. We use Palm hand-held computers with spreadsheets, word processing, and Learner Profile (Sunburst). Standards that will be studied during a student teacher or intern visitation by the university supervisor are downloaded to the PDA. During the visitation, data based upon these standards is collected. The University Supervisor is free to select the type of software comfortable to her/him to collect the data.

One method used to collect and present the data is briefly described here. The data are collected in the field using a spreadsheet (Figure 1) on a Palm computer. The spreadsheet data can be shared immediately with the intern in either printed or electronic format.

![Spreadsheet Data Collection](image)

Figure 1. Data collected in a spreadsheet.

Then the data can be easily imported into a database (Figure 2) where they can be categorized, collated by query, and prepared for export.

BEST COPY AVAILABLE
Figure 2. Data have been imported into a database table.

Finally, the category data can be placed into a word processor in a format for discussion by the observer and the intern (Table 1).

Grant Writing for Preservice Teacher Educators
Using Computer Technology

Qiuyun Lin
Dept. of Professional Studies in Education
Indiana University of Pennsylvania
United States
xrdj@iup.edu

[Abstract] In this short paper, I discuss the potential of integrating technology into grant writing to enhance preservice teacher education, focusing on successful grant writing strategies and ways to integrate computers into grant writing.

Preservice educators can enhance the quality of education by obtaining grants for special projects (Bartlett II., Mupinga & Higgins, 2001). However, for many of the preservice teachers, writing a grant proposal to secure external funding is a daunting task. In this article, I discuss the successful grant writing strategies, and ways to integrate computers into grant writing.

Successful Grant Writing Strategies

Following the format. It is paramount to follow precisely the format specified by the grantor. In addition to a title page, abstract, and a table of contents, most proposal formats contain eight components: title page, abstract, introduction/problem statement, goals and objectives, methods and procedures, evaluation, personnel and budget.

Crafting Proposals. Merely including the required information in each component does not necessarily mean that funding will occur. Writing a successful proposal often requires following directions as stated below:

Tip 1: Know your audience. You must assess your needs and prioritize them before writing a proposal to secure funding (e.g., knowledge of funding agencies). Match your needs to those of the funding agency (Messner, 1996).

Tip 2: Focus on the details. Make sure that in crafting your proposal it includes the important elements of title page, abstract, statement of problem, goals and objectives, methods, evaluation, personnel, and budget. The agencies want to know what they are supposed to fund.

Tip 3: Your proposal must be well written to receive funding attention. No “ifs” “ands” or “buts”! Try to be as convincing as possible!

Tip 4: You must be knowledgeable about the core tools of technology to explore your writing strengths. Go to the word processor, or connect yourself to e-mail and the Internet (Edyburn & Weaver, 1998).

Tip 5: Stay alert. Your knowledge of technology can help you participate in the academic community, locate information, and enjoy receiving funding opportunities.

Integrating Technology into Grant Writing

Using computers to create documents. Today, most people use computer technology when creating documents. The computer, with common word-processing software such as Word and WordPerfect, can automatically generate a table of contents, format all headings, and check for spelling and grammar errors. Some funding agencies even require the submission of proposals online (see the Web sites for the Kellogg Foundation [www.wkkf.org] and the Ford Foundation [www.ford.org]). In such cases it is important to follow the instructions for submission, which may include font type and size and proposal length. The major advantage of using technology to create grant proposals is the availability of features such as templates (pre-formatted documents), spreadsheet calculations for budgets, and copying, cutting, pasting and saving as electronic file (Bartlett II, Mupinga & Higgins, 2001).

Using world-wide web to find potential funding sources. Preservice teachers can find potential funding sources in directories and in the Federal Register, which are carried by most libraries. These sources, however, though useful, may not offer the most current information. The most up-to-date sources and comprehensive listings of funding agencies can be obtained on the Internet. Because the Internet changes daily, it is essential to use search engines to find new funding opportunities.

Using the computer allows the grant writer to make minor changes and resubmit the proposal to other funding agencies if needed. In addition to Internet sites of potential funding agencies, sites are also available that provide grant-writing techniques and tips. Using this technology to its fullest capabilities will make the process of grant writing easier (Hult, 1992; Moursund, 1995a, 1995b; Dyrli, 1996).

Conclusion
Grant writing is a means by which preservice teachers at any stage of development come to see themselves as inquirers about curriculum, pedagogy, and educational issues (Gore & Zeichner, 1991). When teacher educators include the grant writing projects in their curriculums, they acknowledge the complexity of teaching and their commitment to prepare teachers who will continue to learn from their own research experiences.

Computer technology has certainly simplified the process of writing a grant proposal. To increase effectiveness and efficiency as researchers, preservice teacher educators are encouraged to exploit the potential technology can offer, to make full use of an integrated desktop of electronic tools to support their work.

Technology Training for New Elementary School Teachers

Donna Lund
Department of Education
Robert Morris University
United States
lund@robert-morris.edu

Abstract: This paper is a report on the development and implementation of a new elementary education program which emphasizes technology integration in all education and methods courses. Observations of teaching and learning strategies used by the instructor and students in the first required educational technology course, interviews, and surveys administered at the beginning and end of the course show patterns of resistance as well as receptivity to new methods and tools for structuring learning environments. The results of this study can be applied to similar programs designed to enhance technology expertise for both pre-service and in-service teachers.

Introduction

In the National Center for Education Survey of 2000, only one-third of fulltime regular public school teachers reported feeling well prepared to use technology in their classrooms. Many respondents said that they had not received adequate training and needed to learn not only how to work the equipment but how to incorporate technology into their daily lessons (Jones, 2001). Since 1991, the United States has spent more than $19 billion on developing information technology infrastructure for the nation’s public schools, with district-level expenditures surpassing $5 billion in 1999. In spite of the growing access to technology, the U S Department of Education calculates that “only 20% of the 2.5 million public school teachers feel comfortable using these technologies in the classroom” (Are teachers, 2001, p.83). Even schools which have adequate equipment report it being underused or not used at all, simply because “teachers do not know what to do with it” (Harmon, 2000, p.1). Slowenski (2000) reminds us that in order to achieve NCATE accreditation, teacher-training programs must demonstrate a commitment to preparing candidates who are able to use educational technology to help all students learn. Yet, not all colleges follow NCATE guidelines, and as Renwick (1999) points out, eighteen states do not even require courses in educational technology to obtain a teaching license. Teacher training institutions must adjust programs in order to meet the needs of “a new demographic group of students...techno-literates...who expect learning to be fun” and whose parents expect “customization, flexibility, and immediacy” in the learning environment (Wright, 2000, p.37). Our university, which had previously offered only secondary education, responded to the call for creative initiatives by developing an entirely new program for elementary education, with an emphasis on technology. Our experiences with the first class of students to enter the new program demonstrated how a single semester of intense technology instruction can raise the confidence level of future teachers even as it raises their awareness of how much more there is to learn about infusing new classroom technologies into daily classroom instruction.

The Program

Before writing our proposal to the state asking for accreditation of our new program in elementary education with an emphasis on technology, we surveyed over three hundred elementary school administrators to determine the exact areas of technology expertise they want teachers to have. In addition to expressing interest in hiring new teachers with skills in electronic publishing and instructional software,
principals cited a need for teachers who could "trouble-shoot" and solve technical problems wherever they might arise. They also wanted new teachers to be able to assess equipment needs, make recommendations for new purchases, and install and implement new equipment. Rather than re-train existing (and possibly resistant) faculty, these administrators looked forward to hiring new teachers who could bring new knowledge and serve as technical resource persons for the rest of the faculty. In response, we developed a program that would build on the technology requirements already in place for our university's core courses, taught in classrooms which are all equipped with presentation devices (document camera, VCR recorder/players, computer projection systems). The new syllabi we wrote for all elementary education and methods courses require integration of technology into the instructors' as well as the students' planning and presenting of lessons and projects. The college provided funds for a new Education Resource Lab, which contains the following: Dell Personal and iMac computers, a color projector capable of showing images from the computer, a document camera, DVD/ VHS, an overhead projector, LCD panel, smart board, digital camera, digital video camcorder, and an Ellison Press (a cookie cutter for paper used primarily in Elementary school).

The Students

As we recruited our first class for this new elementary education program, we deliberately sought students who had been leaders in high school, who had demonstrated an interest in working with children, and who had high academic credentials—a minimum of 1000 on SAT and 3.4 GPA; or 1050 SAT and 3.2 GPA; or 1100 SAT and 3.00 GPA. To follow and monitor the progress of this select group and to gather data on the strengths and weaknesses of the program, I audited the first education course taken by our incoming class of twenty-three candidates—ELED 1000, Technology for Education. At the beginning of the term, the instructor administered a survey in order to determine the students' current level of knowledge and degree of comfort in using the technology tools that would make up the course content: e-mail, internet, video camera, digital camera, document camera, scanner, smart board, LCD panel with overhead, desktop publishing and spreadsheet software, using software to import graphics, installing software to a hard drive, putting data on a CD ROM, hooking a computer to a VCR or TV, and selecting software for children. All equipment necessary for learning these tools was made available to students in the newly established education resource center, which students could use during class time and during lab hours, under the supervision of the graduate assistant. A review of initial survey findings shows that the incoming students were most confident with common technologies such as word processing, internet searching, using e-mail, and using a still camera. In the middle range were devices such as the video camera, desktop and spreadsheet software, the scanner, the digital camera, and the slide projector. At the lowest levels of confidence were these skills: installing software to a hard drive, using a document camera, setting up a computer from scratch, and hooking a computer to a VCR or TV. The incoming survey also questioned students about their expectations of the challenges and rewards of the technology component of the new elementary education program. Only four students stated they were "not nervous" about the technology component, but all students agreed that their technology skills will be "very important" in landing a job. The majority of the incoming students described themselves as having "average knowledge of technology." Some students had a previous college computer course, CI 212, but others were taking this introductory course concurrently with ELED 1000.

Of the twenty-three students who entered the course, four dropped out of the ELED program at the end of the semester. The course may have helped students to either solidify their commitment or to realize that elementary education was not their best career option. In addition to differing levels of commitment, the students in this class demonstrated differing levels of comfort with technology. Some had extensive experience with computers and other technologies in their jobs or homes, while others were neophytes. In addition to these gradations, I had expected to find gender differences in the way the students learned how to work with the tools in the education resource lab. My own experience as well as recent reports of the reluctance of women and girls to embrace technology (AAUW, 2000, Eisenberg, 2000, Gehring, 2000) had led me to assume that the mostly female elementary education candidates in this class (19 women and 4 men) would be resistant to working with the high tech tools in the education resource lab. Yet, my own observations as well as interviews with the instructor, the lab assistant, and the students showed that success in learning to operate, manipulate, and un-plug equipment was predicated not on gender, but on the sheer amount of time and effort put into practicing and learning hands-on in the lab. Some students were
taken aback by the sheer number of hours required to work through the problems and the assignments. Like tech learners of all ages, they had to accept the absolute necessity for committing large blocks of time to the learning process. Another typical barrier they faced was the technical language, the somewhat arcane acronyms (RAM, ROM), and esoteric words for inputs, outputs, cables, and ports. The students had to develop patience and endurance to forestall the pleasure of using the product until they had carefully deconstructed the time-consuming but necessary steps of the process. The instructor did not explain in class the specific details of how to start up and monitor the working of the equipment. Rather, he spent class time assigning projects, organizing teams and groups, and answering questions. It was expected that students would accomplish the goals of the course by carrying out instructions and completing projects that required them to experiment and practice with the tools in the Education Resource Center, on their own time, under the guidance of the lab assistant.

The Projects

In one class project, students were to demonstrate various software packages such as Word, PowerPoint, Excel, and Mail Merge. The student who did a presentation on Excel said she spent hours on the formula for figuring out grades using a spreadsheet. The problem she had initially, as she described it, was "I did not pay attention to the instructions...I did not see how I would ever use this tool." While it makes sense to train new teachers before they go into the classroom, without real-world experiences it was difficult for many of the students in this class to fully imagine how they could integrate the new tech tools into learning experiences for future classes. Another requirement of the course had the students evaluate software packages that could be used in elementary language arts, science, social studies, and math classes, following criteria such as the purpose of the software; appropriate audience or age group; the learning this software would support; and possible lessons that could be built around the program. Although they demonstrated competence in installing and running the programs, most of the students lacked the real classroom experience required for making good judgments on how best to use educational software to promote learning. One student reported remembering herself as a grade school learner and others relied on informal observations of young siblings or other children to judge appropriateness. These projects revealed to the students that knowing HOW to use a tool does not guarantee knowing WHEN to use it.

Another major class project required teams of two students to read and study the technical manual that accompanied one of the pieces of equipment in the lab and then to write a set of clear instructions for installing and operating the assigned device. A second team then took the original directions and edited, corrected, or simplified the instructions. The test of both teams' success was the ability of a third team to carry out the instructions as written. The first challenge was to actually take home and read the manual. As one student described the problem, "I read the directions but they didn't relate to anything I know." Like others in the class, he lacked a previous knowledge base into which he could assimilate the new information. He had to translate the technical language into words he could understand for himself and then recast the information in a set of directions that his peers (not technical manual writers) could follow. The need to explain a complex process forced the students to develop their own teaching and learning strategies. Some students talked through the steps to themselves, while others found it helpful to experiment on fellow students, trying out different approaches and explanations. Students who invested the time and effort eventually learned to cope with the issue of how to demonstrate the workings of a complex mechanism. Using a combination of jargon and everyday language, students learned to describe the properties and appearance of various parts of the equipment, make analogies to more familiar examples, and break up intricate processes into smaller, simpler steps.

Interviews with students conducted in the semester following this class affirmed that the most useful exercise had been the final examination—not a paper and pencil test but an individual interview during which each student had to demonstrate complete, detailed knowledge and expertise with a piece of equipment chosen at random by the instructor (smart board; color projector; differences between a Dell and Mac; digital camera; video camera; scanner; inkjet printer; document camera; zip drive; VCR/ DVD). Some students opted for luck and/or prayer, hoping that they would be given a tool they felt comfortable with. But the most successful students were those who put in at least fifteen to twenty hours in the lab on their own time, practicing setting up and taking down each piece of equipment, and talking through the explanation in front of another student or lab instructor. Students pointed to this practice-with-a-purpose situation as the most significant element of their learning for the entire semester. Working on their own or
in small groups, they talked through the steps and instructions and asked each other "dumb" questions, echoing the ongoing preference of many practicing professionals for learning new technology skills from peers.

Findings

A comparison of students' own ratings of their levels of confidence before and after course instruction shows a general pattern of improvement in all areas, as well as some unexpected results. Since the majority of students coming into the course expressed a high level of confidence in their ability to use e-mail, surf the internet, or play games on the computer, it not surprising that these items showed the least amount of change in confidence levels from the beginning to the end of the term. Common technology tools such as the video camera, word processing and desktop publishing, which were not the subject of direct instruction in the course but were used by students to accomplish other tasks, also showed little change in the students' over-all confidence levels. One unexpected finding was the lowering of confidence in the ability to "select software for children" from a middle ranking on the first survey to a lower level of confidence at exit. This result can perhaps be explained by the students' new awareness of the many criteria that must be considered (ability of the program to meet lesson objectives, appropriateness for age and ability levels, ease of use, etc.).

There were minor changes in the level of confidence in using tools that were not overtly taught in the course but probably already familiar to students, such as putting data on a floppy disk, using software to import graphics, loading software from a disk or CD ROM, using Internet search engines, spreadsheet and database software, and using a still camera. Significant changes for the better in confidence levels were shown for "installing software to a hard drive," "using a scanner," "using a document camera," "using a digital camera," and for "setting up a computer from scratch." Showing some growth but not complete mastery was "hooking a computer to a VCR or TV," still a complex task for most students.

In follow-up interviews, students expressed concern with lack of opportunities to practice using the new tools they had learned in ELED 1000. Although they reported using the Internet, videos, and power point in subsequent classes taught in regular classrooms, they did not feel compelled to return to the Education Resource Lab to carry out projects or just to practice and experiment with the equipment. The department is now reviewing the sequence of courses for elementary education majors, possibly placing ELED 1000 in the sophomore year, when students will also be taking the methods courses that require full technology integration. While the follow-up surveys and interviews showed that students were still "somewhat nervous" about using technology, their experiences in this class made them "nervous" for different reasons. Now they understood the commitment of time and persistence necessary to develop understanding and skill in using various kinds of equipment to enhance learning. On the first survey, only five students had described themselves as "above average" in technology skill, but after the fifteen weeks of course instruction, fifteen out of eighteen students now characterized themselves as "knowing more about technology than most people."

Conclusions

Despite expectations that variables such as gender differences and previous levels of knowledge and experience would affect students' progress in their first elementary education technology course, the key to learning the new technology tools appeared to be the students' own motivation to invest time in hands-on experimentation and practice. The challenge of "finding time" faced by our pre-service teachers is evidently shared by classroom teachers who consistently report a lack of released time to achieve the necessary learning as a high barrier to their implementation of technology. "Teachers who spent more time in professional development activities on technology use indicated that they felt better prepared to use technology for classroom instruction than those who spent less time in those activities" (Teacher's Tools, 2000, p.102). Even more than money for new equipment, we need to allocate funds to give teachers time and opportunities to gain the level of comfort necessary for them to integrate technology into their plans for classroom instruction. Teacher training institutions and the educational community at large must rise to the challenge put forth by the U.S. Department of Education in PT3 2000: "School boards, school
administrators, parents, and students will expect all future teachers to be well-prepared, technology proficient educators...who know how to infuse technology tools into the curriculum to improve learning and achievement.”

Abstract: Acadia University in Nova Scotia, Canada offers unparalleled opportunities to conduct action research on the innovative use of instructional technologies. This laptop institution (the first in Canada) supplies some 4000 students with anytime-anywhere campus access through the use of networked A20m IBM laptop computers. The School of Education, as a teacher training facility, is particularly interested in the pedagogical applications of computers to classrooms. This paper provides the framework for an institutional session on the evolving use of electronic discussion groups.

Introduction

Electronic discussion has gained a well-deserved place in the arsenal of teaching strategies for the 21st century, particularly in distance education. Since early studies (Harrington & Hathaway, 1994, 1995; Harrington & Quinn-Leering, 1994) it has become clear (Kuehn, 1994) that the asynchronous nature of the electronic discussion group (hereafter EDG) and the accessible transcripts of dialogue, make the EDG a unique phenomena that is decidedly different (Molinari, 2001) from face-to-face (FtF) discussions.

At the onset of EDG use, the obvious application was to allow for an open forum for students to exchange ideas in a relatively unstructured format. Though this model remains prevalent, educators have sought to prime this facile communication to support improved classroom instruction. This has been accomplished by supplementing FtF classroom discussions. As an example, instructors (Joyce, Nodder, & Young, 2001) have used the EDG as a means to 1) extend the classroom discussion by assigning additional topics post-class or 2) preface classroom FtF discussions with readings and preliminary EDG exchanges.

Coding Electronic Discussion Groups

The EDG offers the added benefit of a recorded transcript of discussion and recently the authors have capitalized on this feature. Though the use of analytical rubrics for assessing EDG’s has been explored in distance education, in many EDG settings grades continue to be assigned based on quantity of contributions rather than quality of the discussion. A coding system (cognotes) has been developed (Aylward & MacKinnon, 1999; MacKinnon & Aylward, 2000) for use in EDG’s. The cognote system, based on journal coding (Knight, 1990), encourages students to engage in more substantive electronic
discussion through a grading scheme that favours higher-order discussion patterns (see Table 1). In this scheme the instructor electronically codes the students captured discussion and then returns the coded work to the student. This promotes critical thinking in that students tend to utilize higher order argumentation patterns which in turn yield a higher grade for their participation (MacKinnon, 2000). Over the duration of several EDG sessions, students have an opportunity to reflect on the quality of their contributions and in ensuing discussions improve their discussion patterns.

Lessons Learned: The Partnering of Students with Teachers and Administrators to Achieve Successful School-wide Implementation of Learning Technologies

Sheila MacLeod Potter
Acadia Institute for Teaching and Technology
Acadia University
Canada
Sheila.Potter@acadiau.ca

Abstract: Six years ago, Acadia University became the first in Canada to adopt a campus-wide student notebook program. Concurrently, the Acadia Institute for Teaching and Technology (AITT) was created to take a leadership role in the effective use of technology in learning. Soon after, the AITT began translating its growing expertise into training programs for K-12 teachers in Nova Scotia. On campus, the AITT partners exceptional undergraduate students with faculty members in their disciplines to develop learning technologies for the classroom. The success of this experience inspired the inclusion of outstanding secondary students in our K-12 technology training.

This paper will examine the lessons learned from two new programs in which secondary students play an integral part. Sponsored by General Electric, and Clarica, the AITT is in the process of running two 2-year programs that partner teachers and administrators from across Canada and the state of Maine, with exceptional students in their schools. In developing and running these programs, it has become clear that, just as in post-secondary institutions, tremendous gains can be made to both sides of student-teacher partnerships in K-12 schools.

Introduction

The Acadia Institute for Teaching and Technology (AITT) was established six years ago, as a center for the development of learning applications to support the Acadia Advantage (AA) program, which has since put a notebook into the hands of every faculty member and undergraduate student on campus. Quickly, the AITT became recognized as a center of excellence for the effective integration of technologies into learning, and was funded provincially to train Nova Scotia’s K-12 teachers, training over 950 as of fall 2001. The AITT maintains its dual teaching and development roles by employing a large number of students throughout the year. These students are chosen mainly for their people-skills and teaching ability, and are trained in basic applications before being partnered with faculty to support the development of new learning materials, or teacher-training programs. This past summer, the AITT embarked on two new training programs, each of which built on an aspect of our provincial experience. Over 3 years, the Clarica Scholars program will bring up to 60 teams to Acadia, to spend a week developing a technology solution to a learning challenge in their school. The GE Leaders program will fund 14 teams over two years. As in the Clarica program, GE teams consist of two teachers and two students, but with the addition of an administrator. The GE Leaders week is designed to facilitate the creation by each team of a school-wide technology implementation plan. To date, we have hosted twenty Clarica Scholars teams, and seven GE Leaders Teams.

Lessons Learned

Empowered by a supportive school, and with ready access to the boundless possibilities of technology, students not only rise to expectation, they exceed it.

This premise, more than anything else, has made AA a success. Each year, as the story of the program is told over and over again, visitors to Acadia find it hard to believe that students could be relied upon to the extent that they are: as software developers, instructional designers and teachers. Not until some of the student-developed applications have been demonstrated, and the students themselves have described their involvement, is everyone convinced: with guidance, student energy and ingenuity can result in products that not only meet the expectation of their faculty partners, but far exceed it.

The success of technology implementation at any level of education depends on the teacher finding uses for
the technology, beyond the obvious PowerPoint delivery of lectures. At Acadia, students not only provide busy faculty with much needed development support but gaining some experience, students also consult with faculty to explore what technology can do for their teaching.

High schools all over North America currently face the same challenge: busy teachers have no time to create innovative applications for their classrooms. In our two summer programs, we met administrators who have already recognised that trying to find time for teachers to first learn the technology and then to work with it, only offers a partial solution at best. Instead, these schools rely on their teachers to be content and pedagogy experts, and to a varying extent, on their students for support and development. For example, at Jakeman All-Grade, in Newfoundland, students worked with their teachers, developing support materials for the classroom. Out of the success of this experience, has come a more ambitious project: a CD-ROM based tour of their town. In order to create this CD, students and teachers have to learn a considerable amount of technology, however, in researching and writing the content, the students are also learning local history, geography and sociology, inspired by the knowledge that their work will benefit a much wider audience.

In another example, at Bonny Eagle Middle School in West Buxton, Maine, ‘student assistants’ act as teaching and trouble-shooting support to computer lab users.

**It is time to formalise the role of students as technical support to their peers and to their teachers.**

Many teachers feel great trepidation about the unpredictability that arises from technology implementation in their classrooms. Some react by avoiding new technologies all together, while others create powerful opportunities for learning.

At a training workshop for high schools with notebook programs, the question arose: how does a teacher manage both her students’ learning, as well as the challenges posed by fickle technology? In response, one teacher described how, while preparing her lessons for the following day, she had tried to incorporate a Microsoft Excel function into a class demonstration. After she had spent some time trying to figure-out the software without success, she decided to put the problem in her students’ hands. The next day, she offered bonus points to the first student who could solve the problem, and within five minutes, had given the points away. She had also created a learning environment in which students and teachers are equal contributors.

Similar stories arose, particularly in our GE Leaders Program, where discussions of technology implementation issues included students, teachers and administrators. Clearly, many teachers allow technology to create a collaborative, problem-solving environment in their classrooms. However, students quickly pointed out that although some teachers may not see it, many students expend considerable time, helping themselves, each other, and even their teachers to overcome challenges posed by technology. As two students put it, “I end up spending all of my time helping other people [with the computer] and don’t get to work on my own projects.” and, “sometimes, I know a lot more than my teachers do.”

Believing that students can be formally assigned technology-support roles at their schools, we set-out, in our GE Leaders program, to model how this might be done. We set a few of our programming experts the task of creating situations in which support technologies, such as digital projectors and notebook docking stations, would not function. Our “Student Troubleshooting” workshop, however, did not go as we imagined it would. After having spent less than an hour learning how to confront these situations, the students resolved them too easily and became bored.

As a follow-up to that week, teams (and in many cases, the student members) have agreed to find ways to recognise and reward students’ contributions to technical support. When we conduct our 6-month post-survey, we look forward to hearing how each team has accomplished that goal.

**Conclusion**

The greatest obstacle to successful implementation of technologies into the classroom is time. Teachers are pressed to learn new technologies as well as to use them in developing solutions to teaching and learning challenges. We have seen that by partnering with students, teachers at all levels of education can not only harness the power of technology to enhance their teaching, but also create a more productive and healthier environment for learning.
The Educational Technology Minor at the University of Wisconsin-Stevens Point

Sandra Madison, University of Wisconsin-Stevens Point, US
Elaine Hutchinson, University of Wisconsin-Stevens Point, US

Until recently, the education program at the University of Wisconsin-Stevens Point (UWSP) has not been unlike many teacher preparation programs throughout the United States. For example, a recently released report from the National Center for Education Statistics revealed that less than a quarter of new teachers reported feeling well prepared to use technology in their teaching. Additionally, the CEO Forum on Education and Technology concluded that many teachers do not know how to put the new gadgetry to good use. The Forum noted that many college teaching programs are ‘failing to train the next wave of teachers adequately.’ K. Kay, executive director, observed that “We’ve got to make sure we have a strategy in place in school to bring teachers up to speed to use this technology and make sure we don’t graduate another teacher from a school of education who doesn’t know how to use technology in the classroom’ (Mendels, P. New York Times, 2/24/99).

Recognizing the need to address the issue of improved technology training for pre-service teachers, UWSP introduced the Learning Technologies minor in 1998. The minor, the first of it kind in the state of Wisconsin, is designed to prepare future teachers to integrate technology in their classrooms and to become technology leaders in their schools. The first cohort of pre-service teachers to complete the minor will student teach and begin the search for a teaching position during the 2001-2002 school year.

Concurrent with the development of the minor, the Dean of UWSP’s College of Professional Studies worked closely with the Wisconsin Department of Public Instruction (DPI) to institute a Learning Technologies certification category for elementary teachers. The new certification became effective at approximately the same time as the UWSP minor passed through university governance. The DPI is currently considering a proposal to expand the certification to K-12.

The program at UWSP is noteworthy in that it offers a 24-25 credit inter-disciplinary minor in contrast to the single educational technology course offered in many teacher education curriculums. In addition, our program differs from many in that we require that our pre-service teachers begin working with students early in their education, their first experience coming as early as the freshman year. We are convinced that this early and extended field experience serves our students and ultimately their students well. Moreover, the minor contains a strong technical component, including required courses in computing fundamentals, the rudiments of computer programming, and computer hardware and network architecture. We believe that the extensive integration and field experience and the strong technical background provide graduates with the confidence, credentials, and the credibility necessary to serve as effective technology leaders in their schools and in their districts.

The authors developed the Learning Technologies minor and co-teach the minor-specific courses, the curriculums of which are guided by the Wisconsin Model Academic Standards for Information Literacy and the National Educational Technology Standards (NETS). The paper/presentation will describe the minor, the content of the minor-specific courses, provide excerpts from the field experiences, and share the insights gleaned from the experience of our students and graduates working as pre-service technology teachers in the K-12 school environment.
Unplugged! Pioneering the e-Campus Vision

Abstract. A technology enriched campus with anytime-anywhere access created a challenge for the Oklahoma Christian University Teacher Education program. An academic environment in which every student is issued a laptop computer creates the opportunity for teacher education candidates to be better prepared to teach p12 students to live and work in a world rich in technology. This happens only when faculty adjust their instructional strategies to model the effective use of technology in teaching their courses. The 4-member panel presentation includes: sharing the Vision of an e-campus; changes in teaching strategies; preparing pre-service teachers to assess p-12 students; and challenges yet to be addressed.

Proposals for change are generally met with excitement and anxiety. The extent to which an individual welcomes or opposes such proposals depends upon the perception of the effect of the change. The availability of and the emphasis on the use of technology in instruction suggests that old ways of classroom instruction are no longer acceptable; new learning must be acquired by the teacher if instruction is to be effective.

Sharing the Vision.

Change is accomplished only when those affected have an opportunity to participate in the change. When the proposal to create a wireless campus at Oklahoma Christian in which each faculty member and each student would be issued a laptop computer was first considered, most faculty members were using desktop computers and standard programs. In order to involve all groups who would be significantly affected by the change, focus groups made up of the entire Oklahoma Christian University campus community considered the advantages of moving to a laptop environment and recommended the change.
Technology Mediated Learning. Such learning requires a change in instructional strategy with the goal of improved learning outcomes. The absence of technology in instruction is characteristic of the receptacle model of learning in which the engagement of students in learning is related to the day and time which the class meets. Engagement is moderately high early in the week and highest in the middle of the week; the engagement level drops dramatically by Friday afternoon. This fact has long been recognized by teachers; it is an aspect of instruction in which change is welcomed.

Chickering and Gamson (1987) articulated Seven Principles of Good Practice in Undergraduate Education: encourage student-faculty contact; encourage cooperation among students; encourage active learning; provide prompt feedback; emphasize time on task; communicate high expectations; respect diverse talents and ways of thinking. Although 15 years have passed and technology has become a major resource for teaching and learning in higher education, these goals still state the desired characteristics of the undergraduate experience and are aligned with the mission of Oklahoma Christian University. The value of using technology in instruction can be assessed by the extent to which it makes these Seven Principles more evident.

Technology mediated learning results in the Discovery Model of Learning. Technology-driven activities such as on-line quizzing, simulations, cyber-shows, collaborative writing, presentation preparation, pre-exam chats, and e-mail engage students in learning before the time of the class meeting. During the class meeting the students are further engaged in student presentations, problem analysis, current lectures, one-minute quizzes, discussion, in-class chat, and case studies. Following the class meeting students complete assignments using discussion board, software demonstrations, on-line guests/videos, Internet research, group web sites, notes on line, and email. By employing these options in classroom instruction, the teacher becomes the facilitator of learning and students are able to be more in charge of their own learning. Students with greater levels of capability are able to move to more challenging levels of learning.

Changes in Teaching Strategies.

The support for such change is evident in the opportunities that were provided for faculty to learn new programs. Oklahoma Christian faculty received IBM Tinkpads a year before laptops were issued to students. Classes were offered and individual instruction was provided as needed. Thus, faculty had a number of opportunities for staff development before the campus was "unplugged" last August. Continuing support is provided through a "help desk" which provides instant assistance when a technological problem occurs. Support teams work specifically for faculty members; they help faculty work through problems they may be having with new instructional strategies and help them set up new options for use in classes. Ongoing staff development for the individual instructor or for groups in available.

Preparing Teacher Education Candidates to Assess P-12 Learning. Teacher education programs accredited by the National Council for Accreditation of Teacher Education (NCATE) must be able to demonstrate how they know their candidates can make a difference in p-12 student learning. One approach which is being used at Oklahoma Christian in an elementary education literacy course addresses the need for assessment over time. This method was chosen because it seemed that it could better prepared elementary teacher candidates to assess student learning in literacy. This approach emphasizes the importance of using authentic child-authored print to practice assessment; it provides opportunity for pre-service teachers to develop an understanding of writing rubrics by using and creating their own rubrics.

The Assessment Plan. All teacher candidates were given access to a prepared writing assessment rubric and authentic elementary student writing samples which were provided by an elementary school in which students complete a literacy practicum. The technology used to distribute the work samples to students included the Digital Dropbox in Blackboard. As an out-of-class assignment, each candidate was given the task of using the prepared writing assessment rubric to assess the student writing sample and make annotations using Adobe e-Book Reader. During class meeting time, completed rubrics were projected for the entire class to review and discuss.
Following this activity, all teacher candidates prepared a writing assessment rubric based upon the Oklahoma Priority Student Skills (P.A.S.S.) The rubric prepared by each student was based on the grade level of the writing sample which the teacher candidate had been given for assessment purposes. Candidates submitted their rubrics electronically via the Digital Dropbox in Blackboard to be critiqued by the professor. The completed rubrics were then projected for the entire class to review and discuss. Teacher candidates with writing samples from the same grade level were grouped together for the purpose of using Blackboard’s Discussion Board Forum Page. The purpose of the discussion was to determine particular strengths and weaknesses noted in each grade level.

The final activity was based on an end-of-year writing sample from the same group of students whose work was the basis of the initial activity. Teacher candidates again submitted electronically the completed writing assessment rubrics for end-of-the-year writing samples; these, too, were critiqued by the course instructor. Candidates working with writing samples from the same grade level were grouped for electronic discussion. The purpose of this discussion was to develop summaries of student strengths and weaknesses in a particular grade level. Teacher candidates then presented the rubric assessment results of their two student writing samples to the class using a projection system.

Other examples of instructional use include materials developed by teacher candidates. The preparation of graphic materials and the use of PowerPoint and Hyperstudio for designing instruction have been accelerated. The electronic portfolios which are developed by candidates are aligned with the Oklahoma required assessment portfolio standards and serve as the candidate’s professional portfolio as well.

Positive Learning Outcomes. The ability to disseminate and collect specific documents through Blackboard was invaluable. The use of class time was enhanced because students worked on projects outside of class. Electronic discussions provided an opportunity to solve problems outside of class and stimulated more focused in-class discussions. The teacher candidates projected a high degree of confidence when sharing their rubric assessment results. Class time was used for refining understanding and application instead of answering simply questions about procedures. At the conclusion of these assessment sessions, students were asked to self assess their learning which occurred through their participation in this activity. The success of the activity is indicated in the results of self evaluations. Students were asked to evaluate, using a scale of 1 to 5, the value of this activity to their preparation for classroom teaching. The resulting evaluation was 4.9

Seven Principles are Evident. Student-faculty contact is encouraged, and prompt feedback is provided because both students and faculty have computer access at any time. Instructors send course information including announcements and reminders of course assignments and provide immediate feedback on quizzes and tests. The nature of technology-driven learning activities such as the literacy activity which has been described encourages cooperation among student as well as active learning. Time on task is emphasized by accelerating learning which precedes and follows class meetings. As students use technology work together to reach consensus and develop presentations for class meetings, cooperation is heightened. This contact will result in a greater respect for diverse talents and ways of thinking.

Challenges Yet to be Addressed

Pioneering leads to discovery. The e-campus concept has created many new opportunities, but unanticipated challenging issues have surfaced as well. Ongoing collaboration focuses on these issues. What the faculty in Teacher Education have learned may benefit others who may be considering such a change.

Without a doubt, students on an e-campus are more engaged in learning. But practical issues accompany this engagement. For example, students have had to learn how to make the most out of the life of the battery, when and where documents can be printed, and University expectations in using electronic communication. In a laboratory setting, when a computer-related problem was encountered, a tutor was on site to assist or students simply moved to another computer. Now it is their responsibility to contact support personnel and be “talked through” the problem. When students enter the University as freshmen,
some have graduated from high schools in which technology was evident in classrooms while others enter from high schools where there is very little technology. Adjusting to university life is a challenge to many; the student whose background in technology is weak can easily become discouraged in an e-campus environment.

Faculty have dealt with unanticipated issues when students use laptops for notetaking and exams. The remedies to problems are there, but faculty must be alert that some students will unwise choose to play games, to download movies and music and to e-mail friends rather than focusing on the task. Philosophical problems regarding the extent of computer use have been discussed. The University's technology team believed that computers would be used heavily during class as well as outside the class and that this would be an invaluable tool for teachers. The faculty viewpoint was that greater access to computers would enable students to research and prepare information for classes and class projects. Some faculty did not envision the use of computers in the classroom but felt compelled since students were paying increased tuition to cover the cost of the technology.

Several factors are unique to teacher education. If teacher candidates are to remain enthusiastic about teaching, they must be placed in technologically advance p-12 schools for field experiences and student teaching. They need to be able to practice technology-driven instructional strategies which have been developed during their coursework in the e-campus environment. Students who enter classrooms with this level of preparation can often enhance the efforts of classroom teachers who may themselves be struggling with technology. The teacher education faculty must be involved in the p-12 classrooms working with teachers in order to remain current on p-12 technology issues. The university can and may be expected to "repay" schools for providing field experiences for candidates by offering technology-related staff development for their teachers.

Indeed the e-campus environment has been a learning experience for students and for faculty as well. The positive aspects are evident; the negative aspects can be overcome.
Through the Looking Glass: Preservice Teachers Vision for Technology Use in Classrooms of the Future

Presented by
Trinka Messenheimer, Bill Morrison, Alicia Bevill, & Tara Jeffs
Bowling Green State University, Bowling Green, Ohio

Introduction
The 1995 Office of Technology Assessment (OTA) report, Teachers & Technology: Making the Connection, addressed that “technology is not central to the [typical] teacher preparation experience” and that “most technology instruction is teaching about technology ... not teaching with technology across the curriculum” (p.165).

Teacher education preparation programs are constantly striving to produce “up-to-date” teachers that are knowledgeable in state of the art teaching practices, classroom management techniques, and technology integration. Yet, what technological tools and skills must be integrated into teacher preparation programs in connecting the classrooms of today with preparing learners for the societal technological needs of tomorrow?

Innovative teacher education programs must go beyond a commitment to technology and best practices in teaching. Beck and Wynn (1998) emphasize that a shift must occur to implement technology applications from supplementary to central in university coursework learning activities. We must begin with a closer look at our learners and match university curriculum opportunities with actual learners needs.

Presentation Objective:
This presentation shares an investigation of undergraduate education students’ visions and perceptions of their use of technology and its importance in teaching. Presenters will provide examples of student vision statements of technology use in classrooms of the future and how these visions compare to perceptions of technology skill proficiencies they have acquired in their undergraduate teacher preparation programs. Powerful insight is gained on the need to align curriculum goals with technological competencies in teacher preparation programs to better prepare teacher for tomorrow’s classrooms.

Project PICT
Data collected during the first year of Project PICT (PT3 grant) provided preservice perceptions and visions. “The overall goal of Project PICT is to enable preservice teachers to fully utilize modern technology for improved learning and achievement in their future classrooms.” Collaborative efforts among university faculty (education, and arts & science) and the k-12 are providing the tools and training to restructuring and infusing technology that is meaningful and in the k-12 teacher preparation process.

Method
Participants
Over 450 undergraduate students in the College of Education and Human Development at Bowling Green State University enrolled their senior year of their programs completed a pre - post questionnaire that provided insight to the students perceived proficiencies in 1) the use of technology, 2) technology that students observed faculty in using during their courses and 3) technology that students used within their coursework.

Design and Procedure
A pre / post questionnaire was administered to the students during the first two weeks of the semester, prior to begin class assignments or interaction with technology, and again at the end of the semester, to measure the impact of technology during taking their course. The questionnaire was designed to measure perceived proficiency in the use of technology, various types of technology that students saw their professors use within the class, and various types of technology that they had used within their class.

Findings
Common threads and themes were among the visions of preservice educators. Below is an overall snapshot of how preservice educators envision the use and importance of technology in their classrooms in the future:

The goal of using technology, as an instructional tool is to give students an opportunity to have access to a wealth of information beyond what we cover in the classroom to enhance learning and offer different approaches to learning. A technology rich instructional approach would be implementing different types of technology into the classroom across the curriculum. This could be done through various assignments both in and out of the classroom utilizing a variety of up- to-date equipment and programs as teachers will be knowledgeable about equipment and model its
uses. The use of technology in the classroom should be introduced by kindergarten continuing through high school and college with age appropriate hands on activities.

Preservice teachers describe how technology will be used within the classroom in which they will be teaching:

In a technology rich classroom, I envision both the teachers and students having access to and using computers along with other technology to gather information and as uses to reinforce and support their ideas. Classrooms should be equipped with three to five computers and ideally a laptop on every desk, as access needs to be available for all students on a regular basis. Students need to be given time to learn about and use technology. Technology that is important and necessary for a technology rich classroom would involve computers, word processing, Internet, email, spreadsheet, drawing and graphics, television, electronic references, presentation software, digital cameras, video and multimedia.

Interesting enough, this same instrument (pre/post questionnaire) provided supporting evidence of preservice teachers perceiving their own use of technology as minimal.

Lessons from the Looking Glass

Given an opportunity to reflect and look at self-competencies in using and integrating technology in the classroom preservice teachers shared that they believed that they had minimum basic computer skills, yet their vision and importance indicate high emphasis. This seems such an injustice for preservice teachers, almost in completion of their teacher preparation program, stepping into their final student teaching experience to have such a low perception of their own technological ability.

Perhaps after identifying such discrepancies, it is now time for teacher education preparation programs to stare into the looking glass and systematically begin to fill the gap between curriculum, visions, and actual preservice teachers’ technological skills that can and should be obtain during their teacher education programs. In order to create innovative and technology rich classrooms of the future we must first prepare innovative and technology proficient teachers.

In this session, participants will:

- Explore preservice teacher perceptions, competencies and their implications for teacher preparation programs.

- Exchange through an open discussion, other technology tips, strategies, and innovative curriculum restructuring that enables the use of technology throughout teacher education preparation

Participant Outcomes:

Through the implementation of technology, participants will be able to generate ideas and projects that meet their specific needs of their programs and provide the learners within these programs with choices and activities that will enhance the infusion of technology into teacher education.

Creating a Learning Community: Faculty/Student/Librarian collaboration at
Washburn and Kansas Universities

Anne Millard-Daugherty, Washburn University, US
Jan Guise, Washburn University, US

This paper reports on a pilot project implemented during the Fall 2001 semester at a small liberal arts university (6500 students). Approximately 30 Educational Technology students have 3 weeks to develop an annotated resource list as part of a class assignment and a further 6 weeks to develop the resource list into a unit of work suitable for use in their classrooms. The students, all education majors, vary in specialization from pre-K through High School and include every subject area. They were given a "one-shot" library instruction session at the beginning of the project and then were paired up with one of five instruction librarians. The students will meet with their librarian twice in a one-on-one research consultation, and then submit their list of resources to their librarian for grading. The students were also paired with a student from the western civilization program at the University of Kansas. The collaboration between the Washburn University (WU) and Kansas University (KU) students was to be carried out totally through email. Data will be gathered from pretests and posttests administered to the students and the librarians and anecdotal reports will be solicited from all participants. The project will be repeated in the Winter 2002 semester, and results compared with Fall 2001 data. Among the goals of this project are: improving students' information literacy skills; promoting the librarian as a valuable resource; librarians learning about the needs and research habits of today's students; creating mutually beneficial faculty/librarian/student partnerships. This report will present findings, learning experiences, and suggestions for future projects.
A Study of Developing Reflective Practices for Preservice Teachers through a Web-based Electronic Teaching Portfolio and Video-on-demand Assessment Program

Hitoshi Miyata
Center for Educational Research and Practice
Faculty of Education, Shiga University
Japan
miyata@sue.shiga-u.ac.jp

Abstract: Web-based electronic teaching portfolios and videoclipped teaching episodes using by Video-On-Demand(VOD) System can serve as devices for reflective inquiry and self-assessment by preservice teachers during the student teaching semester. Carefully structured procedures in a web-based electronic teaching portfolio and VOD Assessment Program can assist preservice teachers in developing the pedagogical knowledge and skills necessary to effectively plan, implement, evaluate, and manage instruction. Adequate orientation and training in the program will enable preservice teachers to engage in the reflective processes of observing, analyzing, and evaluating their teaching performance. Carefully designed procedures can result in the videoclipped teaching episodes being utilized as effective tools for the improvement of instruction rather than simply a souvenir or memento from the student teaching semester. This paper presents the web-based electronic teaching portfolio and VOD Assessment Program employed in the Center for Educational Research and Practice of Shiga University in Japan. The Program has been a valuable tool for helping education majors make the transition from student to teacher.

Introduction

The importance of developing in new teachers the ability to reflect on their practice of teaching has been well-established (Posner, 1989; O'Donoghue, 1996). Several studies (Freiberg, Waxman & Houston, 1987; Freiberg & Waxman, 1988) indicate that reflecting upon teaching during student teaching can enhance the repertoire of pedagogical knowledge. Koorland, Tuckman, Wallat, Long, Thomson & Silverman (1985) state that self-assessment may be the key to creating better student teachers. Teacher education programs need to encourage preservice teachers to initiate self-assessment that will develop the type of reflection necessary for a prospective teacher to continually evaluate and modify instruction within the classroom. Most preservice teachers rely on cooperating teachers and university supervisors for constructive feedback on their teaching. Observations and evaluations conducted by cooperating teachers and university supervisors are the most common sources of data during the student teaching experience. Unfortunately, due to the limited number of observations and conference sessions generally conducted, depending solely on outside sources for feedback on instruction may inhibit professional growth. Student teaching is the capstone event of the education program and it is extremely important for preservice teachers to receive as much feedback as possible during this experience. The data provided preservice teachers should be drawn from a variety of sources to complement the feedback provided by college supervisors and cooperating teachers (Freiberg & Jerome, 1988). Encouraging preservice teachers to effectively assess their own teaching will help them overcome weaknesses and maintain strengths. Preservice teachers are capable of analyzing their own teaching, want to improve their teaching skills, and would be willing to evaluate their own instruction if they had the resources (Oliva, 1988). Preservice teachers will be in a position to critique their own classroom instruction if they are provided appropriate background and experience. In order for preservice teachers to effectively assess their own teaching, accurate data must be gathered. This data can be acquired through journals, logs, portfolios, audiotapes, and videotapes. Research supports the use of videotaped teaching episodes to foster self-assessment and enhance teaching performance (Sparks-Langer & Colton, 1991; Struyk, 1991). Simply videotaping preservice teachers and having them analyze their teaching without a systematic set of procedures or
background and training in the process will be ineffective. Carefully structured procedures need to be established that can assist preservice teachers in developing the pedagogical knowledge and skills necessary to effectively plan, implement, evaluate, and manage instruction.

A Web-based Electronic Teaching Portfolio and Video-on-demand Assessment Program at Shiga University

The following information summarizes the process established at Shiga University to utilize a web-based electronic teaching portfolio and video-on-demand assessment program in order to encourage reflection and self-assessment by preservice teachers. It has been developed to enable preservice teachers to engage in the reflective processes of observing, analyzing, and evaluating their teaching performance.

Course-Embedded Instruction on Reflection, Self-Assessment, and Videocliping

The research supports methods course-embedded instruction for self-assessment. A study by Jensen, Shepston, Connor, and Kilmer (1994) indicated that preservice teachers could benefit from more instructional experience with videotaping, self-assessment, and reflection in general. The more familiar students are with assessment measures and the more exposure they have to both self-assessment and assessment by supervising teachers, the more competent they will become (Thomson, 1992). The use of videotaped teaching episodes as an instructional tool in teacher education methods classes prior to student teaching enables preservice teachers to be more self-confident and effective teachers (Thomson, 1992). Although elements of effective instruction are reviewed and discussed in all education classes at Shiga University, a more intense study of effective teaching and appraisal systems is undertaken in methods classes. Carefully developed inventories that are based on behaviors associated with effective instruction are examined. This information is linked with assessment activities conducted in the methods classes. Former students have granted the Education Department permission to use their videoclips on the web in education classes for instructional purposes. Methods class students view and analyze videoclipped teaching episodes to compare with known principles of effective instruction. They are taught to assess procedures and consider alternatives, identify and offer changes for nonproductive routines, and think about ways to improve on the lesson. Once students have become familiar with assessment terminology, the next logical step should be the implementation of the terminology in real class situations that are videotaped for self-assessment (Thomson, 1992). Education methods classes are sequenced and clustered in order to block time for team teaching and field-based experiences. Coordinated with methods classes (currently Language, Arts, Social Studies, Mathematics, and Science) are field experiences that provide students with an opportunity to relate principles and theories learned in class with actual practice in schools and allow students to present lessons to students in elementary classrooms. During this field-based assignment, students (assigned in pairs) are videoclipped at least once for each subject area and are required to complete reflection questionnaires for each episode. Methods class instructors view the videoclip on the web with the students and guide them in methods of self-assessment. Although this process is time consuming for the instructor and students, early feedback on teaching skills during methods classes results in better preparation and success for student teaching (Rogers & Tucker, 1993). Students believe this instruction prepared them to effectively monitor their practices and make adjustments to them during the professional semester.

Student Teaching Semester

Preservice teachers participate in a eight-week, full-time student teaching semester in the Shiga University attached school district. They are generally assigned to one cooperating teacher who has completed workshops or classes in supervision provided by Shiga University. A full time college supervisor is also assigned for the entire experience. The first week of the professional semester are spent on campus for orientation activities. As a part of orientation, guidelines associated with effective instruction and self-assessment techniques that were examined and applied in methods classes are reviewed to encourage preservice teachers to make critical decisions regarding their instructional effectiveness. Preservice teachers also review the procedures and expectations of the Video-on-demand Assessment Program.
**Videocliping Procedures**

Attached school districts that accept Shiga University preservice teachers support the videotaping of instruction. The districts’ only requirement is for permission slips to be sent home to parents/guardians prior to the taping. Students that did not return permission slips to be sent home to parents/guardians viewed the videoclip together and discussed when the student and college supervisor optimum learning from the videoclip occurred see [Figure 2].

Focus on in the next videoclip or observation, reviewed in conferences held with the college supervisor or cooperating teacher and serves as a guide for areas to complete the instrument is accomplished this. And, “What specific areas of instructional skills or classroom techniques will you focus on for videoclip teaching episodes or observations have you shown improvement? Briefly describe how you additional improvement: “In what specific areas of instructional skills or classroom techniques assessed in previous the least three times to focus separately on each area when completing the instrument. The completed instrument is linked this to new information.” Open-ended questions for each area (Classroom Environment; (2) Communication Skills; and, (3) Teaching Procedures) include, “What do you perceive as the best positive aspects of your teaching procedures?” and, “In the area of classroom environment you are not satisfied with, briefly describe strategies you will consider for improvement.” Two additional open-ended questions focus on growth and determine areas that need improvement. Preservice teachers rate specific behaviors as either Proficient (Effectively demonstrated the skill well above the required level), Satisfactory (Demonstrated a steady performance and effectively met the standard requirements), or Improvement Needed (Demonstrated some competencies but improvement required). An example of an item would be: “Activated students’ prior knowledge and linked this to new information.” Open-ended questions for each area (Classroom Environment, Communication Skills, and Teaching Procedures) include, “What do you perceive as the best positive aspects of your teaching procedures?” and, “In the area of classroom environment you are not satisfied with, briefly describe strategies you will consider for improvement.” Two additional open-ended questions focus on growth and considerations for additional improvement: “In what specific areas of instructional skills or classroom techniques assessed in previous videocliped teaching episodes or observations have you shown improvement? Briefly describe how you accomplished this.” And, “What specific areas of instructional skills or classroom techniques will you focus on for the next videocliped teaching episode or observation?” Preservice teachers are directed to view the videoclip at least three times to focus separately on each area when completing the instrument. The completed instrument is reviewed in conferences held with the college supervisor or cooperating teacher and serves as a guide for areas to focus on in the next videoclip or observation, see [Figure 2].

**VOD (Video on Demand) Conferences**

Preservice teachers have indicated that optimum learning from the videoclip occurred when the student and college supervisor viewed the videoclip together and discussed.
the assessment in the context of the lesson being watched. This dialogue between the student and supervisor provided a smoother transition between methods classes and student teaching, resulting in better understanding of the evaluation process and a more positive attitude toward the student teaching experience (Thomson, 1992). Moore (1988) found it imperative that the videotaped lesson is cooperatively analyzed by the preservice teacher and college supervisor. The main purpose of the preservice teacher/college supervisor VOD conference is to promote the preservice teacher's ability to reflect upon his or her own teaching and guide them in considering their own methods for improving instruction. This conference gives preservice teachers time with the supervisor to verbally analyze their own practice and effects on students, generate alternative strategies to use, and commit to self-examination and self-improvement. A college supervisor/preservice teacher conference always follows the first and second videoclipped teaching episode. The progress and ability of the preservice teacher determine a conference for the final videoclip. Most of the cooperating teachers that have been assigned Shiga University student teachers have completed a five credit, tuition-free graduate course, Supervision of Preservice Teachers. In this course they become familiar with the Video-on-demand Assessment program and are encouraged to view the videoclips with the preservice teachers, see [Figure 2]. Through video-on-demand conferences with the college supervisor and cooperating teacher, preservice teachers receive guidance and direction for reflecting on his or her practice. This is also a time for everyone to consider areas to be focused on in the next videoclip or observation.

Conclusion

It is clearly evident the time required by all individuals involved in this process is extensive. However, preservice teachers and college faculty consider the experience worth the time (Blake, Foster & Hurley, 1996; Holodick, Scappaticci, & Drazdowski, 1999). Although the primary purpose of videoclipping preservice teachers is for the improvement of instruction, the practice is also encouraged by some organizations. Not only the National Board for Professional Teaching Standards in USA (1997) but also some Prefectural Board of Education in Japan requires candidates to submit a portfolio as part of the application process for the certification. It is suggested that candidates include in the portfolio four or five classroom-based exercises (may include videoclip of classroom interaction or discussion) and written analysis of the teaching reflected in the videoclip. If colleges of teacher education are going to prepare highly effective teachers who are capable of evaluating their teaching in the light of student learning, the time must be taken to provide education majors with the necessary training and experience in this process. Shiga University places a high priority on developing a preservice teacher's ability to become a reflective practitioner. Time is committed to learning, experimentation, critical analysis, and practice of skills necessary to effectively reflect. The videoclipped teaching episodes are utilized as effective tools for the improvement of instruction rather than simply a souvenir or memento from the student teaching semester. The Web-based Electronic Teaching Portfolio and Video-on-demand Assessment Program in Shiga University has been a valuable vehicle for helping education majors acquire the knowledge and skills required for professional development and a successful transition from student to teacher.

Electronic Reflection in Teacher Education

Laurie Mullen, Ball State University Teachers College, US

Purpose

This session explores how reflection is shaped by the context in which it occurs. The author will share data from two years of prototyping a reflective, standards-based electronic portfolio with preservice teacher education students. Findings indicate that students’ inability to reflect beyond a technical (Cruikshank, 1985) or descriptive level may be, at least in part, due to 1) lack of experience in writing in electronic hypermedia environments and 2) the tensions between the inherent messiness of reflection in learning to teach contrasted with the highly glossy “finished” look of electronic publishing. The research question guiding this inquiry was, “In what ways does the process of reflection change in a hypermedia environment?”

The session will include findings from this research as well as sample student work.

Background and need for study

Due do concomitant national and international teacher education initiatives, namely performance based assessment and educational technologies for teaching and learning, the implementation of electronic or digital portfolios as a major means of assessment is growing. The recent Preparing Tomorrow’s Teachers for Technology (PT3) grant competitions sponsored by the Department of Education have resulted in a nationwide technology focus in teacher preparation institutions. Many PT3 institutions are exploring electronic portfolios as a major grant initiative.

By June 2002, my university is mandated to have in place a performance-based Unit Assessment Plan (UAS) approved by the state. Our institution has identified student electronic portfolios as one performance assessment instrument for demonstration of multiple competencies. In recent years, a number of portfolio types have been used on our campus by faculty from a variety of disciplines. The medium of these portfolios has included paper, PowerPoint, and the World Wide Web. The specific purpose of the portfolios has varied according to the needs of the discipline and the preferences of the faculty member teaching the course.

The electronic portfolio has emerged as a tool to assess students’ competencies in technology and other areas. We believe that engaging in the electronic portfolio process will help students to develop technology-related knowledge and skills. The overall goal for the electronic portfolio process is to meet the learning and competency objectives of the program through a student-centered reflective process that ultimately benefits all stakeholders. Given the longitudinal nature of the student portfolio, reflection will become more rich and complex as students continue in the program providing quality information that can be used to examine growth and progress over time. Primary in each stage are students’ reflective self-evaluations of their progress and readiness to move on. Building with their first education course, candidates will offer an evolving portrait of their growth as prospective teachers, supported by hyperlinked artifacts that demonstrate and exemplify this development.

Portfolios as Alternative Assessment

Reform efforts beginning in the 1980’s advocated for alternative assessment in teacher education. The introduction of portfolios, and other forms of performance-based assessments, reflects an increasing dissatisfaction with traditional assessment methods, which do not attend to process and authenticity. Portfolios emerged as a popular tool and are supported by principles such as providing a new perspective on learning, developmental in nature, and involve self-evaluation or reflection. Thus, portfolios in initial teacher education align with constructivist learning theory.

Reflection

Dewey (1933), is acknowledged as a key originator in the twentieth century of the concept of reflection. He considered it to be a special form of problem solving, thinking to resolve an issue which involved active chaining, a careful ordering of ideas linking each with its predecessors. Within the process, consideration is to be given to any form of knowledge or belief involved and the grounds for its support, (Adler, 1991; Calderhead, 1989).

Instructor Orientation

As author and instructor of the course context described here, I feel it is important to share my perspective on the process of learning to teach. The following description appears in the course syllabus and offers a glimpse of my personal philosophy of teaching and learning.

Learning to teach is developmental, procedural, dynamic, political, and problematical. Knowledge is viewed not as static and permanent in nature, but emergent, contextual, situated, and socially constructed. Therefore, novice teachers need opportunities to construct their knowledge by interacting with new ideas in school settings with structured coaching and appropriate interventions.
Learning to teach is not a process of learning discrete techniques separate from the context of schooling. It must also include reflective capacities of observation, critical analysis and decision making around their identities in interactions with students and colleagues with whom you work.

Method

This study was situated in the secondary education program where teaching majors split much of their time in content-specific methods courses in a particular college and time in Teachers College for field-based coursework. Twelve graduate students enrolled in a methods course which included two field-based experiences. The purpose of the course is to provide curricular and instructional theory and practice in secondary schools and in the experiences of older adolescent learners in the United States. The students represented a variety of subject-area subjects and had no prior field-based experiences. Students had little or no experience in web authoring, publishing or electronic communication.

Students were asked to reflect on each of the ten standards guiding our university’s teacher education program three different times during the semester. I asked them to reflect on and write about their current understandings of the teaching standard and to include an artifact that they felt demonstrated their competency in that particular standard.

I had hoped that students would reflect openly and honestly while incorporating hypertext and hypermedia in the process. An additional requirement was a portfolio presentation where each student would discuss portions of their portfolio with an audience of peers serving as critical friends.

This study uses three major data sources. First, each student’s electronic portfolio was analyzed in relation to the research question. A second source of data was the required public presentation of the student’s portfolio. The presentation was videotaped. The third source of data was informal discussions and other course generated materials. Some of these artifacts include course papers, e-mail, and journal entries.

Data were collected and analyzed according to qualitative research guidelines for grounded theory research and constant comparative analysis (Glaser & Strauss), emphasizing particularly their incremental approach to data gathering and analysis. A key to this approach is the idea of theoretical sampling, described as “the process of data collection whereby the analyst jointly collects, codes, and analyzes the data and decides what data to collect next and where to find them, in order to develop the theory as it emerges” (p. 45). Analysis and data collection occur in a pulsating fashion – data collection, followed by analysis and theory development, more data collection, and then more analysis until research is completed. Inductive analysis is shaped from the data rather than from preconceived theoretical frameworks. The development of themes resulted from constructive analysis, a process of abstraction whereby units of analysis are derived from the “stream of behavior” (Lincoln & Guba, 1985).

Preliminary Findings

In this section, I synthesize some of the findings from the analysis and experience for promoting reflection in electronic portfolio environments into two areas for further discussion.

1. Reflection is not necessarily in the written work.

The quality and depth of reflection which occurred in the oral portfolio presentation was far greater than the students’ written text. The ability to reflect orally in presentation format and in interactions with myself and peers holds great promise for capturing rich reflection. If portfolio requirements ask for only the written reflection and do not provide the opportunity for students to talk reflectively, we change the learning process dramatically.

2. Reflection as two-dimensional

The majority of the written reflections were superficial and shallow. It was clear that the students did not want or feel comfortable reflecting on highly personal or ambiguous issues in a web-based format. One student shared that the gloss of a web page forced her to write in a way that appeared as “finished” and “clean”. In addition, the reflections are mainly text-based as students made limited use of hypertextual language and almost no use of other digital media. Students reported a lack of experience across their curriculum with writing in electronic hypertextual environments.

Significance

Increasing numbers of universities moving to electronic and digital portfolios will require university educators to provide assistance in the process of deep reflection in this new medium of communication. The potential danger lies in the representation of knowledge as superficial and glossy at a time when the concept of knowledge as constructed and dynamic in nature persists. In an attempt to infuse technologies into the teaching and learning process for preservice students, we may inadvertently move our students “backwards” in terms of knowledge growth. It may be necessary to revisit the literature on portfolios in order to “remember” their original purpose as an alternative assessment method capable of capturing long term process and alternative representations of knowledge.

Data from this study suggests that researchers in this area may need to explore new methods of collecting reflection as it appears in new hypertextual and hypermedia forms. The way in which we ask preservice students to verbalize abstract, complex, possibly ethereal, and certainly fragile understandings of the learning to teach process affects what they tell us. If language creates a
particular view of reality and of the self as well as serving as a repository of human interests, we need to investigate how language and meaning are mediated by digital environments.

Van Manen (1990) raises the issue of the epistemology of language and text when he states:

We must not forget that human actions and experiences are precisely that: actions and experiences. To reduce the whole word to text and to treat all experience textually is to be forgetful of the metaphoric origin of one's methodology (p. 39).

The Teacher Education Program at Weber State University is a typical teacher education program in that we teach classes to prepare our prospective candidates for licensure. We require our students to assemble a working portfolio during their student experience that reflects our "strands" of our curriculum. We then require them to create a presentation portfolio for their senior synthesis class. However, we are a non-traditional program because we are assembling guidelines for production of a portfolio that our students can continue to develop when they leave our program. The portfolio will also help them meet a variety of national standards such as the Interstate New Teacher Assessment and Support Consortium (INTASC), National Board for Professional Teaching Standards (NBPTS), and the basic International Society for Technology Education (ISTE) technology requirements.

Our program is based on a model of teachers who reflect, engage, and collaborate (TREC). Underlying this model we have developed a core of classes that include five strands woven throughout the curriculum from the earliest classes to the end of our program. Those strands are: classroom management, exceptionalities, multicultural education, developmentally appropriate practices, and technology. Each strand is addressed within each level of courses offered but may not necessarily be emphasized equally. The strands provide a cohesive blend of content upon which to create a balanced curriculum for our elementary and secondary education students.

However, as our program moves toward our NCATE 2000 review in 2005, we have become increasingly aware of a need for a systematic method for creation of portfolios by our students. We believe that portfolio creation most accurately reflects the changes in the NCATE 2000 accreditation process requiring us to produce evidence of student dispositions.

After surveying our existing guidelines for portfolio production, we found them to be overly simple: create a working portfolio and then create a presentation portfolio before you exit the program. In the past, it has been the individual responsibility of each faculty member to require students to add artifacts to their working portfolios as they progress through our class levels. If faculty have not required this action by the students, then many times no artifacts are added from those courses. What we also found at the senior synthesis level is that our students did not have adequate working portfolios and were using their student teaching experience as the primary source of artifacts for their professional portfolio. This was clearly unacceptable.

After reviewing our TREC model and strands as well as a variety of standards, we began to develop an adaptable model around the ten basic INTASC standards for teacher education program graduates. We felt these standards were reflective of the changes in how licensure is being granted in our state. We also reviewed the ISTE basic technology standards and the broad core concepts for NBPTS and found that many of these standards overlap and would therefore be relatively easy for our students to meet on multiple levels.

We are in the process of developing an adaptable model that meets many of these standards. Our presentation consists of a discussion of the basic INTASC matrix and how those standards overlap into the other standards and how to integrate multiple standards within one working portfolio. Although all standards may not equally apply to all students, we believe that many of our students will benefit from an understanding of how these standards and core concepts overlap as they move forward in their professional development. Further information on this process may be obtained by contacting Dr. Vicki Napper at Weber State University in Ogden, Utah (vnapper@weber.edu).
A Field-Based Initiative for Integrating Technology in the Content Areas: Using a Team Approach to Preparing Preservice Teachers Use Technology

Abstract: Project ImPACT is a technology integration initiative at The University of Tennessee’s College of Education that provides opportunities for preservice teachers to learn to teach with modern technologies. This paper describes a component of Project ImPACT for implementing a field-based team approach to technology integration. Collaboration and teaming is a key component of this model. One major initiative in this project involves the creation of teams consisting of university faculty, clinical faculty and preservice teachers to explore and develop best practices in the use of technology. We will describe our method for providing content-related teacher training and support in the use of instructional technology.

Introduction  
Typical models of technology preparation in teacher education programs focus on providing preservice teachers with necessary skills through a separate computer course as part of the teacher education licensure requirements. While preservice teachers are gaining important skills and concepts, they may seldom see meaningful uses of technology modeled in their methods classes or field placements. To be effective, technology integration needs to occur at multiple points in a teacher preparation program. The team model is an approach that simultaneously involves all of the major stakeholders in a teacher preparation experience in training activities, support sessions, and team meetings. We have found that collaborative efforts often create support structures among teams, allowing them to experiment with new skills and share ideas for further adaptation.

The Learning Team Model  
Development teams at partner school sites consisted of preservice teachers, K-7 faculty, and university faculty. Five school sites (three elementary schools and two middle schools) participated in the first year of the project. Preservice teachers placed at these sites were completing their fifth-year internships, and each school maintained close contact with a faculty liaison who was responsible for the group of interns at each site.

Teaming created a dynamic alliance in which each team member played a role in creating the foundation for technology infusion. In order to identify content areas for inclusion under Project ImPACT, we looked at national trends and local contexts. Based on local needs,
administrators and teachers targeted specific areas for improvement. As a result, Project ImPACT participants chose to explore the potential benefits of technology to support literacy (reading and writing), mathematics, science, and special education. Out of the five sites, four schools chose to focus on using technology to support literacy, and one school (a middle school), chose to explore technology applications in math and science. While the grant initially included Special Education as a third strand, it was decided that special education adaptations ought to be integrated within the existing strands rather than treated as a stand-alone area for the purpose of this grant. Figure 1 illustrates the modified teaming model.

![Figure 1: School-Based Team Model](image)

As content areas were identified, team training was organized into 15-hour Learning Strands and aligned with state and national technology standards and the curriculum needs of each school. Each technology Learning Strand focused on strategies and ideas for using technology to support the curriculum. These five 3-hour sessions were scheduled over a five-week period with ongoing weekly support sessions provided by project staff. Once key topics were identified, project staff created a Facilitator's Manual that provided an outline of critical topics, descriptions of curricular applications at various grade levels, and special education adaptations for each topic being discussed. Learning Strand facilitators were assigned to each site and a follow-up support night session for each week was scheduled and staffed by Instructional Technology graduate students. The follow-up support nights were optional sessions that teams could attend if they needed additional help, or if they simply needed open lab time to work on projects.

**Lessons Learned**

Looking back on the progress we have made thus far, it is clear that the teaming model is having a positive impact on preparing all participants to use technology to support teaching and learning. Multiple sources of evidence are being collected throughout the different phases of the grant and will be discussed in future publications. For the purpose
of this paper, we would like to reflect on what we have learned from implementing the
teaming model at participating school sites.

Learning Strand Facilitators. Four facilitators were hired to conduct the 15-hour
sessions (due to proximity, two school sites were combined). In addition to technical
expertise, each facilitator had K-12 teaching experiences. This combination proved to be
very beneficial for both troubleshooting when technical difficulties arose, and for helping
participants brainstorm relevant curriculum applications. Because facilitators were well
versed in educational applications of various technologies, they were able to tailor
instruction to better meet the needs of individual sites. As a result, although each
facilitator was given a “training manual” with suggested topics and activities, each one
felt comfortable with polling their group, getting feedback, and using this feedback to
plan upcoming sessions. While there was overlap in technology applications, each of the
sites ended up implementing training in different ways. Their teaching experiences
allowed them to shift the focus of the weekly sessions from skills acquisition to one that
included a focus on curricular applications.

Processing Time. Participants were involved in very intense Learning Strand sessions. While
the three-hour extended block of time was needed to focus on a tool in more depth, the
weekly sessions made it difficult for participants to process new information. In the future,
Learning Strand sessions should be spread further apart, with ample time built in for
participants to engage in applying their new knowledge. Although participants’ schedules
were very hectic, mini-assignments for them to complete and share at the next meeting would
allow them to practice what they were learning.

Support Nights. Participants’ usage of “support night” opportunities was sporadic. Some
sites took advantage of these sessions to drop in and work on individual projects, while
attendance at other sites remained low. Alternate support mechanisms developed as the
project matured, and ranged from simple emails for help, to setting up individual times for
project staff to go out to a school to help troubleshoot. At this point, we are asking each team
to meet and decide on a support plan that best meets their needs and their schedules. By
placing responsibility with the teams, support structures will be customized to each site.

Web Site Resource. As part of the project, we provided participants with access to a web site
that included supplementary materials and resources links. We found that this area was
accessed infrequently, even though it contained printable handouts, training guides, and links
that were organized by content areas. To increase participants’ awareness of the site’s
resources, a facilitator at one of the sites began introducing a “Site of the Week” at the
beginning of each meeting, and allowed participants time to explore the selected links. After
introducing this activity, survey responses indicated that access increased. If we want
teachers to take advantage of a web-based resource, we have to continue to find ways to
advertise its content and make direct connections for teachers. One way we plan to do this
will be to upload a searchable database of sample projects and lesson plans created by each of
the project participants. We provided each team with a standard lesson plan template for
consistency and we will be collecting sample projects that are tied into our state curriculum
standards as well as the national technology standards.
Conclusion
The field component of this project directly supports project team efforts to develop creative teaching strategies connecting technology across the curriculum. During field placements, clinical faculty, university faculty, and preservice teachers worked together to explore technology possibilities and to develop, share, and/or implement technology-rich lessons. We believe that this approach will help preservice teachers develop an in-depth understanding of how technology can be used as a tool in teaching and learning. This project has reinforced our belief in the need to restructure coursework and experiences to include uses of technology that are developmentally appropriate, integrated across subject areas, and that actively engage learners.
Online Learning, Online Mentors, and Preservice Technology Education: A Study

Abstract: What happens when secondary education teacher candidates are afforded the opportunity to learn about the role of telecommunications to support teaching and learning using online learning modules coupled with online mentoring? For this pilot study designed to assess the feasibility of combining online learning and online mentoring, five online learning modules were designed. Each module included readings and interpretive activities, tool-based tutorials, and the design of lesson plans. Teacher candidates were paired with online mentors who were veteran teachers in the candidate's content specialization. Each online activity resulted in a product emailed to the online mentor. Online mentors responded to products, asked follow up questions, and discussed technology-using practices. This paper presents results related to the central question: What is the impact of online instructional modules coupled with online mentoring? Particular attention is given to the teacher candidate/online mentor interaction and shifts in teacher candidates' stages of concern.

Some preservice teacher preparation programs require separate courses that examine the role of technology to support learning, while others attempt to integrate considerations about technology and learning throughout preservice programs. Neither solution has been completely satisfactory with a number of concerns continuing to plague preservice technology education. One, opportunities for observing best practices in schools are limited as practicing teachers wrestle with using technology themselves or have limited access (Norton & Sprague, 1999). Two, faculty whose expertise centers on foundations or disciplinary teaching methods or learning and development also wrestle with the role of technology to support learning. They find it challenging to use technology to support their own teaching or to teach about technology to support the learning of K-12 students. Three, too often, teaching preservice teachers becomes the responsibility of instructional technology faculty, all too often resulting in technology education being divorced from the ongoing flow of preservice education.

Few today would challenge the increasing use of technology education's place in the preparation program of future teachers. Thus, professional development programs and courses are being developed and offered in a variety of ways, utilizing technology to differing degrees. Some simply use technology to improve presentations, while others use technology to offer courses entirely online. The U.S. Department of Education's National Center for Educational Statistics (NCES) reported that distance education programs increased by 72 percent from 1994-95 to 1997-98 (Quality On the Line: Benchmarks for Success in Internet-Based Distance Education, 2000). More and more professional development opportunities for K-12 teachers are becoming available online. While there is a great deal of research in the large category of distance education, the field of online learning is still developing its literature base (Dabbagh, 2001). Within that field of research, there are few studies that have specifically looked at online learning for K-12 preservice teachers.
Preservice teacher candidates are generally adult learners accustomed to being responsible for most aspects of their lives. Much has been written about how to best approach the task of educating adults effectively. Principles of effective adult education include the idea that adult education can and should be viewed as a collaborative activity. Mentoring relationships are an ideal way to facilitate collaboration. Although mentoring in general has a broad literature base, online mentoring is a relatively new area of research (Rogan, 1997). The few studies that have been conducted have concluded that online mentoring is an effective instructional approach, mutually beneficial to learners and mentors (Rogan, 1997; Riel & Fulton, 2001). Communication technology such as email provides an excellent way for collaborative learning to take place as novice, preservice teachers enter the community of teachers. Norton and Sprague (1997) reported that online collaboration in lesson planning has a significant and powerful impact on preservice teachers. They concluded that “collaborating with practicing teachers enthusiastic about educational technology . . . has the potential to break the cycle of replicating one’s own educational experience in one’s practice (p. 160).”

Given the potential of online learning and mentoring and in response to a request from the Secondary Education Program, a pilot online learning module was designed to assist eight preservice teachers to learn about the use of telecommunications to support teaching and learning for middle/high school students. In order to assess the effectiveness of this instructional strategy, the following central question was posed: What is the impact of online instructional modules coupled with online mentoring on preservice candidates’ attitudes and understanding about using technology to support teaching and learning? To answer this question, three research questions were addressed: (1) Were teacher candidates successful in completing the modules? (2) Did teacher candidates report changes in their sense of technology competence, their ideas about teaching with technology, and the role of collegial relations in the process of becoming technology-using teachers? and (3) After completing the instructional modules, did teacher candidates’ stages of concern related to technology as an educational innovation change?

Methodology

Subjects of this study were eight teacher candidates enrolled in the secondary education program at George Mason University. All eight subjects were pursuing a second career and currently employed in other jobs. One person was employed as a teacher on a provisional license. The subjects were enrolled in a 4-credit educational psychology course for which one credit requirement was met by completing the online modules. All were simultaneously participating in observations of classroom teaching in their content areas. Candidates ranged in age from 25 to 38. Seven were female, and one was male. The content areas represented were biology (1), English/language arts (3), and social studies/history (4).

Preservice candidates completed five online instructional modules, coupled with online mentoring. The modules consisted of a variety of activities designed to help preservice candidates understand how telecommunications can be effectively used for teaching and learning. For example, in one activity, candidates were guided through the creation of a WebQuest appropriate for their content area. All assignments and instructional material were available to the teacher candidates as web pages with the exception of one reading assignment provided in print. Completed assignments were emailed to the assigned online mentor - a practicing teacher in the candidate’s content area. Online discussions about the assignments resulted in candidates having a better understanding of how the product could be used for teaching and learning, and sometimes revisions were made based on these discussions. Candidates were given ten weeks to complete the five online modules. At the end of that time, online mentors rated the candidates’ performance.

Researcher-constructed surveys were administered before and after candidates completed the online modules. One of the researchers attended the face-to-face class meeting to distribute and collect the surveys at the beginning of week one and the end of week ten. Surveys included questions about basic demographic information; ratings of their sense of technology competency, the importance of collegiality in using technology for teaching and learning, and their desire and ability to use technology for teaching and learning; and ratings of their performance and interactions with online mentors (collected in the post-survey only). Additionally, the researchers used the Stages of Concern Questionnaire (Hall & George, 1979) to collect data about the changes in candidates’ stages of concern about technology as an educational innovation.
Results

The first research question asked: Were teacher candidates successful in completing the modules? In order to answer this question, mentors' responses to the teacher candidate rating form were tallied using 4 for excellent, 3 for good, 2 for moderate, and 1 for poor. These values were used to compute means for each item on the rating form. Results of the analysis are presented in Table 1. As Table 1 shows, online mentors rated teacher candidates' performance as falling in the good to excellent range on all rating items. Clearly, online mentors believed that teacher candidates performed well in the course, mastering concepts and assignments. In addition to the mentors' ratings, students were asked to rate their performance on the varied activities included in the online instructional modules. Summing all teacher candidate ratings and computing a mean resulted in a rating of 72.5 that corresponded with a "fairly satisfied" rating. It is important to note that one teacher candidate's self-rating was very low (in the "not satisfied" range). This teacher candidate's online mentor also rated this candidate's performance low. The low rating by both the teacher candidate and the online mentor skewed the means.

Table 1. Means for Mentor Ratings of Teacher Candidates’ Performance

The second research question asked: Did teacher candidates report changes in their sense of technology competence, their ideas about teaching with technology, and the role of collegial relations in the process of becoming technology-using teachers? In order to answer this question, teacher candidates' responses to pre- and post-surveys were collected, and means were computed for each item. Results are presented in Table 2. Means presented in Table 2 for technology competency reflect a rating scale of 1 for poor/rarely used, 2 for moderate, 3 for good, and 4 for excellent. Means for the usefulness of working with technology-using colleagues reflect a rating scale of 1 for not useful, 2 for somewhat useful, 3 for important, and 4 for very important. The final two items' means in Table 2 reflect a rating scale of 1 for rarely/never, 2 for sometimes, 3 for often, and 4 for very often. Examination of the means in Table 2 reveal a shift from good toward excellent in candidates' sense of technology competency, little or no change in their sense of collegiality or their desire to use technology to support teaching, and a decline in their sense of their ability to use technology to support teaching and learning.

Table 2. Means for Teacher Candidates’ Ratings Concerning Technology and Teaching

The third research question asked: After completing the instructional modules, did teacher candidates’ stages of concern about technology as an educational innovation change? In order to answer this question, teacher candidates’ responses to the thirty-five items on the pre and post Stages of Concern Questionnaire (SoCQ) were grouped by relevant stage, totaled and converted to percentile scores using guidelines in the SoCQ manual. Percentile scores for each stage were averaged for the group and graphed. Results for the group are presented in Table 3 and Figure 1.

Figure 1. Mean Percentile Score for Teacher Candidate’s Stages of Concern

Since this was a pilot study lasting only 10 weeks, it is not possible to draw definitive or statistical conclusions. Nevertheless, it is possible to identify some preliminary trends. Prior to beginning the online modules, the highest concerns expressed by participants were personal concerns followed by information needs. In addition, expressed concerns about consequences for students, collaboration with peers, and refocusing were lower. This profile illustrates normal, interested nonusers who are somewhat aware of and concerned about the role of classroom computers integrated with teaching and learning. This would be an expected profile. Post survey scores indicate a trend toward fewer concerns in awareness, information, and consequences for students (although these remain as the highest reported concerns) as well as demonstrating trends toward increasing concerns relevant to collaborating with others and refocusing. This remains an expected profile for normal, interested nonusers with subtle shifts toward the profile of the beginning user.

In addition to the survey results, preservice candidates were provided the opportunity to share their impressions with the researchers after completing the post surveys. Two categories of feedback emerged. First, preservice candidates expressed deep appreciation for the work of the mentors. All eight candidates felt their interactions with their mentor led to insights into the ways in which the concepts and activities embedded in the online modules might bridge to classroom practice. They felt that the insights and support of the mentors helped them transition their beginning ideas and impressions into ideas for practice. Second, preservice candidates felt that associating the online modules with a foundation course was premature and that the modules would have been more meaningful had they been associated with methods classes. Candidates’ knowledge about curricular and instructional issues as well as their inexperience with lesson planning in general handicapped their ability to create robust connections with practice.

**Discussion**

Once again, it is important to note that this was a pilot study, limited to five learning modules completed during a ten-week period. Nevertheless, trends suggest some insights for technology education. (1)
Preservice candidates were able to successfully learn when online modules and expert mentoring were combined. Mentors rated candidates' success, understanding, quality of products and interactions with mentor in the good to excellent range, students reported being “fairly satisfied” with their performance, and positively impacted candidates' awareness and informational concerns; (2) Participating in the online modules and mentoring activities improved candidates' sense of technology competency but had little impact on their desire to use technology in their teaching; (3) Participating in the online modules and mentoring activities decreased candidates' confidence in their ability to use technology in their teaching, suggesting that candidates' began to understand the complexities of teaching with technology and that technology's role in education is more than teaching mastery of software applications; (4) Participating in the online modules and mentoring activities had a positive impact on candidates' sense of the importance of the role of collaborating with colleagues to improve their practice; (5) Linking preservice candidates with expert mentors who can serve as models of technology-using practice is a powerful strategy for assisting candidates' entrance to practice and the process of becoming technology-using educators. This strategy, linking preservice candidates with expert teacher mentors, appears to offer opportunities for collaborative support systems whose power for promoting technology-using practice may well exceed course work or field experience opportunities; and (6) It is important to recognize the role of the modules in structuring and centering the candidate/mentor relationship. Giving structure and guidance to the mentoring relationship appears to have central importance. Casual or unstructured conversations, while useful, are less productive than conversations that are guided by a clear framework and specific contents put forward by the online modules. This not only supports candidates in structuring informed questions and interactions but also assists the mentor's ability to articulate and share expertise.

Perhaps the most important lesson emerging from this pilot study is what appears, at first, to be the major criticism provided by candidates. Candidates' expressed concerns with linking these modules with a foundations course as opposed to a methods courses and their decreased sense of their ability and confidence to use technology to support teaching and learning suggest that it is possible to design learning experiences for preservice candidates that clearly articulate technology's power to support teaching and learning. Additionally, this instructional design seemed to communicate to candidates that what matters for educational practice is not technology competence but competence with broader issues of curriculum and instruction. If activities focus on teaching and learning with technology and are linked with assistance and support of an expert technology-using mentor, trends identified in this study point to the power of online learning coupled with mentoring to assist preservice candidates' to understand the power of technology for student learning. Clearly, this is an avenue for further research.

A Classroom Discipline Problem Solving Environment for Preservice Teachers

Sangchul Oh
University of Missouri-Columbia
United States
So672@missouri.edu

Abstract: Most Preservice teachers don’t have much experience dealing with classroom management problems such as student misbehavior. Though they learn classroom management principles, they don’t even know how those principles are related to multiple learning perspectives. Therefore, as a learning support tool, for preservice teachers at universities, a classroom management course web site was developed. A basic assumption of the site is that preservice teachers can more effectively solve classroom management problems if they are exposed to multiple learning perspectives and engage in real world problem solving activities. The classroom management course web site has problem context, problem representation, and problem manipulation space for preservice teachers to engage in authentic classroom management problems. Also, multiple perspectives on problem solving process are presented in two different points of view-learning theorists and field experts.

Introduction

Lots of different approaches have been used to solve classroom management problems (Levin & Nolan, 2000). Those approaches assume that the use of certain classroom management techniques can be successful enough to resolve classroom discipline problems if it were well applied. However, some researchers suspect the effectiveness of the classroom management techniques. Research on the effects of teacher education has been done to examine how those techniques affect teacher’s classroom management performance. Evertson’s (1989) study showed that one teacher education program has been successful in decreasing classroom discipline problems. The teachers who had been trained demonstrated greater use of classroom management skills, and their students made less misbehavior. However, though teacher education programs include learning activities in the area of developing course materials, planning classroom activities, and developing classroom rules and procedures, those do not provide real life classroom discipline problems so that learners may manipulate and simulate the problems. Thus, multiple approaches need to be connected to authentic real world problem situation and several different perspectives in educational field.

The purpose of this study is to examine how preservice teachers solve classroom discipline problems. To explore the answer, two questions were addressed: “Who do preservice teachers confer with when they need to solve classroom management problems?” and “What are the effects of scaffolding when preservice teachers solve classroom disciplines?”

Design Issues

The Classroom Management Web site has four features of problem solving process-problem representation, problem manipulation, problem justification, and problem reflection. To guide students’ cognitive development, questioning strategies were selected. Ge (2001) argued that formulating and answering questions enabled students to identify the main ideas and the ways the ideas related to each other and to the students’ prior knowledge and experiences. Jonassen (1999) argued that an effective method for representing problem is “narrative.” Gick (1986) claimed that learners extract the given information and
attempt to understand the problem or try to connect it to their existing knowledge base so that an integrated representation can be built. Problem manipulation space enables learners to manipulate, simulate and experiment their problems. By seeing the results of their experiments, they can test their own hypotheses about the problems (Jonassen, 1997). Learners should develop arguments to support their decisions. Learners can be asked to reflect on what they have done, what assumptions they made, and what strategies they used (Jonassen, 1999). By reminding them of their initial conditions of the problem and helping them to reflect on their solutions, reflective prompts can help students to integrate knowledge and serve to guide the inquiry process.

Method

This study examined three participants’ problem solving process. A pilot test was conducted to test web site for classroom discipline problems which had been developed for preservice teachers. Preservice teachers’ decision making processes were examined by analyzing their log files. In addition, preservice teachers were asked to solve various case problems. They could get access to multiple problem solving advice. All problem solving processes were recorded and analyzed using qualitative description.

During the test, the participants were asked to solve a classroom discipline problem. While doing the task, they answered to three question prompts: What do you think the problem is?, What would you do in this situation?, and Why would you choose this course of action? Besides, the “think aloud” technique was used to capture what the participants were thinking while working with the task. In order to examine the participants’ problem solving processes, whole problem solving processes were videotaped. This videotaping provided a record of the process while the testing was being conducted.

Results and Conclusions

The findings from this study point to two conclusions. First, authentic learning environment which is supported by multiple perspectives from “Field experts” and “Learning theorists” will naturally invoke students’ higher order thinking. While participants used the classroom discipline web site, they tended to get advice as much as they could. Rather than responding to three question prompts, they conferred with several online experts before making decisions. It showed that participants wanted to confer with the persons who have lots of real world experience in school. Second, question prompts can be an important strategy for helping students’ problem solving process. Question prompts guided preservice teachers’ learning activities. However, despite three different question prompts which encouraged students to engage in a real problem solving processes, they were not effective enough to enhance students’ problem solving skills. It was supported by the results of students’ inconsistency in their solutions. Therefore, the finding suggests that scaffolding strategies used in online learning environments should be dynamic, adaptive, and immediate to students’ learning activities.

Integrating Technology to Enhance Performance Assessment

Lori Olafson  
University of Nevada, Las Vegas  
Department of Curriculum & Instruction  
lolafson@ccmail.nevada.edu

Linda F. Quinn  
University of Nevada, Las Vegas  
Department of Curriculum & Instruction  
lquinn@ccmail.nevada.edu

The International Society for Technology in Education (ISTE) has recently developed standards related to the integration of technology into teacher education programs. These standards state that teacher candidates should demonstrate a sound understanding of technology operations and concepts as well as the ability to plan and design effective learning environments and experiences supported by technology (ISTE, 2000). Additionally, the new National Council for Accreditation of Teacher Education (NCATE) 2000 Standards call for standards-based performance assessment of teacher education candidates that verifies their knowledge of the content of their fields. These assessments must give candidates an opportunity to demonstrate professional and pedagogical knowledge, skills, and dispositions. According to Eisner (1999) performance assessment is a practice "that requires students to create evidence through performance that will enable assessors to make valid judgements about 'what they know and can do' in situations that matter" (p. 2).

As teacher educators at a large, urban university in the Southwest, we were faced with the daunting task of incorporating ISTE and NCATE standards into our practice. We chose to focus our energies on revising an undergraduate course. The course, Strategies for Effective Elementary Classroom Teaching, is an introduction to instructional techniques and management strategies for the elementary classroom. To fulfill our obligation to meet national standards, we sought to revise the course simultaneously in two ways: 1) to integrate technology into our teaching and our students' teaching and learning, and, 2) to develop performance assessments that provide teacher candidates opportunities to demonstrate their knowledge, skills and dispositions in realistic settings. Field experiences for teacher candidates are regarded as central to the development of knowledge and skill (NCATE 2000) and we believed that partnering with a professional development school would allow candidates to develop and utilize their knowledge of both effective teaching strategies and technology skills. Because hands-on, student centered approaches to learning are an essential condition for creating learning environments conducive to effectively using technology for teaching and learning (ISTE, 2000), we developed performance assessment tasks that involved student and/or instructor use of technology. These performance assessments, we hoped, would allow us to accomplish our goals for authentic candidate learning tasks and the integration of technology.

We embarked on a program of research in order to evaluate and document the integration of technology, supported by our institution's PT3 grant. Additionally, we were supported by our College of Education with permission to team teach this course. It must be noted that both instructors are elementary education generalists, and that neither researcher was proficient in the technologies we hoped to integrate. However, according to Carlson and Gooden (1999) it is critical for teacher educators to model technology use in order to prepare teacher candidates to integrate technology into their instruction. In a previous paper (Olafson & Quinn, 2001), we report complete findings from this qualitative study, including the impact of technology integration on the learning environment. In this paper, however, we focus on describing three performance tasks (and the ways we assessed these tasks) in which we integrated technology.

Data Sources/Methods

Participants included 65 pre-service teachers in three sections of the Strategies for Effective Elementary Classroom Teaching course. At the beginning of each term, after reading the Consent to Participate form, students were given the option of transferring to another section of the course. Over all semesters, four students chose to withdraw from our sections.

We approached the study through participant-observation; that is, classroom observations, in-depth interviewing, and document collection were conducted. Data collection was extensive and ongoing throughout the semester. On the first day of class, students were asked to complete a technology survey so we could gauge their current understanding and use of technology. Students completed this survey again at the end of the semester. They also completed The Epistemic Beliefs Inventory (Schraw, Bendixen & Dunkle, in press) so that we could gain an understanding of their beliefs about learning. Additionally, a graduate assistant took detailed field notes during each class session. We collected artifacts produced by the pre-service teachers (e.g. statement of philosophy, in-class assignments, responses to reading) and their technology products (the Video Case Project and their Team Teaching Project). We videotaped their presentations of the technology products. At mid-term and at the end of the term students completed written reflections that were intended to evaluate the course. And, finally, at the end of the term, one-on-one interviews were conducted.
We considered all the forms of data that we collected as texts to be interpreted. Our approach to uncovering or isolating themes from the data was the selective reading approach advocated by van Manen (1990). After reading and viewing the texts several times, we asked ourselves what statement(s) or phrase(s) seem particularly essential or revealing about the phenomenon being described? These statements were then highlighted and used for further analysis (Bogdan & Biklen, 1998; van Manen, 1990).

Context/Performance Tasks

Our pre-service teachers were organized into teaching teams and assigned to a classroom and a teacher at a Professional Development School. Teams were expected to become familiar with the teacher, the students and the curriculum currently being taught in the classroom to which they were assigned. These teams were given three performance tasks requiring them to demonstrate their knowledge, skills, and dispositions toward the use of technology in developing an understanding of effective teaching. Each performance task was designed explicitly to foster a connection between authentic elementary classrooms and our university classroom. In addition to participation in classrooms, real time viewing of a variety of classrooms provided candidates with depictions of typical complexity and spontaneity (Edens, 2001).

Performance Task One: Video Case

Each team worked together using digital cameras to photograph teaching in elementary classrooms. Teams scheduled a time when they photographed a lesson taught by their assigned teacher. In order to demonstrate their understanding of dimensions of effective teaching, teaching teams selected images from their collection of photographs and created PowerPoint presentations showing evidence of students being grouped for instruction. In the second and third semesters of the current project, we revised the video case project to a "Storyboard" assignment. Candidates again used digital cameras to photograph a lesson taught by their assigned teacher. Instead of capturing images of grouping for instruction, in this assignment candidates selected photographs that showed the beginning, middle and ending of a lesson. Using PowerPoint, candidates constructed storyboards by importing these photographs and including a written description of the progression of events. Descriptions included the following components: lesson context and content, purpose, motivation, teaching and student behaviors, assessment, student outcomes, and reflections.

Candidates were assessed using a point system that included an evaluation of the content of their storyboard (the written descriptions for each picture) and an evaluation of their presentation design. We believed that technology should enhance content knowledge and that presentations needed to reflect the integration of technical skills and content knowledge. Therefore, assessment criteria for presentation design included graphical design, screen design layout, logical sequencing of information, selection of pictures that conveyed meaning, and clear and appropriate subject knowledge.

Performance Task Two: I-Movie

For their second project, teaching teams scheduled times for the team to teach and videotape two lessons, one with a direct instruction approach, and one with an indirect instruction approach. In the third semester we revised this assignment because we found that candidates had more difficulty with adopting an indirect approach. We decided that it would be more helpful to students if we devoted additional time for planning and implementing lessons that were student focused rather than teacher directed. In all three semesters, teams were expected to create multimedia presentations of the teaching experience using I-Movie. The final presentations included their lesson plans, edited video clips of their videotaped teaching, and a commentary and reflection on practice.

Candidates were assessed using a scoring rubric that focused on two main dimensions of their technology products: the lesson and their technical skills. Using three levels of performance (not evident, evident at an acceptable level, evident at an exemplary level) candidates were expected to demonstrate in their presentation that objectives had been met for planning an instructional event, implementing instruction, developing relationships with students, gathering evidence of student learning, and reflecting on the lesson taught. For the second dimension assessed, technical skills, candidates needed to demonstrate competent use of imaging devices and editing software, and presentation software skills. For example, both design principles and presentation content were assessed: assessment criteria included appropriate amounts of video, stills, and audio enhancements, and clear and correct subject knowledge evident throughout the production.

Performance Task Three: Post-RAVO Reflections

RAVO is a Remote Audio/Video Observation system designed for recorded and real time observation of elementary classrooms in a professional development school. Observations between the university classroom and the elementary classrooms are made possible through two cameras (located in the ceiling) and four wide-range microphones in each of 12 elementary
classrooms. The cameras and microphones can be remotely controlled from the university classroom. A full screen (7' by 7') in the university classroom makes it possible for teacher candidates to view student and teacher behavior. Broadcast-quality images can be enhanced through a zoom feature that provides minute details of student interactions and work. For example, it is possible to read individual student's journal entries from the university classroom. Throughout the semester, teams completed three written reflections regarding their observations of particular teaching strategies. Structured observations were completed for the following topics: instructional strategies, classroom management, and questioning strategies. For each observation, candidates were provided with focus questions prior to their viewing experience.

Written reflections were assessed on a credit/non-credit basis, based on candidates' abilities to address the focus questions. The focus questions (e.g. “What are the modes of instruction that you observed? Cite support from the textbook”) were intended to elicit from the candidates connections between the text and lectures and their real-time observations of life in elementary school classrooms. We hoped, as Edens (2001) found, that technology would provide powerful new collaborative learning tools and assist with the transition from campus classroom to a field setting.

Findings

Designing assessment tasks that incorporated technology resulted in three main findings. First, we found that students became proficient in the use of imaging devices, editing software, and presentation software. Based on the results of the technology survey, students perceived that their video production and presentation skills improved dramatically over the course of the semester. One student exclaimed, “The use of technology in this course was amazing. We started with a lesson on paper and finished with an I-movie!”

Secondly, we found that teacher candidates began to see that the integration of technology could be beneficial for students at any level. They were able to articulate how they might begin to use similar technologies in their future classrooms. In the second semester, many of the teaching teams attempted to integrate Inspiration software into their lessons. In other words, candidates demonstrated both an understanding of technology operations and an awareness of designing learning experiences supported by technology. It seems that our candidates met Gillingham and Topper’s (1999) definition for technology literacy for new teachers: “having the skill and dispositions to use technology in flexible and adaptive ways for the purposes of classroom instruction and professional development” (p. 305).

Our third finding was that integrating technology enhances pre-service teachers' understandings of effective teaching strategies. We were consistently impressed by their rich discourse about specific strategies and their awareness of the ways in which novice and expert teachers implement strategies. The experience of observing and reflecting on their digitized images and remote observations increased candidate learning of content. The remainder of this section focuses on evidence of candidate learning.

Performance Task One: Video Case/Storyboard

Both the Video Case project and the Storyboard assignment required multiple viewings of digital images from an actual elementary classroom. Repeatedly watching teacher and student behavior allowed teams to engage in critical reflection, and provided them with opportunities to reflect on classroom experiences in an environment outside the classroom setting yet in a context where the “discourse of teachers” is shaped by the experiential realities of the classroom (Profriedt, 1995, p. 33). In particular, candidates reflected on observed teaching strategies. For example, one student commented on the impact of completing the Video Case project: “I really love the video case project because I feel that I have a physical example of the teaching modes, classroom management techniques, and grouping techniques we have read about and discussed.”

In order to complete the Storyboard assignment, candidates needed to be selective in choosing three images that best represented the content and strategies utilized by the teacher. At the same time, candidates demonstrated their understanding of the progression of events when implementing a lesson. One of the teaching teams, for example, titled their three slides in a manner that indicated understanding of the development of a third grade lesson on prepositions:

1. Getting Started: Pulling out the pieces for the preposition Halloween book
2. Busy at Work: On, under, above beside. Where do the monsters belong?
3. The Finished Product: Working together to create the Halloween book

In their written description, these candidates noted that students were motivated to complete the activity because they were constructing a student-made class book that was connected to a Halloween theme. They noticed that teaching strategy is connected to student behavior: “the teacher’s modeling and guided questioning led to students’ participation in the demonstration and their eager involvement.”

Performance Task Two: I-movie

Candidates' I-movies and their presentations of their products to the class demonstrated growth in knowledge, skills and dispositions in three areas: student learning, content knowledge, and collaboration. In their presentations, candidates recognized
the role of prior knowledge and the importance of connecting content to students’ lives. The following excerpt from a presentation highlights this growing recognition:

We structured our lesson to familiarize the second graders with weather terminology. Instead of just standing at the front of the room and going over the vocabulary with them, we decided to bring in an element from their lives outside of school. We constructed a 6 X 4 television set and Mitch dressed as a meteorologist and gave a weather forecast. In the forecast, he used the weather words and explained their meanings. This was a great way to introduce the vocabulary.

Each team was also expected to provide evidence of student learning. That is, teams were expected to demonstrate that their teaching had an impact on K-5 learners. The following examples show that candidates developed an awareness of assessing student learning:

- We found that using centers provided an atmosphere conducive to enrichment, exploration, motivation, and creative discovery. We assessed students’ participation in each center and their completion of activities.
- We did our lesson on classification and how to use rocks to explore classification. Students sorted rocks by observable qualities. Students were able to organize collected data visually, and we assessed their understanding by observing they way they sorted rocks.
- Candidates also demonstrated their ability to connect content knowledge of general teaching strategies to the lived reality of the classroom. One of the teaching teams gave a homework assignment, and explained that “Our text states on page 275 that homework can have many positive contributions to a child’s learning when it is thoughtfully planned to extend classroom learning.”

And, finally, candidates demonstrated behaviors that are characteristic of developing teachers. Candidates were expected to develop collaborative and collegial relationships with their peers and with experienced classroom teachers. As Phelps (2000) notes, “the need for creating collegial communities is critical” (p. 47). In order to complete their technology products, candidates needed to work collaboratively. For the majority of teaching teams this was a positive experience. “Getting to collaborate with my group” was frequently mentioned in the interviews as one of the benefits of technology integration.

Performance Task Three: Post RAVO Reflections

In this third set of performances, we again found that candidates were able to make connections between their content learning in the textbook and elementary classrooms. In order to successfully complete the post-RAVO reflections, candidates had to recognize teaching strategies as they were occurring in the lived reality of the classroom. The following example shows how a teaching team identified the instructional mode utilized by the teacher during a fifth grade math lesson:

The math lesson was clear example of expository or direct instruction. On page 228, our text states that transmitting knowledge from those who know it to those who don’t know is expository instruction. An example of this is when the teacher provided rules for graphing.

Another teaching team realized the interconnectedness of instructional strategy and classroom management, noting that there were fewer disturbances when students were engaged in learning: “the students were self-directed in the learning centers. We saw that students who are actively involved behave much better and seem to truly enjoy learning.”

As teaching teams developed their observational skills, they became more insightful and were able to produce interpretations that were supported by evidence. In the next example, a team identifies types of questions asked by the teacher and provides a summary that shows their observation of a questionning pattern: “We noticed that the teacher worked in a pattern, beginning with comprehension questions, then restating and clarifying, and then asking reflective questions.”

Each performance task required candidates to use technology in various ways to demonstrate newly acquired teaching skills. These performances satisfied the dual purpose of learning about teaching strategies and learning about technology. An inherent goal in the tasks was to help candidates understand that technology must enhance student learning. Like Hartley (2001) we believe that new technologies do not have any inherent value. Only through their use do they become valuable.

Discussion

We agree with Morey, Bezik, and Chiero (1997) who believe that “Technology can also be a valuable resource for improving teacher education” (p. 21). In particular, the use of technology can ground the program in real-life situations (Kenny, Andrews, Vignola, Schilz, & Covert, 1999). “Unfortunately, the majority of teachers are not trained in their preservice programs to effectively integrate computers and other technologies into their classroom teaching” (Perry & Talley, 2001, p. 26). Our candidates observed and participated in real-life situations that required the use of technology. And furthermore, perhaps this participation was made possible only through the use of technology.

In the realm of technology, the learning curve is steeper for some than for others. Teachers caught in the maelstrom of classroom life may be hard pressed to learn and use current technology in educational settings in order to incorporate them. According to Sprague, Kopfman, and de Levante Dorsey (1998), “Classroom teachers sometimes feel ill-prepared to integrate technology into the curriculum” (p.24). In addition to integrating technology into the curriculum, teachers are expected to be technology instructors in the classroom. ISTE (2000) states that “Our educational system must produce technology-capable kids.”
kids who will be able to use technology in an “increasingly complex and information-rich society” (p. 2). Obviously teachers, as implementers of the education system will be expected to help produce these ‘technology capable “kids.” By no means is this an easy task.

Given all that is currently known about classroom teachers integrating technology into instruction, the role of technology in pre-service teacher education is critical. In teacher education settings where candidates have the time to experiment, explore and practice technical skills in an environment that is low-risk and focused on pedagogy, the gaps between theory, practice and technology can be narrowed. Because of the support received from our institution’s PT3 Grant, we were able to create conditions necessary for the integration of technology in pedagogically appropriate ways. Teacher education candidates developed an understanding of the interplay between teaching and technology, and faculty experienced, first hand, ways technology can facilitate powerful learning. Through completion of performance tasks requiring the use of technology, candidates and faculty recognized the potential of technology for changing assumptions and current educational practices and perspectives.

Technology as a Practical Tool for Real World Teaching

Jeffrey Parker, North Carolina A&T State University, US

Discussions concerning distance education and web enhanced teaching strategies for colleges and universities continue to be directed towards ways in which technology can be used within a conventional university or public school structure. Optimistic points of view argue that using technology encourages, if not actually requires faculty members to think outside the box. In theory, this call for innovative and more flexible teaching strategies seems promising. Unfortunately nobody seems to agree on how this transformation might be implemented or how to transform theory into practical applications. From the perspective of faculty members, “thinking outside the box” seems nothing more then a plea to find new and innovative ways to accommodate vast technology expenditures by utilizing course delivery systems. In public school environments, thinking outside the box generally means figure it out, or, just do it.

For distance education programs to be successful they must be grounded within the context of actual needs and reachable objectives. Courses need to be structured in ways that will give ownership to the professors or public school teachers who design and teach them. Course development must offer a solution for something other than technology integration for its own sake or for the sake of earning required certification credits. These issues are crucial in the design and delivery of online courses in teacher education programs. In this paper I will offer a model developed by The Technology Outreach Project that we have put into practice at North Carolina A&T State University. In addition to providing technology instruction for pre-service teachers, this model combines pre-service teachers with in-service teachers who are seeking required technology certification credits.

Every spring semester I teach English 460 – Technology and the Teaching of English. This course is designed to instruct English Education majors in the second semester of their junior year in effective and appropriate strategies for using technology to enhance their teaching. These students are given instruction in the use of Blackboard as a tool for developing and enhancing the quality and the delivery of their curriculum materials. After approximately three weeks of technology instruction, pre-service teachers in Engl. 460 are paired with our list of in-service teachers seeking required technology or certification credits. All pre-service and in-service teachers are enrolled on our 460 Blackboard site. The first task for pre-service teachers is to instruct in-service teachers in the use of Blackboard by utilizing the virtual classroom and other available telecommunication resources.

After both groups feel comfortable in the Blackboard environment, in-service teachers are asked to critic, refine, and offer advise after viewing curriculum programs posted on Blackboard by our pre-service teachers. In-service teachers are given a set of guidelines for this activity. Once portions of the curriculum have been identified as appropriately designed for electronic classroom delivery, the in-service teachers provide instruction in the use of Blackboard for students in their classroom who will actually use the curriculum materials developed by pre-service teachers. In addition to Blackboard, we also utilize other software programs such as PowerPoint, and for writing components we utilize Storyspace. This model serves the needs of three audiences: pre-service teachers, in-service teachers, and actual students in the in-service teachers public school classroom.

The benefits of using this model include more then just learning technology skills for pre-service and in-service teachers. We are also increasing the technology skills of actual students in a public school environment. Pre-service teachers gain experience by being mentored and guided by in-service teachers. We believe that what makes this a viable model is that in addition to learning needed skills and gaining experience, in-service teachers view their participation in our program as an efficient and practical means for earning technology credits and re-certification. Rather then attending a class or workshop for a few days to enhance their technology skills, teachers are actually integrating their learning experiences into their own classroom, as they are learning technology skills. In short, we have provided a real world, semester long program with actual hands on experience. Mentoring is a key component of this model. Pre-service teachers are available to instruct and assist in-service teachers in learning to utilize Blackboard and a wide range of other programs. Each pre-service teacher is required to maintain a minimum of six online office hours per week. Pre-service teachers are also required to make a minimum of three visits per semester to the in-service teacher’s computer lab where they will act as lab facilitators and will be evaluated at the end of the semester by their in-service mentors.

Our experience has clearly indicated that simply telling teachers or university faculty to use technology is simply not going to work. Arguing for the existence of the “information age” is not an agent for basic changes in curriculum or in
instructional methodology. What does work is not only pointing out to pre-service teachers the value of hands-on experience that includes first-hand interactions with students in a computer lab, but actually giving them the opportunity to do so. In-service teachers are already overburdened with a wide range of responsibilities to the extent that they frequently view acquiring technology skills as just another time-consuming task. Even more problematic is that traditional technology seminars are physically removed in both space and time from their students, classrooms and from the curriculum they actually teach. Often, teachers forget new technology skills by the time they return to their classroom.

Clearly, pre-service and in-service teachers enrolled in our model find that not only are they able to integrate new skills as they are learning them, but that they are functioning in an environment that actively encourages contemporary teaching behaviors and practices such as co-investigating and team learning activities. In-service teachers are learning, pre-service teachers are learning, and students enrolled in the classroom are learning. I would like to conclude by pointing out that all of the technologies used in our program have been around for quite some time. The development strategy utilized by The Technology Outreach Project was based on a cultural model that took into account time management and needs assessment. Our objective was to integrate the needs of three separate groups of learners by implementing technology as a tool to accomplish specific goals. We were not interested in using technology as an enhancement or simply for the sake of learning to use technology in the isolated, and frequently sterile environment typical of many computer workshops and short courses.
WebQuest Collaboration for Special Needs Awareness

Denise_Peterson@sdstate.edu

Abstract: This poster session focuses on a collaborative project for students in preservice education that combines technology integration and special needs awareness. Students designed a WebQuest in the technology integration course and students from the Special Needs course became the non-expert reviews. The non-expert review process was used to evaluate the WebQuests on their design for students with disabilities. Based on the evaluation, the planning for the next semester's projects began to take into account the Universal Design Learning Principles.

Introduction

Today, teacher education programs have numerous responsibilities to provide teachers with a comprehensive preparation that includes content, methods, classroom management, special needs and technology. In our teacher education program technology (2 credit hours) and special needs (1 credit hour) are both offered as required courses but with minimal credit hours attached to them. Thus both courses have difficulty covering all comprehensive relevant content that is necessary.

Two instructors, one teaching the technology course and the other teaching the special needs course, have been working together in the area of Universal Design Principles of Learning. A plan was developed to incorporate the WebQuest Process into both courses with collaborative components. This paper describes the collaboration efforts between students in both classes.

WebQuest

A WebQuest is "an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web" (Dodge, 2001). WebQuests consist of a task that engages students in authentic problem solving using prescribed processes and requiring some final product in which the web resources can be synthesized. The WebQuest process is used in the technology course as one of the means to fulfill many of the International Society for Technology Education Standards Professional Performance Profile indicators. The technology course has used this format in the spring 2001 semester and found that students really enjoyed the process and could demonstrate ISTE proficiencies. The only proficiencies not easily met were the exposure to Universal Design for Learning principles and assistive technology and along with the opportunity to peer teach their lesson.

Universal Design for Learning Principles

Universal Design for Learning Principles is the design of instructional materials and activities that allows the learning goals to be achievable by individuals with wide differences in their abilities to see, hear, speak, move, read, write, understand English, organize, engage and remember (Orkwis & McLane, 1998). The principles for universal design include multiple representations of content, multiple means of
expression and control, and multiple means of engagement (CAST, Universal Design for Learning). Universal design implies the use of technology in curriculum materials as the content is in digital format. Technology allows teachers the ability to meet the universal design principles by providing various mediums to compensate for the differences in student’s skills and abilities.

The Collaborative Process

The idea of working together to provide exposure to both technology integration and special needs was an intriguing one but could we pull it off? In the technology course, the overriding consideration was that students needed the opportunity to gain an understanding of technology integration as it applies to a classroom. According to the International Society for Technology in Education (ISTE) Standards for Professional Performance Profile indicators (2000), students needed to be more aware of the various learner needs as they integrate technology into curriculum. Students also needed to have an opportunity to evaluate curriculum materials in order to explore the various methods they could use to provide materials to all students in the format they needed.

The other consideration in this project was the collaborative aspect. Many teachers work closely with other professionals regarding students with special needs and this requires a collaborative relationship to best meet the needs of these students. In doing this project, students would get a better understanding of how this collaboration could occur.

The needs of the classes were also discussed. The technology course was looking for “expert” evaluators for the WebQuest projects and the opportunity to introduce some of the universal design of learning principles into the curriculum. The special needs course really needed practice in identifying materials that could be adapted and determine strategies of how materials could be used effectively.

Coordinating the project was not easy. Because of the program structure, both courses contain students who have varied backgrounds and responsibilities. There are students from a secondary education program, students with a K-12 emphasis and early childhood students in both courses. There was a concern that the material they would evaluate may not be at their particular grade level.

The special needs students were introduced to assistive technologies. Students were then introduced to WebQuests by examining Bernie Dodge’s WebQuest Site. Based on the exposure to the WebQuests and the rubric the instructors developed, students were asked to examine a specific WebQuest being build by the technology course. Students were looking for multiple items.

Conclusions

The outcomes of the project are anticipated to be a better quality WebQuests due to the feedback opportunities. The students should also have an understanding of how technology integration can enhance opportunities for students with diverse learning needs. The evaluation process is also important for the students in seeing how constructive feedback through collaboration can provide both parties with a product that can be used for multiple purposes.

Guiding Principles for Technology and Teacher Education

Susan M. Powers, Ed.D.
School of Education
Indiana State University, USA
powers@indstate.edu

Howard D. Mehlinger, Ph.D.
Indiana University, USA
mehlingea.indiana.edu

Abstract: How does a teacher education program begin the process of integrating technology? This paper provides a framework for technology integration that incorporates guiding principles, technology standards, and the developmental stages of teacher education. Additionally, the paper discusses that technology integration must be more systemic than just teacher preparation and must involve educational administration and special education. For technology integration to be successful, it needs to be implemented in an environment of strong leadership and where a technology vision and infrastructure are in place.

Introduction

While school systems and other organizations are working hard to meet the training needs of those teachers already in service, teacher education institutions must guarantee schools that all newly employed teachers will be able to use technology well. Unfortunately, the reality is that there is a deficit in the teacher education community to be able to ensure that technology competency of graduates (NCATE 1997; RTEC Consoritia 1998; Moursand & Bielefeldt 1998). Schools and departments of education (SCDE) need a guide to determine what their own technology integrated programs can look like.

A Framework for Teacher Education

There are numerous ways that an SCDE can bring technology into its teacher education program. Some programs elect to use a stand-alone course to introduce technology skills and applications. Other programs may elect to put technology components and instruction into a variety of courses. A few programs are able to use a university-wide technology competence requirement for skills, and then focus on educational application in later courses. The variations can seem endless and there is good reason for it. In other aspects of teacher education, an SCDE seeks to establish a focus of specialty. Some programs feature a strong liberal arts education with a fifth year for teacher education. Others may extol their excellent field experience. It is these variations that may programs unique, interesting to students, and provide outlets for their faculty. The systematic integration of technology into teacher preparation therefore needs to take these differences and points of excellence into account and complement them. There is not a “one size fits all” approach that can be used with technology integration; however a guiding framework can be used to make technology an enhancement to the program.

A graphical representation of this framework is shown in Figure 1. The framework is provided as a model that can be used and modified to suit a program’s need. First, there needs to be a base upon which all other elements are built and integrated. For many SCDEs this might be a knowledge base, or a set of guiding principles, or perhaps a set of standards that a state has adopted. This example uses the INTASC Principles (Interstate New Teacher Assessment and Support Consortium). These ten basic principles have been adopted for teacher preparation by numerous states and have served as a catalyst for the development of state-specific teaching standards. The principles are a thread that weaves throughout the teacher preparation program and cover areas such as content knowledge, child development, learning differences, instructional strategies, motivation, communication, planning, assessment, reflection, and community. These are foundational elements that are present to varying degrees throughout teaching programs.
Courses and Students Transformed Through Technology

Figure 1: Framework for Teacher Education

The next level of the framework builds upon this foundation by introducing a set of technology expectations or standards. These standards could be nationally recognized such as the Professional Skills for the Digital Age Classroom (Milken Exchange on Education Technology, 1999) or the ISTE National Educational Technology Standards for Teachers (2000). Alternatively, a SCDE might have formally adopted its own set of technology standards. Whichever path a SCDE elects to take, these standards need to be joined in with the foundational elements – this becomes one of the essential pieces to integration.

Finally, a SCDE places on the top of the framework the stages of the teacher education program and the unique nuances of that program. For instance, there is a beginning stage to teacher education, when a student is first exploring the field. Just as the elements in regard to the INTASC principles are covered in different depths and with different types of experiences, so to should technology. As a student moves to more advanced courses, the expectations of technology application should also become more advanced and reflect more of the advanced principles and standards. With technology, a student will move from the observation of technology-rich classrooms or learn the basics of application skills to using the technology in the field for assessment and differential learning strategies. This presentation will provide a more detailed look at the framework and the types of integrated activities that support the framework.

The Case for Special Education
Technology for special education is worth separate mention because of the different technologies available and the different training and opportunities provided. Recent philosophical changes in the field of special education, coupled with legislative amendments have lead to widespread inclusive education. Although paraeducators, or special education teachers are often available to help the classroom teacher, s/he must be ready to use the available assistive technologies to help students achieve learning goals. The Council for Exceptional Children has developed a set of core technology competencies that beginning special educators that lay a foundation for a technology curricula (2000). Furthermore, the ISTE National Educational Technology Standards for Teachers (2000) also suggest that prior to a student teaching experience that all candidates be able to identify and use assistive technologies.

Preparing Educational Administrators

SCDEs prepare teacher to go out and teach in schools. However, they are not alone in the schools with the students; their work is guided and often managed by the administrators present in the school and the school system. Technology will impact the role of school administrators as much as teachers, if perhaps in a different way. Administrators need to be aware of the technologies that teachers can use to impact teaching and learning and be prepared to facilitate that work. Administrators also need to be able to use technology to document and report out the teaching and learning that occurs within each class, building, and corporation. Technology has the power to influence and impact the daily work life of an educational administrator, and in order to ensure that the administrator has the capacity to use that available power, SCDEs that prepare educational administrators must be prepared to integrate technology into their programs as well and to help their students understand the role technology plays in the 21st century classroom.

A Systems Approach

What should be clear from all of the above information is that technology is not mutually exclusive to segments of teacher education or the SCDE as a whole. In order to integrate technology into the mission and very core of an SCDE, a systematic approach must be considered. However, the system includes more than the programs. An SCDE must first have a vision for how technology will manifest itself in the programs and the desired outcomes. There must also be strong leadership within the SCDE to build the necessary vision, provide the leadership to guide the curriculum development, guide faculty and student competence with and use of technology, reach out to alumni and community, and to build the necessary SCDE infrastructure. And as strong as that leadership might be within the SCDE, it alone will not be enough. There must be campus-wide leadership that recognizes and acknowledges that the successful preparation of a good educator is the task of more than just the education program because a campus-wide infrastructure for technology must also be in place and the necessary support must be provided to the SCDE.

Conclusion

The integration of technology should not and cannot become the purview of a few individuals. To create a SCDE that successfully employs technology, all members of the unit must be involved. The systemic effort extends beyond the program to all those who teach and work with the program. Not only the instruction, but also planning and evaluation must be systematized by the SCDE. It is also not a process that will happen overnight or show immediate widespread results. Technology integration is an evolving process, and the vision and infrastructure will take time to grow. The evolution will continue as the technology changes and user sophistication increases. This evolution will provide yet another opportunity for a SCDE to develop and find its distinctive niche in the preparation of educators.

Understanding Teachers' Purposes for Using the Internet with Their Students

David Pratt, PT3, University of California, Santa Barbara, US

Purpose

The purpose of this paper is to better understand the different purposes teachers have for using the Internet with their students. It utilizes Bandura's theory of self-efficacy as a framework to conduct a study with experienced teachers.

Consideration of the purposes teachers have for Internet use with students is important when considering the potential of the current investment of money related to the increase in school-related technologies. According to one report, $5.4 billion was spent on computers and related infrastructure in 1999 (Ballard, 2000). The federal government estimates another $5-10 billion per year as the cost for maintaining and improving those infrastructures.

More importantly, we need to realize the potential this technology can have in helping train students to become prepared for the Knowledge Age. At the end of the 20th century, computer technologies, particularly the Internet, revolutionized the American household and workplace. It has only been ten years since the U.S. spending for Industrial Age capital goods was exceeded for the first time by the spending for Information Technology (Trilling & Hood, 1999). According to some educational researchers, this marked the first year in a historic shift from the Industrial Age to the Knowledge Age (Stewart, 1997). This turning point to a new age requires a renewed examination into education and its purposes for society.

The present study focuses on answering the following research questions: 1) What kind of educational purposes do teachers have for using the Internet with their students? 2) What is the nature of the association, if any, between teachers' confidence for using the Internet with students (Internet Teaching Efficacy) and the purposes for Internet use with their students?

Theoretical Framework

Self-efficacy theory is helpful to use as frame to better understand both the quality and quantity of teachers' integration of Internet use with their students. Bandura (1997) understood self-efficacy as an individual's judgment of one's ability to complete future actions. He contended through his theory that humans are active participants in producing behavior and that they exercise control over their own destinies. In his description of social cognitive theory, he suggested that the full understanding of human behavior required an integrated causal perspective in which social influences operate through self-processes that produce actions.

Personal Teaching Efficacy is a specific form of self-efficacy. The construct of Personal Teaching Efficacy, a specific belief about one's ability to teach, has been used by researchers to describe the mediating effects one's beliefs can have between knowledge or skill and one's actions. A teacher with high efficacy, for example, would persist in the face of obstacles and rebound from temporary setbacks.

Bandura's theory of self-efficacy, therefore, provides the framework in which we can examine the role beliefs have in a teachers' selection or creation of Internet activities they may use with their students. A scale assessing teachers' beliefs about using the Internet in the classroom has been recently developed and follows Bandura's claim that self-efficacy is task-specific. Understanding this belief about using the Internet with students is an important factor that has been overlooked in previous studies related to Internet use.

The role of purposes. The purposes a teacher has for engaging students in an Internet activity can vary widely. One research report on the effectiveness of technology in schools reported "goals of instruction" as one of four factors contributing to the effectiveness of use (Software and Information Industry Association, 1999). According to Copeland et al, (1994), beliefs about educational purposes is a central way to understand how teachers interpret and understand classroom events and has been linked to a part of a larger system of beliefs and perceptions generally referred to as a teacher's "practical theory".

Methods
Participants

A purposeful sample was chosen so that information-rich cases could be examined. Patton (1990) describes the type of sample obtained for the present study as "criterion sampling". Each of the participants will provide information-rich data since all will have been predetermined to have the following characteristics: 1) participate as master teachers in partnership with a large university, 2) use the Internet with students for educational purposes at least several times a year, and 3) teach in grades 4-8.

Data Sources or Evidence

An initial survey was given to 120 K-12 cooperating teachers. Teachers were given a choice to take the survey in either paper or electronic (online) form. The purpose of the survey was to collect data about each teacher's technology ability, amount of Internet use with students, and level of efficacy for using the Internet with students. Twenty-five teachers were found to meet the criteria listed above and became participants in the study.

A semi-structured interview guide was used to elicit information for three general categories: background information, context of use, and purposes for using the Internet with students.

An established coding procedure developed by Copeland & Caston (1994, 1998) was used to categorize purpose statements as "broad" or "narrow". An example of a narrow purpose would include concern with students' cognitive thought typified by simple recall. A broad purpose would be considered a response related to such a concern as the development of a student's ability to proceed in a learning task independently. These tend to mainly be related to pupil-oriented responses. Teacher-oriented purposes are considered a separate category of responses not sub-categorized as narrow or broad. However, over ninety percent of responses discovered by the authors mentioned above were associated with the pupil-oriented category (Copeland & D'emidio-Caston, 1998). The focus of the present study is primarily on understanding the differences displayed among the ratio of broad purpose statements with total number of purpose statements among teachers.

The second interview will utilize what Patton (1990) describes as "illustrative extremes" to access information regarding beliefs about confidence and purpose for teachers' use of the Internet with students. Illustrative examples of Internet use with students will be created based on levels of purpose for use. One example will have an extremely narrow, while the other would contain an extremely broad purpose.

Results and Conclusions

Preliminary results of survey and interview analyses indicate that a relationship exists between teacher's purposes for using the Internet and their Internet Teaching Efficacy. Specifically it was found that teachers who have higher Internet Teaching Efficacy include broader purposes for using the Internet with students. Specifically, the majority of teachers who had higher Internet Teaching Efficacy included in their description of the lesson the notion of information literacy, while those that had lower Internet Teaching Efficacy did not. This finding of mentioning information literacy, or including as a purpose the students ability to locate, select and choose sites for relevance and accuracy, was categorized as a broader purpose using Copeland et al's categorization scheme. This could be a fundamental shift in the way that higher Internet Efficacy Teachers view learning in general or learning through the use of technology such as the Web.

The present study includes a specific sample of teachers in partnership with UCSB as cooperating teachers and included a relatively small number of participants. Therefore results should not be generalized to a broad population. It does, however, provide an interesting window into the uses and motivations behind using technology and suggests that further studies should be conducted.

Educational or Scientific Importance of the Study

Teacher education issues. Besides adding to the existing research base on efficacy and technology use of teachers, it may be helpful to know what type of preparation is necessary for teachers under current contextual conditions. For example, it may be important to determine whether one should specifically consider addressing efficacy in the preparation of teachers. If the purpose for using technology by teachers differs not just on skill but by efficacy, then one would assume that along with proficiency workshops, support for specifically increasing one's computer or Internet efficacy would be necessary.
Program implications. Teacher education programs may need to consider that providing a strong knowledge base of content and pedagogy may not be sufficient to help teachers grow and succeed as professionals. Many researchers suggest that teacher education programs should be revised to incorporate this notion of explicitly acknowledging the beliefs teachers bring with them to a program (Ashton & Webb, 1986; Hollingsworth, 1989; Ross, 1995). Although not aiming explicitly at developing a teacher education program intervention, the results of this study may help to develop an understanding of the role teachers' beliefs have in the purposes teachers have in using the Internet with students. It is hoped that this new knowledge will help programs appreciate the need for a focus on providing not just skill but opportunities to enhance one's efficacy.

The cost and potential. Considering the cost of having Internet compatible computers suggests the nature of its purpose should be greater than that of drill and practice. Besides the cost involved with such a resource, many agree that teachers should employ methods to increase the use of technology as a tool to support higher order thinking skills with their students. Several studies specifically state the importance of higher level thinking as a necessity for survival in a rapidly changing world (Lee & Dinkins, 1998; Paul et. al., 1990). This study supports the notion of including higher level or broad purposes among the existing low/narrow purposes of teachers: although like other, it does not state to what degree they should be employed. However, in order to reap some of the benefits of the great expenditure related to technology, this paper argues that more teachers must use technology for higher purposes, so that technology can be transformed from the token and peripheral aspect of the classroom it is today.
Web Resources for Student Teachers

David Pratt, PT3, University of California, Santa Barbara, US
Heidi Stevenson-Bagnall, University of California, Santa Barbara, US

Examining the best, easy to use, and free resources for student teachers to integrate into their teaching

This interactive session allows participants to experience the best the web has to offer for student teachers. Most of the time will be spent on reviewing interactive activities for students, resources for teachers such as lesson plan and photo galleries, and powerful online applications that can be used immediately. All of these resources are located on an independent, easy to use web portal. The focus will be on how these resources can be implemented in methods, technology, and other teacher education program courses to help facilitate the use of technology in the student teachers’ placements.

Students belonging to an education program may be generally aware of the wealth of information that is available to them via the Internet. Many of them interact with the Internet daily in order to meet certain needs or gain access to specific information. Unfortunately, many student teachers are not incorporating that use of the web in their coursework or placements. One possible reason for this is that they may not be cognizant of the multitude of free activities and applications designed specifically for teachers and their students.

During this session, participants will be able to interact with web resources in order to: access student activities such as WebQuests, gain access to thousands of lesson plans, create a website, utilize a rubric generator to create a rubric, and design their own personalized web quests, quizzes, and games. Discussions will focus on how to best integrate these on two levels. First, university instructors need to model appropriate use of these resources and begin to demonstrate their effectiveness in their own courses. Second, we will share how student teachers have used the resources in their school site placements to help meet the technology standards required before receiving the California Teaching Credential.

Participants do not need to have any prior knowledge or experience with technology to be a part of this session. The main web site used for this presentation can be found at: http://www.freesites4teachers.com
Technology, science and preservice teachers: Creating a culture of technology-savvy elementary teachers

Rose Pringle, Kara Dawson & Skip Marshall
University of Florida
United States
rpringle@coe.ufl.edu

Abstract: The purpose of this study was to explore how preservice teachers incorporated technology into a microteaching activity that was a component of their science education and educational technology course. The preservice teachers displayed various levels of technology use ranging from additive and nonessential to being an integral aspect of the lesson. Four use of technology emerged; as knowledge source, data organizer, information presenter, and facilitator. In our presentation we will discuss microteaching as a tool in teacher education and share the preservice teachers’ efforts to integrate computers and other related technologies in the teaching of science.

Introduction

There is no doubt that technology has strongly influenced the course of history and the nature of human society. Schooling has also been influenced by this increasing wave of new technologies. As a result, both science and technology educators have articulated the importance of understanding such technological advances and their relevance to teaching and learning in general and science in particular. In an article discussing the implications of science and technology interaction on scientific literacy, Cajas (2001) commends the science education community in taking a strong step toward including technology studies as part of science education by selecting and clarifying specific technological concepts and processes relevant for scientific literacy. The National Science Education Standard (NRC, 1996) recommends that technology in the classroom should provide opportunities for students to investigate science content beyond superficial levels, establish connections between the natural and designed worlds and provide students with opportunities to develop decision-making abilities. This is supported by the recommendations of the National Council for Accreditation of Teacher Education (NCATE) and the National Educational Technology standards (NETS) that seek to define standards for integrating curriculum, technology and technology support. NCATE stipulates students at the preservice and graduate levels in teacher education are prepared as 21st century teachers. They should be able to design developmentally appropriate learning opportunities that apply technology-enhanced instructional strategies to support the diverse needs of learners.

As the debate surrounding technology and its role in teaching and learning intensifies, and as technology becomes more pervasive in society and more available in schools, the focus is on teacher educators to prepare preservice teachers with the capabilities to effectively integrate technology into their teaching. Many possibilities exist for the integration of educational technology into the curriculum and most content-specific governing bodies include statements related to effective technology integration (Churma, 1999).

With the goal of creating a group of technologically savvy elementary teachers, both the science educators and educational technologists collaborated intensively during the 2001 spring semester. The purpose of this study was to explore how preservice teachers incorporated technology into a microteaching activity that was a component of their science education and educational technology course. In our presentation we will discuss the microteaching as a tool in teacher education and share the preservice teachers’ efforts during their teaching activities as they integrate computers and other related technologies in the teaching of science.

The Program

In the seventh semester of the teacher education program, students are enrolled a science education, mathematics education and educational technology course. This semester is referred to as the
Math, Science, Technology (MST) block and focuses on individual pedagogy and content of the three subjects while emphasizing their integration as an important component of teaching and learning in elementary classrooms. Throughout the semester, efforts are devoted to developing teaching and learning activities aimed at achieving integration across the three subject areas in the inclusive elementary classroom. This is accomplished through collaborative planning among instructors and the administration of common assignments.

One common assignment is the microteaching activity. Students develop and teach a thirty-minute lesson that integrates math, science and technology. The lesson is developed for a grade level of their choice and is correlated to the state’s curriculum standards. Students submit the written lesson plan to the instructors on the day of the teaching and make the necessary arrangements to acquire the technologies needed. These lessons are taught to their peers and observed by the math, science and technology instructors who provide feedback on lesson development, content, questioning and classroom organization strategies and the appropriateness of the technology used. The feedback from each instructor is compiled into one document and students receive one common grade for each of the three courses.

Data Collection and analysis

Data collection methods included observations of microteaching, analysis of lesson plans and content of both instructor feedback and student reflections. These multiple methods of data collection were used to triangulate the themes of technology use that emerged during analysis. Rigorous content analysis occurred as we examined the students’ words and actions, (Maykut and Moorehouse, 1994) and categorized the use of technology in a variety of ways to understand the preservice teachers’ perspectives on technology integration and the teaching of elementary science.

Findings

Four themes of technology use emerged: (1) technology as a knowledge source, (2) technology as data organizer, (3) technology as information presenter, and (4) technology as facilitator.

Technology as knowledge source

Many lessons used the WWW as a source of information. This was characterized by pre-determined websites, worksheet style questions, and, in most cases, lower level thinking skills. For example, in a grade three lesson, the preservice teachers provided bookmarked websites on clouds, required the group to observe the types of clouds shown, and read the information given. They then drew the clouds as seen on the computer screen, and provided responded to worksheet questions as they documented the characteristics of each cloud. These worksheets were then pasted in their science journals to become part of their science notes.

In other lessons, a number of sites were pre-selected and this information then became the focus of the lesson. In a lesson on bald eagles, students were organized into groups and each given a folder, four questions and a list of websites from which to elicit the information. The next step of the lesson as observed and documented in their lesson plan showed the importance of the technology in providing the knowledge. The plan states: ...“When all groups have completed the questions, the class will come together for discussion. Each group will be given the chance to explain their answers to questions three and four (all the questions if we have time). The teacher will then give a summary to the discussion about the causes for population decrease of bald eagles”. In another lesson, students were provided with the software “A World of Plants” and were instructed to listen to the story on seeds and use the information to answer the questions on the investigation sheet.

As indicated in the examples, there was a heavy reliance on the technology to provide the content knowledge for the lessons. The learner involvement became one of reading and writing the information that was then used in whole group question and answer sessions, with the teacher highlighting the main points. The preservice teachers had merely substituted the traditional textbook and allocated a large amount of time to copying in formation from the technology rather than involving the learners in meaningful science activities.

Technology as data organizer

Many lessons involved collection of numerical data such as recording temperatures, densities, and masses. Some students used technology in the form of spreadsheets or databases to organize this data.
These lessons typically involved small groups collecting and inputting data, which was then compiled into a whole class document. In a lesson on Healthy Heart, students recorded their pulses at rest and after running in place for two minutes. These data were then recorded onto a spreadsheet that was set up in advance by the teachers. Bar graphs were then constructed from the data with the teachers asking the students to observe the graphs. In another activity on computing density of candy bars, the same format was followed. The teachers had the spreadsheet already outlined and the students went to the computer and added their information in the appropriate columns.

While collection and inputting facilitated observation of whole class data, students showed significant weaknesses in their ability to involve the class in data analysis and in the use of other skills such as extrapolating and making predictions from the trends and or patterns indicated. In some cases, they struggled with converting from the tabulated information to the appropriate graphs and showed weaknesses in manipulating the technology to construct the graphs. Some students literally fell apart when they attempted the graph construction and the steps were not indicated in the plans they were following. However, other students stepped forward to assist, demonstrating that among the group there were different levels of skills and confidence with technology use.

Technology as information presenter
This was the most common use of technology among the preservice teachers during the microteaching activities. Many of them simply used the computer as a glorified overhead projector; paying special attention to colors, fonts and transitions. While presentation software lends itself to nonlinear forms of communication; students utilized it in a linear, lecture-based fashion. Students learned how to develop PowerPoint presentations and were able to vary sound and colors and to import images. In most cases, hands-on activities were incorporated into the lesson. However, the technology was used for information presentation and subsequent fact recall on prepared worksheets. Few deliberate attempts were made to make the presentation relevant to the hands-on activity. In a lesson on leaves, students were provided with a leaf and instructed to measure the length and width and to observe the veins using magnifying lens. This generated many activities at each worktable but with the introduction of the PowerPoint students merely sat, watched and listened to the information being given about leaves.

Technology as facilitator
Active involvement in learning science is a hallmark of the National Science Education Standards. They advocate for the learning of science as inquiry as a central learning goal for all students and state that this cannot be met by having the students memorize facts. It can be met only when students frequently engage in active inquiries. (NSES, 1996). In some lessons, the technology was used to facilitate the inclusion of a number of skills into the lesson. Some of these were allowing for observation and description, critical thinking and the construction of explanations. These were integral components in facilitating inquiry and were essential for the success of the lesson. For example, teachers took digital photographs of animals in their natural habitats displaying various kinds of camouflage. These images were projected via presentation software and formed the basis for the discussions on how animals use camouflage as a survival mechanism. Students were instructed to observe, talk among themselves about their observations and to recognize and construct explanations why camouflage was important to the animals being observed. Their responses were solicited in a whole group discussion and the preservice teachers facilitated higher order thinking skills as they interacted with students.

Another lesson began with students sharing their experiences about a trip made to a lake, pond or to the sea. The preservice teachers then projected an image of a group of individuals floating in a body of water while reading and doing other activities. The class was asked if this was similar to their experiences and were instructed to suggest reasons for the phenomenon being observed. Students were given time to observe and think and then a discussion around the pictures solicited the students responses which were written on poster papers and hung to one side of the room. The lesson continued as students placed eggs in pure water and in salt solutions of varying concentrations noting that the more concentrated the solution the higher the eggs floated. Using the questions developed from this activity, students developed hypotheses about density. At the end of the lesson, the image of the floating people was again projected and students were required to write their own explanations of the occurrence.
Discussion

The goal of this study was to explore how preservice teachers incorporated technology into their integrated lessons during their microteaching activities. Our results parallel findings in K-12 classrooms with inservice teachers and technology. The preservice teachers displayed various levels of technology use ranging from additive and nonessential to being an integral aspect of the lesson. Four use of technology emerged: as knowledge source, data organizer, information presenter, and as facilitator. Preservice teachers also displayed differing levels of competence with the technology. Some were unable to deviate from the lesson plans and showed signs of nervousness and apprehension in instances when things did not go as planned while in such instances, other students were eager to lend a helping hand.

The microteaching allowed the preservice teachers to bring together some components of good teaching including curricular integration, reflection and content-specific uses of technology. We observed the use of the technologies in a variety of ways, ranging from simple presentations to computer simulations, resources for content and spreadsheets for data recording, analysis and constructing graph. In addition, further analysis suggests that the preservice teachers were beginning to value the use of computer technology in teaching science in elementary classroom. Many reported in their reflections that they had developed some level of comfort with using technology in their teaching. In part, they had developed an appreciation for technology as a tool to facilitate the learning of science. These results also offer clues and direction related to efforts to sensitize and expose preservice teachers to the use of technology in teaching and will provide a framework for us from which to consider our efforts to prepare technology-savvy science educators.

Conclusion

The study provided support for collaboration between content-specific teacher educators and educational technologists. Preservice teachers were engaged in the use of technology as a teaching tool and consequently developed new perspectives on the use of technology in their teaching. However, a crucial and obvious component to incorporating technology advances in the classroom is to ensure that teachers are comfortable and knowledgeable with its use as a tool to facilitate learning. The development of a cadre of teachers armed with the capabilities to effectively integrate technology into the teaching of science in elementary schools will require the integration of technology into the science education course and the ability to work through simulated teaching experiences such as a microteaching activity.

References

If we want teachers to create exciting and engaging learning contexts which respects all students’ right to learn, the best way to do this might just be to create exciting and engaging learning contexts for teachers that respects their ability to shape education.

(Riel, 2001.)

One major finding of the 1998 Teaching, Learning, and Computing Study (Becker & Riel, 2000) was that the role of the student as a learner in the classroom mirrored the role of the teacher in the larger educational community. Students in classes taught by teachers who were engaged in a range of professional development endeavors are asked to think deeply about issues, generate their own ideas, work collaboratively on projects, share and evaluate their own work in a public forum, and use technology to support these types of activities. This finding points to the need to create learning experiences for educators that reflect the learning environment we want for our children.

Produced by the Research Center for Educational Technology at Kent State University, the CD-ROM, TECHNOLOGY & EDUCATION: THE RESEARCH ON WHERE WE HAVE BEEN • A VISION OF WHERE WE ARE GOING, is designed for university faculty working with preservice educators, staff developers in a preK-12 environment, and practicing teachers engaged in study groups. The purpose of this session is to demonstrate the use of an interactive CD-ROM that was developed to actively engage teachers in reflective dialogue regarding best practice research, their teaching philosophies, and instructional practices. Session participants will have the opportunity to navigate the CD-ROM as facilitators guide them through the layers of information. Facilitators will also report on the usage of the CD-ROM since its release in August 2001 and feedback that has been received from educators both at the university and K-12 level. Some of the primary users of the CD at this time are teaching faculty that are involved in PT3 initiatives.

The content of the CD-ROM illustrates how technology is changing our lives and our schools. A video message by Dr. Thomas Carroll, former Director of the Preparing Tomorrow’s Teachers for Technology program, addresses the issue of teachers and their changing role in the classroom. Dr. Linda Roberts, former Director of the Office of Educational Technology for the United States Department of Education, speaks to the importance of research in educational technology.

The CD takes an in-depth look at current research findings on the impact of technology on teaching and learning. Dr. Henry J. Becker & Dr. Margaret Riel (University of California at Irvine), who conducted the research on the Teaching, Learning, and Computing study, talk about the significant findings of this work. Dr. Rob Tierney (University of British
Columbia), one of the researchers in the *Apple Classroom of Tomorrow (ACOT)* project, shares results from his ACOT research.

The CD also provides real examples of how these important research results translate into the classroom. A series of guided discussion questions and related staff development activities can be accessed during the course of the CD. These can be used as a stimulus to engage educators in deep conversations about the implications that educational technology has for a real classroom. Content of the CD crosses all disciplines.

The creators of the CD strongly suggest that it be used in a discussion group setting where education professionals and/or teacher education students collaboratively study some current research and issues surrounding technology and its impact on teaching and learning. Viewers are challenged to call on their collective wisdom as practitioners to examine the value and potential of emerging technologies on teaching and learning.

The Research Center for Educational Technology (RCET) was founded in 1999 to provide a collegial network for university researchers and preK-16 educators committed to studying the impact of technology on teaching and learning.

ICT for Pre-service Teacher Educators

Petrea Redmond
Faculty of Education
University of Southern Queensland (USQ)
Australia
Email: redmond@usq.edu.au

Abstract: Pre-service teachers have diverse perceptions of ICTs in educational forums. This paper discusses one University’s attempt to assist pre-service teachers to use and plan for ICTs as an integral part of the learning process for early childhood, primary and secondary students through their completion of a 1-semester course.

Introduction

Treuhaft (1995) states that “Educational institutions do not exist in a vacuum”, and as such we must reflect current trends in society. As technology pervades our society we must ensure our graduating students have the knowledge, skills and attitudes to educate our children to participate in tomorrow’s world. One of the underlying issues for teacher educators in 21st century is to promote the capacity of Information Communication Technologies (ICTs) to improve teaching, learning and assessment in classrooms.

In 1997, Education Queensland released their “Schooling 2001 Project”. The aim of this project was to improve student learning outcomes though the integration of technology (Education Queensland, 1998). Funding was provided to state schools, to achieve a number of targets. These include: the use of computers in every classroom across all key learning areas and all year levels, school networks that give every classroom access to the Internet, and all teachers with a minimum level of skill in the use of computers for learning.

Funding, personnel and professional development opportunities were available to assist all teachers to reach the Minimum Standards for Teachers in Learning Technology (1998). These standards cover four main areas: IT skills, curriculum applications including classroom planning and management, school planning and student centred learning. It is expected that all practicing teachers in Education Queensland will achieve the Minimum Standards by the end of 2001.

Context

In 2000, USQ introduced a course, “IT for Educators” as an elective course for teachers in response to Education Queensland’s Minimum Standards for teachers. In 2002 this course will become a core course for all Bachelor of Education students. One of the benefits for our students taking this course is to increase their employability by Education Queensland, the major employer of our graduates.

Education students at USQ can now access ICTs in their pre-service education in four ways. Firstly, in first year students complete an “Introduction to Computers” course, which is taught by another faculty and is not linked to education. All students within the University complete this core course because it is seen as an essential element for the employment future of all Australian professionals. Secondly, students can take courses in ICT’s in education as a major (6 courses), a minor (4 courses) or electives. Thirdly, students are briefly exposed to ICTs in the context of their general study courses. And finally, the “IT for Educators” course is now a core part of the course for all Bachelor of Education students in the areas of early childhood, primary and secondary. This course gives pre-service teachers experiences to ensure students can demonstrate the Minimum Standards for teachers by graduation. Universities are unable to credential students and formal credentialling must occur when they take up their first teaching position in a State School.

The IT for Educators course comprises of the following major areas:
* Review of Basic IT skills: word-processing, file management, Email, Internet searching, PowerPoint, basic web
  authoring, and different forms of electronic communication;
* Discussion of Education Queensland’s Policy and Guidelines for Using Computers in Learning;
* Demonstrating educational uses of the web; and
* Planning for curriculum and technology integration.

Students engage in individual and group activities both online and in person where they investigate the possible uses of
technology in the field of education. Unfortunately many students have limited experience either using or observing
appropriate use of technology in the classroom; this results in significant discussions regarding use of ICTs to support
teaching, learning, assessment and administration within educational contexts.

Assessment within this unit takes several forms: a portfolio of samples demonstrating students IT skills, a short teaching
session where students teach a IT micro-skill within a lab situation, contributions to multiple electronic communication
forums, and the planning and preparing of a teaching unit or series of learning episodes where curriculum, literacy, and
technology are integrated to solve a problem or perform a task.

Conclusion

There have been significant developments in ICTs, their access and use in all educational facilities. Teachers’ current
skills, pedagogy, beliefs and attitudes will influence how the computer is used in their classroom. Sheingold (1991, p18)
states “it is not the features of technology alone, but rather the ways in which those features are used in [the classroom]
that shape its impact’. Prior to completing the course, pre-service teachers preconceptions regarding the use of
technology in classrooms is usually limited to drill and practice use for fast finishers and word-processing of reports.

Rosenberg (2001) and others have stated that teachers must change from sage on the stage to the guide on the side. This
course focuses on the new role of educators as being one of a facilitator or manager of learning rather than one of
imparting knowledge. Students are required to create real or life-like tasks where the use of ICT is integral to the
learning process and curriculum is student centred. Students are aware that how they use technology in their classroom
after graduation is not limited to their personal IT skills and it will depend on the resources available, their personal
pedagogical style and their ability to create a flexible learning environment.

Technology Integration: A Practical Model

Stephen R. Rodriguez, Ph.D.
College of Education
Texas A&M University-Corpus Christi (USA)
Stephenr@tamucc.edu

Abstract: The concept of technology integration has emerged as a key to effective use of technology in K-12 schools. This discussion presents a concrete model incorporating specific steps which teachers can follow when planning for technology integration.

To integrate means to make whole by bringing together parts. Thus technology integration as related to teaching may be defined as the act of utilizing appropriate forms of technology to enrich or complete instruction. Of course, use of technology may be more or less appropriate for given instructional goals and specific target audiences. Similarly, use of technology does not necessarily insure that instruction will be more effective than instruction which omits use of technology. However, many agree that technology—on the whole—is a “good thing,” insofar as it holds high potential to enrich instruction, to motivate students, to further attainment of curricular goals, and to prepare students to survive in our technology-rich world. As always, one should avoid using technology just because “it’s there,” but should rather plan to use technology in ways that will truly have positive effects on students’ learning.

Learning with Technology: A Task Focus

What kinds of tasks are most beneficial for students when using technology to learn? The ACTIVE framework provides general guidance on the kinds of learning tasks that fit well with technology use (Grabe & Grabe, 1998). The framework describes the characteristics of learning tasks which are well suited to student use of technology:

1. Active: tasks should require that students transform information into personal knowledge;
2. Cooperative: tasks should require meaningful interaction among students;
3. Theme-based: tasks should allow for flexibility, should be multidisciplinary, and should be based on an organizing theme;
4. Integrated: tasks should emphasize content area knowledge and require use of technology tools to encourage learning that content in meaningful ways;
5. Versatile: tasks should make efficient use of technology skills and develop skills that can be reapplied later;
6. Evaluative: tasks should allow for assessment of students’ ability to use the targeted skills and knowledge.

The ACTIVE framework provides useful guidance for educators in considering which kinds of learning tasks would most appropriately involve student use of technology.

Steps for Technology Integration

What steps can a practicing teacher take to incorporate technology into teaching? There is no single, “right” answer to this deceptively simple question. The model presented here is derived from the author’s personal experiences as a professor of educational technology and as an instructional designer. It is intended as a beginning point for planning for technology integration. Teachers should keep in mind that additional related insights may be gleaned from related literature and their own “trial and error” experiences (cf. Roblyer & Edwards, 2000; Grabe & Grabe, 1998; Jonassen, Peck, & Wilson, 1999).

Step 1. review the technology landscape: The teacher should first determine what technological resources are available at the school. Are open computing labs available? What resources are available in individual classrooms? Is portable or
wireless equipment available on a pre-scheduled basis? Answering these questions is an important first step in the planning process.

Step 2. identify the learners: The teacher should next consider the characteristics of the intended learners. Thoughtful consideration of students' age, cultural background, reading ability, technological competence, and interests can improve the likelihood of successful instruction.

Step 3. identify the curricular focus: The teacher must pinpoint which curricular goal is to be addressed. It is important to keep in mind that instruction should focus on attainment of clear instructional goals and objectives, not upon development of technology skills in and of themselves although this can be an “added bonus.”

Step 4. specify the teaching team: Although an individual can teacher can make effective use of technology with students, teachers should also consider a team-based, multidisciplinary approach under which teachers work collaboratively across multiple subject areas such as writing and social studies, or whatever.

Step 5. specify the learning task(s): Here the teacher specifies the nature of the problem or project which will be posed to students. The focus should be on a traditional curricular student outcome such as understanding the water cycle or the three parts of the federal government. The timeframe for the instruction should also be specified. A rubric or other guidance explaining what students are expected to accomplish or produce should also be developed along with other supportive instructional materials.

Step 6. specify how students will use technology: Hand-in-hand with step 5, the teacher must determine how students will use technology to accomplish the task at hand.

Step 7. learn to use the technology as students will: The teacher must be able to demonstrate how students are to use technology and be able to guide them through the process. This requires that the teacher can actually perform the tasks expected of students and related preparation may be required.

Step 8. prepare students for technology use: Depending upon the level of students' existing skills, it may be appropriate for the teacher to spend some time instructing students on the actual use of required technology, though this is clearly not the overall purpose of the total instructional plan.

Step 9. implement the plan with students: This step is self-evident; the teacher tries out the complete plan with students.

Step 10. evaluate results: Here the teacher reviews student projects and collects attitudinal data to ascertain how students felt about the instruction, what suggestions they may have for improvement, and whether instructional goals were attained. Results should be used to revise the plan for next time.

In closing, the model suggested here provides a planning framework which teachers may use to begin their technology integration efforts. Teachers are encouraged to see additional related literature on this critical matter.

Infusing Technology in the Classroom: Positive Intervention Makes the Real Difference in Student Learning

Linda Runyon, Ed.D.
Department of Communications
Robert Morris University
United States
runyon@robert-morris.edu

George W. Semich, Ed.D
Department of Communications
Robert Morris University
United States
semich@robert-morris.edu

Abstract: The emphasis on technology as a tool for instruction has intensified as the public’s belief and reliance on computers has increased. School districts are demanding that new teachers have the knowledge, skill, and expertise to integrate technology in public school classrooms to enhance student learning. This emphasis has required preparing institutions to re-evaluate, review, and restructure programs to ensure that new professionals have opportunities to practice integrating technology. The process of reviewing programs to integrate technology as an instructional tool is the first step to ensuring that new teachers are prepared. The second and most difficult step is to implement necessary changes into existing programs. At Robert Morris University, we have begun the process of review, implementation, and continued evaluation of our English education program that will allow our students to integrate technology into their classrooms as an instructional tool to increase student learning.

Introduction

Infusing technology into classroom instruction is a major part of technology plans for most public schools, colleges, and universities today. The goal is to implement various instructional technologies and media for the improvement of student learning and retention. Education budgets at all levels reflect increasing monetary support for technology as the major learning tool. The issue, however, is not to use financial resources to provide technology as a “stand alone” educational add-on, but the effectiveness of using technology to improve student learning. It is important for new teachers to understand when and how to use technology to aid students’ learning in classrooms to understand and apply concepts and information for various content areas. Specifically, new professionals need opportunities in their training to focus on discerning what technologies can be applied in various contexts and concepts to address student learning styles, interests, and specific subject areas and themes. As Dale Mann (1999) argues, technology does work—with some students and some of the time—not with all students all of the time. Teachers must be given opportunities to share, discuss, and experience appropriate ways to utilize technology in classrooms as they would any other pedagogical methodology. In this way, educators will go beyond using instructional technologies merely to justify expenditures to infusing technologies in a manner that creates a positive intervention in student learning.

Using technology as a positive intervention implies a conceptual understanding of technology as more than a motivational tool or a substitute for more traditional types of instructional methods or pedagogy. It means that technology must not be thought of as a reward for students who have finished their schoolwork. Understanding technology as a positive intervention means that teachers do not use technology for drill and skill programs for remedial students and a reward or enrichment activity for their gifted and talented students; instead, technology must be thought as a way to help all children, whatever
their ability level, use technology in the same ways they use and are given access to other intervention techniques and methods.

Enabling preservice teacher candidates to have the experiences and information necessary to infuse technology in classroom planning and to understand its use as an intervention is a difficult task for many preparing institutions. Stand-alone college technology courses do not appear to help preservice teacher candidates understand how to infuse or integrate technology as a tool for learning. Our experiences working with both classroom teachers and preservice teacher candidates at Robert Morris University, has led to a shared concern that technology has become the primary goal while the pedagogical goals of the lesson are secondary. In these cases teachers use rather than infuse instructional technologies.

Restructuring the RMU Program

In restructuring our program, the questions for us became, how do teachers design classroom instruction in ways that infuse instructional technologies for a positive learning intervention and how can we teach this to our preservice teachers? The answer lies in teaching careful planning. Lesson planning can follow a design format such as ASSURE (Heinich et al, 2000). This design formula considers such pedagogical factors as: anticipate audience (A), state objectives (S), select technology (S), utilize technology (U), require learner participation (R), and evaluate lesson (E). Certainly not unique, this formula follows a general blueprint for lesson plan design with one exception—integration of technology. In this model, teachers first anticipate the type of learners in their classrooms and second write the objectives for the class from a pedagogical point of view based on the specific course outline. Technology planning then occurs in the execution the objectives of the lesson. Thus, technology is selected to better facilitate the objectives of the lesson and the type of learners in the class. Next, the teacher must utilize the technologies in a professional manner. A fluid delivery helps to ensure learning; therefore, we require our students to practice their delivery. Finally, the preservice teacher with the help of the instructor and a videotape of the practice lesson reviews the objectives and determines the best way to assess the lesson and the learning that occurred within the classroom. Essentially, this design formula promotes a positive intervention of technology into teaching. The answer to our first question, then, was to use the ASSURE model in conjunction with our lesson plan design to help our preservice teachers infuse technology into their lesson plans.

How to teach the model was fairly simple, the difficult part became in teaching our preservice teachers when and how to implement technology as a learning tool, our second question. They understood and could generate lesson plans based on the ASSURE model, but could not evaluate the effectiveness of their use of technology on learners. Our challenge became how to help our preservice teachers know when they should and should not use technology in classroom instruction.

In deciding on the use of technology in the classroom, Zaho and Cziko (2001) noted that there are three conditions for teachers to consider using technology:

1. The teacher must believe that meet a higher-level goal than what has been used.
2. The teacher must believe that using technology will not cause disturbances to other higher-level goals that he or she thinks are more important than the one being maintained.
3. The teacher must believe that he or she has or will have sufficient ability and resources to use technology.

These three conditions must be met prior to the implementation of any instructional technology in the classroom. Using technology for the sake of demonstrating that technology was applied to the lesson but without regard to the fundamental or primary of objectives for student learning would certainly be a waste of time for students. A distinction must be made between using technology and integrating technology for learning. It should also be noted that many of the skills in computer technology require time, support, and colleagues to work with to move toward this integration process for effective lesson planning (Sheingold and Hadley, 1990). A positive intervention of technology in teaching is a matter of training, expertise, and creativity on the part of the teacher. It is a basically a process of delivery for the learning objectives.

Newman (1990) argues that educators must determine whether the technology intervention has changed or not changed the educational environment, and subsequently, the learning or pedagogical goals established by the teacher. The argument has been that technology stimulates or demands positive transformations in instruction (cf. International Society of Technology in Education, 1998; Means et al. 1993; Papert, 1993.) Research indicates that technology interventions have not produced the desired outcomes (e.g., Bruce & Rubin, 1993). The fact that teachers do experiment with the technologies inside
and outside of their classrooms and the public's instance to provide instructional technologies in public schools should not, however, be the intended reason for using it.

Newman (1990) examined this issue of intervention and formulated the framework for six critical questions. These include the following:

1. What is the pedagogical goal of the lesson, and what pedagogical theory does it satisfy?
2. What is the instructional intervention that has the potential to achieve the identified pedagogical goal?
3. As the intervention is implemented, what factors enhance or inhibit its effectiveness in achieving the pedagogical goal?
4. How can intervention and its implementation be modified to achieve more effectively the pedagogical goal?
5. How has the instructional environment changed as a result of the intervention?
6. What unanticipated positive or negative effects does the intervention produce? (Reinkins & Watkins, 2000).

By using Newman's questions in conjunction with the ASSURE model, we thought our preservice teachers would be better prepared to evaluate the use of technology as an instructional tool for learning. The following sections examine the data we collected for evaluation of the program and the recommendations we have made for the future.

At Robert Morris University, all students are required to take two technology courses as part of their core requirements. In addition, our preservice teachers are required to use technology in many of their courses and educational requirements. We realized, however, that our preservice teachers were not required to carefully evaluate the use of technology as an instructional tool for public school students. Although there are several ways to help preservice teachers learn to evaluate their use of technology in the classroom, we decided that the best approach for our students would be to design a culminating component to their methods course that would enable them to first integrate technology into instruction, and then to "test" the effectiveness of that technology.

Implementing the RMU Program

Our next step was to test and evaluate our belief that the ASSURE model and Newman's questions would help our preservice teachers make appropriate technology decisions. Through observations of presentations, interviews with the preservice teachers, and analysis of their lesson plans we were able to test our theory and evaluate our effectiveness of teaching the infusion of technology as a learning tool.

The course, Infusion of Technology in Classrooms, is taught as an integrated technology component for our preservice secondary English teachers during their Instructional Methods block prior to student teaching. Our students met with the instructor each Friday for approximately three hours. The initial sessions focused on understanding the application of instructional technologies in public school classrooms. These sessions, which were primarily hands-on, allowed students to review the basics of the technological skills they currently have and to build on these skills. Our students learn, for example, more sophisticated PowerPoint techniques for presentations, basic web design, integration of clip art and animation into presentations, how to write to CDs, and how to participate and set up threaded discussions. More importantly, our students learn how to apply these technological strategies to classroom discussions presentations, demonstrations, skill practices, simulations, and cooperative learning to positively influence student learning.

This component is taught in one of the university's presentation/laboratory classrooms. These classrooms are equipped with an instructor console that has a computer with Internet connection, a document camera, a microphone, two VCRs, a tracking camera (to tape student presentations), a CD player, and approximately 20 student computers with Internet connections. Teaching in these classrooms allows the instructor to demonstrate a technique and then have students immediately practice that technique. Our preservice teachers are familiar with using the equipment found in these presentation/laboratory classrooms. Approximately 70-80% of all classrooms at RMU have document cameras, computers, Internet connection, VCRs, and projectors for instructors and students to use for demonstrations, presentations, and instruction.

The final sessions focus on the infusion and evaluation of technology on instructional practice. In these sessions, our preservice teachers first design a lesson plan for their future public school students. Next, we ask them to integrate technology as an instructional tool in the lesson plan and link the technology to the specific objectives and method of the lesson. Often, this is the most difficult part of the course for our students. They are comfortable with the use of technology—many of them want to use as
much technology as possible; however, they are not comfortable with evaluating its effectiveness. Prior to presenting the lesson plan to their peers, therefore, they must provide a rationale for the technology they choose. In short, they must explain how learning would be enhanced or improved by the technology intervention over traditional or non-technological methods.

Lesson plans are evaluated using a variety of design criteria including: the objectives, the technology, and the assessment of the objectives. We focus on how technology intervention enhanced the learning objectives. We ask students to explain how the lesson could be taught without the use of technology and to compare instruction. This is a way of overseeing that there is not a misuse or unnecessary use of the instructional technologies. To illustrate, one student created a series of grammar exercises with sound and pictures in a game format. She called her CD – Grammar Safari. Essentially, her use of technology provided a series of challenging questions used for bonus points. Another student introduced The Canterbury Tales by using PowerPoint slides to explain Middle English and medieval writing. She also added an Internet URL that connects students to a site where excerpts from The Canterbury Tales is read aloud. Other preservice teachers created threaded discussions on the Internet on various literary topics, while others led research groups to discover historical backgrounds and related literature and still others created CD packages for collaborative learning exercises. The importance of this preservice lesson presentation design is to encourage teachers to make choices about the selection of technologies to have a more positive influence on student learning.

Evaluation and Recommendations for the RMC Program

After the first few sessions of the technology component, our preservice teachers showed a high degree of mastery in the use of instructional technologies. Our goal to have our preservice teachers demonstrate their knowledge of integrating technology as an instructional tool by crafting a lesson where a specific technology is linked to a method, to meet the lesson objectives was met. The challenge for our preservice teachers was understanding the use of the instructional technologies more from the standpoint of motivation or as means of providing variety to lesson planning.

The decision to incorporate this technology component during the four week block, proved to emphasize technology as another strategy teachers had to improving instruction, rather than as an “add on” to a lesson for the purpose of fulfilling a district or school requirement to use technology in some way in the classroom. Our preservice teachers were able to effectively evaluate the use of technology as an instructional tool in this setting.

The fact that our preservice teachers are successful in evaluating technology as an instructional strategy is encouraging. We realize, however, that the setting (a university classroom filled with friendly peers and helpful instructors) is not the real world. We recommend that as a next step, our preservice teachers plan, teach, and evaluate lessons using technology as a tool for learning in their classrooms during student teaching. We also recommend that these preservice teachers teach technology lessons as they are being evaluated by university supervisors who have been trained in the ASSURE model. Further, we recommend that our preservice teachers teach the same lesson to two groups of students—once without the use of technology and later with technology, measure student learning, and then evaluate the use of technology as an instructional tool. In these ways, we hope to encourage our preservice teachers to continue to evaluate carefully their choice of technology and to provide additional data on the effectiveness of technology as an instructional tool in public school classrooms.

The infusion of technology as a positive intervention for student learning requires training in how to best use these technologies to meet the learning objectives. The research has attempted to clearly demonstrate the positive results of technology intervention, but given the number of variables associated with the teaching/learning process, it is difficult at best to show definitive results. Many researchers are continuing to explore this technology intervention, and perhaps in the future there will be studies that may bring conclusive evidence to the forefront. One researcher, R. Kozma (1991, 1994) offered an interesting and functional interpretation in referring to technology not as a medium to deliver information per se, but rather as a device to connect the learner with that medium to construct knowledge. It may also be the efforts of the preservice teachers at Robert Morris University and other colleges and universities that will help provide the necessary research answers to the use of instructional technologies as positive interventions for student learning in the classroom.

Abstract: Elementary teachers often are required to integrate technology in their classrooms and to teach students to utilize technology. In Pennsylvania, preservice elementary teachers typically receive one course in technology instruction. Giving preservice elementary teachers the training and experiences they need to make valid decisions in the use of technology, as a tool for instruction is required of preparing institutions. In the program described previously, our goals were (1) to have preservice teachers mastered the use of technology for their personal needs, (2) to evaluate software packages, and (3) to create lesson plans that integrate technology in appropriate ways. The following discusses the program and provides an update on the changes and revisions we have made during the first two years of the RMU elementary certification program.

Introduction

Today, elementary teachers often are required to integrate technology in their public school classrooms. At best, most of these teachers believe that integrating technology means teaching their students how to use equipment or software. At worst, many teachers use technology in their classrooms as an add-on to satisfy requirements for their evaluations or to meet the demands of administrators. In Pennsylvania, preservice elementary teachers typically receive only one course in technology instruction. There is little or no attempt to demonstrate ways to integrate technology into their future classroom assignments in education or methods courses. It is important to give preservice teachers the training and experiences they need to make valid decisions in the use of technology as a tool for instruction. In the RMU elementary education program described at SITE in 2000, preservice teachers first were to master the use of technology for their personal needs (Lund & Runyon, 2000). Second, preservice teachers were to be taught ways to evaluate software packages. Next, our preservice teachers were to have opportunities to create lesson plans that integrated technology in appropriate ways. Finally, preservice teachers were to use technology in actual classroom situations with small groups of elementary students. Now in its third year, the elementary education program at Robert Morris University is being evaluated for its effectiveness in meeting the goals and objectives of the program.

As we began the evaluation process, we first turned to the research on teacher training and technology. We discovered that many researchers and experts agreed that it is important to continue to stress the importance of using technology as an instructional tool rather than as a “add-on” to instruction. Maers et. al (2000) argue that preservice teachers need opportunities to learn and use technology and to have instructors model technology as an instructional tool. We have found that the more comfortable and familiar our preservice teachers are with instructional technology the more likely they are to use it and, more importantly, the more likely they are to integrate technology for personal uses.

The Program: A Review

Given the opportunity by the Pennsylvania State Department of Education to develop a new elementary education degree program with a focus on integration of technology, Robert Morris University (RMU) responded by incorporating technology throughout the program—specifically in all education and methods courses as reflected in department syllabi. The integration of technology in course assignments illustrates to preservice teachers in a concrete manner ways in which technology can and should be used by educators as a tool instead of a “by-product.” Some examples of learning activities in various courses include:

- searching for appropriate Internet sites and creating hyperlinks for elementary students.
- corresponding via e-mail to elementary students.
evaluating software packages in content areas such as interactive reading software for reading and language arts methods.

- creating graphic organizers and data bases, using commercially packaged software such as PowerPoint™ and Claris Works for Teachers™

- evaluating on-line lesson plans and teacher materials

- using scanners to integrate pictures of students' work into text and presentations

- evaluating video segments for use in the classroom.

Through these courses and activities, preservice teachers learn that technology is a natural extension of their lessons and can be incorporated in the classroom as a tool for learning. They learn when the use of technology is inappropriate as well as when its use can enhance instruction.

At RMU preservice elementary education majors are required to take 15 credits of technology courses: nine from the college technology core and six from the RMU core. With this background, students are prepared to effectively use technology to teach content in specific subject areas. These technology core requirements are not intended to make technology experts of elementary majors: rather, the goal is to produce competent, confident elementary teachers who are comfortable with the use of technology as a tool when implementing successful teaching strategies. To accomplish this goal, RMU faculty used the National Education Technology Standards published by the International Society for Technology in Education as a model for designing courses and assignments.

The Program: an Update

Elementary preservice teachers in the Robert Morris University elementary education program have used technology as a tool for their own learning in many of the institution's core courses that they have taken. Specifically, they have been required to use word processing software in their Communication Skills I and II courses, and to incorporate graphics, tables, and charts into these documents. They have had some experiences with Internet research and have used technology to help in preparing presentations especially in Communication Skill III-V. More importantly, instructors have modeled the use of technology as an instructional tool. Our preservice teachers have finished two "stand alone" technology course (Tech Literacy for Educators I & II) that focus on configuring hardware to meet the specific needs of their future classrooms. Preservice teachers learned, for example, how to set up equipment, cable scanners, printers, monitors, and document cameras together. They learned how to use digital cameras and video cameras. They also learned how to cable VCR and DVA players to other equipment. Our intent was not to make technology "gurus" out of our preservice teachers, but to give them the information and skill they would need to perform basic maintenance and trouble shooting on the types of equipment they find in their classrooms. In this way, we hoped to give our elementary preservice teachers the ability to lessen instructional "down-time" waiting for the technology specialist or support staff. We do realize that most public school classrooms will not be equipped with the amount of technology that we require of our elementary preservice teachers, but we feel that it is important for our preservice teachers to become familiar and comfortable with a variety of technologies.

As our first group of elementary preservice teachers completed Tech Literacy for Educators, we began evaluating ways in which we could improve and expand technology literacy. Our elementary preservice teachers were extremely helpful in voicing their views about the course and the ways they thought it might be improved. With the help of our preservice teachers, we have begun the process of reorganizing and restructuring the course to better meet their needs.

In addition to the technology courses, our preservice teachers have completed Developmental Literacy and Children's Literature. Both of these courses require our preservice teachers to utilize the information they received in their technology course and to integrate technology into these areas. Preservice teachers in Children's Literature, for example, have created spreadsheets, graphic organizers, and charts using the computer and appropriate software. They have begun work on a database for teacher recourses and a course web page that will continue to be updated each semester.

The technology requirements for our preservice teachers has meant that instructors in these courses have had to reevaluate their own teaching, assignments, and requirements to provide preservice teachers the opportunities they need to understand the use of technology as a learning tool. As Basinger (1999) argues, institutions that reported the highest levels of student technology skills and experiences were ones that did not demand several stand alone technology courses, but those that integrated technology throughout the teacher training program.

As RMU began to design the elementary education program, the concerns about the demands placed on faculty were discussed and ways to resolve these concerns were explored. This demand on the RMU faculty has meant that seminars to disseminate information about the use of technology in curricula design, software availability, and hardware updates must be convenient, appropriate, and timely. Faculty interaction must also take place to ensure that
the necessary skills have been taught and that assignments build on one another instead of conflicting or overlapping. Since adjunct faculty who are full-time elementary classroom teachers teach many of our method courses, full-time RMU faculty must work with adjunct faculty to ensure that the level of technology integration modeling is maintained. This also means that RMU must remain committed to providing faculty development and resources.

Our preservice teachers have had to make adjustments as well. No longer is the course over at the end of the semester. The information they learn in one course has been integrated into another. In fact, this concept of demonstrating how information should be used from course to course has been working so well with the technology that we have begun to incorporate it in content courses. The work done in Children's Literature, for example, is expanded in Reading and Language Arts methods and used in Science, Social Studies, and Mathematics methods.

Currently, these preservice teachers are in their third year of the program and are enrolled in Educational Assessment. This course will require them to create ways to assess student learning. It will also require them to plan and evaluate the ways in which they organize and deliver instruction to their future students. The goal of this course is to help preservice teachers understand the ways in which technology might be used as an instructional tool to both aid student learning and to aid in student assessment.

Future Plans

As our first class of elementary preservice teachers are finishing their course work, we are making plans to have our adjunct faculty (those elementary classroom teachers) come to the campus for training on the equipment our students have been using. We are also planning workshops for these teachers in the ways to integrate technology as an instructional tool for public school elementary students. We plan, for example, to have these adjunct faculty develop units in content areas that require their students to use the Internet, scanners, and document cameras. We also plan for these teachers to learn to use and teach PowerPoint in their classrooms. Adjunct faculty will be asked to bring an existing lesson plan and to integrate technology into that plan with the help and guidance of RMC full time faculty. Then, teachers will teach the plans with and without technology to groups of their students. RMC full time faculty will be available to assist the teachers in the classroom. Finally, these teachers will evaluate the effectiveness of technology as an instructional tool. We feel that it is important for our adjunct faculty to go through this process with us so that they can better evaluate our preservice teachers in their methods courses and during student teaching.

In addition, our future plans include a post baccalaureate program in elementary education and a masters program and exploring the possibility of a doctorate in elementary education or curriculum and instruction. Many of our current preservice teachers are expressing an interest in continuing their education at RMU. Several of our adjunct faculty and their colleagues have asked about the possibility of completing a doctorate at RMU.

A Final Word

The use of technology in elementary preservice teacher programs requires a new mind set for instructors and elementary preservice teachers. Programs such as ours are beneficial only when elementary preservice teachers are given clear instructions, time to practice, and requirements to integrate technology throughout their program. This means that instructors must work closely together to ensure that technology requirements remain consistent and yet build toward helping elementary preservice teachers become familiar with the use of technology as a tool, not as an add on, and helping elementary preservice teachers distinguish when technology enhances rather than detracts from learning.

We had an advantage when we began our elementary education program; we had never had such a program at Robert Morris University. We, therefore, did not have to deconstruct traditional practices. We did not have the political or territorial conflicts that other institutions might encounter. We are able to experiment and change as we discover problems and solutions within our program. With the help of our elementary preservice teachers, we are continuing to refine and hone our program to meet their needs and the needs of public school children.

Shifting the Teacher and Student Roles in the Classroom
Blending Web Design and Service Learning for Classroom Change

Chris Sande, Teacher
Rogers High School: Spokane, Washington
chrisS@sd81.k12.wa.us

Anuja Dharkar, Curriculum Specialist
Macromedia: San Francisco, California
adharkar@macromedia.com

Abstract: Students in the process of learning web design are often unable to experience
the real-world design process that takes place between a client and the web designer.
Interpersonal and group dynamic skills are essential in order for one to be successful in
education and business. By linking Web design and service learning, students have an
authentic experience to learn and apply these skills while designing web sites for their
community. Community organizations are often without time or skill to build their Web
sites and students can fill this need. To provide for these student experiences, two main
changes need to occur in the classroom dynamic: a paradigm shift from teacher to
facilitator and shift from student to team player.

Service learning provides students with skills for teamwork, individual responsibility, and accountability.
These skills help students become productive members of their communities by forming a connection with local
organizations and community members. Professional Web designers also rely on teamwork, individual
responsibility and accountability when developing a Web site. Using Web design skills in service learning
accomplishes two main goals. First there is an authentic, real audience and/or client for whom students can
build Web sites. Second, students can apply the universal values and skills of service learning to provide them
with an authentic Web development experience. Using Web design skills in service learning allows students to
become active participants in their communities while applying knowledge and skills from the classroom.
Students can make connections in the community, transfer community service concepts to Web design, and
practice the professional skills of Web design. To support this type of work, teachers need to be prepared to
shift their roles in the classroom and provide students with experiences that will promote teamwork.

Shifting the Teacher Role
Service learning requires building ties in the community. To promote the authentic experience of working with
actual organizations, teachers need to expand their classroom roles to build relationships outside the classroom.
This action causes teachers to move towards a facilitator role as they forge relationships and set up explicit
expectations between the classroom and community organizations. The facilitator role becomes important in
preserving outside relationships with the classroom and helps to model professional Web design and
development practice when the project begins. The teacher can maintain instructing and helping students
accomplish Web development work for the community. A successful example of this type of work is the Hands
on the Land project conducted through the Wilderness Technology Alliance (WTA). This project links
classrooms with federal lands. Teachers, with the help of the WTA plan the visitation and exploration of the
site, build the expectation and relationship, and coordinate student Web site production. This method helps the
teacher transition towards the facilitator role.

Shifting the Student Role
Professional Web design requires team participation. To successfully model and engage students into the
professional team process, teachers must help student understand the dynamics of team interaction. A possible
method to help students understand the importance of teamwork would be to engage students in other activities
that involve teamwork. For example, the Wilderness Technology Alliance (WTA) has created a model for
teaching students about teamwork and the important skills that team building provides. During a two-week summer camp teachers will take students on a weeklong hike to collect data on Mt. Rainier and then these student groups will apply their team building skills to creating a Web site to represent the data they collected. These team skills will help students model professional practice and ease their transition into group work for outside clients. Teachers create links between professional practice, classroom practice, and a familiar environment for teamwork such as the wilderness.

**Conclusion**

When teaching Web design, teachers will need to shift the roles in the classroom to provide an authentic learning experience. As the facilitator of the classroom, teachers will build their role by creating ties in the community and helping students model professional behavior. As exampled by the WTA and it projects, there is much success that stems from building partnerships and helping students learn to be better team players.
The pedagogical scenario: as a tool of professional development in the in-service teachers and pre-service teachers.

Abstract: Within the framework of our research-action-training, we propose the interaction among the in-service teachers and pre-service teachers in professional development courses for the conception and implementation of a pedagogical scenario to integrate ITC into the classroom. As a consequence, both in the creation and implementation of the scenario, our aim is to allow in-service teachers and pre-service teachers in professional development to go through a socio-constructivist learning experience which is to the same extent a sharing experience in a practical learning community that will provide a new belief concerning the development and use of pedagogical scenarios.

Introduction

The Internet contains a growing number of resource sites containing pedagogical strategies and practices linked to various educational content. These sites contain suggestions for lesson planning procedures, integrating TIC, and at times, various other tools which may enable their application in the classroom. These procedures are meant to guide the teacher in planning the learning process, while taking into account the different variables such as teaching tools, participants, context, as well as the question of who may contribute or thwart the learning process. The result of this planning is called the pedagogical scenario or lesson plan. The majority of these scenarios, which are available in the database and on the Web, have been devised by students of education as part of their coursework.

The Study

Within the framework of our research-action-training, we propose the interaction among the in-service teachers and pre-service teachers in professional development courses for the conception and implementation of a pedagogical scenario to integrate ITC into the classroom. This training takes place within a course conceived as a professional training laboratory, at the University of Montreal. In this course the learning and teaching socio-constructivist dimensions such as collaborative learning, student centered learning, stimulation leading to learning autonomy in a meaningful and realistic context (Viens, 2000) are taken into account. Thus, the in-service teachers and the pre-service teachers are invited: to participate in pedagogical and technical training workshops; to group up in working teams made up of one in-service teacher and three pre-service teachers; to hold individualized meetings with the tutor as a group; to take part in the discussions forum; finally, to contribute to Les Scenaristes site in the creation of the pedagogical scenario for ITC integration. In this way, in-service teachers and pre-service teachers become members of the same working team.
In order to construct a lesson plan, Les Scenaristes site proposes a systematic procedure in five phases: situation analysis, lesson plan design, pedagogical material production, lesson plan application, and finally, the evaluation and revision of lesson plans and pedagogical material.

The pedagogical procedure of the lesson plan design contains five elements: situation, learning situation, objectification situation, evaluation situation and transfer (réinvestissement). These are presented as the basic elements of a lesson plan, which must be combined and orchestrated according to the needs of the students in question, as well as the peculiarities of the learning context.

While in traditional practice, the conception of a pedagogical scenario is considered an instrument for teaching planning; we see it, from a socio-constructivist perspective, as a tool which leads, in the first place, to reflection before, in and after action; adding they fix an interpretation and a solution, but are open-ended and easily revised; they take account the external factors and they use them in order to consolidate the learning experience (Carrol, 2000), and above all, it is an instrument to share experiences and practices.

However, in the first steps of our research, we noticed that in order to conceive a pedagogical scenario from this new paradigm, there are barriers to be overcome, such as the association of the scenario to a traditional pedagogical planning, closely related to objective cognitivism, beliefs related to its use as well as models and recipes which provide an anticipative vision of reality. These beliefs appear already at the beginning of our research and they oppose to the socio-constructivist dimension we wish to follow in both its conception and implementation.

As the activities develop, the groups are led, by the tutor, to reflect on the roles of each of the actors of the scenario: teachers and students, as well as on the importance of providing the models of the necessary tools for the support of learning in a socio-constructivist context, such as the suggestions for the implementation of evaluation tools and the strategies and questions of objectification. We hope that the teacher will venture beyond pedagogical planning in order to implement a new approach set out by the education reform.

Bearing in mind that the research is still in the data collection phase, it seems to be too early to make conclusions. Nevertheless, we can state that there is a growing interest in this problematic on the part of the teachers dealing with evaluation tools in education, as well as on the part of the students engaged in coursework projects. Consequently, we need to reflect on the priority level which the elaboration of these tools might occupy in the process of lesson planning, as well as on the importance it might have in supporting the teacher in the milieu of a new pedagogical practice.

Nevertheless, we believe that an essential advantage of the scenario is misunderstood: its role as a tool to share pedagogical practice and tools for this practice.

Therefore, both in the creation and implementation of the scenario, our aim is to allow in-service teachers and pre-service teachers in professional development to go through a socio-constructivist learning experience which is to the same extent a sharing experience in a practical learning community that will provide a new belief concerning the development and use of pedagogical scenarios.

Conclusions

We believe that the study of this educational device will enable us to know more about the priorities set out by teachers in connection with their training in TIC. We also believe it is possible to observe the position which planning, elaboration, and lesson plan tools have in the formation of a new pedagogical practice, using TIC in order to support it.

Developing Appropriate ICT Competencies in Trainee Teachers: An Australian Example.

John Schiller
The University of Newcastle
NSW, Australia
john.schiller@newcastle.edu.au

Abstract: This presentation will explore the rationale for, the strategies used, and the initial implementation successes and failures as minimum ICT competencies were determined at a regional Australian university for each year of the four year, double degree teacher training programs. Catering for the diverse ICT needs of nearly 2000 early childhood, elementary and high school teacher trainees necessitated changes in program structure, modification of existing courses, creation of new course components, changes in assessment requirements, establishment of additional infrastructure, and training of staff. Issues such as staff involvement in the decision making processes, determining entry ICT competencies of entry level students, providing for ICT skill development, assessing ICT milestones and future challenges, will be explored.

Introduction

Although Information and Communications Technologies (ICT) have been used in some aspects of undergraduate teacher training programs for many years in Australian universities, it is only in the last few years that any systematic attempt has been made to identify and clarify expectations of minimum ICT competency standards for all graduates from teacher preparation programs.

This presentation will explore the rationale for, the strategies used and the initial implementation successes and failures as one regional Australian university determined minimum ICT competencies for each year of its four year, double degree teacher training programs. Catering for the diverse ICT needs of nearly 2000 early childhood, elementary and high school teacher trainees necessitated changes in program structure, modification of existing courses, creation of new course components, changes in assessment requirements, establishment of additional infrastructure, and training of staff.

In 1998, the NSW Department of Education and Training (New South Wales is the most populated state of Australia), the major employer of graduates from university Faculties of Education, expressed concern that the minimum ICT competencies of many graduates from NSW universities did not meet the needs of the schools and that appropriate demonstration of ICT minimum competencies would be expected prior to an offer of employment. Although a report on "Preparing a Profession — Report on the National Standards and Guidelines for Initial Teacher Education Project (Australian Council of Deans of Education, 1998)" had identified 14 graduate attributes deemed as necessary for effective beginning teachers, including use of appropriate technologies, particularly information technologies to facilitate learning, for administrative purposes and for professional interaction, many Faculties of Education had only paid lip service to ensuring that these attributes were appropriately developed in all programs. The threat of the major employer for the state to refuse to offer teaching positions to graduates who did not meet minimum ICT competency levels focused attention on program redesign and changes in assessment processes!

Determining basic ICT competencies

Using a report "Computer Proficiency for Teachers", prepared for the Ministerial Advisory Council for the Quality of Teaching in 1997 (see http://www.det.nsw.edu.au/macat/comppro.htm), the Faculty of Education at the University of Newcastle, Australia, redesigned programs and assessment requirements in an attempt to include the basic competencies identified as critical to beginning to teach in NSW schools. The report recommended that all graduates of initial teacher education courses should have as a minimum proficiency, ICT skills in the areas including:
Basic operational skills including understanding the various components of the computer, using a variety of software applications such as word processing, database and spreadsheet functions, information retrieval, use of graphics, simple desktop publishing and use of drill and practice activities.

Information technology skills including the ability to find information, select appropriate applications and software for the classroom, organise material sequentially, assess the relevance of information and present it appropriately.

Software evaluation skills such as the ability to determine underlying pedagogical assumptions, gender and ethnic bias, educational relevance and suitability for the classroom.

Pedagogical skills for classroom management such as the ability to create student centred learning environments, to develop innovative ways of using technology to enhance the learning environment and to encourage students' creativity and research.

Awareness of values and ethics related to the social and educational use of computers and associated software and applications

The report highlighted that the major challenge to be faced in the integration of technology in the classroom would be the pedagogical implications, the impact on the structure and content of curriculum, classroom organization and practices and the changed role of the teacher. Moreover, the report argued that the key issue is pedagogical rather than technical, that teachers need to come to terms with the pedagogical challenges posed by effective classroom use of ICT (p.5).

Implementing a basic ICT skills approach

The first steps to implement these recommendations were taken in 1999 by a part time lecturer who developed a matrix to map where these skills were dealt with across all existing teacher education programs provided by the Faculty of Education in Early Childhood, Elementary and High School specializations. These matrices demonstrated that few ICT skills were covered within courses and that there was a completely ad hoc approach to development of ICT skills across all teacher education programs. To ensure that basic ICT skills were required of all teacher education students, a series of tutorial sessions were established in the first year core course on learning processes which was taken by all beginning students. However, the range of ICT skills of the tutors presenting these sessions was so variable that the decision was made to supplement these computer lab based sessions with workshops for those students who needed additional help. A part time lecturer presented these workshops and devised a self help manual to cover basic skills of word processing, presentation, email use, web page construction, spreadsheet use and software evaluation. At the university level, infrastructure was set up to provide every student with a free, Internet based ‘Studentmail’ email address and self-instructional software was evaluated and purchased so that all students could access online tutorials to learn basic and advanced use of a wide range of software applications.

The poster session will present data collected from all first year student teachers at the end of the first semester 2000 and 2001 which shows that there was a significant increase in student use of and perceived competency in a range of software applications but that there were still a surprisingly high proportion of first year university students who claimed only occasional use or no use of some software applications. Samples of scenarios used to develop basic ICT competencies and presented in tutorials will be shown. Positive and negative experiences in using an online tutorial system “Skillbuilder” will be outlined. The current assessment criteria for development of “Computer Competency Milestones” in MS Word, Powerpoint and Excel will be shown. Issues in convincing academic staff to embed ICT competencies in their course assessment will be explored and challenges in developing academic staff understanding of wider applications of ICT in all aspects of student teacher learning will be outlined.
Creating a Technology Competency Agreement between Colleges

Kathleen M. Sindt

The teacher education program at Montana State University - Billings (MSU-Billings) is in a unique situation in the types of students it receives. Approximately 40% of the student population in the teacher preparation program are transfer students from the community colleges in the region. We have formalized partnership agreements with many of these colleges.

The partnerships formed with the neighboring community colleges allow students who have completed an Associate’s Degree to use this degree to show completion of the General Education requirements. Most of these students are ready to be formally admitted to the teacher preparation program.

One of the requirements to entry into the teacher education program is a basic computer competency. This competency can currently be met by either taking an introductory Educational Technology class, or by showing mastery of the skills taught in the introductory class.

The problem that has been occurring is that many of the students transferring from the partner schools have not been provided with an opportunity to meet the competencies prior to arrival at MSU-Billings. This puts them behind their colleagues who have had the chance to earn these competencies early in their college experience.

As part of the PT3 grant, the MSU-Billings educational technology faculty are working with faculty from the partnership schools to develop a plan to ensure that all students have the same competencies prior to applying to the teacher education program at MSU-Billings. The plan will include an agreement between faculty from the different institutions about what competencies need to be met by the students from the partner schools, and a plan for each institution, including MSU-Billings to institute policies to ensure these competencies are met. It will be up to each individual institution to determine the means by which the competencies are met by the students.

As competencies change, the faculties will need to continue to meet to update the competencies. Eventually, it is hoped that this process will be formalized and agreed upon by the administrations of the various institutions involved.

This presentation will discuss the process being used to reach an agreement between the partner institutions. It will include a discussion of the steps taken along the way by the various partners and the steps that need to be taken to formalize the agreement.
Meeting the Educational Technology Standards for Teachers: Measuring One College of Education and Human Services

By Kathleen M. Sindt
Assistant Professor
Montana State University – Billings
Billings, Montana

Introduction

In the fall of 1999, the college moved into a newly renovated and expanded facility. This facility has state of the art technology in each of the new classroom, including a digital projector connected to a DVD player, a VCR, an electronic overhead (ELMO) and an instructor’s computer station. In addition, several new computer classrooms were added, as well as a set of wireless laptops.

As a part of a college wide effort to evaluate and improve the teacher education program, the College of Education and Human Services (CEHS) faculty wanted to know how well we are using the technology found in the new building to prepare our students to use technology in their classrooms upon completion of our program. The guidelines for judging the technology integration abilities of our students are the National Educational Technology Standards for Teachers (NETS•T) (International Society for Technology in Education, 2000). This paper discusses what activities the faculty members are doing to help prepare their students to be technology-using teachers.

Instrumentation

A survey instrument was created to evaluate how well the faculty was preparing the student population to meet the technology standards (See Appendix). The survey listed each component of the NETS•T and each faculty member was asked to check which of the standards they were addressing in each of their classes. The survey was designed to allow quick responses by the faculty. Once the results of the survey were received, each faculty member who indicated they were addressing the standards was sent a follow-up. The faculty was asked to describe the activities that they had the students engaging in that addressed the standards they had checked on the survey.

Results

Approximately eighty percent of the faculty (28 out of 35) faculty members completed the survey. Most of the faculty who did not respond are graduate faculty and do not teach students in the teacher preparation program. Of the faculty members who responded to the survey, only three of the faculty indicated they did not address any of the technology standards in their classes. The rest of the faculty indicated that they addressed at least one of the standards in their classes.

Of the faculty members who address the NETS•T in their classes, there are some differences in how many and what types of standards were addressed. The faculty who teach the general preparation level education courses that are required prior to admittance to the teacher education program use less technology in their classes than those faculty who teach the professional preparation classes (teaching methodology classes).

The general preparation faculty concentrate on aspects of Standards I: “Technology Operations and Concepts”, II: “Planning and Designing Learning Environments and Experiences, and V: “Productivity and Professional Practice” of the NETS•T (International Society for Technology in Education, 2000). The aspects of the standards addressed in the foundational classes ensure that students can use technology to help with their own learning. These faculty members expect their students to be able to use and evaluate technology resources, to use technology in their own learning, and to apply technology to increase their productivity. The activities that these faculty have their student engage in center around using the Internet for research and in creating PowerPoint (Microsoft PowerPoint, 2001) presentations based on their research.
Prior to admittance to the teacher education program, students are encouraged to take the Educational Technology course. While this is not officially a requirement, the faculty of the teacher preparation courses expect their students to be proficient in technology prior to enrollment in these classes. The Educational Technology course concentrates on Standard 1: Technology Operations and Concepts, Standard V: Productivity and Professional Practice, and Standard 6: Social, Ethical, Legal, and Human Issues (International Society for Technology in Education, 2000). This course teaches students how to use several tools, including word processors, spreadsheets, databases, and a multimedia development tool. In addition the students are expected to learn how to use the Internet effectively, know how to send and receive email and how to use peripheral devices, such as scanners, digital cameras, and printers. In addition, students participate in discussions related to copyright, equity, and diversity issues that are related to technology.

The faculty that teach the courses for professional preparation build on using the tools learned in the Educational Technology tend to concentrate more on Standards II: “Planning and Designing Learning Environments and Experiences”, and Standard III: “Teaching Learning and the Curriculum” of the NETST (International Society for Technology in Education, 2000). In addition to and the students activities described above. In addition to the types of activities described above, these faculty members expect their students to create more extensive projects. For example, in Science Methods, students are exposed to several projects that involve technology, look at lesson plans that include technology and that can be used with students. In Math Methods, students are required to teach their peers how to use various mathematics software programs, such as Tessellation Exploration (Lee, K, 2001) and Microsoft Excel (Microsoft Excel, 2001). They are also expected to incorporate technology into the required unit plan for the course. In Social Studies Methods, all students are expected to conduct research on a country. Part of the research includes finding web sites related to the country they are assigned. They are then expected to create a multimedia presentation using HyperStudio (HyperStudio, 1999) that incorporate graphics, sounds and the web sites that they found. In other courses, students evaluate software, and explore issues related to special education.

Conclusions

Based on the results of the surveys and follow-up responses, it appears that the faculty in CEHS are doing a good job of addressing many of the NETST. However, there are some gaps in where the standards are addressed and in which standards are addressed. Currently, Standard IV: Assessment and Evaluation, is only addressed a couple of times, and not in great detail anywhere in the curriculum. It appears that this is an item that needs to be included into the curriculum at some point.

Also, while most of the standards are addressed at the teacher preparation level, there is little carry over into the field experiences of the students. Students are expected to create a technology rich lesson for their introductory field experience seminar, but are not required to use this unit with children. Students are not required to use technology in their student teaching experiences at this time. This is an issue that will need to be addressed in the near future.

Multi Media Meets Multiple Intelligences: Training Teachers for the New Century

Gail Slye, Drury University, US
Ed Williamson, Drury University, US

Introduction

The National Educational Technology Standards (NETS) Project, a program that concentrates on preservice teacher education as a division of the International Society for Technology in Education (ISTE), has defined specific concepts, knowledge, and skills considered essential in order to apply technology in educational settings. Preservice teachers participating in their preparation programs are expected to demonstrate competency in Technology Operations and Concepts. Requisite proficiencies range from using technology tools and information resources to increase productivity, promote creativity, and facilitate academic learning to examining acceptable use policies for the employment of technology in schools, including strategies for addressing threats to security of technology systems, data, and information. The availability of diverse multi-media based technology in the academic arena promotes a re-evaluation of traditional methodological strategies to now include concepts that promote the recognition of various categories of potential intelligences.

The theory of multiple intelligences was developed in 1983 by Howard Gardner, Hobbs Professor of Cognition and Education at the Harvard Graduate School of Education. Multiple intelligences theory holds that each person has abilities of varying degrees in several different and discrete areas. This is in contradistinction to general theories of intelligence that have been advocated during the past century. The theory promoted by Gardner in his 1983 book, Frames of Mind, claims that each individual has capabilities or potentialities in seven distinct areas: linguistic, musical, logical-mathematical, spatial, bodily-kinesthetic, interpersonal, and intrapersonal. Another area of intelligence according to Gardner in his 1993 book, Multiple Intelligences: The Theory in Practice, is designated the naturalist. Further possible areas of intelligence - spiritual, existential, and moral - are explored by Gardner in his 1999 book, Intelligence Reframed; however, after extensive discussion, Gardner (1999) has decided not to add them to the current framework. The key to understanding the theory of multiple intelligences is to recognize that each person has strengths and weaknesses in each of these areas, as well as a uniquely individual combination of abilities acquired from all intelligences. These intelligences are dynamic in nature rather than static, that is, they are capable of changing over time. This paper will explore the eight multiple intelligences that currently compose Gardner’s theory and examine their relationship to educational technology.

Multi-Media Technology Meets Multiple Intelligences

The current culture of multi-media technology allows for many interactions between technology and multiple intelligences. Jonassen (2000) advocates the use of computers to support meaningful learning through cognitive tools. These “mindtools” are computer applications that require students to think in meaningful ways or produce actual representations of what they know through critical thinking.

Roblyer and Edwards (2000) state, “Gardner’s theory meshes well with the trend toward using technology to support group work. When educators assign students to groups to develop a multimedia product, they can assign students roles based on their type of intelligence. For example, those with high interpersonal intelligence may be the project coordinators, those with high logical-mathematical ability may be responsible for structure and links, and those with spatial ability may be responsible for graphics and aesthetics” (p. 66).

Multi-media technology, in particular, is a remarkable vehicle for allowing the expression of multiple intelligences. Armstrong (1994) correctly ascribes the potential applications of the multiple intelligences theory with computer technology. The list of software recommended to activate multiple intelligences can serve as a template for the exponentially expanding varieties of software available to educators. With the rapid increase of software, both in sheer volume as well as complexity, applicable to each of the eight areas of multiple intelligences, there seems to be no limit to the integration possibilities of multi-media technology and multiple intelligences.
Drury University and Multi-Media Efforts in Teacher Preparation

The renowned Drury University teacher education program requires students to complete five foundation courses, including Technology in the Classroom, EDUC 200. This is a three-hour introductory course enabling participants to explore a number of technologies that can be used in the classroom. The course focuses on three areas: how to operate the technologies, how to use the technologies to enhance personal productivity, and how to use technologies in a learning/instructional environment.

Multi-media and multiple intelligences coordinate to create opportunities for both individual as well as group learning. In the case of the Drury University teacher preparation program, multimedia applications are stressed at both levels - personal and group. This allows for a synergistic confluence of multiple intelligences. On the one hand, individuals will draw upon their strengths in each of the eight intelligences to create a product. Conversely, a group project is enhanced due to each individual bringing into the mix a unique blend of intelligences that interact with the intelligences of the other group members. The result is the same, the whole is greater than the sum of the parts.

Specific Utilization of Multiple Intelligences through Multi-Media

**Linguistic:** Each of the course projects requires the students to use written and oral language skills. The Microsoft Power Point presentations contain text and Microsoft Word documents are required in the lesson plan presentation and the final project. The projects require the students to make oral presentations.

**Musical:** Each project allows the student to utilize musical selections to augment moods and experiences. In the lesson plan presentation and final project students may choose musical topics for their themes.

**Logical-mathematical:** The capacity to analyze problems logically is required in all of the assigned projects. Students may also choose mathematics for their theme in the lesson plan presentation and the final project.

**Spatial:** Each of the projects features a need to recognize and manipulate patterns. To create multi-media presentations using the Microsoft Power Point software, students must be able to discriminate spatially and to integrate colors, graphics, and texts in a balanced format.

**Bodily-kinesthetic:** This intelligence is not just limited to sports or athletic activities, but it also includes the use of the individual body or parts of a body to fashion products. The field of multi-media presentations requires the use of the hands to create the text documents and the Microsoft Power Point presentations. Students must also demonstrate physical coordination to present their slide shows while delivering their oral presentations.

**Interpersonal:** This intelligence is utilized primarily through the presentation of finished products. It is used to the greatest extent during the group review process for the final project.

**Intrapersonal:** This intelligence is employed during each of the required projects for as students utilize the capacity for self-understanding, including personal desires, fears, and aptitude.

**Naturalist:** Students who select a science theme for their lesson plan presentations or the final project could be expressing and utilizing the naturalist intelligence.

Preparing Teacher Educators to Use Technology: Applications and Perceptions of Technology Integration

T. Colette Smith
College of Education
Arizona State University
United States
tesmith@asu.edu

Thomas A. Brush
College of Education
Arizona State University
tbrush@asu.edu

Abstract: The purpose of this paper is to describe a work in progress that reveals teacher educators' perceptions and applications of technology integration in the methods courses they teach. Data sources comprise of survey results and semi-structured interviews. The International Society for Technology in Education/National Council for Accreditation of Teacher Education (ISTE/NCATE) standards served as a model for the development of the online survey and interview questions. The Educational Technology Teacher Educator Survey (ETTES) was developed to measure technology integration skills, applications, and perceptions of teacher educators. Online survey administration and the interviewing process will be discussed.

Background

Teacher educators rarely utilize technology in their own research and teaching, therefore the realization of the demands on K-12 teachers to integrate technology into the classrooms does not exist (National Council for the Accreditation of Teacher Education [NCATE], 1997). It appears that teacher educators do not know the potential involved with integrating technology into the classroom therefore they basically use technology for administrative purposes (Wetzel, 1993). Research suggests that the traditional teacher preparation programs are not up to par in the field of integrating technology (National Center for Education Statistics [NCES], 2000). In order to effectively integrate technology in methods courses, collaborative efforts should be maintained between the methods and educational technology faculty to develop technology appropriate activities (Brush, Igoe, Brinkerhoff, Glazewski, Ku, and Smith, 2001).

Purpose

This research effort is an attempt to identify the perceptions of teacher educators and effective applications that are implemented in the methods courses they teach. The study will identify the goals and objectives of teacher educators relating to their individual technology experiences to find out what technology activities and support will assist them in preparing future teachers. Teacher educators are the missing link to prepare future teachers to teach in the technological age. Teacher educators who are prepared and obtain a high level of confidence with integrating technology can successfully restructure the teacher preparation process.

This study investigates initiatives that assist teacher educators to integrate technology into the methods courses they teach. This study will answer the following questions:
1. Is there a significant difference between subject area and perceptions of technology integration?
2. What are the perceptions of teacher educators of technology integration in the subject area they teach?
The Survey

The ETTES is divided into four sections: (1) Technology Skills and Experiences, (2) Application of Technology in Instruction, (3) Perceptions of Technology Integration, and (4) Demographic Information. The first part of the survey, questions 1-8, ask participants to select what best describes their technology skills and experiences by answering if they can do a certain task with responses (1 = I can do this independently, 2 = I can do this with minimal assistance, 3 = I can do this with much assistance, 4 = I can not do this). Part II of the survey, questions 9-18, asks participants to select the number that best describes how often they apply technology integration skills during instruction (1 = Often, 2 = Occasionally, 3 = Rarely, 4 = Never). Part III of the survey, questions 19-28, asks participants to select the number that best describes how strongly they feel about perceptions of technology integration (1 = Strongly Agree, 2 = Agree, 3 = Disagree, 4 = Strongly Disagree).

The final section, section IV, asks participants for demographic information. The questions ask about employment location, methods courses they taught, years of teaching, employment status, level of education, computer usage, technology training, knowledge of technology, age, and gender.

Interview questions

The semi-structured interviews with teacher educators lasted approximately 35 to 45 minutes. The interviews focused on three areas as outlined in the survey: technology skills and experiences, applications in instruction, and perceptions of technology integration. The first section of questions asks teacher educators to describe training experiences and technology support. The second section of questions solicits modeling techniques, technology requirements of students, communication and classroom equipment. The third section asks about barriers, recommended changes, and improving technology experiences for teacher educators.

Creating a Constructivist Classroom Using Technology:
Preparing Preservice Teachers

One of the most effective ways to integrate technology into the teaching and learning process is to create a classroom environment based on constructivism, a theory that views learning as the product of experience and social interaction. Constructivist theorists contend that the learner is an active participant and builds knowledge based on individual experiences (Adams & Burns, 1999). The individual understands new experiences by relating them to prior experiences. Sense is made of the world by individuals synthesizing new experiences into what they have previously understood. According to K. Smith-Gratto (1995), if an individual's current experience doesn't make sense in relation to prior experiences, disequilibrium occurs within that individual. When disequilibrium occurs, the individual must readjust existing schemata or create new schemata in order to create meaning or understanding of the event that caused the disequilibrium (Smith-Gratto, 1995).

Creating meaning is at the very heart of constructivism. A constructivist-oriented approach is essential in a classroom if students are to develop problem solving and critical thinking skills and to apply, analyze, synthesize and evaluate knowledge, skills and attitudes (White, 1995). Constructivism can also provide a framework for using technology in productive, and interesting ways to support student learning. In a constructivist classroom, the learner is immersed in an environment that supports the way they learn. A constructivist learning environment encourages students to engage in the active process of creating, rather than acquiring knowledge.

In a constructivist classroom, technology can be used as a tool to help students gain a better understanding of their world by providing unique experiences and resources (Boethel & Dimock, 1999). When technology and constructivist ideas are combined, students become empowered and spend more time in active construction of knowledge. Technology provides resources for student use in problem-solving and reflection. Students using technology spend more time collaborating with other students and communicating with teachers when developing technology projects (Southwest Educational Development Laboratory, 1998).

According to C. White (1995), there are four major themes central to teacher education programs preparing preservice teachers for a constructivist classroom. These include modeling by both instructor and students, reflecting, involving the students actively, and developing a community of learners. The use of technology must also be the focus of teacher education programs integrating these four themes.

Research suggests that educational technology is most effective when used to enhance constructivist instructional strategies (Southwest Educational Development Laboratory, 1998). Using technology as a tool to enhance a constructivist environment should be integrated throughout teacher training programs. Preservice teachers must understand that technology supported learning environments provide a variety of computer-mediated communication methods to support conversation and collaboration in a constructivist classroom.
Reitz (1983) maintains that it is what teacher educators do, not what they say, that affects preservice teachers’ learning. Therefore, in order to prepare preservice teachers to transform constructivist beliefs into instructional strategies, university faculty must themselves become what Connect University’s Scott Noon calls a “Techno-Constructivist”. These Techno-Constructivist are teachers who integrate technology into the curriculum so that it not only complements instruction but redefines it. These teachers have realized the full potential of technology to help children build on their own experiences, construct their own meanings, create products, and solve problems successfully (Education World, 2000).

The integration of technology is vital in teacher education programs preparing preservice teachers to teach in constructivist classrooms. The major components of modeling, reflecting, involving students actively, and developing a community of learners will be facilitated through the use of technology.

Abstract: This short paper reports on two outcomes from an ongoing evaluation of the infusion of technology into a large, multi-section, undergraduate preservice teacher education course at The University of Memphis. The two outcomes address how the students' (N = 294) assessed their own learning and how the students' rated their instructors. With both outcomes, student-student and faculty-student interactions were the important variables.

Only through assessment can we begin to focus on what is actually being accomplished with the infusion of technology in higher education classrooms. The question of whether or not to infuse technology is no longer the important issue. It is mandatory. As Dolence and Norris (1995, p. 2) have aptly explained in their book, "Transforming Higher Education: A Vision for Learning in the 21st Century," society is undergoing a fundamental transformation from the Industrial Age to the Information Age and students simply must be prepared. This is especially the case for preservice teachers who will be expected to use technology in the classrooms of tomorrow yet who are graduating from teacher preparation programs feeling unprepared (Johnson-Gentile, Lonberger, Parana, & West, 2000).

The use of technology will not replace the need for instruction and instructors. Students crave personal interaction and guidance (Carr, 2000). After all, education is basically a human endeavor (Theobald, 1997). As the past president of EDUCOM Robert Heterich stated, classrooms are highly personal, human-mediated environments (Noble, 1997, p. 6).

The purpose of this paper is to address "what happens" as technology is infused in a large undergraduate education course (N = 294), taught in 11 sections by different faculty. The course is a human development course required of all preservice teachers. Prior to the 1999 fall semester, the course was a traditional lecture-based, teacher-centered course, low (no) tech and high touch as differentiated by Green (1999). Beginning with the 1999 fall semester, the use of technology was infused throughout the course and the course became more medium tech and high touch (Green, 1999).

The sample size for the first semester evaluation was 207 students (70% response rate), primarily sophomores and juniors. The gender composition was 33 men and 174 women. The racial/ethnic composition was: 71 African-American, 121 white, 1 Hispanic, 14 other. The context for data analysis was multiple regression. The variables for the study included the: amount and quality of student-to-student interaction; amount and quality of student/faculty interaction; overall experience using technology; number of times the instructor e-mailed the student during the semester; amount of time the instructor used the available technology in the class; general rating of the instructor; student interest in using the Internet for schoolwork; amount of time the student used technology during the semester for schoolwork; and amount of problems the student had in using technology.

The first analysis addressed how the students' assessed their own learning. The dependent variable was called LEARN and consisted of three questions which addressed the amount of student learning, their motivation to learn and their familiarity with computers (Cronbach alpha = .82). The regression was significant, F(6,188) = 16.59, p < .001 and the variables accounted for 35% of the variance in LEARN. The significant predictors of LEARN, as determined by the standardized beta weights, consisted of
student/faculty interaction ($b = .20, p = .009$), student-to-student interaction ($b = .293, p < .001$), the
general rating of their instructor ($b = .159, p = .016$), and student interest in using the Internet for
schoolwork ($b = .174, p = .015$). What the first analysis indicates is that as the quantity and quality of both
the student/faculty and student-to-student interaction increased, the students’ assessment of their own
learning (LEARN) increased. In turn, as the students’ assessment of their own learning increased, so did
the general rating of their instructor and the students’ interest in using the Internet for schoolwork.

The second analysis addressed the students’ general ratings of their instructor. The dependent
variable was called INSTRUCT and consisted of a single question rating their instructor. In this analysis,
LEARN became part of the independent measures. The regression was significant, $F(5,194) = 15.46, p < .001$,
and the variables accounted for 29% of the variance in INSTRUCT. The significant predictors of
INSTRUCT, as determined by the standardized beta weights, consisted of the number of times the
instructor e-mailed the students during the semester ($b = .180, p = .015$), and the amount of time the
instructor used the available technology in the class ($b = .220, p = .001$). What the second analysis indicates
is that as the number of times the instructor e-mailed the students during the semester increased and the
amount of time the instructor used the available technology in the class increased, the students’ assessment
of them increased.

It is important to note that the variables used in the study accounted for a small amount of the total
variance in either LEARN or INSTRUCT. Since there has been very little data reported in this area and we
know that much goes into student learning as well as evaluation of instruction, it is hard to say whether or
not the amount of variance accounted for is small or indeed quite large.

What does this study mean? First, the results indicate that students do draw a distinction between
student-to-student interaction and student/faculty interaction. The two types of interaction are different and
serve different purposes. Classroom research has generally focused on the importance of student-to-student
interaction, the incorporation of cooperative/collaborative learning activities and addressing the different
learning styles of students. While student/faculty interaction has been shown to be an important factor in
retention, scant research has been done to address the interaction in terms of student learning.

Second, the results from this study indicate that student/faculty interaction is just as important a
factor in student learning as student-to-student interaction. It is not enough to just create an on-line
discussion group for students. Students need feedback and guidance from instructors. Student/faculty
interaction has traditionally meant time spent on teacher-directed activities inside the classroom and to a
lesser extent, due to its time consuming nature, outside the classroom. With the infusion of technology the
distance between the student and the faculty member is lessened and the dividing line between inside and
outside the classroom becomes blurred in a very short period of time. In fact, faculty who received higher
evaluations e-mailed students more times and used the available technology more often in their class. In
turn, by increasing the amount of interaction via technology, students' learning increased.

Using Web-Based Modules to Support an Introductory Computing Course for Preservice Teachers

Aileen Nonis
Assistant Professor
Instructional Technology, Curriculum and Evaluation
The University of Tennessee, Knoxville
anonis@utk.edu

Jennifer Summerlin
Graduate Teaching Associate
Instructional Technology, Curriculum and Evaluation
The University of Tennessee, Knoxville
summerlin@utk.edu

The utilization of online materials and/or online modules is being rapidly implemented in many higher education courses. With online modules students and instructors are not confined by the limits of scheduled face-to-face class time. Online modules can provide learners the opportunity to work at any time that fits into the individual’s schedule and at their own pace. We decided to explore the potential of using online modules in our introductory computing course as a means for preparing prospective teachers to learn and teach with technology. This self-paced module is designed to help students understand the nature, purpose, and function of graphic organizers as a cognitive tool to represent information and support learning.

Preservice teachers at The University of Tennessee are required to take a semester long introductory computing course which covers topics ranging from word processing to Web page design. “Breadth” versus “depth” is a typical challenge for these types of introductory computing courses. Instructors struggle between (1) the need to cover a wide range of tools so students can begin to envision the possibilities of learning and teaching with technology, and (2) eliminating certain topics in order to focus on a smaller subset of skills and information in more detail. An ever-present challenge for course instructors is to provide students with optimal learning experiences, balancing acquisition and application of skills within a given, and often limited, period of time.

Due to their significant benefit as an educational tool, graphic organizers seemed to be an appropriate choice for our initial module. As part of the course, students learn how to use Inspiration, an electronic concept-mapping software application. Since time is limited, students are often introduced to basic graphic organizer formats (such as brainstorming webs and concept maps) and do not learn about other functions and formats that are available for representing information. Students may be unaware of the various types of graphic organizer formats such as Venn diagrams, Fish Bones, KWHL, T-charts, matrices, and cyclical diagrams.
However, students who participate in the online self-paced module are exposed to a wide variety of graphic organizers, their suggested uses, and their advantages. By asking students to complete a self-paced module, we believe that students will come to class with a broader understanding of graphic organizers and their educational applications. In a face-to-face class that follows, students can use software to create meaningful graphical organizers and apply the knowledge gained from the module.

Because of time constraints, we see the value of using online modules to prompt the thinking, learning, and reflecting process prior to formally introducing a topic in class. We believe this pre-exposure will facilitate more informed in-class discussions and a more complete understanding of the subject matter. However, as with all out of class assignments, it is essential that students are interested in completing the assignment. Therefore, our challenge has been to ensure that the modules we develop actively involve students in constructing their understanding of the topic as opposed to passively reading information from a computer screen.

To facilitate active student involvement, interactive components were developed within the online module using Flash software. This type of interaction allows students to view a “show me” sample on screen, followed by the opportunity to construct their own graphical organizer. In addition, students are provided with immediate feedback regarding their performance at frequent intervals throughout the simulation.

The online graphical organizer module will be pilot tested during the spring 2002 semester. Preservice teachers enrolled in the introduction to instructional computing course will have the opportunity to explore the content of the site as an online self-paced module. By allowing instructors to cover essential topics in an online environment, we believe this module will assist instructors in maintaining the breadth necessary in introductory courses. Moreover, online modules will conserve the limited face-to-face instruction time for in-depth coverage of more complex topics. Finally, the interactive format of the online module facilitates an active learning experience that increases student participation both in and out of class.
Technology Standards in Teacher Preparation - ISTE NETS
Distinguished Achievement Award Program

2-3 representatives of the first group of ISTE NETS Distinguished Achievement Award institutions

Abstract:
The National Educational Technology Standards for Teachers (NETS*T) have been widely adopted by teacher preparation institutions. The ISTE NETS Distinguished Achievement Award has been created to recognize institutions that have exemplary examples of integrating the NETS*T standards into their teacher education programs. The first awardee institutions are to be announced in February with a second round of competition in April.

This presentation will include information about the award process with an emphasis on criteria for the April solicitation of nominees. It will also provide details of the first group of 6 awardee institutions, including concrete examples and models of the programs. This should be of value to those just starting the technology infusion process as well as those who have already made significant movement towards NETS*T implementation in their programs.
ISTE NETS on the Digital Edge: Accomplished Teaching With Technology

Lajeane Thomas, Louisana Tech University, US
Don Knezek, ISTE, US
Dianne Porter, Louisiana Tech University, US

DESCRIPTION: Session features video exhibits of National Board Certified Teachers using technology effectively in their classrooms and associated curricular activities addressing ISTE NETS and NBPTS standards.

SUMMARY:
The purpose of this session is to inform the audience of exciting new resources for use in a variety of professional development environments that are designed to be used in preparing teachers or teacher candidates to use technology effectively in their classrooms. This session will provide video examples of exemplary teaching supported by technology with reflections from both the ISTE NETS for Teachers standards development team and National Board for Professional Teaching Standards (NBPTS).

The International Society for Technology in Education (ISTE), the National Board for Professional Teaching Standards (NBPTS), and Apple Computer joined forces to support new electronic learning environments where teaching resources and collaboration can occur. The resources will strengthen the mentoring relationship between the preservice teacher and experienced educators who guide them through the capstone student teaching and field experiences and/or provide opportunities for teachers to communicate for purposes of exchanging ideas for effective teaching.

Research has indicated that successful development of new teachers depends heavily on the student teaching experience. Key elements in the success of the new teacher include the collaboration and communication between the student teacher, the university supervisor, and the cooperating teacher; as well as, the models for excellent teaching that the student teacher observes and interacts with during this important phase of preparation. The Digital Edge project strengthens key experiences for student teachers by developing new strategies for a technology-based learning and communications environment. This environment provides a communications vehicle for a cohort of highly effective teachers who guide student teachers in their development.

A digital library of videos show examples of effective teaching with technology. National Board Certified Teachers (NBCTs) were videoed and support materials for each lesson including the teachers' own reflections were developed. Their reflections and those of National Board and ISTE representatives provide insights into the lessons and how those lessons address best classroom practice as well at NBPTS standards and National Educational Technology Standards (NETS).

The university teams and the NBCTs will develop curricula for integrating the digital library resources systematically providing resources first for early childhood and upper elementary; and then middle and secondary grade levels over the course of the project.

The project cohorts of ten -- one University Supervisor, three Preservice Teachers, plus their three respective National Board Certified Mentors and three K-12 Cooperating Teachers -- will begin Fall 2001 using their redesigned student teaching curriculum, digital video resources, and collaborative environment at each of the three collaborating university partner institutions: California State University, San Marcos; George Mason University, and Louisiana Tech University. The video exhibits, curriculum activities, and online collaborative environment may also provide opportunities for professional development and collaborations among inservice teachers as well.

The strong collaboration among the National Board Certified Teachers (NBCTs), university and K-12 faculties, and the preservice teachers will establish new learning environments resulting in future generations of teachers with high professional expectations and abilities related to effective use of technology in the classroom.

Participants will leave this session having experienced visual examples of how technology can be used effectively to support student learning, reflections from highly accomplished teachers (National Board Certified Teachers) on the
lessons and how technology standards and National Board for Professional Teaching Standards have been met within the lesson, and with information regarding how the resources from this project can be accessed for use in their districts, universities, or classrooms.

An Award Winning Technology in Teacher Education Program: Description of a Comprehensive Approach

Ann Thompson, Director, Center for Technology in Learning and Teaching, Iowa State University, USA, eat@iastate.edu

Denise Schmidt, Associate Director, Center for Technology in Learning and Teaching, Iowa State University, USA, dschmidt@iastate.edu

Abstract: The structures developed in the comprehensive technology in teacher education program recognized in 2000 by AACTE for "Best Practice in Teacher Education" are described. These structures include a technology mentoring program for faculty, a faculty technology scholar program, a school-based technology integration model that created technology-rich field experiences for students, a minor for preservice teachers in educational computing, and an undergraduate technology club for preservice teachers. The interconnection of all the structures is emphasized.

Introduction

Technology as a tool to improve teacher education is the primary vision that drives the comprehensive technology in teacher education program in the College of Education at Iowa State University. This innovative approach involves technology integration initiatives that impact the entire teacher education curriculum, including collaborative efforts with the College of Arts and Sciences, the College of Engineering, and PreK-6 schools. In the program, Iowa State University strives to prepare educators who are leaders and change agents in their schools and districts, who examine the role of technology in education, and who share their knowledge with colleagues and students. The program was recognized by the American Association of Colleges for Teacher Education (AACTE) in 2000 for Best Practice in Technology Integration in Teacher Education.

The purpose of this paper is to describe the structures and approaches that have been developed in this award-winning teacher education program. The major objective of the paper is to provide generalizable information that will be useful to other teacher education programs. Emphasis will be placed on the systemic and comprehensive nature of the technology in teacher education program at Iowa State University. We begin with a brief summary of the documented need for technology in teacher education programs like the one described here.

Need for Technology in Preservice Teacher Education

Although preservice teacher education is the logical way to address the PreK-6 technology use problem, little has been done by most teacher education institutions to help faculty use instructional technology or to prepare preservice teachers who are capable of using technology in classrooms (Schrum, 1994). After completing a comprehensive review of the literature on information technology and teacher education, Willis and Mehlinger (1996) concluded: Most preservice teachers know very little about effective use of technology in education and leaders believe there is a pressing need to increase substantially the amount and quality of instruction teachers receive about technology. The idea may be expressed aggressively, assertively, or in more subtle forms, but the virtually universal conclusion is that teacher education, particularly preservice, is not preparing educators to work in a technology-enriched classroom (p. 978).

In 1998, the International Society for Technology in Education (ISTE) was commissioned by the Milken Exchange on Education Technology to survey schools, colleges, and departments of education to identify how they were preparing new teachers to use technology in classrooms (Milken Exchange on Education Technology, 1999). The primary purpose of the survey was to collect baseline information about the preparation of preservice teachers to use technology. Approximately one-third of the schools of education across the nation responded to the survey. Findings from the survey indicated that the technology skills of teacher education faculty are comparable to the
technology skills of the students they teach; however, most faculty do not model the use of technology in their teaching. Although technology is accessible in the PreK-12 classrooms where preservice teachers receive their field experience, most preservice teachers do not use or integrate technology during their field experiences. One recommendation from the Milken Exchange report was for researchers, professional societies, and education agencies to provide models that would identify, study, and disseminate effective uses of technology for both teacher education and PreK-12 schools. Preservice teacher education programs can significantly impact the future use of computer-related technology in PreK-12 schools by effectively preparing teachers who have the knowledge and the ability to use and integrate computer-related technology to enhance teaching and learning (Berney, 1991). Several expert groups strongly suggest that colleges and universities must take a leadership role in preparing preservice teachers to use and integrate computer-related technology in schools (Espinoza & McKenzie, 1994; International Society for Technology in Education, 1998; Office of Technology Assessment, 1995).

It is with these needs in mind that the teacher education program at Iowa State University has worked to establish a comprehensive approach to effectively integrating technology. The structures described in this article provide the basis of the program.

The Structures

Several interconnected technology integration structures that have been designed and implemented to enhance faculty development, teacher education courses, field experiences, and extracurricular activities for students are described in this paper. Collectively, these structures serve to improve the quality of the teacher education program through the careful and meaningful integration of technology. The structures that will be described include a nationally-recognized technology mentoring program for faculty, a faculty technology scholar program, a school-based technology integration model that creates technology-rich field experiences for students, a minor in educational computing program, teacher education courses in which faculty members model effective uses of technology, and an active undergraduate student organization called TECC (The Educational Computing Club). It is important to note that the department emphasis began in the early 1990's and that most of the structures have developed over a number of years (Thompson, Schmidt, & Hadjiyianni, 1995). One of the structures, the educational computing minor, was started in 1984, and although requirements for the minor have changed over time, it has continually provided the program with a core group of student leaders who positively influence students and faculty in the program.

Technology Mentoring Program for Faculty

The technology mentoring program in the Iowa State University teacher education program has been in existence for eleven years. It may have the longest history of any such program in the United States and has been an integral part of our work in integrating technology throughout the program. The program began in 1991 and arose out of the need to provide more effective technology training experiences for the faculty in a large teacher education department. The original program developed from very practical considerations. It had become apparent that our workshop approach was not working and that faculty needed more individual attention. Given limited resources, the idea of using graduate students to provide the one-on-one experiences was especially appealing.

Thus, the program began in 1991 with the offering of the first graduate course, Curr 610 (Technology in Teacher Education). The seminar course included a field component and readings and discussions on issues in technology in teacher education. For the field component, the students were asked to mentor a teacher education faculty member for one hour each week during the semester. In the seminar class, discussion centered on both current readings and the mentoring experiences of each of the students.

The first semester of our mentoring experiment was successful, from the perspective of both the mentors and the mentees. Faculty participants were generous in their praise of the model, and the graduate students made it clear that the mentoring was an extremely valuable experience for them. Although we have changed and adapted our model over the years, the basic structure remains much the same. In ten years, we have had more than 100 graduate
students work as mentors and more than 50 faculty members participate as mentees. Many of our graduate students have gone on to establish similar programs at colleges and universities around the country.

Faculty Technology Scholar Program

Started through our PT3 Implementation grant, the faculty technology scholar program provides opportunities for faculty to focus upon developing classroom applications of technology. Through the grant, faculty are provided release time to work on technology, and graduate students assist them in this work. All of our technology scholars have also participated in the mentoring program and so come to the technology scholars program with previous experience. The technology scholars program builds on their previous experience by providing time and development support. Most of our faculty participants have chosen to use a summer month to work intensely to develop new technology-rich approaches in their courses. The technology scholars meet regularly to share ideas with each other and they also participate in workshops together. Faculty in the program include methods instructors in reading, mathematics, and science and also foundations and multicultural education professors. Applications developed by the scholars have included video case work in mathematics, palm pilot applications in science, and virtual reality applications for methods courses.

School-Based Technology Integration Model That Creates Technology-Rich Field Experiences for Students

The Milken Exchange Report (1999) indicates that most teacher education students are not using technology in their field experiences. One obvious explanation for this problem is that PreK-6 schools may have neither the technology nor the teacher expertise to make such field experiences possible for students. In the early years of our technology in teacher education program, we found that many students were not finding opportunities to use technology in their student teaching and pre-student teaching field experience. In order to address this problem, we identified several partner schools and began work with technology integration with these schools.

The professional development model that emerged from this work shares characteristics with our one-on-one mentoring programs. We found that teachers in the partner schools were looking for technology solutions to instructional problems and that the needs of each teacher were different. Thus, we developed a model that allows teachers to work individually on their classroom technology integration ideas.

Each month, a team of technology experts spends one day in each of our partner schools. The team includes Iowa State education faculty, graduate students, technology consultants from our local Area Education Agency, and a master teacher in the area of technology who is in residence at Iowa State. Teachers in the partner school sign up for a two-hour period to work with the team, and during this time, a substitute teacher takes their class. Teachers are asked to bring an instructional issue to their inservice time and then are provided assistance in addressing this issue. Teachers may also bring team members back to their classes to provide assistance when they are trying their technology application in class.

Like the Iowa State faculty, participating PreK-6 teachers have been very positive about the individual assistance provided in this inservice model. After several years of work with our PreK-6 partners using this model, we now have technology-rich PreK-6 classrooms as placement sites for our preservice teachers. The preservice teachers themselves also bring expertise to the field, and they now have the opportunity to share this expertise and thus further develop the technology integration in the partner schools.

We believe that the field experience component is extremely important in preparing future teachers to use technology in schools, and that meaningful school partnerships are essential for technology in teacher education programs.

Educational Computing Minor
In response to the need to prepare preservice teachers to use and integrate computer-related technology throughout the curriculum, a minor in educational computing was designed for undergraduate students at Iowa State University. The minor, which was established in 1984, is offered for those teacher education students who wish to prepare themselves to become leaders in the use of technology in schools. Between 60-80 students majoring in early childhood education, elementary education, and/or secondary education are currently enrolled in the educational computing minor. All students in the minor are required to take at least 15 credit hours of coursework in educational computing and related areas.

Currently, the educational computing minor includes six courses: five instructional technology courses and one engineering course. In addition to the introductory instructional technology course and the three upper-level technology courses, students enroll in one engineering course offered by the College of Engineering. Faculty in the College of Engineering at Iowa State University have developed a course entitled “Toying with Technology.” In the course, students examine how technological innovations work and the engineering principles behind them. Also, students are required to participate in a technology field experience. During this pre-student teaching technology field experience, preservice teachers have the opportunity to work in classrooms with area PreK-6 computer-using educators.

In recent years, students who have completed the minor have been the target of recruiting efforts, both in Iowa and around the country. As school districts work to improve their use of technology in schools, they seek out the Iowa State University students who have a specialization in this area.

The Educational Computing Club (TECC)

In addition to the educational computing minor, students have the opportunity to participate in extracurricular and leadership activities involving technology. In 1996, the Educational Computing Club (TECC) was established by a group of preservice teachers in the College of Education at Iowa State University. TECC is an undergraduate student organization in the Department of Curriculum and Instruction that strives to help students learn more about technology use in the department and in PreK-6 learning environments. Although most TECC members are early childhood, elementary education, or secondary education majors, students from other university departments such as computer science, management information services, and industrial technology have joined the club. Currently, there are about twenty active members in TECC who organize and participate in the variety of activities the club offers. Many of TECC’s activities involve working with teachers and students in PreK-6 classrooms and assisting the faculty, staff, and students in the College of Education with the use and integration of technology.

Students: the Product

The ultimate products of all the structures in the technology in teacher education program at Iowa State University are the students who graduate from the program and begin their teaching careers. We are striving to prepare students who have had extensive experience learning and teaching with technology and who have the vision necessary to assume leadership in PreK-6 technology integration. With this goal in mind, the structures described here are all continually evolving as technology, students, faculty, and PreK-6 teachers all change and develop. The structures all work to reinforce each other in the creation of a comprehensive approach to technology integration.

The Impact of an Intensive Technology Integration Internship Program on Pre-Service Teaching Practices

Lee Vartanian
ACTT Now Program (PT3)
Old Dominion University
United States
lvartani@odu.edu

Abstract: Old Dominion University has partnered with Brunswick County Public Schools (Virginia) on a mutually beneficial program aimed at improving the instructional technology practices of Old Dominion's pre-service student-teachers and Brunswick County's in-service teachers. Part of the ACTT Now PT3 Program (Aligning Certification with Teacher Training), the ACTT Now internship program brings student-teachers from Old Dominion University—an urban university in Norfolk, Virginia—to Brunswick County—a poor, rural county, two hours from Norfolk. ACTT Now interns act as technology-integrating student-teachers exploring the rich variety of instructional technology options at their disposal in Brunswick County Schools.

Introduction

One impediment to the integration of technology in schools is the lack of instructional technology training in pre-service institutions. Studies have shown that new teachers have not received adequate training in instructional technology at their university (Hargrave & Hsus 2000). Consequently, many of today’s teachers are unprepared and disinclined to integrate technology into their classroom.

As a result of the increasing importance of technology in our society, teacher colleges and K-12 schools are attempting to train and encourage teachers to use technology in their lessons. Nationwide, new standards for student technology use in K-12 have been implemented (ISTE 2000). At the college level, program planners are frantically beefing up the technological components of their teacher training programs. At the national level, technology standards have been developed for the accreditation of new teachers, as well (NCATE 2000). However, even new teachers, recently out of university, are generally not given the kind of training and exposure they need in order to be proficient and feel comfortable integrating technology into their teaching (Solmon 1999).

The Internship Program

The ACTT Now internship program is one component of the ACTT Now program (Aligning Certification with Teacher Training) that aims at promoting the integration of technology into everyday instruction in Brunswick County Public Schools. Operating in conjunction with Old Dominion University's Darden College of Education, the ACTT Now internship program is a fully credited alternative to the standard student-teaching model provided by the university. The program seeks to prepare pre-service student teachers to become effective, confident teachers and technology leaders in their schools. The high emphasis on instructional technology training and everyday use provides ACTT Now interns with a structured and supportive environment to experiment with new technologies.

The ACTT Now internship program uses a unique approach to accomplish its technology goals. A weeklong orientation program starts off the semester. In addition to introducing instructional technologies, the orientation schedule includes interactive seminars on subjects like classroom management and goal setting. Once school starts, two-hour technology seminars are held each week to continually introduce new classroom technology strategies. The interns are then expected to implement what they have learned in their classrooms and include it in an electronic technology portfolio they are required to create.
The program lasts a full semester, according to Brunswick County's schedule (18 weeks). Because Brunswick County is 100 miles from Old Dominion, all of the interns stay in houses that the school system rents and furnishes for them (with internet connectivity), free of charge. Additionally, the interns are provided the use of a personal laptop computer for the duration of the program and a $4,000 stipend. Generally, they teach for half of each school day, taking on full instructional responsibility during that time. The rest of the day, they use for lesson planning, observation of other teachers, tutoring, and curriculum planning.

Results

The ACTT Now internship program has completed three semesters since its inception in the Fall of 2000. To date, 29 interns have participated in the program. A variety of assessment strategies have been used to determine the strengths and weaknesses of the program. Surveys and recorded interviews have been utilized to assess intern’s perception of technology. Through these surveys, it has been found that interns learn more about how technology can be used in the classroom than they did during their pre-service training. Perhaps the most significant finding from these surveys has been that every intern, without exception, has felt that this program has better prepared them for teaching than a standard student-teaching experience. Not only do ACTT Now interns feel like they are more familiar with the latest classroom technologies, they feel like they have attained a higher degree of comfort and confidence managing the classroom than they would if they had participated in a more traditional student-teaching setting.

Interns are required to document every time they use technology in the classroom using a simple technology log. With the information contained in the technology logs, the ACTT Now staff is able to assess what kinds of technology the interns use in their classrooms and how frequently they use it. From the three semesters of the internship program, it is clear that each group of interns has succeeded the previous group in the diversity and number of instructional technology applications in their classrooms. During the first semester of the program (Fall 2000), the interns began using digital projectors, the Internet in their classrooms, and simple presentational programs such as PowerPoint. The second semester saw interns moving past the initial steps of the first interns. Aided by a group of interns who had prior experience with technology, the Spring 2001 interns used a variety of educational software options, developed and implemented web quests, created personal web pages, used digital cameras, projectors, and mobile laptop labs. The third semester (Fall 2001) has been the most successful semester so far. This cadre of interns has exhibited a focused and consistent effort to integrate technology into their classes. They have succeeded in making technology a central part of their instruction. Three of the interns modeled their unique technology infusion strategies in training sessions attended by Brunswick in-service teachers. A few others have taken the initiative to help start a monthly technology training seminar for the parents of their students and interested members of the Brunswick community.

Simulations, educational technology, and teacher preparation: Working towards authentic student experiences in a required technology course

Rick Voithofer, Ohio State University, US

Abstract

This study examines efforts to improve students' knowledge of and comfort with technology by incorporating simulations and constructivist strategies in a short (five week) educational technology course serving 150 students. The web-enhanced lecture/lab course is offered as one of the first courses in a year-long M.Ed. teacher preparation program at a large urban Midwestern university. The study uses multiple data sources including questionnaires, professor and teaching assistant field notes, course projects, and online postings in order to determine how students responded (in terms of efficacy, knowledge, and comfort using technology) to a simulation in which they acted as a consultant hired to help a fictitious teacher become compliant with the six (6) ISTE National Educational Technology Standards (NETS) for teachers.

Introduction

The five week course examined in this study (ET700 - not the real course number) was offered during the summer in 2001. ET700 is the only required technology course for pre-service teachers in a year-long M.Ed. program at this university and is generally taken as one of the first classes in the students' coursework. In response to research indicating a single stand-alone technology course is not sufficient to prepare pre-service teachers to use technology effectively in their early practice (Hunt, 1994; Moursund & Bielefeldt, 1999; Wetzel, 1993) the teacher education program in which ET 700 is offered is moving towards an infusion model of technology across multiple courses (Topp, Thompson, Schmidt, 1994).

Using a web-enhanced (WebCT) lecture/lab format, ET700 provides students with basic technology skills (Strudler, 1991) in web development, presentation software (e.g., Microsoft PowerPoint), and spreadsheets (i.e., Microsoft Excel) and teaches them how to evaluate technology resources (i.e., web sites and educational software), use electronic communication including discussion boards and create lesson plans that incorporate technology in teaching higher order thinking skills including problem solving. A consistent challenge in ET700 has been offering students an authentic context in which to complete course projects because most students in the course have had no classroom teaching experience.

During the quarter in which this study took place the course incorporated a new strategy. Students were asked to engage in a simulation in which they acted as a consultant to help a fictitious K-12 teacher (i.e., teacher-client) become compliant with the ISTE National Educational Technology Standards (i.e., NETS) for teachers.

Through the use of web-based resources, scenarios, and online discussion, students constructed a teacher-client profile that provided the foundation for all course projects. Online resources to complete the teacher-client profile included links to local school districts and schools, national curriculum standards for K-12 general education and subjects including English, Science, Math, and Foreign languages. The teacher-client profiles required students to consider issues related to technology integration including school environment and resources, classroom makeup and technology resources, and the teacher-client’s pedagogical philosophy and attitudes towards technology.

Students created all course projects for their teacher-client.

Students leave ET700 with a complete web-based teaching portfolio that includes all course projects, as well as their reflections on these projects. The course teaches students a constructivist approach in which technology is treated as only one aspect of the classroom ecology.

Theoretical Framework

Constructivist theories (see Ernest, 1996) and theories of situated learning (Brown, Collins, & Duguid, 1989) were used to guide course planning, delivery, in-process course modifications, and evaluation. The planning of discussions and lessons surrounding the introduction of technical topics reflects, in part, the social constructivist positions of Vygotsky (1962), and his followers. At the same time the ways in which the technical material was introduced reflect the influence of the constructivist theories of individual knowledge building following von...
Glasersfeld (1994), situated learning (Lave and Wenger, 1991), and instructional design for constructivist learning (Duffy & Jonassen, 1992; Willis & Wright. 2000).

Data Sources

Data collected for this study includes questionnaires administered online to students at the beginning and end of the course, online postings of students on a discussion board, course projects and papers, and professor and teaching assistant observations and field notes.

The initial questionnaire included questions about students knowledge of and comfort with various media and computer technologies including, word processing, computer graphics, videography, spreadsheets, databases, platform knowledge (i.e., Macintosh and Windows), desktop publishing, web authoring, email, digital photography, presentation software, asynchronous and synchronous online communication, and lesson plan development.

Students concluded the course by filling out a questionnaire that contained many of the same questions as the original questionnaire, as well as the following open ended questions:

1) How helpful did you find the teacher-client profile in creating a context for your assignments? In your response, please address what information that you drew from to create your profile (i.e., links to national curriculum standards, links to school districts and schools, personal experience, etc.). How did the profile influence your thinking about your projects?

2) How would you describe your general level of knowledge and comfort using technology to teach after taking this course? Please be as specific as possible.

Other sources of data include students online postings in which they discussed their attitudes about and comfort with technology, reactions to course readings that focused on more critical examinations of technology in education (Healy,1998; Postman, 1992). Course assignments including a final reflection paper in which students assessed how their projects met the six ISTE standards.

In addition to the above mentioned data sources, the professor visited each lab session daily and took field notes focusing on student’s processes of learning software, questions about the teacher-client profile, and interactions with each other and the teaching assistant. The professor took these notes as a participant observer helping students with technical and conceptual issues. Teaching assistants also took field notes related to how students were utilizing their teacher-client profiles and progressing through their assignments.

Preliminary Results

Initial analysis of the data indicates that students were most knowledgeable and comfortable with basic word processing, email and web browsing. Their low self reporting of knowledge and comfort with lesson plan creation is consistent with this course being an early class in their teacher education program. For most of the measures that asked questions about desktop publishing, graphics, multimedia development, database software, etc. students answered with means for knowledge and comfort below two (out of five). Therefore students entering into the course generally possessed little more than basic knowledge about computers and Internet technologies and had little methods background in education.

Initial analysis from field notes (Professor and TA) indicates that many students struggled with writing the profile although they were supplied with all the basic materials of the profile including information about local school districts, classrooms, and curriculum standards, classroom considerations relating to special needs students, multicultural issues, and the use of technology resources. The assignment was vague enough so that students would not follow a formula, but rather work through their dissonance to see the interrelationships between each aspect of a class including technology. By the end of the quarter students had been required to refer to their teacher-client profiles to complete all course assignments including a web site/educational software evaluation, spreadsheet and presentation software project, and technology-based lesson plan. The final course assignment was to write a reflection paper reviewing how student’s projects had helped their teacher-client meet the 6 ISTE NETs standards for teachers.

Many students in their reflection papers and end-of-course questionnaire indicated that the teacher-client profiles were helpful in thinking about their projects by giving them concrete design parameters. In addition, TAs who had taught the labs before, indicated that projects were more consistent, compared to previous classes, with one another in terms of grade and subject appropriateness due to the profile. A closer examination of the reflection
papers, however, revealed some of the disadvantages of the simulation. One observation that became immediately apparent when reading the reflections papers is that the teacher-client profile represented a static snapshot and that it did not and could not capture the ever changing dynamics within a K-12 classroom.

Conclusion

Other areas that are receiving further analysis of the data in this study include comparing students comfort with and knowledge of educational technology integration before and after the course. This data will be further compared with field notes taken towards the end of the quarter to determine if students self-reporting were consistent with the field notes. In addition, a closer analysis will be undertaken of the students’ projects to determine which classroom issues students gave their primary pedagogical attention. This will provide further evidence of how successful the teacher-client simulation was in inviting students to think beyond computer skill acquisition to the multiple issues affecting successful technology integration.

Practical applications of technology in the General Methods course

Roxanne Walker Bridges, College of St. Catherine, US

Beginning in the 2001-02 school year, the College of Saint Catherine implemented a requirement of laptop computers for all new Education majors. This created an opportunity for the faculty to reexamine their teaching methods and course content. How could courses be designed so that technology would be utilized during class and for outside class projects? Successful instructors in higher education know that adults are self-directed and expect to take responsibility for their decisions (Knowles, 1984). Technology enhanced instruction that allows students to follow at their own rates on personal computers allows self-direction and personal responsibility.

General Methods and Teachers as Leaders are two of the foundation courses in the Education program. The students are preservice teachers who have little, if any, experience in the classroom. Along with inexperience in the field of teaching came students with varying levels of technology expertise. Pedagogy and foundation information had to be taught along side technology instruction. Collaborative learning, multimedia presentations, and interactive learning have been used in other higher education classrooms with mixed success (Taylor, 2000). St. Catherine's was very supportive in providing in-house training for faculty and staff. Despite the support of time, materials, and a technology team, the challenge to implement came in changing how the faculty teaches classes. This is not unique to St. Catherine. Kim Carter (2001) sees teaching teachers to use a new approach to teaching has a major challenge in the k-12 setting and college setting. Only through continuing practice and a willingness to risk can a laptop program exist and hopefully improve.

As students in the General Methods classes searched the web for resources, they were pleased with the amount of resources available to educators. The instructors facilitated the "surfing" by providing web links and teaching students how to use key word searches to find additional sources. Lesson planning, assessments, and sample lessons were abundant. One of the first tasks worked on together was setting up criteria to determine the usefulness and reliability of specific web sites. Technology assignments were given in the areas of philosophers of education, parental involvement, special education advocacy, assessment methods, and lesson planning. Students explored and wrote about two of the topics citing three web sources in each paper. This information was placed in a public file so that the entire class could access the information.

Deciding if a web site was reliable was done with a consensus model. The class would visit the sites and study the information. Criteria eventually evolved. Creators and authors of the web site were identified and any additional information, such as affiliations were noted. The critique continued by examining the content of the site based on our definitions. For instance, when a lesson planning site was presented, the objectives and plan itself were examined to make sure that the lesson was well organized. If a plan was sketchy or if components were missing, students begin to see this and comment.

In the attempt to make lessons coherent and uniform, a lesson plan template was also created. This occurred early in the term and the template was used for all lesson planning. As the students continue in the program, the template will be used to create future lessons in their special methods courses. This uniformity will allow the instructors to use common vocabulary and also provide a continuum of improvement. As the students become use to the template, they will be able to concentrate fully on the content of the special methods course rather than struggle with lesson plan format.

PowerPoint presentations were used extensively by both the instructor and the students. In order to encourage discussion, the PowerPoint presentation for the classes were emailed as an attachment to the students before the class. A copy was also placed in the public folder so that students could access it throughout the course. As compared to previous years, students came to class ready to discuss the information presented in the PowerPoint. Often they would bring questions that had arisen while they viewed it. Because they had the opportunity to preview it at their leisure, they could time to read it closely, review it, and respond to it.

Email was used extensively during the school term. Uses included questions to the instructor and assignments sent as attachments. One organizational trick that was learned is to use a specific address line with incoming email. By using a common subject, individual emails would be placed in a folder. It was not unusual when assignments were due for the instructors to open email and find 60+ responses and
attachments. By using a coded address line, the mail will automatically go into a folder for viewing at a later time.

The students themselves used technology to enhance their units and assignments. Products ranged from brochures to PowerPoint presentations. Traditional assignments, such as creating a unit and producing a research paper, were done with the WORD program. Worksheets, assessment tools, including rubrics, and graphics were all submitted. The quality and creativity of the units this year are higher than previous years. Instructions on programs were offered in class with additional support from "brown bag" lunch instruction with the media specialist. This took pressure off the instructors and allowed students to progress at a rate that was comfortable for them.

Students also will have a complete electronic portfolio at the end of their teacher training. This portfolio will be burnt onto a compact disk. As students move through the program, the instructors will encourage additions to the portfolio. In Teachers as Leaders and General Methods, students created and inserted a cover page, resume, essay on why they choose teaching, and a philosophy of education.

Student opinions
At the end of the term a survey was distributed. Results showed that the majority of students found the technology component of the class at the right level. Frustrations, however, were noted.

"Have everyone's right email address." A comment like this shows the details that can easily be overlooked when setting up a lap top program. Generally students were positive about learning about a PowerPoint, templates, and what to look for when accessing a web site.

Most negative or neutral expressed opinions dealt with the cost of leasing a lap top computer. The students must lease a computer from the College of St. Catherine with the fee being levied each term. Although the lease fee may be added onto financial aid, many students were dismayed because they had their own personal lap top computers. This criticism became heard less often as the term progressed. Students appreciated being able to move readily from one site to another because everyone was using the same server and computer platform.

In conclusion, as the program moves into a second term, students and instructors both appear to be more comfortable with the use of laptops in the classroom. As instructors work through these first sections, journals of what worked and frequent meetings have eased some of the anxiety. The students in the program witness the extensive use of computers in k-12 settings during their field experiences. They know that personal computer skill, an electronic portfolio, and an ability to train other teachers in technology will make them much more marketable. The content of the classes will continue to be presented in a technology heavy way. The goal for the College is to give future teachers the ability to use technology to save time and help their own students flourish.

References

Abstract

This paper focuses on one teacher preparation program’s efforts to address a lack of congruence between modeling the effective use of technology in university coursework and appropriate use of technology during the teacher candidates’ field experiences (Strudler, McKinney, & Jones, 1998). Questionnaires were administered on technology proficiency and different uses of technology to 54 elementary mentor teachers who participated in a “clinical faculty” class designed to strengthen their mentoring of pre-service teachers. The mentor teachers’ responses indicated self-perceptions of proficiency, areas of need for further training, and contradictions related to the teachers’ self-perceptions of their skills and abilities.

Theoretical Overview

Teacher candidates need opportunities to see, use, and implement technology during their field experiences, especially student teaching. Strudler, McKinney, & Jones, (1998) found that while effective modeling of technology in education courses had positive effects on students’ attitude toward using technology, the improved attitudes were limited if teacher candidates were not provided opportunities to learn about and apply skills and strategies in field experiences and student teaching. To insure that teacher candidates have these opportunities, mentor teachers need to model the integration of technology in the curriculum. The purpose of this study was to examine the technology proficiency and different uses of technology of elementary mentor teachers who participated in a school/university partnership “clinical faculty” class designed to strengthen their mentoring of pre-service teachers.

During the 1998-99 academic year, George Mason University redesigned its teacher preparation programs in response to changes in state licensure requirements. In the program redesign, technology was integrated across all courses so students were provided with models of how to teach with technology (White & Sprague, 2001). Field experiences were also integrated into all coursework with a full time internship serving as a “capstone” of the program. In the first year of the program the pre-service teachers indicated that even though there was access to hardware in their classroom, some of the mentor teachers were not using technology on a regular basis or were using technology in ways that were incongruent with the models of how to teach with technology provided in their coursework. Based on this feedback from these first year pre-service teachers, it became apparent that there was a need to work directly with mentor teachers on: 1) how to use technology (skills and proficiency) and 2) how to use technology effectively (integrating technology into teaching) in elementary classrooms.

Survey Administration and Results
Questionnaires were administered on technology proficiency and different uses of technology to 54 elementary mentor teachers who participated in a school/university partnership "clinical faculty" class designed to strengthen their mentoring of pre-service teachers. The surveys were developed to assess the mentor teachers' areas of interest for a session intended to provide different strategies for effectively integrating technology into elementary classroom instruction. The mentor teachers' responses provided information on self-perceptions of proficiency and areas of need for further training. Areas of highly perceived proficiency (over 70% of the mentor teachers responded positively to their perceived proficiency on particular types of technology) included performing computer basics, selecting software for a particular subject area or instructional goal, integrating technology activities into their classroom, and allowing students to use the Web to conduct research. The two lowest areas of perceived proficiency were using spreadsheets (44%) and databases (41%) while 62% of the teachers indicated that they could create graphics or digital displays and 61% indicated they have students create multimedia presentations (mostly with PowerPoint). In terms of proficiency as measured by the state technology assessment for teachers, 87% of the teachers indicated they were familiar with the Virginia Technology Standards for Instructional Personnel (TSIPS) while 75% of the teachers indicated that they had passed the TSIPS.

The responses indicated that there were contradictions and problem areas related to the teachers' self-perceptions of their skills and abilities. The teachers' perceptions did not match the expectations of technology proficiency outlined by the state department of education and the teacher education program. Virginia requires teachers to pass eight technology standards (TSIPS) in order to renew licensure (http://www.pen.k12.va.us/VDOE/Compliance/TeacherED/tech.html). These standards are assessed by the local school district. To determine proficiency, many of the districts require the teachers to either enroll and complete a technology course or produce a portfolio demonstrating their technology competencies. In terms of this research, 75% of the mentor teachers indicated that they had passed the state-required technology proficiencies and yet, many of them also indicated they did not typically use technology in their classrooms and were not familiar with databases, spreadsheets, or multimedia, although these areas were part of the state-required technology standards. A better assessment of teachers' proficiencies in the area of technology integration needs to be developed to determine if these teachers have truly mastered the competencies required by the TSIPS. The university also needs to work closely with these teachers to ensure that the skills learned in the district-required technology course transfer to actual practice within their classrooms. This will allow preservice teachers to see technology modeled in their field experience placements in addition to their teacher preparation courses.

Another area of interest has to do with the number of clinical faculty who felt comfortable sharing what they do with other teachers in the course. All of the teachers in this course were learning how to mentor a preservice teacher. Their principals had been selected them as outstanding teachers. These clinical faculty were being asked to supervise a preservice intern. Even more important they were asked to demonstrate how they teach and discuss their thinking behind each lesson, a process that requires them to be open to questions and to be reflective. However, when asked if they would be willing to share one idea they have for integrating technology only 21% were willing to share with their fellow teachers in the course. The majority of the teachers were unwilling to share despite the fact that 92% indicated they integrated technology regularly in their classrooms. If these teachers are uncomfortable with sharing their ideas for integrating technology with their colleagues, how open will they be to sharing their technology ideas with the preservice interns? Opportunities need to be provided that would allow mentor teachers to become comfortable with sharing their technology integration ideas with others. They need to be encouraged to present workshops or at local conferences so they gain self-confidence in sharing their technology integration ideas.

Introduction

Isaac Asimov said, "I do not fear computers, I fear the lack of them." The field of education seems to concur with this statement as a recently developed survey posed the following question: Are your teachers required to demonstrate technology skills for new or continued employment with your district? If technological competency is to be considered a decisive factor regarding teacher employment, then it is the responsibility of every teacher education program to provide the necessary training. According to the National Center for Education Statistics (2000), "the barriers most frequently reported by teachers to be ‘great’ barriers to their use of computers or the Internet for instruction were not enough computers and lack of release time for teachers to learn how to use computers or the Internet" (p. 89). The National Council for Accreditation of Teacher Education (NCATE) (2001) stipulates that institutions of higher learning must integrate technology into all aspects of their teacher education programs. The International Society for Technology in Education (ISTE) in affiliation with the National Council for Accreditation of Teacher Education has developed rigorous accreditation guidelines for the inclusion of technology in teacher preparation. The National Educational Technology Standards (NETS) Project (2000), a program that concentrates on preservice teacher education as a division of the International Society for Technology in Education (ISTE), has defined specific concepts, knowledge, and skills considered essential in order to apply technology within educational settings.

The Internet provides access to newly developed disciplinary and interdisciplinary databases; authentically-based, real-time experiences; and other communities not available through text-based material. Recent research and evaluation studies indicate that the school improvement programs employing technology in the areas of teaching and learning show positive results for both students and teachers. Responses of students regarding electronic instruction include the following positive observations: participation in class discussions took place without any one individual monopolizing the conversation; students felt that a greater depth of learning occurred; and the flexibility and convenience of on-line activities were considered beneficial (Brown, 2000). Negative aspects of electronic instruction include a feeling of disconnectiveness from class members with no face-to-face contact, a lack of consistent communications, technical challenges, and confusing feedback (Brown, 2000). In spite of the negative perspectives, technologically mediated instruction offered at a distance is becoming an important feature in the realm of higher education.

While many advantages to on-line instruction (ease of scheduling, convenience, lower cost) exist, numerous concerns (the quality of instruction, lack of interaction with faculty and fellow students, technical limitations) have also surfaced. This article examines a bridge between an on-line course and traditional classroom based instruction. Software developed by Docutek Information Systems, Inc. (www.docutek.com) has enabled faculty members at Drury University and over 220 other institutions of higher learning to utilize the best of both worlds. This software is ERes v4.1 and has been in use at Drury University since the beginning of the 1998-1999 academic year.

ERes Systems in the Literature

ERes is short for electronic reserves. ERes systems have helped to shape the teaching and learning environments of higher educational institutions around the world. Kesten and Zivkovic (1997) described ERes as a stand-alone system that used intuitive, point and click interfaces along with context-sensitive help. This eliminated the need for extensive technical training in order to use the system. Dugdale (1999) highlighted the scarcity of resources in academic libraries as well as pressures from growing student populations and the introduction of new pedagogical processes as the main reasons for the rise of ERes systems. Major institutions in the United States, such as Kent State University, have also utilized ERes (Kristof & Klinger, 2000). One possible limitation of ERes systems revolves around the issue of copyright infringement. An excellent article showing how Portland State University resolved this conflict is found in Anderson and DeMont (2001). One exciting application for the future is described by Rodoni, Bertone, and Estella at Santa Clara University in Santa Clara, California. These students acknowledge the current limitations of ERes allowing students and faculty the ability to search for course
information only at their own institution. They conceptualized the creation of a collaborative function within the ER es system enabling students and faculty to search for course material from other universities as well as their own. This will provide a powerful tool for faculty collaboration and virtual learning (Rodoni, Bertone, & Estella, 2000).

**Rationale for Incorporating ER es**

One of the problems with traditional classroom-based instruction is the limitation of time. Students are expected to be in class at a certain time and to remain there until the class period is over. Professors are expected to have posted office hours and be available to their students. All of this depends upon time and physical proximity. It results in a synchronous dilemma. If the student or professor cannot be at a certain place at a certain time, then instruction and/or mentoring and advising cannot take place. What is needed is an asynchronous system. Better yet, a combination of the two.

The advent of email has made communication between students and professors a much easier task. It has limited the need for synchronous interactions. With email, a student can communicate with the professor from anywhere at anytime. This is the basic premise also of on-line, web-based education. The student and professor conduct their business in an asynchronous fashion. The lessons are posted to web sites and the students view the material at their leisure.

What about the student whose technical limitations (whether personal or computer-based) interfere with the learning process? What about those students who need the social interaction that comes from traditional classroom-based instruction? Fortunately, the issue is not an either/or proposition. There is a middle ground or bridge between the synchronous and asynchronous methods of teaching. This is the domain of ER es.

With the ER es system, a professor can make available on-line any course-related information. While students and professors interface in the traditional classroom environment, professors can also post messages for students to view when they access the ER es page, or students and professors can participate in an on-line chat room. These components provide for an educational experience that combines both in-class interaction and instruction (synchronous) and out-of-class (asynchronous) activities that are available anytime.

**Drury University and Teacher Education**

Drury University is a private, liberal arts university established in 1873. Drury offers numerous programs of study at the undergraduate and graduate level, including teacher education. Drury operates from two main campuses, in Springfield, Missouri and also Fort Leonard Wood, Missouri, with smaller, statewide satellite campuses in Rolla, Lebanon, Ava, Stockton, Thayer, and Cabool. Students wishing to be certificated to teach in Missouri may take introductory education courses at any of the satellite campuses, or they may complete their degree at either Springfield or Fort Leonard Wood.

In order to facilitate teacher training, Drury University faculty have begun utilizing the ER es system to provide students with necessary materials and asynchronous communication abilities. Drury University has made a commitment to provide current technological tools to students and faculty members.

Many of the students at the satellite campuses would be considered non-traditional. Since most of these students commute to class once or twice a week from a significant distance, it is difficult to schedule appointments with the education faculty members. One way of facilitating a balance is through ER es.

**Specific Examples of Teacher Training Facilitation**

During the spring semester 2001, one course (Teaching Methods of Elementary Science-EDUC 382) was conducted using ER es by posting course syllabus, scoring guides, lesson plan templates, a link to the School of Education and Child Development homepage at Drury University, and pictures. Other functions of the ER es page included the capability of posting announcements, discussion boards, chat rooms and links to education resources, the university library, and university homepage. Students do not have the ability to post material directly to the page (with the exception of the discussion board and chat room); this is the responsibility of the professor teaching the course. Students do have the ability to view and download any of the submitted lesson plans by entering a password.

While there are other programs and software available for faculty-student interaction, including some very high powered and sophisticated systems like WebCT, BlackBoard 5.02, or Web-Mediated CourseAssistant (Web-MC), what is sometimes needed is simply a way for faculty and students to interact without a great deal of extra features. ER es provides for the posting and downloading of information without requiring extensive training. Although it does not contain as many “bells and whistles” as other programs, it does meet the needs of the education
students at Drury University. From one course using ERes in Spring 2001, the authors have expanded the use of ERes to include a majority of their courses.

Pre-service and In-service Teachers' Knowledge, Experience, and Perspectives on Portfolio Assessment: A study in Taiwan

ABSTRACT: This study focuses on pre-service and in-service teachers' knowledge, experiences, and views of portfolio assessment and its use in school settings, as well as the possibility of applying portfolios in their classrooms. This paper first describes the rationale of portfolio assessment; then describes the research purposes and questions as well as methods used in the study. It also reports the results of data analyses and provides conclusions and implications in relation to portfolio practice and teacher education.

Rationale

Portfolio assessment has become more and more popular within general educational settings (Simmons, 1990). It presents one of the alternative ways to measure student performance in a broader range and context that measures both the product and the process of students' learning and also values the evaluation of students' achievement along with their effort and improvement (Tierney, Carter, & Desai, 1991). Paulson, Paulson, and Meyer (1991) proposed one of the most specific definitions: "A portfolio is a purposeful collection of student work that exhibits the student's efforts, progress, and achievement in one or more areas. The collection must include student participation in selecting contents, the criteria for selection, the criteria for judging merit, and evidence of student self-reflection" (p. 60). Portfolio assessment allows students to learn different kinds of complex skills and to demonstrate their ability in an authentic context where their learning occurs naturally. On the other hand, portfolio assessment also provides teachers the opportunity to observe students' performance in the authentic context and to get rich information and valuable quality of data for evaluation and instruction. In this regard, portfolio assessment could be a very powerful technique to serve as both instructional and assessment tools for program with special objectives, which can help teachers in a variety ways.

As researchers have pointed out, there certainly are both positive and negative aspects of the use of portfolio. Calfee & Perfumo (1993) conducted a nationwide survey of portfolio practice that includes states, districts, schools, school teams, and individual teachers, focusing on writing assessment. They found that teachers who are in portfolio movement show an intense commitment and personal renewal. On the other hand, most teachers experienced portfolio practices revealed that they have been struggled with management problems such as time and organization in using portfolio and some teachers even thought that the portfolio was not worth the effort (Salinger and Chittenden, 1994). Moreover, another major concern about the portfolio assessment is that it has often been criticized as lack of technique adequacy such as validity was assumed to exist and reliability were not discussed (Calfee & Perfumo, 1993; Moss, 1992, 1994; Nolet, 1992). Still another critical issue in using portfolio in the classroom has to do with the amount of support from the school or district. However, Salinger and Chittenden (1994) claimed that, even though portfolios may not have spurred instructional reforms in their district, the use of portfolios with the intention of assessing instruction helped improve their program.

Since the concepts of portfolio assessment are still relatively new to many educational practitioners, teachers may need to improve professional development to be able to implement portfolio practice effectively (Calfee & Perfumo, 1993). Both pre-service and in-service teachers need to be trained to have better understanding of theories and practices of portfolio assessment and well as to increase their awareness of emerging perspectives of portfolio and the technology...
applications. While the portfolio assessment is especially not yet so prevalent in schools of Taiwan, it is very important to understand to what extent teachers are acquainted with the idea of portfolio assessment and how well they have prepared to take this movement. Therefore, this study set forth to investigate pre-service and in-service teachers' experiences of, and attitudes toward their use of portfolio assessment in classroom practices. Moreover, this study tries to examine how the knowledge and experience of portfolio assessment as well as some background variables can affect both pre-service and in-service teachers' willingness in implementing any kind of portfolio practice in their teaching.

Methods

The target subjects were both pre-service and in-service teachers who had or are enrolled in the Education Program of a university in northern part of Taiwan. A survey questionnaire developed by the researchers composed of 50 Likert-type questions and 6 open-ended questions were distributed to collect knowledge, experiences and views of 124 subjects on portfolio assessment and electronic portfolio application.

Results

Most pre-service and in-service teachers in this study stated that they have none to few experiences in portfolio practices. Some of them have learned theories and applications of portfolio assessment in pre-service or in-service training courses, and many of them have shown positive attitude toward the portfolio assessment approach. Moreover, the results of data analysis reveal that there was a statistically significant difference in knowledge, experience, and perspectives scores between pre-service and in-service teachers. In addition, most teachers in this study preferred using portfolio as a tool of their professional development rather than to use it as an assessment tool while they attested to the fact that time and their abilities are two of the greatest limitations in implementing portfolio practice in the classroom.

Based on the findings of this study, two major suggestions are made to the field. Firstly, while the concept of portfolio assessment are still relatively new to both pre-service and in-service teachers, the teacher education programs should consider carefully to include theories and applications of portfolio assessment in the curriculum. Secondly, results of this study shown that most teachers in this study preferred using portfolio as a tool of their professional development rather than to use it as an assessment tool would convey an important message to the field of education and some further studies are required to explore further information.

Teamwork... Collaboration... Learning... Integrating... Mentoring—these words permeate the project papers presented in the following pages and form the basis of the common language shared by all PT3 grant participants; they have been goals and many have become accomplishments over the past year. They form the vocabulary of a common endeavor of which we should be proud. 142 papers covering several different aspects of PT3 grants from across the country will be presented at SITE 2002. While the foci of these papers are broad and diverse, the common endeavor, the infusion of technology into pre-service teacher education, ties them together in a way that facilitates dialogue. And yet, effective dialogue requires not only a common vocabulary but also a time and a place, just the sort of time and place provided at SITE 2002.

SITE 2002 provides us with the invaluable opportunity to share our experiences in achieving these goals and allows us the opportunity to reflect. In all good design, a time for reflection and evaluation is provided. Whether at the end of a project or as an ongoing part of it, reflection allows participants to both look back and attempt to see forward. As we all discover, however, the reflective process can be difficult and time-consuming—it is sometimes simply easier to continue forward without looking back. SITE 2002 offers the time and opportunity required for reflection. Whether nearing the end of a grant cycle or only at the beginning, we are all at a point where reflection and evaluation are advisable and necessary.

As groups with a shared vision for the future of pre-service education, we can use this time to reach out to our fellow grantees and provide them with the benefits of our experiences. Shared knowledge regarding what has worked and what has not may keep others from treading treacherous paths or guide them toward success. Along with sharing our advice and successes, we can also share our perspectives on working as teams to create change in a changing world.

This conference also provides the opportunity for communication between different PT3 groups as they share the results of the past year's work and their plans for the sustainability (sustenance) of their work.

While we reflect on accomplishments, we need to look realistically at what remains to be done. Sustainability of the progress that has been made and the changes that have been engendered by these grants can also become a focus of discussions at the conference.

Above all, see this conference as an opportunity to share, reflect, and renew. Look to the progress that has been made in the past year and share the pride of every presenter in their accomplishments.

Mary Thompson is a Doctoral Student in Instructional Technology at the University of Houston in Houston, Texas.

Jerry Price is the College Information Services Manager in the College of Education at the University of Houston and the Technical Coordinator for AACE and SITE 2002.
Sharing Expertise: The Technology in Urban Education Summit

Abstract The Modeling Instruction with Modern Information and Communications technologies (MIMIC) Project housed in the Cleveland State University (CSU) College of Education sponsored a Technology in Urban Education Summit in Spring 2001. Serving as a dissemination component of a PT3 Implementation grant, this event explored current, relevant educational technology and possibilities for its integration in urban K-16 classrooms. This paper provides an overview of the Summit and presents practical recommendations based on data collected from the Summit participants.

Overview

A Technology in Urban Education Summit (Techs in the City) was held at Cleveland State University (CSU) as a dissemination component of the MIMIC Project which supports educational technology mentoring for higher education faculty by technology-proficient K-12 classroom teachers. The Summit brought together local, state, and national educators who share a common interest in educational technology. Faculty representing nine urban universities, and eight Ohio Colleges of Education joined with MIMIC participants and K-12 classroom teachers from urban districts to share perspectives on teaching with technology.

Techs in the City consisted of a day of presentations and conversations culminating with an in-depth panel discussion focused on timely issues surrounding the implementation of educational technology in urban K-12 schools. A marketplace of interactive presentations highlighted the ongoing educational technology activities of participants from the CSU College of Education and MIMIC partners Baldwin-Wallace College, Notre Dame College of Ohio, Ursuline College, and John Carroll University. Many of the Summit presentations provided insights into how faculty/mentor teams work to examine pre-service education curricular goals and implement technology that is appropriate and specific to achieving those goals. Additional presentation topics included technology integration in specific content areas, digital video, technology use in K-3 settings, program evaluation, and professional development in educational technology.

Eleven Round Table discussions were conducted midway through the day. The Round Tables provided participants with opportunities to enter into discussions about specific topics of interest such as educational technology publication, classroom videotaping, and technology integration in K-12 urban schools. Each discussion was facilitated by an expert on the topic. In addition, informal activities and breaks were scheduled throughout the day to encourage continued dialogue among participants. Urban educators with expertise and rich backgrounds in teaching, research, and administration presented a panel discussion, which capped the Summit proceedings. A video of Summit highlights was shown to close the day's events.

Participant Feedback

A survey form was distributed as attendees exited the Summit. The survey consisted of 25 Likert scale response items and 10 open ended questions. Thirty-two of the 65 attendees, 49 percent of the participants,
completed the survey. An online follow-up survey was conducted approximately two months after the Summit. Seventy four percent of the participants completed and returned the follow-up survey.

On the initial survey, three questions were posed for each of the four types of sessions; morning interactive, Round Table discussions, afternoon interactive and the Panel discussion. The first question related to level of interest generated by the Summit, a second addressed each session's connection to the Summit theme, and the third dealt with the perceived usefulness of the session. The scale for response was Strongly Disagree, Disagree, Agree/Disagree, Agree, and Strongly Agree. Ninety three percent of the respondents "agreed" or "strongly agreed" that the interactive sessions and Round Tables were interesting, related to the Summit, and were useful. Seventy five percent of the respondents "agreed" or "strongly agreed" that the Panel presentation had the same characteristics but six respondents either "strongly disagreed" or "disagreed" with the statements in regard to the Panel discussion.

Five Likert scale questions were posed on overall Summit satisfaction. The same response scale was employed. One hundred percent of the respondents either "agreed" or "strongly agreed" that the Summit was interesting, the companion video was enjoyable, and that they looked forward to meeting next year. Ninety three percent of the respondents either "agreed" or "strongly agreed" that they would be able to use the ideas presented at the Summit in their work.

The responses to the follow-up survey were quite consistent with the participants' initial feelings about their experiences. Eighty three percent of those responding indicated they "agreed" or "strongly agreed" that they have used information attained at the Summit. Fifty three percent "agreed" or "strongly agreed" that they have tried new technology as a result of the Summit.

Open-ended questions were presented regarding educational technology ideas that participants could use on their own, Summit strengths and needed improvements, and suggestions for next year's Summit. Overall, the open-ended comments were very positive. Contacts and collaborations were key aspects of participant satisfaction. In particular, the opportunity to engage in one-on-one conversations was significant to participants. Increased awareness of Internet materials appeared to have influenced some participants to examine the potential of web-based instruction, and exposure to software and hardware broadened participants' use of new technologies. Two areas of discontent were the small size of some of the presentation rooms and the short duration of the interactive sessions. Based on the number of open-ended responses, the presentations were enjoyed the most by the participants. However, the participants appreciated the Round Tables and opportunities for informal interactions, which served as mechanisms for extending the information presented in the sessions. Comments on the positive nature of the networking appeared in numerous responses.

Additional comments suggest that there was a mixed reaction to the Panel discussion. While some participants found the discussion pertinent, many others found the format limiting since audience participation in the discussion was minimal. Several suggestions were made for future Summits including the addition of "how-to" sessions, cutting edge technology demonstrations, more "hands-on" activities, and sharing exchanges.

Lessons Learned

The goals of the Summit were twofold. First, the Summit was designed to provide MIMIC Project participants with an informal but structured opportunity to disseminate information regarding their Project activities. Second, the Summit was designed to offer attendees new perspectives on integrating educational technology into urban pre-service education courses. Survey responses indicate that dissemination efforts were well received. Achievement of the second goal was supported by responses from the participant follow-up survey. Techs in the City met the needs of the intended audience. As such, a second Summit is scheduled for the spring of 2002. Well-received events such as the Round Table discussions, interactive presentations and the "highlight" video will be retained. The addition of a Reception/Poster session event will accommodate shorter, more intimate presentations and open up time for lengthier "hands on" interactive sessions in larger venues. Other suggested changes include a keynote address, cutting edge technology demonstrations and professional development sessions. Updates on the 2002 Summit are available at http://mimic.ed.csuohio.edu/summit.html
Providing for Student Professional Development as part of the Teaching, Learning and Technology Project

College of Education, BEP 272
Highland Heights, KY 41099
United States
amburgey@nku.edu

Abstract: Northern Kentucky University’s College of Education faculty want to ensure that their teacher education students are technology proficient. Students must demonstrate mastery of technology standards through their course assignments and professional portfolios. Students can only demonstrate technology proficiency if they experience effective and appropriate instructional applications of technology. Curricular review and the implementation of the Preservice Technology Leadership Program are some of the initiatives utilized by NKU to provide for professional development of teacher education students to be technology proficient.

Introduction

In 1998, the College of Education at Northern Kentucky University (NKU) adopted the ISTE Recommended Foundations for Teachers and a five-year Technology Plan for the College of Education. In May 1999, the Education Professional Standards Board of Kentucky implemented a new technology standard for beginning and experienced teachers. The statewide technology standard is based on the ISTE technology standards. NKU’s College of Education recently adopted the National Education Technology Standards (NETS) for teachers to replace the 1998 ISTE standards. Adoption of technology standards, state mandates and four broad goals of a technology plan set the College on a course to infuse technology into the teacher education program.

The TLT Project

NKU received funding from the United States Department of Education (U S DOE) for a one-year capacity building grant in 1999 and a three-year implementation grant in 2000. These grants allow NKU to begin a full implementation of the five-year technology plan.

The goals for NKU’s Teaching, Learning and Technology (TLT) Project are based upon three of the four goals outlined in the Technology Plan for the School of Education. The goals for this three-year project build upon the successful integration of technology into the teacher preparation curriculum by providing (1) Technology-rich Environments for students and faculty, both on-campus and in field placements; (2) Faculty Professional Development for NKU faculty; and (3) Student Professional Development that ensures students seeking initial teacher certification have the necessary skills and resources to use technology in their teaching and learning.

The third goal of the TLT Project includes the need to address professional development for students. Within the grant project several initiatives are in place to ensure that preservice teachers are trained on effective instructional applications of technology. Curricular review and reform is necessary to ensure that all preservice teachers will be trained and evaluated according to national and state technology standards. A new initiative, the Preservice Technology Leadership Program (PTLP) provides an opportunity for some preservice teachers to develop leadership skills and to collaborate with teachers from partner districts.

Curricular Review

NKU uses a continuous review and program evaluation model for curricular matters. Faculty who teach one or more courses in the teacher education program are often asked to identify which standards, including technology,
are being assessed within the courses they teach. Program folios include matrices that identify each course and type of assessment for each standard. During the 1999-2000 academic year, matrices related to the technology standards were completed.

As part of the TLT Project, a maximum of five teacher education faculty members receive a one-course (3 semester hours) of reassigned time for the purpose of reviewing targeted teacher education programs in regards to the national and state technology standards. Faculty who participated in this curricular review during the 2000-2001 academic year noted discrepancies in the technology matrices. This group developed a technology utilization survey and began conducting interviews with elementary and special education faculty. During year two of the TLT project, the technology utilization survey is being administered to middle grades and secondary faculty. By the end of the TLT grant project, all teacher education programs that lead to initial certification will be analyzed and reviewed for levels of technology implementation and evaluation. This review will allow NKU to identify strengths and weaknesses within the teacher education program.

Preservice Technology Leadership Program

Another initiative within the TLT project is the Preservice Technology Leadership Program (PTLP). This program recruits a select group of preservice students in their first semester of professional coursework and pairs them with mentor teachers from partner districts. The students and teachers participate in 24 hours of training each year. The training sessions focus on learning how to use various hardware and software components. Outside of the formal training times, the mentor teachers and the preservice students collaborate on the instructional applications of the technology in which they have been trained. Collaboration includes participation in additional training from the partner districts and development of instructional activities. Mentor teachers and students are encouraged to try out the technology-rich activities and evaluate their use within a typical classroom environment. The mentor teachers and students provide additional professional development to the partner districts either through inservices/workshops at the district or technology seminars for the consortium. A few mentors and their students also present at the statewide technology conference.

Concluding Remarks

The TLT curricular review process has been instrumental in identifying strengths and weaknesses in the teacher education programs. A few of the curricular revisions made to the teacher education program have been based upon the data collected from the technology utilization survey.

PTLP has provided another means of collaboration between the College of Education and partner districts. Participants gain knowledge and skills on the use of technology and have the opportunity to share their experiences through leadership opportunities on campus and in the schools.

A Framework for Integrating Technology into Teacher Preparation Programs

Staples Amy, UW-Milwaukee, US
Marleen Pugach, UW-Milwaukee, US
Dj Himes, UW-Milwaukee, US

The lack of highly qualified teachers for urban schools continues to be a well acknowledged problem nationwide. The educational needs of children and youth, and particularly for those who attend the nation's urban schools, can best be met by assuring that each student, no matter what school he or she attends, has a highly qualified, competent, and caring teacher (National Commission on Teaching and America's Future, 1996). Faculty at the University of Wisconsin-Milwaukee (UWM) define highly qualified teachers as those who (1) are deeply knowledgeable in the content areas they are to teach, (2) possess and demonstrate a high degree of pedagogical content knowledge, (3) engage in culturally relevant pedagogy to foster high levels of achievement for all learners and to bridge the discrepancy between primarily majority teachers and primarily minority students, and (4) embed technology across all aspects of their teaching as a central means of creating active, engaging, and challenging learning communities that enable their students to meet high standards of achievement. Teachers who possess these four qualities have the potential to close the perennial gap in achievement between students in urban schools--who typically are members of minority, and often lower socioeconomic, groups--and their more advantaged peers.

But if teachers in urban schools are to use technology to close the achievement gap, they must draw on technology to transform traditional teaching--teaching that to date has clearly left students in urban school systems like the Milwaukee Public Schools (MPS) the least well served. Technology holds unique potential for assisting teachers in moving away from traditional, teacher-centered instruction to highly engaging, challenging, student-centered learning environments. To reach this level of technology use, however, new and experienced teachers alike will require sustained professional development to acquire a vision of what is possible through the integration of technology-rich educational approaches--opportunities that were not in place prior to the receipt of a PT3 Implementation grant.

It is our belief that to be skilled in appropriate technology use, students must learn about technology through both explicit instruction via technology courses and through more integrated means within content area courses. As part of the work to integrate technology into our program, a framework for technology was developed. The framework was developed to help students consider their roles regarding technology (e.g., promoter of ethical practice, troubleshooter), how technology could be used to help them (e.g., teacher's assistant, teacher's tool) and how it could be used to promote learning (e.g., communicating or sharing information via various technologies) in their students. Using the ISTE standards and Collaborative Teacher Education Program for Urban Communities Core Values, the framework was constructed. The framework drove the revision of two required technology courses and stimulated the integration of technology projects in a number of content area courses.

This presentation will share information about the Collaborative program and the technology framework, as well as explain how coursework has shifted in both content and delivery. Examples of student and faculty projects will be shown.
Meeting NCATE Standards for Technology Integration: Survey Results of Technology Integration in an Elementary Education MAT Program

Abstract: This article is a report on findings of a survey that was given as a pre- and post-test of an introductory technology in education course. Introduction to Technology in Education was integrated into two other courses. In general, students' perceptions of their ability to operate a computer, use computer operating systems, increase their knowledge of computers and technology, evaluate software, use technology as a tool for instruction, using technology as a teaching tool, developing a technology plan, and disseminating their technology expertise increased.

In its effort to reform teacher preparation, NCATE has moved to ensure that teacher education candidates are prepared to use technology in teaching and learning. Expecting technology to be "central to teacher preparation in 2000 and beyond" (Wise, 1997-2001, p. 2), NCATE anticipates that technology will "be integrated throughout the curriculum, instruction, field experiences, clinical practice, assessments, and evaluations of the school" (Bradley, 2000, p. 2). As SCDEs develop curriculum and discuss instructional strategies to meet these standards, they turn to recent research and model programs for guidance.

Survey research conducted in 1998 by the International Society for Technology in Education (ISTE, 1999) initially suggested that integration of technology experiences in other coursework was more effective than a separate stand-alone technology course in helping preservice teachers to learn to use technology in education. However, a follow-up study of high-scoring institutions (as identified in the 1998 study) found that "technology courses within the teacher training program were rated as essential...followed by training integrated into other education coursework and informal individual learning (Bielefeldt, 2001, p. 9). The outcomes of these two studies reflect the various approaches being tried by SCDEs: stand-alone courses emphasizing tool use or basic computer applications, integration of technology across the liberal arts and teacher education programs, or a well-coordinated combination of both. Deciding on the best approach was identified as an obstacle to infusing technology into preservice teacher education in an ERIC Digest written in 1995 (Ismat, A., 1995).

The National-Louis Preparing Tomorrow's Teachers to Use Technology grant, Transforming Learning and Teacher Preparation through Technology-Rich Cohorts, was designed to train elementary and secondary teachers for partner school districts participating in the grants using a program that differed from the traditional program by adding a strong element of technology training and providing students with Gateway laptop computers. This MAT program reduced the number of credit hours for Foundations courses and replaced those hours with an Introduction to Technology in Education course.

Preservice teachers involved at the beginning of this PT3 training program took three classes during their first semester, an Introduction to Special Education class, a Practicum I class and the technology class. The classes met one night per week with technology instruction occurring in an elementary school equipped with a Macintosh computer lab. During this one night per week, hours were allotted for the three-hour special education class and the three-hour practicum class, but the technology class was integrated entirely within the class time of the other two courses. The instructors of the classes met together and correlated their respective syllabi. As the other two classes covered topics that permitted the integration of the goals and objectives of the technology class, the technology instructor taught technology skills within that class. In this way, the two-hour Technology in Education course was entirely embedded within the other two courses.

To measure the success of this program, students completed a survey at the beginning and end of the semester of the program. This instrument was developed from one used by Anderson and Petch-Hogan (2001) and measured such areas as students' technology skills, their knowledge of the use of computers, their ability to evaluate software, their use of technology to facilitate instruction, their ability to use technology as a teacher tool, their ability to develop a technology plan, and their ability to disseminate their technology knowledge. Using a t-test, the pretest and posttest forms of the survey were analyzed to determine gains in these areas.

Results indicated that students perceived themselves as improving in several areas measuring the operation of a computer and peripherals. They learned to install software, explain the best operating conditions for computers, perform simple maintenance on their computers, and operate CD-ROMs. Areas that were not significant included operating computers, operating projection devices, hooking up external devices, explaining safety features, maintaining printers, scanners, and digital cameras. Mean scores for computer operation, hooking up external devices, and maintaining printers were high on the pretest, indicating that students felt they knew how to perform these areas before the semester.
Results measuring student perceptions of their increased knowledge of computer operating systems indicated that students felt that they significantly increased in operating and navigating a Windows system, finding files in a Macintosh computer, making an alias in a Macintosh computer, changing settings in a Windows computer, making a shortcut in a Windows computer, and configuring peripherals in a Windows computer. Nonsignificant areas were initializing disks, operating a Macintosh system, and finding a file on a Windows machine. High mean scores on the first surveys for initializing disks, beginning and deleting software on a Windows computer, and finding a file on a Windows machine would seem to indicate that students already felt competent in these areas before the program began.

Results of student perceptions of their knowledge of the use of computers and related technology indicate that students felt that they gained in all areas: defining concepts related to technology, identifying major issues associated with the use of technology, identifying ways that computers can be infused into the curriculum, taking steps to keep knowledge up-to-date, and identifying sources of technology information. Using the integrated format for this course in educational technology seems to have made students feel that they improved in their knowledge of the use of computer technology.

Results for evaluation of software were also generally significant. Students felt that they increased in their ability to identify the purpose of a software program, match student characteristics to software, identify characteristics of software for instruction, evaluate the content of software, match the difficulty of the software with the learner, evaluate documentation, and determine teacher options. Setting up software options for use was nonsignificant.

Results on the surveys measuring the use of technology to facilitate instruction reported a significant increase in all the subskills that measure this area. Students reported a significant increase in their ability to use technology for instructional practice; set up the classroom for technology instruction; use tutorial programs, drill and practice programs, problem solving programs, tool software for both students and teachers, and assistive technology; evaluate the effectiveness of applications; use the Internet for research; use multimedia, and create Web pages. The only area they failed to demonstrate a significant increase was in the use of the Internet for online learning activities.

Results of students' perceptions on how technology can be used as a teacher tool were also largely significant. Students reported an increase in their ability to use a word processor to develop learning tools; search the Internet for lesson plans and information to aid teaching; use listservs, bulletin boards, use IEP generators; use word processors to create IEPs; and use portfolio software. There was nonsignificant gain in using utility programs, using databases or spreadsheets, using email, conducting regular backups of data, and transferring files between computers. Initial mean scores for utilities and using email were high, so students felt they already knew how to do these. The remaining areas were skills for which the students reported little gain.

Results of students' perceptions of improvement in their ability to develop a technology plan were all significant, indicating that students felt they were better prepared to create a technology plan. These areas included identifying goals for using technology in education, identifying how technology could be implemented in the curriculum, planning appropriate classroom changes, ensuring equitable access, creating guidelines for technology use, developing a budget, determining funding, and writing grants to obtain technology.

Finally, survey results measured students' perceptions in their ability to disseminate their technology expertise. The skills measuring this area were all significant with the exception of one, making presentations about technology. They did feel that they made significant gains in their ability to maintain a file of information on technology, provide consultation to colleagues and parents, and prepare written reports on technology.

To summarize the results of the survey on integrating technology in education students seem to indicate that while their hands-on technology skills did not increase in all areas, they felt that they increased their knowledge of effective planning and integration of technology into the classroom in most areas. Like the findings of the initial study by ISTE, the students gained in these areas when they were provided technology instruction in an integrated fashion.

Future research should explore other methods for training teachers to use technology. Since the Beilfeldt findings indicated that strong technology -using teacher education institutions provide a class for skills, this should be a focus of future research. Since these students did not report significant gains in all the computer operation skills on the survey, the Technology in Education class might be offered as a separate class, allowing for more time to make students comfortable with their laptops. These findings could be compared with the integrated method used in this study. This research could help identify which method is most effective at training teachers to use technology.

Faculty Use of WebCT: Impact of P3T3 Faculty Development Initiatives

Abstract: A study conducted within the School of Education, Purdue University, explored how a PT3 implementation grant project helped the faculty integrate the use of WebCT in their teaching. Data for this study were collected using both quantitative and qualitative approaches. An online survey was conducted. In-depth interviews were conducted with 3 faculty members who had attended WebCT workshops and were using WebCT in their courses. The results indicated that the overall rating of support services to the faculty was high. However, the faculty suggested changing: 1) the structure of the workshops to facilitate learning of WebCT, and 2) the quality and timing of the assistance that the P3T3 staff provides.

Introduction

The implementation of educational technology has been closely linked to the evolution of faculty development (Shapiro & Cartwright, 1998). Previous research (Dusick, 1998; Matthew, Parker & Wilkinson, 1998; Quick, 1999) has indicated that training and support are two significant factors in helping faculty to effectively integrate technology into the classroom. A major goal of P3T3: Purdue Program for Preparing Tomorrow’s Teachers to use Technology, a PT3 implementation grant project, is to prepare teacher education faculty to teach pre-service teachers in technology-rich environments, modeling approaches that future teachers should use themselves. To achieve this goal, P3T3 provides activities and extended support for faculty members. These include: 1) workshops on various technology topics, 2) help sessions, and 3) one-on-one faculty assistance on technology integration. For more information about P3T3, please visit our website at: http://p3t3.soe.purdue.edu.

WebCT is a web-based course development and management tool that allows faculty to construct and manage online courses, put materials online to supplement existing courses, create online communication environments, and keep track of students’ performance electronically. It is the “standard” platform for web-based courses and course support at Purdue University. To help faculty master the tool, P3T3 offers three workshops that provide step-by-step guidance for course design using functions available in WebCT. In addition, the P3T3 staff provides assistance for those who have difficulty when using it.

Study on the P3T3 Project WebCT
This study collected both quantitative and qualitative data. An online survey was conducted to obtain general information about faculty use of WebCT. Twenty-two faculty members from the School of Education participated in the survey. Results showed that 77% of the participants had attended P3T3 workshops on WebCT. All participants incorporated WebCT into their teaching. Most (59%) used WebCT for basic content presentation such as putting course notes, syllabi, and assignments online. Many (41%) posted and organized students’ grades and used the quizzes/survey feature. WebCT e-mail (71%) and discussion forums (82%) were among the most popular features. Few faculty members had experimented with the WebCT live chat feature. Among those who attended the workshops, 25% continued to seek help from the P3T3 drop-in help sessions, and 63% had requested one-on-one assistance. Besides the help from P3T3 staff, several faculty members had sought assistance from elsewhere, such as personal help from friends and peers, and help from various centers around the university. Overall, participants rated the services from P3T3 high: 50% great, 25% good, 6% ok, and 19% no opinion.

In-depth interviews were conducted with three faculty members who had attended WebCT workshops and were using WebCT to get more details regarding P3T3 project impact on faculty use of WebCT. In general, faculty members liked WebCT because it helped them better organize course materials for students. All three faculty members mentioned that, because of the features available in WebCT, they could conveniently make all course materials available in one place. Although all three liked WebCT, they thought the interface was not intuitive. Two interviewees found the P3T3 workshops very helpful in getting started with WebCT. However, one felt that they went by too quickly; he recommended they be restructured to accommodate less experienced users. Two faculty members had attended a P3T3 help session as well as requested one-on-one help available during the semester. One commented that the help sessions and the one-on-one assistance were very helpful. He added that he learned more from the personal help sessions than from the workshops. Another faculty member who had also requested help from the P3T3 staff commented that it was somewhat inconvenient to go for help to get answers to minor questions. Since the P3T3 project is not dedicated to WebCT support, the staff does not always know the answers to the questions. Therefore, this faculty member found it was quicker to go to the campus support group that dealt exclusively with WebCT. The one faculty who had never requested help from P3T3 explained that he didn’t know much about the assistance available from P3T3 and had received support through the campus center instead.

WebCT is one tool that the P3T3 team supports. This study uncovered both positives and negatives. Overall, P3T3 faculty services are rated highly. However, there are concerns to address. The two major ones are: 1) structuring the WebCT workshops to facilitate faculty learning of the program and 2) providing quality and timely assistance. In brief, the workshops should be more hands-on and learner-centered with mastery of one topic before moving on to the next. Staff assistance should be promptly supplied by knowledgeable personnel.

Results after two years of a Preparing Teachers for the Digital Age (PT3) Grant on a State University Teacher Preparation Program.

William Barker, Indiana University of Pennsylvania, US
Kurt Dutt, Indiana University of Pennsylvania, US

Introduction Three Pennsylvania state universities (Indiana, Clarion and Edinboro) successfully obtained a 1.73 million PT3 grant. We developed a plan to infuse technology into teacher education programs. We will present the first and second year results of this project for the fall and spring semesters for Indiana University of Pennsylvania faculty, students and course syllabi.

Sample The sample sizes are: 1999 Fall - 20 faculty, 571 students, and 13 course syllabi; 2000 Fall - 9 faculty, 566 students, and 10 course syllabi; 2000 Spring - 29 faculty, 837 students, and 20 course syllabi; and 2001 Spring - 25 faculty, 653 students, and 25 course syllabi.

Areas to be Assessed The areas of activity by pre-service students and faculty to be assessed using surveys include knowledge, attitudes, application, and integration. Knowledge represents what one knows and can do with respect to the use of technology in the classroom. Attitudes indicates how one feels about the use of technology in the college classroom. Application involves the ability to demonstrate the use of technology both in the college classrooms. Finally, integration requires the use various technologies alone and together in achieving the goals of the lesson plan for the college. We also collected a syllabus from most courses. Specific questions included: 1. Operating Systems Management (e.g. Windows, Macs), 2. Word Processing (e.g. Microsoft Word, Word Perfect, Claris), 3. Spread Sheets (e.g. Microsoft Excel), 4. Web Browsers (e.g. Internet Explorer, Netscape) 5. E-mail (e.g. Microsoft Outlook, Netscape, Eudora), 6. E-mail Distribution Lists (e.g. Microsoft Outlook, Eudora), 7. Presentation Software (e.g. PowerPoint, QuickTake), 8. Databases (e.g. Microsoft Access, Clasisworks), 9. Multi-Media Packages (e.g. CD Rom programs), 10. Video Conferencing, 11. Moderated Chat Rooms, 12. Internet in Teaching (e.g. Web CT, Course Info, Blackboard), 13. Digital Camera, 14. Laser Disc Player, 15. Scanner, 16. WWW/Internet Resources, 17. Computer Aided Graphics, 18. Ethical and Legal Issues (e.g. Copyright, Privacy) [2000 Fall and 2001 Spring only], and 19. Social and Human Issues (e.g. Empower Diverse Learners) [2000 Fall and 2001 Spring only].

Demographic Data Collection Demographic data were collected from pre-service teachers and faculty who teach relevant education courses. This included age, sex, year in school, number of credits, overall grade point average, major courses grade point average, socio-economic background, resident status, major, data available at admission to college, and other relevant information.

Instruments We developed Faculty, Student, and Syllabus instruments to assess the nineteen areas. They will be included for review.

Data Collection Baseline survey data for faculty, students, and course syllabi were collected during the initial year of the project (1999 Fall and 2000 Spring). Follow-up data were collected from each cohort during the second year of the project (2000 Fall and 2001 Spring).

Goals, Objectives, and Evaluation Goal Overview: To infuse instructional technology more deeply into the teacher education curriculum in both education core courses and selected majors. Students will be taught technology and it will be modeled for them by faculty teaching in the college of education core curriculum. To evaluate this goal we analyzed survey data for each years' cohorts and over time, i.e. baseline data for the year one cohorts and follow-up data for year two for the same yearly cohorts.

Goal - Objective 1: Train faculty to effectively and appropriately use and teach the key competency skills. This objective was evaluated by basic record keeping of attendance by faculty at workshops.

Goal - Objective 2: Have university faculty model how to teach effectively with technology in education core courses and elementary education/subject area courses. The collection, collation, and analysis of faculty surveys and student surveys for the same courses over time allowed us to evaluate this objective.

Goal - Objective 3: Create assignments within education core and subject area courses based upon the appropriate use of the technology areas. Pre-service teacher and faculty survey sub-scale data were used for this objective.
Goal - Objective 4: Revise course syllabi to reflect and recognize the integration of technology into the curriculum. Analysis of syllabi were used for this objective.

Results A brief summary of results by Objective will be presented.

Objective 1: The number of faculty attending various types of workshops will be presented for each year.

Objective 2: 1999 Fall Baseline Results - A comparison among faculty and students suggests that faculty and students are not in agreement with respect to how often technology is demonstrated in courses. For sixteen (16) areas the faculty ratings were higher than the student ratings and in one (1) areas the student ratings were higher. 2000 Fall Follow Up Results - 2000 Fall data when compared to 1999 Fall show that for faculty, meaningful decreases (effect sizes of .30 or larger in absolute size) occurred in all areas, whereas for students, no meaningful changes occurred.

2000 Spring Baseline Results - A comparison among faculty and students suggests that faculty and students are not in agreement with respect to how often technology is demonstrated in courses. For sixteen (16) areas the faculty ratings were higher than the student ratings and in one (1) areas the student ratings were higher. 2001 Spring Follow Up Results - 2000 Spring data when compared to 2001 Spring show that for faculty, meaningful increases (effect sizes of .30 or larger in absolute size) occurred in "6. E-mail Distribution Lists (e.g. Microsoft Outlook, Eudora)" Effect Size (ES) = .31; "11. Moderated Chat Rooms" ES = .85; "12. Internet in Teaching (e.g. Web CT, Course Info, Blackboard)" ES = .43; and "15. Scanner" ES = .34, whereas, meaningful decreases occurred in "10. Video Conferencing" ES = -.39 and "14. Laser Disc Player" ES = -.30. For students, meaningful increases occurred in "4. Web Browsers (e.g. Internet Explorer, Netscape)" ES = .47, "5. E-mail (e.g. Microsoft Outlook, Netscape, Eudora)" ES = .39, "7. Presentation Software (e.g. PowerPoint, QuickTake)" ES = .36, and "16. WWW/Internet Resources" ES = .39.

Objective 3: 1999 Fall Baseline Results - A comparison among faculty and students suggests that faculty and students are not in agreement with respect to how often assignments based upon appropriate use technology are created in courses. 2000 Fall Follow up Results - 2000 Fall data when compared to 1999 Fall show that for faculty, meaningful decreases (effect sizes of .30 or larger in absolute size) occurred in all areas, whereas for students, one meaningful increase occurred in "1. Operating Systems Management (e.g. Windows, Macs)" ES = .30. 2000 Baseline Results - A comparison among faculty and students suggests that faculty and students are not in agreement with respect to how often assignments based upon appropriate use technology are created in courses. For sixteen (16) areas the faculty ratings were higher than the student ratings and in one (1) areas the student ratings were higher. 2001 Spring Follow Up Results - 2001 Spring data when compared to 2001 Spring show that for faculty, meaningful increases (effect sizes of .30 or larger in absolute size) occurred in "6. E-mail Distribution Lists (e.g. Microsoft Outlook, Eudora)" ES = .48, "11. Moderated Chat Rooms" ES = .85, and "17. Computer Aided Graphics" ES = .35, whereas, meaningful decreases occurred in "2. Word Processing (e.g. Microsoft Word, Word Perfect, Claris)" ES = -.40, "8. Databases (e.g. Microsoft Access, Clarisworks)" ES = -.54, and "14. Laser Disc Player" ES = -.30. For students, meaningful increase occurred in "2. Word Processing (e.g. Microsoft Word, Word Perfect, Claris)" ES = .32, "4. Web Browsers (e.g. Internet Explorer, Netscape)" ES = .45, "5. E-mail (e.g. Microsoft Outlook, Netscape, Eudora)" ES = .33, "7. Presentation Software (e.g. PowerPoint, QuickTake)" ES = .35, and "16. WWW/Internet Resources" ES = .46.

Objective 4 - 1999 Fall Baseline Results - A comparison among faculty, students, and the syllabus suggests that faculty and students are not in agreement with respect to what is in course syllabi. 2000 Fall Follow up Results - 2000 Fall data when compared to 1999 Fall show that for faculty, meaningful increases (effect sizes of .30 or larger in absolute size) occurred in "4. Web Browsers (e.g. Internet Explorer, Netscape)" ES = .40 with all other showing decreases except for "1. Operating Systems Management (e.g. Windows, Macs)". For students meaningful increases occurred in "1. Operating Systems Management (e.g. Windows, Macs)" ES = .36, "2. Word Processing (e.g. Microsoft Word, Word Perfect, Claris)" ES = .36, "4. Web Browsers (e.g. Internet Explorer, Netscape)" ES = .39, and "16. WWW/Internet Resources" ES = .37. 2000 Spring Baseline Results - A comparison among faculty, students, and the syllabus suggests that faculty and students are not in agreement with respect to what is in course syllabi. For fourteen (14) areas the faculty percentage was equal to or higher than the student percentage and in three (3) areas the student percentage was higher. For fourteen (14) areas the syllabus ratings were equal to or lower than the faculty or student ratings.

2001 Spring Follow Up Results - 2001 Spring data when compared to 2001 Spring show that in the syllabus, meaningful increases (effect sizes of .30 or larger in absolute size) occurred in "1. Operating Systems Management (e.g. Windows, Macs)" ES = .49, "2. Word Processing (e.g. Microsoft Word, Word Perfect, Claris)" ES = 1.60, "4. Web Browsers (e.g. Internet Explorer, Netscape)" ES = .89, "5. E-mail (e.g. Microsoft Outlook, Netscape, Eudora)" ES = .98, "7. Presentation Software (e.g. PowerPoint, QuickTake)" ES = .49, and "16. WWW/Internet Resources" ES = .35.

Discussion All of the above will be discussed and various theories put forward to explain why things happened this way.
Assessing of the ISTE NETS for Teachers

Helen C. Barrett
School of Education
University of Alaska Anchorage
United States
helen.barrett@uaa.alaska.edu

Abstract: Learn about performance-based strategies for demonstrating achievement of the ISTE NETS for Teachers, including web-based basic skills assessments, performance tasks, electronic portfolios, and observation tools. Preview a new publication from ISTE that provides a Framework for Assessing the NETS-T.

Background
This paper will cover the process that has been conducted to develop an assessment system covering the ISTE NETS for Teachers. Following that description, the Assessment Component of ISTE's 2001 PT3 Knowledge Development Catalyst Grant will be described, entitled the STATE project (Supporting Technology and Assessment in Teacher Education).

The NETS for Teachers Project held a focused Assessment Writing Meeting in Tempe, AZ in December, 2000. Through an exhaustive selection process, an elite group of educators from across the nation were selected to thoughtfully examine the issues of assessment and technology. The contributing team members included teachers, technology coordinators, administrators, teacher educators, college of education administrators, and professionals from the assessment community. Four subcommittees were formed, each of which worked on different strategies to assess the National Educational Technology Standards for Teachers. The areas of focus for each subcommittee and their tasks were:

- General Preparation – Listed specifications for the assessments meeting the tasks described in the profile;
- Performance Assessment Tasks and Rubrics – Developed a meta-rubric to address the Professional Preparation and Student Teaching/Internship Profiles
- Electronic Portfolio – Outlined the process and content for development of an electronic portfolio for the Professional Preparation and Student Teaching/Internship Profiles with links to the First Year Teacher Profile, and
- Observation and survey Tools – Identified a series of options to address the Student Teaching/Internship and First Teacher Profiles.

The outcomes of the Assessment Writing Meeting contribute to the basis of this presentation. Additional specific products and ideas from the meeting will be found in later ISTE publications. ISTE has based the NETS for Teachers Assessment Model on NCATE's Specialty Areas Studies Board (February, 2000) Principles For Performance-Based Assessment Systems in Professional Education Programs. The NETS for Teachers project used the following diagram as a framework for the Assessment System to address the attainment of these standards.
The rows going across the chart represent the six individual standards, the columns represent the four profiles identified as phases in a teacher preparation program, and the boxes in the chart represent individual standards within each profile. At least three benchmarks were identified for which assessments were considered:

- **Candidate Readiness Benchmark:** at the end of the General Preparation, or at entry into the Teacher Education Program (the “solid” line). At that point, the teacher education program needs to determine the readiness of the teacher candidate to have the technology skills to be successful in both Methods and Student Teaching.

- **Initial Certification Benchmark:** at the end of the Student Teaching/Internship and graduation from a Teacher Preparation Program (the dashed line). At that point, the program needs to determine the readiness of the graduates from a teacher education program to be successful using technology in the classroom.

- **Experienced Teacher Benchmark:** at the end of the First Year of Teaching, when Schools of Education may need to prepare a USDOE Report Card on their graduates (Higher Education Act. Title II, Section 207) (the dotted line). At that point, ISTE defines the professional proficiency with technology of all experienced teachers.

- **Advanced Professional Proficiency Benchmark:** In the future, ISTE will be working with the National Board for Professional Teaching Standards to develop an advanced certificate to recognize those highly effective teachers who integrate technology into their classrooms and who provide models for others to emulate.

**PT3 Knowledge Development Catalyst Grant.**

ISTE’s PT3 Catalyst grant will address the first two benchmarks, because they are within the direct control of teacher education programs and consistent with PT3 funding. The last two benchmarks will be addressed at a later time. The STATE project will use both traditional hands-on workshops and distance learning strategies to deliver the training on technology-supported assessment strategies. Dr. Helen Barrett has already provided traditional, face-to-face workshops on Electronic Portfolio Development for PT3 grantees at Montana State University-Northern, Iowa State University, University of Central Florida, and National-Louis University. She has also provided distance-delivered workshops for PT3 grantees Clarion University and Indiana University of Pennsylvania, using a combination of video tape, CD-ROM, live CUSeeMe videoconferencing, and telephone conferencing.

**Specifications for the assessments of the General Preparation Profile (1st Profile)**

Colleges of Education are at a crossroads in determining how to assess prospective teachers' knowledge and skills in use of technology prior to admission into the core program. Universities are asking for a set of tools to select from to assist them in determining whether or not a student has sufficient technology skills and knowledge to enter into the teacher preparation program. This assessment should determine if a prospective teacher has the prerequisite skills to participate in and eventually facilitate learning activities for students that focus on the teaching and learning with technology. It is not expected that there is one solution to assessing this profile. Rather, this group examined both commercial and non-commercial options and described ideal options that currently do not exist. In addition to the quality factor, important issues the group considered were scalability, economics, and equity of student access. The specifications developed with accompanying examples and narrative should provide guidance to Colleges of Education in making a decision that fits their unique circumstances.

Through a partnership with several assessment developers, this project will partially cover the development of an on-line assessment that will be made available to SCDEs at a no cost (for students taking a “practice test”) or at very nominal cost once the assessment is validated, to provide a much-needed tool to assist with determining readiness for using technology in Teacher Education programs, as well as access to a system for remediation of basic technology skills.

**Performance Assessment Tasks and Rubrics to address the 2nd and 3rd Profiles**

Another group in the Writing Team Meeting addressed performance assessments that may be used in an exam setting, or as part of the on-going assessment in a course and/or at the end of a program of study that may form the contents/artifacts for a portfolio or as part of an overall assessment of prospective teachers’ competence in meeting the standards. The group took into account the variety of types of teacher preparation programs and the various settings in which they occur. This writing team developed a sample rubric that could be used to assess the attainment of these standards. A variety of performance assessments need to be gathered as part of this project, and will be published by ISTE in an online Clearinghouse on Electronic Portfolio and Performance Assessment.

The NETS Leadership Team has developed preliminary rubrics to assess the NETS for Teachers. These standards will be shared with the group at the conference, to get a first round of feedback on the content. There will also be an opportunity to give feedback online through the ISTE NETS website.

**Electronic Portfolios and rubrics for 2nd and 3rd Profiles with links to the 4th Profile**
The task of that Writing Team was to define the purpose, audience, process, and various development strategies for using technology to maintain authentic samples of a prospective teacher's work, demonstrating achievement of not only the ISTE NETS-T Standards, but also the School of Education's teaching standards and any other standards that the student is responsible for demonstrating. The purpose of the electronic portfolio is to demonstrate the prospective teacher's growth and change over time, and will provide the ideal container to organize and document the various performance assessments that demonstrate achievement of the standards. This team described development strategies using a variety of software tools; possible contents of the portfolio and suggested table of contents; strategies for assessing these portfolios; strategies for scalability, or how to manage the assessment process with large numbers of students in a Teacher Education program. Suggestions were also made on how to extend the use of the portfolio that is developed at the end of the 3rd Profile, into the first year of teaching as a tool for professional development throughout the teacher's professional career, possibly preparing for the National Board for the Professional Teaching Standards.

The diagram above represents an adaptation of the Assessment Model to address the progression of the teacher candidate's electronic portfolio through the stages of the Teacher Education program into the classroom teaching experience and on to advanced certification, possibly through the National Board for Professional Teaching Standards. Students are encouraged to become a "digital packrat" from the beginning of the program. A student will create three types of portfolios. At first, the portfolio is a collection of products that the teacher candidate has produced in their coursework (formative). By the end of the Student Teaching program, the portfolio could be used for more summative assessment, to demonstrate achievement of any group of standards (i.e., NETS, INTASC). The teacher candidate can transform their portfolio into the format and content suitable to facilitate their seeking employment. Once in the teaching profession, the portfolio becomes a learning tool again, where teachers can document their work and samples of their own students' work. During the course of a teacher's career, the portfolio can be used for performance assessment, based on appropriate teaching standards. Finally, after years of classroom experience, the collection could be transformed back into a summative portfolio for National Board Certification.

The Electronic Portfolio Development team at the ISTE NETS Assessment Meeting developed a list of artifacts that could be included in an electronic portfolio to demonstrate achievement of the ISTE NETS for Teachers. In addition to artifacts that a teacher candidate may choose, the team also identified six required entries for the portfolio that demonstrate the appropriate standards. The writing team also adapted a generic "meta-rubric" to assess the electronic portfolio designed through this process.

Several major activities under the second goal of this project will be to provide training and technical assistance to SCDEs on the implementation of electronic portfolios to document the professional growth of teacher candidates, and will begin with training teacher education faculty members to create their own electronic teaching portfolios. The facilitator of this writing team, Dr. Helen Barrett, co-PI of this project, has done innovative work on electronic portfolios, and is a nationally recognized leader in this area. As Assessment Coordinator for the NETS project, she will coordinate the development and dissemination activities provided to SCDEs under this goal.

**Observation and survey tools to address the 3rd and 4th Profiles:**

Once prospective teachers move into their student teaching/internship experience, there is a need for classroom observation tools to assess appropriate uses of technology in the curriculum. Not only will this work assist with the assessment of prospective teachers by teacher education faculty and master/cooperating teachers, but also the instruments will potentially assist administrators as they assess the appropriate use of technology in the classroom. In addition to observational instruments, the use of survey information collected from students, parents, and other stakeholders, provides valuable data for assessing the impact of technology to support student learning. The writing team developed a series of observational assessment protocols that need to be field tested and validated before they can be made available. This project will provide support for further refinement of the observational assessment protocols that were developed, so that they can be more widely disseminated to SCDEs. Dr. Doug Daniel, with ISTE's Assessment and Evaluation Department, will coordinate these efforts.
Abstract: While computers and other technology have become more ubiquitous in public school classrooms, teachers who have graduated from ASU west's College of Education have reported feeling a lack of confidence in their ability to use the technology to reach lesson objectives. Our research has revealed that although students were experiencing models of technology integration in their teacher education courses, they were not experiencing exemplary models of technology use with children in the classrooms in local schools where they were assigned for field experience. Through a federal grant, we have been addressing this issue. This study reports on our efforts to address lack of exemplary practica sites — although a program developed in collaboration with school district partners. Together, the mentor teacher and student intern attended workshops, learned technology applications, and designed...
curricular units that incorporate the technology. Our evaluation of the Practicum Plus revealed that the program was effective in meeting the professional development goals. The preservice and inservice teacher pairs integrated technology into instructional Units of Practice (UOP) for culturally and linguistically diverse students in K-8 classrooms. Although the Practicum Plus program was found to be effective, the researchers also noted difficulties encountered in implementing the program on a broader scale.

Introduction

Preparing Tomorrow's Teachers to Use Technology (PT3) staff, Arizona Classroom of Tomorrow Today (AZCOTT) teachers and education faculty at Arizona State University West are completing the second year of the Practicum Plus Program. The program provides technology professional development to K-8 preservice teachers and their mentor teachers. Preservice teachers are recruited from classes in the College of Education; mentor teachers are recruited from those local school districts in which preservice teachers complete their required internship experiences. The Practicum Plus Program prepares them to integrate appropriate technology into grade level curriculum. The inservice and preservice teachers experience the instructional applications of information technologies and learn to develop and implement an instructional Unit of Practice (UOP). Participants have opportunities to explore the integration of technology with multicultural and English as a second language instructional strategies so that they may provide maximized learning experiences which accommodate the rich cultural and linguistic diversity found in their classrooms.

The Practicum Plus Program, made possible through a PT3 Grant, consists of collaborative, hands-on training in technology integration led by PT3 staff, AZCOTT teachers and faculty in the Arizona State University West College of Education. The UOP is a framework for organizing content and embedding technology into teachers' classroom instruction. Components of the UOP bring into focus seven specific elements of instruction (i.e., Standards, Invitation, Situations, Interactions, Tasks, Tools, and Assessment) that align curriculum with developmentally appropriate standards across grade levels and content. Inclusion of State and national academic standards were a requisite part of the participants' UOPs. The ESL Standards for Pre-K-12 Students (TESOL, 1997) provides the framework for language activities that promote English language acquisition. The UOPs also incorporate Chisholm's (1998) six elements for technology integration in multicultural classrooms.

Diverse Populations and Technology

In 1998, 40 percent of the total school population in the United States were minorities (National Center for Education Statistics, 2000). By 2000 immigrants accounted for 8.6 million school-age children in our schools (Camarota, 2001). The number of school age children who spoke a language other than English and who had difficulty speaking English rose from 1.3 million in 1979 to 2.4 million in 1995 (Federal Interagency Forum on Child and Family Statistics, 2000). American schools also serve children from a range of socio-economic backgrounds. In 1999, one in six children lived below the poverty line (Children's Defense Fund, 2000). Given that by 2006, half of all jobs in the United States will be in information technology or will require information technology skills (Carvin, 2000), it is imperative that this diversity of students have technology access and opportunities to use information technologies for authentic purposes involving problem solving and higher level thinking.

However, racial, ethnic and economic parameters determine children's access to technology. Households earning $50,000 to $75,000 are twice as likely to own a computer than those earning $10,000 to $14,000 (Nickell, 2001). Whereas 52 percent of White children use a computer at home, eighteen percent of Hispanic children do so (ERIC Clearinghouse on Urban Education, 2001). The proportion of rural Native American households with access to computers is nearly half that of the national average (Luening, 2000). Further, children from the poorest households and living with adults with the least schooling are least likely to have Internet access at home (Carvin, 2000, The Children's Partnership, 2000).

Though the number of computers at schools is increasing and school connectivity is rising, school access remains inequitable. Those with the largest concentration of children in poverty have a 9:1 ratio of students to computers as compared to the national school ratio of 5:1 (Cattagni & Westat, 2001). Sixty-eight percent of Hispanic children use a computer at school as compared to eighty-four percent of White students (ERIC Clearinghouse on Urban Education, 2001). Half of schools in the poorest communities report that students use the Internet (The Children's Partnership, 2001). And teachers in more affluent schools are more
likely than those in the poorest schools to assign computer-related and Internet work to their students (Rowand, 2000).

Research on English language learners (ELLs) suggests that integration of technology can augment positive self-concepts, promote English and native language proficiency, enhance motivation, stimulate positive attitudes towards learning, improve academic achievement, and foster higher level thinking skills (Diaz, 1984; Knox & Anderson-Inman, 2001; Meskill, Mossop & Bates, 1998; Soska, 1994.) Technology, in conjunction with the teachers’ goals, purposes and epistemologies, allows students to take control of their own meaning-making and creates socially-mediated literacy activities that foster the development of language and thinking (Meskill, Mossop & Bates, 1998). When ELL students use technology in small groups, their verbal interactions enhance interpersonal and communication skills (Steinberg, 1992). Technology provides opportunities for cooperative learning which not only increase instructional effectiveness and efficiency, but also promote positive social interactions (Johnson, Johnson, & Stanne, 1986; Schlechter, 1990).

Technology-based activities can transform the classroom into a rich learning environment and prepare minority children for the technological world. While information technology has a potentially positive effect on ELLs, its presence in our schools is not sufficient. Teachers are central to the creation of a computer-supported learning environment that is learner-centered and motivating. Effective use of technology requires new teaching models where technology becomes an integral component. ELLs, often among the disenfranchised and the computer-destitute, need teachers who can effectively integrate information technologies and the Internet into the learning process. Without such teachers these children’s exposure to technology remains limited and inequitable.

The Study

The investigators looked for answers to the following research questions. Question 1) How effective was the Practicum Plus program in preparing mentor teachers and their university practicum students to create a curriculum unit of practice in their K-8 classrooms? Question 2) How did mentor teachers and practicum students use the cohort listserve to support the community of learners? Question 3) To what extent have faculty participating in the Plus program learned to use and integrate technology in their subject area curricula and model the use of technology in their classes?

Method

Subjects

Participants (43) consisted of two groups, 19 university students who were in the semester prior to student teaching (12) or completing their professional education preparation program as student teachers (7); and 24 inservice teachers, 19 of which were supervising the participating interns/student teachers and 5 working on their own. The majority of students were in Elementary Education programs including Elementary, Bilingual, ESL, and Early Childhood Education.

As a result of suggestions from year one, recruitment for PLUS courses in year two included advertising earlier in the semester, presenting in student courses and at school faculty meetings, and early notification of PLUS course dates and locations.

Technology Questionnaire

A 42-item, Likert-scale questionnaire, which assessed teachers’ beliefs and self-reported skill levels related to technology use and technology integration, was administered pre and post. (For a full description of
The questionnaire see Zambo, Buss, & Wetzel; 2001). The pretest was administered the first day of the workshops in the summer of 2001. The posttest was administered on the last day of the workshops in November/December of 2001.

Questionnaire items were developed to provide coherent sets, which formed subscales that could be more readily analyzed. Subscales completed by both inservice and preservice teachers were: 1) general confidence in using technology; 2) confidence in computer setup and general operation; 3) confidence in using non-computer equipment; 4) confidence with software selection and use; 5) confidence in addressing students with special needs; 6) confidence in developing lessons with technology; 7) beliefs about appropriate use of computers; 8) beliefs that computers are integral to classroom instruction; 9) beliefs about the cost effectiveness of computer integration; 10) knowledge about the technology standards; and 11) knowledge and beliefs about UOP.

Cronbach’s alpha for the total test was .92. Individual subscale alphas ranged from .90 to .49 with a median of .79. The test overall was reliable. Mean pretest subscale scores for all subject combined ranged from 2.76 to 4.70 on a scale from 1 to 6 with 6 being the most positive. Mean posttest scores were generally higher and ranged from 3.46 to 5.28.

Repeat measures analysis revealed scores on 8 of the 11 subscales (1-6, 10-11) increased significantly (p < .01) from initial testing, prior to the workshop, to testing at the end of the semester. All eight subscales with significant gains were those related to confidence in, or knowledge of, various factors. This is a strong indication that the workshops were effective in increasing teachers’ confidence and skills in those targeted areas.

The subscales that did NOT show significant increases were those related to beliefs (numbers 7, 8, & 9 from above). This is an indication that the students and teacher who participated in the workshops came with a predisposition in favor of educational technology. The workshops did not increase these factors that were already at high levels at the time of the pretest.

One-way Anova detected between-subjects differences for group (preservice teachers vs. inservice teachers) on one pretest subscale and on one different posttest subscale. On the pretest, preservice teachers scored higher than inservice teachers on the belief that computers were integral to instruction with means of 5.11 and 4.38, respectively \[F(1, 42) = 8.53, p < .006\]. This difference had dissipated and was not significant by the time of the posttest with means of 5.04 and 4.72 for preservice and inservice teachers.

On the posttest, preservice teachers were more confident in developing technology lessons than were inservice teachers with means of 5.12 and 4.50 respectively \[F(1, 42) = 5.86, p < .020\]. This difference was not significant on the pretest with means of 3.76 and 3.71 respectively. Although the confidence had increased for both groups, the increase was larger of the preservice teachers. This may be attributed to the fact that the majority of preservice teachers were also taking methods courses during the Fall semester, concurrent with workshop activities. Lesson planning is a major component of methods courses and most likely confounded the effects of the workshop.

Discussion Board

The five cohorts of the PLUS program participated in on-line discussions through an electronic course using Blackboard. The purpose of the discussion board was threefold:

- To provide the participants with skills of electronic communication,
- To encourage collegial sharing, and
- To create a community of learners who could interact beyond the time and place of the actual workshops.

Participants consistently used the discussion board to share teaching ideas and resources, for reflection and discussion of activities that occurred during the PLUS course time, to stay abreast of current events that had impact on their classrooms, to share information about websites, information about how to accomplish assignments, and to support each other on how to implement new information and technology applications into their classrooms.

Unit Of Practice

A rubric was used to evaluate and identify proficiency levels for each category of the UOP: Standards, Invitation, Situations, Interactions, Tasks, Tools, and Assessment. Each was evaluated on a scale of Accomplished, Developing, or Emerging (http://www/asu/p3).
Results from analysis of the Unit of Practice generally agreed with the results from year 1. Participant’s strengths were in the Invitations, Tasks, Interactions, and Situations components. Additionally there was an increase in percentage of participants achieving the Accomplished level in the standards components including the TESOL standards for English acquisition by bilingual and ESL teams.

**Faculty Technology Use**

During the past two years 13 tenured and tenure track ASUW faculty participated in the PLUS program. The faculty were surveyed to determine the extent to which they have modeled the use of technology in their classes with an open-ended survey item: Write a brief description of how you are using technology in your teaching to help our university preservice teachers incorporate technology in their work. Data was categorized and tabulated in these categories: technology for course structure, use of web resources, and student assignments using technology.

70% of the faculty reported using technology in their teaching. Uses clustered around five areas: faculty using technology to present information to the class such as semantic nets using Inspiration, PowerPoint or HyperStudio (67%); threaded student on-line discussions (44%); Blackboard assignments and discussion areas (22%); incorporation of web resources for readings, simulations and links to National Educational Technology Standards for Students and Teachers (http://cnets.iste.org) and State academic standards (22%); structured lessons requiring students to use technology in and out of class for graphing of data, multimedia book construction, digital portfolio, etc. (56%).

**Discussion**

In this model of teacher preparation, the preservice and inservice teachers participate in technology integration workshops together during the summer. In the semester following the training, the preservice student helps to implement the technology-rich unit created in the workshop. The researchers found that the mentor teachers and the preservice students appreciated the opportunity to work together prior to the practicum experience. In addition to the trust established between the pair, they also increased their knowledge of hardware and software and confidence in their ability to design and implement technology in the curriculum.

In comparison to the previous year, the units of practice created during the training were better designed and more complete. Further they included the TESOL standards which helped to meet the needs of second language learners in our urban schools.

Finally, the faculty who participated in the training also adapted many of the technology rich activities for their courses. Faculty use of technology was not the primary purpose of the Plus program, but the benefits for faculty were evident. For example, many of the faculty used the Unit of Practice format for lesson planning in their courses. Thus, students in their courses incorporated technology in each of the assignments involving lesson planning.

Although this model of professional development was found to be effective, the researchers noted that the implementation of the Plus program was difficult. For example, it was not easy to locate the mentor teacher to match with the student in the early summer, months before the practicum semester. Typically, the field placement office finalizes the matches just before the semester begins. Consequently, we recommend that universities contemplating the adoption of similar professional development models, consider this difficulty. If the problems involved with creating the mentor and student teacher pairs can be resolved, then this program model is promising.

Despite the extended efforts to advertise and recruit participants for the PLUS course, year two enrollment numbers were lower than year one. Several factors seemed to affect enrollment:
Repeat participation by mentor teachers was low without financial or graduate credit incentives for teachers attending the course a second year while working with a new preservice teacher.

Unstable school district environments, resulting from negotiations of teacher contracts and salary issues, hindered the mentor teachers’ enthusiasm to participate in the program.

Changes in district or school administration, teacher requested school changes, and new school openings hindered mentor teacher recruitment and placement with preservice teacher because location and/or grade level of teacher was uncertain.

Students experienced conflicts with the PLUS course schedule and required program courses that they needed to complete during summer session.

Mentor teachers who were required to attend district training or teach district summer school were also not able to attend due to scheduling conflicts.

The preservice /mentor teacher pair was not established until after the PLUS courses had begun. Mentor and/or preservice teachers who might have attended, did not because they were uncertain if their counterpart would be interested, or in the case of the mentor teacher, if they would actually receive a preservice teacher.

Year 2 results compared very favorably to year 1 in most aspects. It is apparent from the results, there was an overall increase in UOP development as regards the inclusion of appropriate standards and in technology integration and applications by all participants. Preservice teachers and mentor teachers used the discussion board effectively as a communication tool. Additionally, University faculty reported greater emphasis on inclusion of technology in their own teaching, providing further modeling of technology in classrooms. The only aspect of the workshops that did not compare favorably to year 1 was in recruitment of participants. This issue has been evaluated and is being addressed for year 3 planning. Plans include relocating the workshops sites to a central location at the ASUW campus, and offering a more flexible schedule in order to accommodate schedules of preservice and mentor teacher routines and responsibilities.

Using Immersive 360 Degree Images to Enhance Active Involvement and Comprehension in the Learning Process

Peggy Benton (PeggyvB@sfsu.edu), Mercedes del Rosario (merce7@sfsu.edu) and Yen-Ling Shen (Yshen@sfsu.edu)

Teaching with Technology PT3 Grant, Instructional Technologies Department
San Francisco State University
United States

Abstract: The purpose of this paper is to introduce three types of panoramic or 360° by 360° immersive images as a powerful, active learning tool to enhance understanding in a wide array of curriculum initiatives. The underlying principles of learner control and active engagement, plus the power of contextual cues immersed in an entire scene will be demonstrated. Participants will experience the learning potential of this technology by visiting and exploring an entire context through this medium. The process of creating and using these images for use in the classroom and web-based learning activities is described. Curriculum can be augmented by re-purposing available immersive images integrated into lessons. Examples showing the use of these images in standards-aligned science and social studies integrated thematic lessons will be presented.

Introduction

Computer technology offers the capability of presenting text in combination with photos, illustrations, charts, graphs, audio, video and animated representations to enrich comprehension. In addition to still and animated images, now 360-degree panoramic images can be presented on CD-ROM or the web. In a 360-degree format, students can explore an entire virtual environment as if they were at the actual site. The term for these images is immersive. Learners are in control and can move about at will within rooms, around historical monuments and landmarks using the mouse or other mouse emulators such as a tablet or track ball. The 360-degree panoramic images provide learners with rich contextual and relational cues. They can see and explore such wonders as the Great Wall of China or take a virtual trip to the Grand Canyon and study striations in the rock formations, or they can freely roam the virtual White House.

Teachers want their students to be able to experience these environments in a meaningful, constructive way, to gather and evaluate relevant information. Immersive images offer this opportunity. Teachers report that students become more interested in academic content after a real or virtual field trip that brings the subject matter to life and gives them a lifelike experience. Since most students have limited opportunity to visit important sites relevant to their lessons, immersive images fill an important need.

Originally, the term virtual reality (VR) was used to describe computer presentation of digital still images in a 360° panorama format. Typical virtual reality software allows users to develop their own virtual environments by "stitching together" a number of flat images in such a way that the computer can present them as a seamless 360 degree panoramic scenes or environments. These images are an improvement over "flat" digital still photographs. They provide more information in one image; thus the learner can focus on particular selected areas to explore.

A second type of immersive technology, called 360 One™, from Kaidan and EyeSee360 Inc (www.Kaidan.com), makes creating the 360° panoramic image easier. Only a single camera shot is required so there is no stitching together of flat images. Using a special parabolic lens attachment, digital camera and software, this optical system captures a complete 360° panoramic image. The resulting image is a complete 360° horizontal panorama with a 100° vertical field-of-view (50° above and 50° below the horizon). 360° panoramas with 100° vertical field-of-view is sufficient to see all of a scene except the floor and ceiling.

A third approach, even more comprehensive than the 360° by 100° panorama, is the spherical 360° by 360° immersive image. In this virtual environment, students can have a realistic visit that immerses them in the photographed scene and allows them to move about in the entire space. They can navigate in any direction, up-down, left-right, close and distant, along either the vertical or the horizontal plane and anywhere in between. Therefore, on a virtual visit to the Capitol Rotunda students can see the ceiling, the floor, the architecture and all of the paintings on the walls. Although the images are mere stills, students move around freely inside visual space that seems identical to video. They are fully immersed in the environment.
Development and Use of 360° by 360° Images

For educators, 360° by 360° technology offers maximum field of view within a single immersive image. Many learning environments have important information above and below the typical horizon. Now the full scene can be documented and presented. These spatial arenas are easy to use and navigate. Using such images requires active involvement by the student in order to explore, find, and zoom into the important visual content. Because they are made up of two standard JPEG images, immersive images are low memory (50 to 400 kilobytes) and faster to serve from the Web or use in presentations. These 360° by 360° immersive images are relatively easy to create and have been photographed and assembled by educators for the classroom as well as professional photographers for commercial uses.

Several types of virtual reality software support the development of 360° by 360° still images, usually by overlapping flat stills seaming them together. A newer technology has been developed by Internet Pictures (www.ipix.com) which allows the user to create 360° by 360° still images by combining two 180° digital still photographs. They can be used alone or in combination with other digital media such as audio or video. With the same amount of training required to use the other virtual reality development programs, teachers and students can develop this type of content. They take the two 180° digital still photographs and seam them together to create the 360° by 360° immersive sphere using iPIX software.

Creating the 360° by 360° image involves first taking two 180° photographs of the exact halves of the scene that will become the immersive image. A 180° fisheye lens on a digital camera is used to capture each hemisphere. A tripod with a special rotator cuff is used to control the exact angle of rotation of the camera to facilitate photographing the two halves precisely. The user simply takes the first 180° image then rotates the camera exactly 180° around to capture the other half of the scene. Nikon has developed a 185° fisheye lens that allows the user a little (ten degree) overlap at the seams so that when the halves are assembled in the computer, adjustments can be made for the best fit at the seams. The second part of the process is downloading the two 180° images to the computer to bring the images together. At this point any imperfections need to be removed with image editing software such as PhotoShop, Photo Elements or Paintbrush. The final step consists of bringing the two hemispheres together in a 360° by 360° spherical immersive scene. iPIX Wizard software is used to align the edges of the two halves, seam them together and remove or compensate for the minor distortion that occurs in this type of spherical image. QuickTime VR and an iPIX plug-in support the showing of these images on Macintosh and PC Platforms. The resulting immersive image can be viewed in any direction by moving a cursor inside the image or using the navigation bar.

Curriculum Applications

When immersive images are used as part of a curriculum they generate interest and provide a simulated experience of “actual reality.” Students are actively engaged researchers. We use teacher generated and professionally developed 360° immersive images. We assemble the lesson components, including text, images and links within a web page, or embedded in a slide show program such as PowerPoint. An inquiry-based approach to learning sets the context and provides the initiative. The lesson begins by asking a good guiding question such as: “What were the threats to independence?” As part of the lesson, students travel to distant or inaccessible places and explore the situation as a 360° virtual scene. They achieve a new awareness for the actual events, the locations, the times, and how they fit together. Simultaneously, they gather relevant information for the development of their projects. Curriculum examples showing the use of these images in standards-aligned science and social studies lessons will be presented and disseminated on our web site at www.sfsu.edu/~teachers.
Preparing Teachers to use Modeling and Visualization in Science and Mathematics

Lisa Bievenue, NCSA, University of Illinois, US
Sharon Derry, University of Wisconsin - Madison, US
Marcia Linn, University of California - Berkeley, US
Mary Ellen Verona, Maryland Virtual High School, US

This panel will report on the Workshop to Integrate Computer-based Modeling and Scientific Visualization into K-12 Teacher Education Programs (October, 2000). The National Science Foundation and the Department of Education's Preparing Tomorrow's Teachers to Use Technology (PT3) program co-funded this national meeting of educational researchers, teacher educators, teachers, and scientists to research and develop sustainable strategies to integrate computational modeling and scientific visualization within science and math teacher preparation programs nationwide.

Relation to National Technology and Science Education Standards
Modeling and visualization tools support several areas of the NETS technology standards, especially the sections on technology research tools and technology problem-solving and decision-making tools. Students can use the tools presented in this workshop to process data and report results, and to solve problems and make informed decisions. These tools also support the science curriculum standards, including using technology for scientific inquiry, especially analyzing alternative explanations and models. The AAAS Benchmark science standards also indicate the need for computer-based modeling. The benchmark common themes emphasize connections between seemingly disparate science content. In using and creating computer models, student attention can be focused on similar structures and behavior. For example, a predator prey interaction model and a physical spring model share the oscillation structure. Disruption and resumption of equilibrium can be found in both biological and earth systems. Assimilating an understanding of such structure and behavior leads to acquisition of the schemas of science content which have been shown to distinguish experts from novices. (Chandler, P. & Sweller, J. 1991. Cognitive load theory and the format of instruction, Cognition and Instruction, 8, 293-332.)

Outline of Panel
The Panelists will report on the following goals of the workshop:
- defining the needs and uses of computer-based modeling, scientific visualization tools, and computational methods in science education, and identifying the major barriers to their integration into classroom practice;
- examining and developing strategies for overcoming known barriers to transfer of advanced technology into school environments, including schools of education;
- identifying promising methods of integration into teacher education programs, especially addressing pedagogic models (scaffolding, student inquiry, assessment), professional development opportunities for faculty and strategies for providing faculty with time necessary to restructure courses;
- identifying how national partners can begin to build an infrastructure of technology and knowledge transfer to support those methods of integration; and
- establishing collaborative research relationships among teacher educators, K-12 teachers, scientists, learning scientists, and computational scientists to learn how these tools and methods can best be integrated into teacher education programs.

Qualifications of Presenters
The panelists are co-chairs of the Workshop to Integrate Computer-based Modeling and Scientific Visualization into K-12 Teacher Education Programs.

Lisa Bievenue is the K-12 lead for the EOT-PACI (Education, Outreach, and Training Partnership for Advanced Computational Infrastructure) and Education Program Coordinator at NCSA (National Center
for Supercomputing Applications). Her current research interests include systemic professional development programs to support the use of technology in the classroom, the development of technology tools to support constructivist learning, and web-based courses to support engaged and inquiry-based learning.

Sharon Derry is Professor of Educational Psychology at the University of Wisconsin-Madison. She graduated from the University of Illinois at Urbana-Champaign in 1982, receiving her PhD in Educational Psychology with specialties in both cognition and instruction and quantitative/evaluative methods. Derry is a team leader within the National Institute for Science Education and manages several curriculum and instructional technology projects that focus on individual and collaborative problem solving, critical thinking, literacy, and basic mathematics.

Marcia Linn is Professor of Education at UC Berkeley, Director of the campus-wide Instructional Technology Program, and a member of the AAAS Board. She co-directs the Visualization and Modeling theme team, leads the CILT postdoctoral program, and coordinates the involvement of Berkeley's Program in Education in Mathematics, Science, and Technology in the R&D and research training components of CILT. Her research interests include gender and science, the development of scientific understanding through a "scaffolded knowledge integration" framework for instruction and assessment, and innovative applications of Internet resources to improve science learning (KIE and WISE).

Mary Ellen Verona has been the project director of the Maryland Virtual High School (MVHS) since 1994, and is currently Principal Investigator of the MVHS CoreModels Project, funded by the NSF REPP program. She has taught science, mathematics and computer science on the k12 level for over fifteen years, most recently at the Montgomery Blair Mathematics, Science, and Computer Science Magnet Program. Currently ABD in the climate dynamics strand of the Computational Science and Informatics program at George Mason University, she has a bachelors degree in physics and masters degrees in computer science and mathematics education.
Consortium Building: The Northern Arizona University Teaching And Learning With Technology PT3 Project

Michael Blocher, PhD – NAU – USA -- Michael.Blocher@nau.edu
Patty Horn, Ph.D. Arizona K-12 Center – USA – Patty.Horn@nau.edu
Sherry Markel, Ph.D. – NAU – USA – Sherry.Markel@nau.edu
Ann Batchelder, Ph.D. – NAU – USA – Ann.Batchelder@nau.edu
Greg Sherman, Ph.D. – NAU – USA Greg.Sherman@nau.edu

Abstract

Northern Arizona University's (NAU) PT3 Grant is a consortium of individuals from very unique organizations that provide specific expertise to handle the collaboration among all state colleges and universities, Arizona K-12 schools (AZ-K12 Center), the Governor's Office, and the Arizona Department of Education. Building a consortium of this nature is, although extremely complex and challenging, tremendously important and rewarding in fulfilling the goals of the grant—especially in light of possible changing federal educational funding policies. Building and maintaining good working consortia is essential in the success of any project, but especially for PT3 projects. This paper describes the organizational structure and provides examples of how each party plays a pivotal role in the success of this PT3 endeavor.

PT3 Design

The NAU PT3 project is designed to support: a) the training of its education college faculty to model and teach the use of technology; b) the redesign of its teacher preparation curriculum to include technology integration; c) the redesign of its distance learning teacher preparation program for pre-service teachers in 34 remote sites to include on-site mentoring for integration of technology; d) the development of a culturally sensitive mentoring model for use with Arizona's minority students and teachers; and e) the development of a Technology Integration Best Practices Clearinghouse including electronic, print, video, and audio resources available to schools and colleges statewide. To do so, each component is led by a Principal Investigator with specialties in their specific area—Dr. P. Horn, director of The AZ-K12 Center provides organizational leadership, Dr. S. Markel, Associate Professor of Instructional Leadership provides leadership in the redesign of education methods curriculum, Dr. A. Batchelder, Associate Professor of Instructional Leadership will coordinate the design and implementation of a school-based technology integration mentoring model piloted with pre-service teachers on the Navajo Reservation, and Dr. J. M. Blocher, Assistant Professor of Educational Technology provides leadership for technology integration and faculty support throughout the project.

Roles

Although this PT3 project, like many others, is designed to provide faculty and cooperating teacher workshops, the primary focus for the NAU PT3 project is to provide support for and collaboration between education methods faculty in the redesign of the teacher preparation curriculum to include technology integration and thereby model and teach the use of technology. Faculty are supported in a variety of ways. Most importantly they are supported with the help of a technology liaison. The role of the technology liaison is to coordinate and communicate pedagogical needs of the individual faculty to the project instructional designer who will help in the re-design, development and implementation of technology-supported curriculum. Furthermore, the technology liaison will work closely with the faculty and the instructional designer in making suggestions and the development of online media and instructional systems that will support both campus-based and distance delivered courses. Together the technology...
liaison and instructional designer form a knowledgeable team that design and develop pedagogically sound technology integration solutions.

Probably the most unique organization and role is that of the AZ-K-12 Center because of its distinctive mission to improve the quality of K-12 teaching and learning in Arizona classrooms. On its inception, Governor Jane Dee Hull called for the creation of the Center and through the state of Arizona committed $2 Million to support training and re-tooling of teacher skills based on best practices. As part of their mission, the AZ-K12 Center provides a clearinghouse that fosters communication and shares knowledge and information throughout the state. However, one of the most unique roles the Center plays is to build consortia between state governing and funding entities and other Arizona universities in their efforts of preparing future teachers. In this pivotal role, Dr. Horn acts as a liaison between a variety of state decision makers. For example, Dr. Horn meets regularly with the state's law makers, including the Arizona State Superintendent of Schools, and has other collaborative projects with universities and colleges such as: Northern Arizona University, Arizona State University, Arizona State University West, Grand Canyon College, Central Arizona College, to mention a few.

Northern Arizona University also has a unique role in that its mission is to provide educational opportunities to rural and underserved populations within the state. For example, many of the students are located in vastly remote areas, and access to course work is often delivered to remote sites via Instructional TV courses, Web-based courses or even site based. This presents challenges for cooperating teachers trying to integrate technology where support and training can often be limited. To address these issues, an alliance has been established between Educational Technology and the Instructional Leadership to provide technology training and support along with mentor training and support for the cooperating teachers. Through both on-campus workshops and site-based visits, cooperating teachers receive mentor and technology training to be supported in their expansion of modeling technology integration for their student teachers. For example, Dr. Markel provides expertise and leadership with the methods faculty. Dr. Batchelder provides expertise and will provide training on building good mentors. Dr. Blocher provides expertise and leadership in the area of Educational Technology, support for faculty, and supervision for the additional technology support personnel – the technology liaison and instructional designer. All members are working closely together to design training and support materials for both the campus-based methods faculty and cooperating teachers of our students. With these two foci, the students of our pre-service teacher preparation program are provided good models of technology integration while taking course work as well as while they student teach.
Evaluation: Challenges in Measuring a Moving Target

Abstract: Learning Through CyberApprenticeship (LTCA) is a PT3 implementation grant conceptualized as a forum for connecting preservice teachers with veterans in the field. Federal funds allowed for establishment of a system through which preservice teachers could work directly with technologically skilled teachers (TMTs) to create projects for immediate classroom use. But more interesting evaluatively is the metamorphosis of the course preservice teachers must complete to earn their Level 1 (preliminary) credential. Through comprehensive and well-structured evaluation — and our own willingness to change course as circumstances dictate — we have been able to capture students’ pedagogical growth (rather than their “skill” with isolated features and functions), camaraderie among the instructional team, and attitudinal changes that portend how teachers may use technology to meet the many mandates for which they’re increasingly held accountable.

Learning Through CyberApprenticeship (or LTCA) was conceptualized as a forum for connecting preservice teachers with veterans in the field. Federal funds allowed for establishment of a system through which preservice teachers could work directly with technologically skilled teachers (TMTs) in the field to create projects for immediate classroom use. The process itself is relatively straightforward. Project ideas are generated at the start of each semester, during one or more colloquia to which TMTs and education faculty (methods instructors as well as disciplinary specialists) are invited. All projects adhere to multiple criteria sets, ensuring that student experiences are relatively equivalent and that grading or scoring is as equitable as possible.

Projects are showcased at the close of each semester and may include activities, lessons, or larger units. Exemplary projects become part of an online library (see, for example: http://edweb.sdsu.edu/ltca/spgr01/projects.htm) for electronic distribution … “tracked” via a sophisticated management system.

In point of fact, however, much of our effort has gone into ongoing revision of the one-semester course preservice teachers must complete prior to their earning a preliminary (or Level 1) California teaching credential (http://edweb.sdsu.edu/Courses/EDTEC470/). The State’s position is that teachers must come to the classroom with basic technology proficiencies/competence.

EdTec 470 is taught by several instructors (both adjunct and tenured or tenure-track) and in several configurations. It’s structured to be responsive to changes in State requirements … and to be flexibly presented. [In other words, modules do not have to be taught in a prescribed order; they’re designed to stand alone.]
Our SITE 2001 session focused on the overarching “gaps” the project aims to remedy, and they’re important to note once again:

- Placement and modeling
- Integration
- More ideas than time
- Breadth of experience
- Authenticity
- Practicing what we preach

These gaps clearly inform the project’s several overarching outcomes:

- Design/use of an apprenticeship model
- Design of a management system
- Establishment of an online library of exemplary teaching materials
- Twice-yearly colloquia to open lines of communication
- Twice-year showcases to highlight accomplishments
- Refinement of a curricular system

*But as the project reaches maturity, it’s critical to share our lessons learned – many of them with broad applicability to other technology infusion efforts planned or in place.*

The first centers on evaluation, and the many benefits of a comprehensive framework to guide ongoing data gathering and analysis. Our efforts are multifaceted and increasingly attend far more to pedagogical growth (and camaraderie among the instructional team) than to students’ “skills” or “abilities” with isolated features and functions. Among our core data collection strategies are:

- Pre/post student surveys (deployed online; see, [http://www.zoomerang.com/recipient/survey-intro.zgi?ID=5D8XYMQTQC6L&store=1](http://www.zoomerang.com/recipient/survey-intro.zgi?ID=5D8XYMQTQC6L&store=1))
- Limited class observation
- Review of extant data (websites, email/listserv exchanges)
- An instructor survey (see, [http://www.zoomerang.com/recipient/survey.zgi?ID=V0T4EA1Q5X4G&store=1](http://www.zoomerang.com/recipient/survey.zgi?ID=V0T4EA1Q5X4G&store=1))
- Attendance at major project events

Our evaluation design (a hybrid undergirded by Stufflebeam’s four-dimensional CIPP framework but supplemented by elements of the Concerns Based Adoption Model) attends to specific project goals as well as to the several GPRA indicators with which the project aligns. Our techniques are innovative – and an extension of evaluation efforts with which we’ve been associated in the past (Innovation Challenge Grants, Literacy Challenge Grants, Digital High School Initiative).

The second focuses on the challenges (posed as reflective questions) we … and likely all PT3 evaluators … face:

- Who does the project really serve?
- Who are our core stakeholders? Who are our core constituents?
- What are we trying to accomplish?
- Are we simply replacing “old” ways with “new” ones? Are we modeling the benefits of adaptability and flexibility?
- Are we focused on skills or competence? To what extent are we interested in pedagogical impact?
- What are the complexities of measuring long- v. short-term change?

*Specific challenges* facing evaluators include the following:
Challenges related to the proposals themselves. Program goals and outcomes that “wowed” reviewers just a short while ago were (perhaps) overly focused on isolated skills and proficiencies. But as evaluators, we feel considerable pressure to continue/follow through with our original designs – many of them structured to measure growth or change in such areas as: the ability to identify and select hardware features and software functions or the amount or proportion of time students spend using technology. The zeal to be faithful to evaluative tasks comes with a price, the most serious of which is missed opportunities to critically examine the real (and often subtle) innovations that spell real project success.

Terminology challenges. As evaluators with short- and long-term deliverables, we’re constantly wrestling with definitional AND interpretive differences with such ‘basic’ words as pedagogy, competence, and technology.

Challenges that derive from orientation. Are evaluators thinking strategically when assessing the pedagogical implications (strengths, weaknesses, and impacts) of their projects, or is the view tactical only? Do we really have a clear picture of educational reform?

As important, are we as evaluators too process (rather than policy) oriented? Do we really understand our mission? Are evaluators overly willing to fall back on traditional evaluation “models” (frameworks, approaches, orientations) and study designs?
Implementation Strategies for PT3 Grant

Robert Bowe, National-Louis University, US
Daniel Ryan, National-Louis University, US

We are pleased to submit a proposal to SITE because of our continued commitment to the improvement of technology integration in teaching and learning, a goal of our PT3 Implementation Grant. We look forward to sharing the research and applications our grant has provided regarding graduate teacher education. In the 28 months that we have been working on this grant much has been learned and many assumptions have been challenged. This abstract describes our grant and the discourse we wish to generate around various activities and involved in overseeing the grant implementation process.

In the summer of 2000, National-Louis University was awarded a Preparing Tomorrow's Teachers to Use Technology (PT3) grant. Now that this multi-year grant has been running for almost a year with over 100 students in 5 cohort groups, reflections can be made on what decisions helped make this program start (OFF) successfully.

The PT3 program at NLU revolves around three areas. The first is a modified version of the Masters of Arts in Teaching (MAT) program that integrates technology directly into the regular coursework. A Technology Integration Specialist (TIS), working with the regular teacher, models for pre-service teachers how technology is integrated into courses. The second area focuses on developing the technical skills of the NLU faculty so that they can better demonstrate effective use of technology in Education. The third area focuses on developing a learning community online that allows pre-service teachers to tap into the skills and experiences of NLU faculty.

The MAT program has been a key component of NLU's National College of Education which trains over 500 new teachers a year. This makes it the second largest private teacher's college in United States. Since 1886, the National College of Education has been a leader in the field of teacher education and with the new PT3 grant, it continues to expand on the already established program. The Master of Arts in Teaching degree will lead to certification in the state of Illinois. It is designed for individuals with undergraduate degrees in fields other than education.

The key difference in the MAT program is the integration of technology, which is the prime focus of the PT3 grant program. NLU has kept the program relatively the same except that along with the faculty advisor working and in some cases, teaching the students, there is also a TIS who assists in technology integration which is a multi-layered role. The TIS is responsible for introducing students to the basic workings of the laptop computer given to each student at the start of the coursework. By interweaving computer basics into many of the required courses, students meet the requirements of yet another course. Another role of the TIS is to work with NLU instructors in designing lessons with the instructors that take advantage of the students' developing technology skills. The third role is to suggest improvements and communicate problems to the entire PT3 staff in order to utilize and take advantage of the grant's resources.

During the handling and exposure of the laptops by the students, certain issues arise that need to be identified and solved. This can take some time, especially when all the students have different experience levels. Through our extensive surveys, we were able to keep records on how much time students spent on content and how much was spent on technical issues. Our TIS was integral in expediting solutions to problems and seeing that future ones are avoided.

Another key difference with the MAT program is an additional faculty position called the Academic Technology Facilitator. This person's role is to oversee the proper functioning of equipment, such as the web site, recurring laptop problems, and purchases. This position also requires active participation in the second area of the grant, faculty development.

When modifying the MAT program to include technology, it was important to consider the needs of the faculty. Many had shown interest in including technology into their lessons but never had the resources to do so. A major part of the grant, therefore, was to provide 16 hours of technology workshops to over 100 faculty members in a three-year period. Having completed a third of this requirement, we have made constant changes, including better web site instruction and more detailed information about Personal Digital Assistants which really spur on active interest in technology. Handheld devices are excellent triggers for getting faculty interested in technology innovations as well.

During the faculty development workshops, one of the greatest outcomes simply is the discussions that are generated. By starting out with a discussion concerning some of the basics of what technology is, other topics spring up and create seemingly endless areas for conversation. These conversations include ideas for lessons that the teachers have wanted to develop, but were unclear on the logistics of how to proceed. In many cases, people were uncertain what software or hardware to use. In other cases, not realizing the amount of time needed to implement a project was another hindrance.
Eventually, after a comfort level is achieved with all participants, other topics are introduced. The focus now turns toward concepts that affect the higher education faculty member. Topics now include copyright and what rights the faculty member has concerning online material; online tools and what advantages and disadvantages they hold; the effects of Hypermedia and how it affects teaching and learning; and finally what are the advantages of building a community online.

This final topic brings us to a third area of NLU's PT3 grant. Through exposure to online tools, like WebCT, both students and faculty have a common bond even though they may be separated by hundreds of miles. Both groups are given access to a common online area that they have received training on. This online area provides them with communication tools such as e-mail, chat rooms, and discussion areas. It is through increased exposure and as our grant progresses, that we can create a rapport between the two groups that is beneficial to all. One of the biggest lessons we have learned, is that even though this community can serve both group's needs, without the leverage of making it a requirement in a specified course, busy students find it difficult fully utilize the online community. During our presentation, we will explain our latest approach to the online community and what new lessons have been learned from its implementation.

It is our intent to examine this implementation grant through the eyes of the staff and administration who see that all implement the process successfully. Since June of 2000 this grant has offered insights into prior assumptions, newfound discoveries and successes regarding the various ideologies inherent in the grant. During the one-hour session at SITE we would like to encourage discourse around several areas, including the realities of what challenges and successes arise out of the grant, what was achieved or not that was scheduled into the plan for the grant, and what are we learning through our reflections. For example, we initially thought that placing a course on-line would offer greater ease of access to many students located in geographically dispersed areas. Initially we found it difficult to get students connected to the Internet and to have confidence in their ability to utilize the on-line resources. Likewise we discovered that the choice of WebCT challenged our university faculty in ways we hadn't anticipated. The work to get the course into an on-line format was daunting for many. Yet there have been many successes, including the completion by all students of the on-line courses offered in the program and the ease in which our faculty now use WebCT.

We feel that a discussion of PT3 projects is vital within the framework of organizations such as SITE. The invaluable resources and ideas within the participant population guide PT3 projects towards new ways of integration and success in meeting project goals. Through a shared discourse around our implementation project we hope to both inform the conference participants who attend and to learn from each other.
Abstract: This paper is a report on the findings of a case study (in-progress) of Technology Fellows at the University of North Texas. The purpose of the “Preparing Tomorrow’s Teachers to use Technology” (PT3) grant program of the Department of Education is to make changes at the university level where the next generation of teachers is being trained. This study looks at how participating in the fellows program impacted individuals, school districts, and universities. Findings indicate that participating in the program has had a positive and far-reaching impact on the Technology Fellows and their schools.

Introduction

Computer technology is forever changing. According to Dyrli & Kinnaman (1995), computer technology greatly empowers teachers, affording the opportunity to make sweeping changes in education. However, technology needs to be used effectively. A popular theme in education today is planning for and integrating technology into the classroom. Teacher training is among the essential elements for technology planning (West, 1994). Access to computer technology as well as peer coaching is an important part in training for technology.

It is important for future teachers and faculty to experience technology hands-on. Training requires a focus on learning as well as a focus on technology, teaching with technology what would normally be taught without technology, as well as changing perceptions of what is important to teach (Boettcher, 1995).

The purpose of the “Preparing Tomorrow’s Teachers to use Technology” (PT3) grant program is to make systemic changes at the university level where the next generation of teachers is being trained. The University of North Texas received three different PT3 grants, one of which was called Millennium II: Bridging the Digital Divide. A key component of that grant was capitalizing on the rich and rare resource available in North Texas: practicing K-12 educators who are already integrating technology into their classrooms. The Technology Integration Fellows program (a part of Millennium II) gathered 14 integration practitioners and encouraged them to pursue higher education degrees while sharing their expertise with current faculty and the next generation of teachers.

The Millennium II consortium proposed implementing seven preservice teacher initiatives in the North Texas area (see Table 1). Technology-infusion activities were designed to continue the expansion of services to meet educator preparation needs of the state and nation. The emphasis for this three-year project was “closing the digital divide,” and the key areas of quantity, quality and equity were addressed in the preparation of technology competent and confident new teachers.
Increasing the quality and quantity of preservice technology integrating educators

<tr>
<td>Establishing technology enhanced academic content courses for preservice teachers</td>
</tr>
<tr>
<td>Establishing “fast track” credentialing for technology aides to be degreed teachers</td>
</tr>
<tr>
<td>Developing Internet-based quality resources for preservice teacher courses</td>
</tr>
<tr>
<td>Recruiting new millennium teacher educators from technology infusing classroom teachers to work as technology fellows in the project</td>
</tr>
</tbody>
</table>

Table 1: Major objectives of the Millennium II consortium

As the saying goes, from the New York islands to the Gulf Stream waters, the technology fellows gathered. Having studied in Indiana, Hawaii, Australia, Georgia, Illinois, and other states and countries, the Technology Fellows that came together brought unique experiences and backgrounds. Working in different states and countries with all age groups from three year olds to octogenarians, the Technology Fellows shared programs such as Flash and amazing equipment like Topocam while teaching web courses and utilizing the VTEL system. Standing on the shoulders of the giants who go before enable all to reach higher. From Dr. Dunn-Rankin and Dr. James Gallager, the master educators who helped to shape Dr. Tandra Taylor-Wood and Dr. Gerald Knezek, the link to educators who forge with other educators is powerfully affecting UNT and other universities, partner schools, and future teachers.

The Study

Technology Fellows were asked to respond to questions concerning applications and programs presented and worked with in class meetings, such as: Flash, Topocam, Creating Web Pages with HTML, Web Netiquette, Integrating the Internet using Email, Mailing Lists, Chat, Discussion Boards, Asynchronous Voice, Video Conferencing, The Classroom Performance System (response system for obtaining immediate feedback from students), Lightspan, Digital Video, & Blackboard. Their responses indicated the use of these programs and applications in their schools, the impact from their use, and possible future uses of technology as a result of being part of the Technology Fellows. Responses so far have been extremely encouraging.

PT3 has helped current faculty to integrate technology into existing courses. Modeling for a new generation of teachers has occurred in diverse departments from Art to Journalism. Each partner school implemented the grant uniquely to meet the needs in the different school districts. The Technology Fellows, working with UNT and independent school districts from San Antonio to Aubrey, integrated technology into teaching and learning. Sometimes sharing with one teacher or one student and sometimes sharing with entire staffs through training groups, the Technology Fellows utilized and implemented different technologies not for the sake of technology but to support curriculum, learning, and related tasks in increasingly efficient and meaningful ways. The strength of the PT3 grant and of the Technology Fellows is in the continuous and permanent network, stronger then wireless or wired. The human connection and experiences across geographical boundaries and varied experiences and linked to the giants who have gone before are intricately woven into tomorrow for the teachers and the learning that is yet to be.

Abstract: The directors of PT3 projects at Washington State University, University of Idaho and Milwaukee Public Schools articulate the participation incentives each of their programs offers teachers. The group also sent a request to PT3 project directors nationwide, asking for descriptions of incentives they were offering their program participants. The various enticements and restrictions used by PT3 projects to motivate faculty of K-12 schools and institutions of higher education are presented and discussed.

Introduction

At last year's (2001) SITE conference, PT3 director Tom Carroll observed that the United States Department of Education's Preparing Tomorrow's Teachers to use Technology (PT3) program had achieved a sufficient scale to drive change: enough programs exist nationally to impact the culture of teacher education. As stated in the welcome message on the PT3 Web site, "PT3 grants support innovative programs to develop technology-proficient educators who are well prepared to meet the needs of 21st century learners." This preparation includes exposure to K-12 teachers and university faculty members who model the behaviors of making good use of innovative technologies in their own professional practice, as well as adhering to new standards of educational technology use (e.g. ISTE's National Educational Technology Standards for students and teachers, 2000). This type of change is often not an easy one to manage, and members of the culture of teacher education must find significant motivation to do so (Perkins, 1985 in Surrey and Land, 2000). A key issue in the success of many PT3 projects is motivating faculty to embrace and experiment with innovative technologies.

The directors of PT3 projects at Washington State University (WSU), University of Idaho (UI) and Milwaukee Public Schools (MPS) have spent part of this past year engaged in discussion about participation incentives each of their programs offers teachers and university faculty and discussed the various strategies used to motivate their constituents to experiment with and adopt innovative educational technologies. The group also sent a request to PT3 project directors nationwide, asking for descriptions of incentives they were offering their program participants. The results of such an examination reveal what technology change agents around the country are doing to promote the adoption of innovative (primarily computer-based) technologies for teaching and learning.

Motivating Change

The Department of Education's PT3 officers work to achieve a change in the culture of education nationally; PT3 grant recipients do the same locally and regionally. As all PT3 participants seek ways to make these changes, questions about what motivates teachers and university faculty to adopt innovative technologies into their professional practice become important ones to answer. As a sufficient scale to drive change is achieved, it is critical that we examine what incentives work best to bring change about.

Factors that may affect an individual's adoption of an innovative practice include: the appeal of the innovation based on externally placed or internally generated pressures to adopt a new practice; the perceived value
of the innovation based on whether a punishment or reward system is in place that offers incentives for adopting new practices; and viability of the innovation based on the resources and/or restraints placed on adoption by the practitioner's work setting. Thus, a person may be successfully encouraged to adopt an innovation if he or she: feels the satisfaction of personal growth or a professional obligation to do so; gains increased prestige (status, promotion) by virtue of the fact that he or she is adopting new practices; or receives added resources such as money, goods, services and/or support that facilitates the adoption of an innovation.

The Milwaukee Public Schools (MPS) PT3 project offers the following incentives to facilitate the adoption of innovative technologies: Stipend based training; “Technology Thursdays for Teachers” and “Talking Teaching on Tuesdays” (in-service sessions); ISTE NETS Curriculum Materials; and access to K12 Teachers as mentors. Other incentives to participate in PT3-related activities include: paid expenses to NECC and the Wisconsin State Technology Conference for teams of IHE, K12 and pre-service teachers; Personal Digital Assistants (PDAs) for participation in training; digital cameras for submission of best practice standards-based instructional plans; door prizes for workshops and meetings; as well as invitations to participate in National Technology Advisory Board activities.

The University of Idaho (UI) PT3 project supports the adoption of innovative technologies among its participants through: training stipends; week-long intensive workshops (in-service sessions) demonstrating integration of skills into the classroom; technical support with hardware and software; instructional support (creating/implementing ideas); Providing necessary software & hardware (on a limited basis). The state of Idaho has a mandatory performance assessment for teaching certification; a motivating factor for many UI project participants is their increased ability to demonstrate competence on the Idaho Technology Performance Assessment (ITPA).

Washington State University’s (WSU) PT3 project offers incentives to facilitate the adoption of innovative technologies that include: funding for pre-service teachers and teacher-education faculty that is linked to the awardees’ demonstration of knowledge of NETST and NETSS; “Geek Speaks” – one-hour in-service sessions for faculty and staff; “Geek Week” – a week of workshops and discussion sessions designed to support the development of technology skills (Brown, 2001); technology assistance, hardware and software to support teaching and learning.

In June of 2001, the following message went out to the PT3 listserv, which consists of project directors and coordinators nationwide. The message included the following request:

... we'd like to gather as much information as we can about what incentives different PT3 projects have been offering to faculty members in order to get them to participate in PT3-related activities. A brief reply to this message, offering a few words on what kinds of participation incentives you're providing would help us out immeasurably.

Twenty-three project directors and/or coordinators responded to the message with answers that ranged from a few sentences to lengthy descriptions of what individual projects were doing to motivate their constituents. A preliminary examination of the data using a simple coding scheme (essentially generating a list of topics by reading through the messages looking for common ideas) revealed eleven incentive types: Equipment (10); Support (9); Travel Funds (5); Release Time (4); Required Training (4); Voluntary Training Sessions (4); Social Support/Community Building (3); Food (2); Event Hosting (2); Competency Requirements (2); and Promotion & Tenure Documentation (1). These eleven incentive types echo the activities of MPS, UI and WSU.

With examples from a total of 26 major institutions involved in the process of fostering the development of technology-proficient educators, it is possible to develop a preliminary classification system of the incentives currently used to facilitate change in this area. The most significant, binary distinction among the various incentives is between positively and negatively oriented incentives. Three of the authors have referred to these as “carrots” and “whips” in a presentation to PT3 directors (Brown, Davis and Onarheim, 2001). The carrots offer an enhancement (e.g. release time, funding); the whips offer the ability to maintain one’s professional status without enhancement (e.g. competency requirements, promotion and tenure documentation). As one might suspect, the number of carrots is far greater than the number of whips. The “whips” are not harsh reprimands either, they are, for lack of a better term, “institutional rewards” – a means of facilitating technological proficiency in a way that is easily documented; for this reason, we recommend referring to them as “velvet whips” because, although they are not professional enhancements in terms of receiving something extra that others may not have, they are not intended to cause pain or take anything away from one’s professional resources (this point might be argued in terms of denial of promotion, but the authors suggest the term “velvet whips” regardless of this argument).
Discussion and Recommendations

The findings and suggestions articulated here are preliminary and require a great deal more consideration before adopting them for practical (or even theoretical) purposes. However, the basic premise, based on the authors' experiences as directors of projects intended to promote the integration of innovative technologies into teaching and learning and the information provided by a significant number of other directors of similar projects, seems sound and reasonable. In order to promote change, organizations must offer incentives of some type. In the case of the PT3 projects, incentives range from outright rewards (carrots) to vague threats (velvet whips).

Mehlinger and Powers (2002) recommend nine steps for successful technology implementation. Their third step: “Provide Leadership for Technology” includes a recommendation to, “create incentives to influence the way faculty and staff use their energies” (p. 291). In creating these incentives, it is the authors’ hope that the types of incentives described in this paper might serve as a guide.

Abstract:
Most grant applications seek proposals that make a serious effort to sustain the impact of the grant beyond the funding period. How is it possible to fulfill requirements for sustainability at budget-strapped institutions of higher learning? In writing the proposal and implementing a $1.7 million PT3 grant (Preparing Tomorrow's Teachers to use Technology) from the U.S. Department of Education, three public universities in Western Pennsylvania have tried to build longevity into the grant itself. Strategies include uses of matching funds, collaboration with permanent staff, types of training and support during the grant, development of instructional materials, using incentives to promote changes in syllabi, and placing grant offices and activities within permanent organizations. In addition, several institutional factors, outside pressures for change, and serendipitous events will also prolong the influence of the grant, enabling and motivating faculty to continue to use and explore new technology in teaching after the grant.

Problem Statement and Background
Most grant RFP's seek proposals that include a serious effort to sustain the impact of the grant beyond the life of the grant and details about how this will be accomplished. To take just one example, the application for Preparing Tomorrow's Teachers to use Technology (PT3) specifically states: "The consortium should have a strong capacity to sustain the program innovation after the grant ends.” (U.S. Department of Education, 2000) How is it possible to fulfill such requirements for sustainability at budget-strapped institutions of higher learning?

"Preparing Teachers for the Digital Age: Implementing a Dynamic Model of Pedagogical Change" is a project funded by a $1.7 million PT3 grant from the U.S. Department of Education. The proposal was written by the ADEPTT Consortium (Advancing the Development of Educators in Pennsylvania through Technology Training), composed of three public universities in rural areas of Western Pennsylvania – Indiana, Clarion and Edinboro Universities of Pennsylvania. Our overall goal is to infuse technology into the pre-service teachers’ core curriculum and several teacher education programs. Three of the major objectives are: 1) Instructional Technology will be moved from the periphery to the core of our curriculum. 2) Future teachers will apply and integrate Instructional Technology into the teaching/learning process. 3) Additional faculty, instructional designers, and technical support staff will assist with the transition, providing professional development opportunities and support for faculty. Technology infusion at our institutions will have a significant impact, for together we graduate some 1500 future teachers per year. These universities provide excellent faculty-student ratios but have limited support staff and budgets. Both faculty and non-managerial staff are unionized.
In writing the proposal and implementing the grant, we have made an effort to sustain the impact of PT3 well beyond the life of the grant. In other words, we have tried to build longevity into the grant itself. Our strategies include the uses we made of matching funds, collaboration with permanent IT staff and university administration, the types of training and support offered during the grant, the development of instructional materials, using incentives to promote changes in syllabi, and placing grant offices and grant activities within permanent structures in our own and other institutions. In addition, several institutional factors, outside pressures for change, and serendipitous events will also prolong the influence of the grant, empowering and motivating faculty to continue to use and explore new technology in teaching after the grant-funded personnel and incentives are gone.

Strategies

Uses of Matching Funds

Matching funds can be structured to extend the impact of the grant beyond its funding period. In many cases, we have taken advantage of changes the university or College of Education was already planning. For example, one of the goals we built into the grant - to enhance our technological infrastructure to support project initiatives - is helping to achieve a measure of permanence. Since PT3 implementation grants do not fund equipment and infrastructure, we are achieving this goal through university and college match. Upgrades to labs and computers were performed as promised (at Edinboro an entirely new technology center opened); by Year Two of the grant, all three campuses had completed their wiring programs; campus networks were expanded and extended to all faculty and students, and student and/or course directories were created or expanded; training in course authoring systems began or intensified; and faculty are involved in technology planning at multiple levels of their institutions. At IUP, web sites began to be migrated from the VMS server to NT servers that are user-friendlier, and the university adopted standard web editors; the majority of faculty switched to GUI email; there has been greater desktop and lab standardization and a university-wide 3-year replacement cycle for faculty computers; a university-wide student help desk and faculty help desk have been created. Infrastructure improvements are continuing in the final year of the grant, in part propelled by grant initiatives. For example, the IUP College of Education purchased a server dedicated to housing student electronic portfolios, which have been a focus of both college and grant activities, and is converting a faculty lab to a Portfolio Studio to assist both faculty and students with electronic portfolios and other technology projects. The PT3 grant monitored institutional improvements, modifying training and support for faculty as needed, pointing out changes that made it easier to use technology in teaching, and taking advantage of the improvements to promote the goals of the grant. Improvements in infrastructure and planning mechanisms will extend the impact of the grant beyond its formal conclusion by assuring the quality of the computing resources available to faculty and input from faculty that have begun to use technology in teaching.

Grant-funded personnel have been an undeniable factor in the success of the grant. They have made it possible to expand and customize faculty training specifically for teacher preparation faculty. They have co-taught classes, modeling to faculty how technology can be taught and integrated directly in their courses, rather than in isolation. They have also taught workshops, developed instructional materials, and provided individual consultation and support.

In the area of personnel, however, the universities also committed match. University and college commitments to create or revise permanent technology support positions guarantee that, even when grant personnel are gone, the support available to faculty will still be better than it was before the grant. Both Clarion and Edinboro added instructional designers to their staff with the intention of switching them to university funding when PT3 ends. The IUP College of Education upgraded a technical support position to that of Assistant Dean of Technology, adding faculty training duties. This individual will pick up some of the work now done by grant-funded faculty and student workers. As mentioned above, the College is also redefining the mission of its small Incubator lab. Originally intended for one-on-one help and project development for College of Education faculty, the lab began to permit teacher preparation faculty from other IUP colleges to use it as well. The lab experienced declining utilization, however, as more equipment (e.g., printers, scanners) became available in individual faculty and department offices. So it will now be renamed the "Portfolio Studio" and give both faculty and students support in developing electronic portfolios. On the university level, IUP added an
academic user services coordinator. She began a university wide faculty training program modeled on workshops originally offered by the ADEPTT grant, which concluded in 2001, and implemented a university faculty help desk.

Collaboration

PT3 has collaborated with permanent IT staff and committees on training, services and planning. By working together, we avoid duplication and provide more services than we could separately. For example, PT3 cosponsored many workshops with the Assistant Dean of Technology in the College. In addition, two PT3 faculty sit on the College of Education’s Technology Committee, a technology planning body, and one sits on ACPAC, the Academic Computing Policy Advisory Committee of the university; they help shape policy, and the permanent faculty member that sits on both committees will have continued influence after the grant. PT3 staff and the Assistant Dean approached the university technology services about sharing storage of electronic portfolios in their first stage of development. Since portfolios are initially created in a technology course required for admission to teacher preparation, instructors can make use of the new, university-wide course directories at this early stage. Taking advantage of a university service reduces by more than 250 per semester the number of students for whom the college must manage network security and makes the long-term management of portfolios more feasible. Collaboration keeps regular IT staff informed about uses of technology in teaching, gives them a role in achieving the goals of the grant, and keeps PT3 abreast of impending changes. The grant also provided some professional development for regular IT staff, with similar effects. Since our ability to add staff is extremely limited, it is essential that existing employees understand and buy into the implementation of grant goals both during and after the grant.

But prospects are not entirely rosy for continuing infrastructure and personnel improvements after the grant. As noted in the introduction, we belong to the State System of Higher Education, which provides limited operating budgets and a strict cap on personnel FTE. This is one reason why the grant has had such a big impact on our universities — it has supplemented meager support resources. The budget situation in the state of Pennsylvania declined with the economy in the year 2001, especially since September 11. SSHE universities have been advised to expect little new funding in the next fiscal year. Pennsylvania State University (though not a member of the state owned State System of Higher Education, PSU is state affiliated) was actually obliged to return some of its state funding for the current fiscal year. So the amount of technology improvements at our institutions can be expected to decrease in the immediate future. In Year 3, for example, IUP honored the three-year replacement cycle but reduced the amount of money made available for each replacement computer. (Some colleges and faculty were able to supplement that amount from other sources in order to get precisely the kind of computer they desired, however.) When a recently hired instructional designer decided to leave Clarion, the university was unable to complete its search for a replacement before a hiring freeze was imposed.

Types of Training and Support

Training now offered by the grant will not continue, but we structured our training in ways that, we hope, will prolong its impact. For example, by co-teaching classes, PT3 personnel not only provided training for faculty and their students but also modeled how faculty might introduce the technology in their courses. During the final semesters of the grant, we are weaning faculty from our support by having them assume increasing responsibility for technology-enhanced lessons. Another example is our cosponsoring training with regular IT staff, which will help shape the training they offer after the grant. In addition, the grant produced materials, templates, videotapes of workshops, and workshop outlines that faculty and IT staff can continue to use for as long as they are relevant. Final editions are being posted on the web, and the workshop videotapes can be borrowed from a departmental library. Production of a CD on creating electronic portfolios is getting under way, which will support new or diffident faculty and can even be distributed to students after PT3 trainers are gone. Taking a cue from Indiana University and Purdue University at Indianapolis, we are publishing a collection of technology success stories both to document grant accomplishments and to model what faculty can do. Finally, the grant co-directors encouraged faculty that wished to present on grant results to do so at conferences which publish proceedings so that they will live on after the grant.
Incentives: Carrots and Sticks

The grant provided incentives for faculty to modify course syllabi to reflect their increasing use of technology, and at the start of Year 3, more than 80 modifications to syllabi had been submitted. Most of the incentives will disappear after the grant, but we do not expect faculty to remove the technology from their syllabi. Since they were in control of the changes, most chose technologies that were relevant to their courses and that were within their abilities. Changes in course syllabi ensure that our support will have a greater impact than will mere attendance at workshops. The ideal would be to change the official department syllabus or course designation, but at some institutions the approval process itself can take years. In our consortium only Edinboro, which had already started the process, designated special “T courses” or technology enhanced courses that will remain on the books for a long time to come. Otherwise, we relied upon providing incentives and help in revising individual faculty syllabi. It has been important to attach the incentives to the specific outcomes that we promised in the grant. Hence, we offer incentives not only for attending workshops but also for submitting syllabi revised to incorporate technology, for team projects that accomplish the same, and for minigrants to support technology use in courses. Many faculty members used their stipends to purchase software and peripheral devices that further supported the integration of technology in teaching. With revised syllabi and the technology needed to implement them in their hands, faculty will be more likely to continue to teach with technology and teach their students to do the same.

Although grant incentives have been successful, they are not the only motivation for increasing the use of technology in teaching. All three universities have either just completed or are preparing for NCATE review (National Council for the Accreditation of Teacher Education). The number of faculty participating in PT3 workshops or requesting class assistance surged when the IUP College of Education, beginning preparation for NCATE review, mandated that students start an electronic portfolio for admission into teacher education programs and complete it for graduation. Suddenly the technology needed to create portfolios became relevant and urgent to both faculty and students. Although NCATE does not require that portfolios be electronic, the College has implemented it in this way because, in a large teacher education program, electronic portfolios are the easiest to archive and make available for review. This external pressure from NCATE will continue, and so we can count on continued measures to implement electronic portfolios in all teacher preparation courses.

To facilitate technology infusion in general, and electronic portfolio development in particular, the IUP College of Education has moved its traditional technology course to the freshman level and is requiring completion prior to admission to teacher education. This move will ensure that students will arrive in teacher preparation courses better prepared in technology. Faculty can spend less time teaching technology and more time guiding students toward appropriate documentation for their portfolios and toward applications of technology to teaching. Thus, the learning curve for faculty can be reduced even while technology infusion is increased.

Some faculty members who gained an interest in technology through PT3 are likely to continue simply because they are so enthusiastic and have even assumed new technology roles. For example, one faculty member collaborated with us on a PT3 workshop and publication and became involved in a second PT3 grant. Another has started to serve on a technology committee within a professional organization in her discipline. A third changed the textbook she is writing to incorporate technology in it – this will have a lasting impact.

Placement of Grant Activities – The Case of Teaching Circles

Teaching circles are another strategy to accomplish the PT3 goal of providing professional support. They have been implemented in different ways at the three member campuses, but one thing they all have in common is a chance of continuing beyond the end of the grant. Some of the teaching circles consist of small reflective practice groups on technology; these circles will continue after the grant wherever the members truly become peer mentors and develop ongoing collegial relationships (Hutchings, 1996).

Where grant programs are located can make a critical difference in their impact and longevity. At IUP, the teaching circle model has been blended into a preexisting program of the local intermediate unit called Academic Alliances. In this program, K12 teachers and faculty are invited to an early evening program and
opportunity to share experiences over supper. With PT3 help, a new Teaching with Technology Alliance was created, and preservice students were invited to join faculty and teachers. With attendance ranging from 25 to 78, this Alliance is likely to receive continued support from the intermediate unit after the grant. It can be expected to continue because it has been successful, because it is housed in a permanent organization, and because a partial funding mechanism independent of the grant is already in place. (Our experience with previous grants suggests that the placement of the entire grant both physically and within the organizational structure in a permanent office or organization increases and prolongs its impact. For example, grant money that helps fuel the work of an ongoing technology or instructional design center is likely to have a more permanent effect.)

Conclusion

This paper has demonstrated how grant activities, incentives, organization, and collaborative relationships with other parts of our institutions can be fashioned in order to prolong the effect of the grant. Nonetheless, resources will be lost when the grant ends. Some grant RFP's frown on the argument that their grant will be sustained by securing additional grants. But at many institutions of higher education, an entrepreneurial and collaborative spirit is in fact essential to keep funds flowing for innovation and change. Budgets are tight and becoming tighter. Grant agencies and donors should consider the capacity to attract additional funds and implement new, related programs a real plus. Our consortium was able to leverage its initial $500,000 ADEPTT grant from Bell Atlantic and Microsoft into a $1.7 million PT3 grant, a $234,000 TLCF grant (Technology Literacy Challenge Fund) from PDE (Pennsylvania Department of Education) to United School District (IUP was the sub-recipient), a $100,000 PDE grant to Clarion University, and a $50,000 CAPE grant (Community of Agile Partners in Education) to the consortium. In so doing, IUP has come to recognize the need to make administrative changes that increase our capacity to facilitate grant writing and implementation, contracts, and fund raising. Such changes will make it possible to embark on more projects of national importance that create a lasting impact.

Abstract: Michigan's Consortium for Outstanding Achievement in Teaching with Technology (COATT) was formed in 1999. From an initial membership of 10 higher education institutions, the consortium has grown to include 16 private and public teacher education institutions and 9 K-12 organizations. COATT was awarded a PT3 catalyst grant in 2001. This paper presents details of the COATT PT3 activities. COATT’s PT3 activities include providing leadership for the revision of the state’s existing technology standards for entry-level teachers, extending those standards to in-service teachers and administrators, and the delivery of intensive technology training workshops. A full paper that includes more detail may be found at http://www.coatt.org/conferences/site2002/fullpaper.pdf.

In 1999, United States Senator Carl Levin, recognizing an opportunity for Michigan to improve its preparation of new teachers to use technology, spearheaded the creation of a new organization of teacher education and K-12 institutions (McManus, Rubio, Lenze, Charles & Hoffman, 2001). This organization, the Consortium for Outstanding Achievement in Teaching with Technology (COATT), has taken a leadership role in encouraging student teachers to reflect upon and continuously improve their use of technology in education. By setting a high standard, establishing a means of consistently assessing and recognizing accomplishment of the standard, and rewarding outstanding achievement, COATT has both unified the efforts of educational institutions and motivated pre-service and in-service teachers across the state to move in new directions in their classroom practice.

In July 2001, COATT was awarded a grant from the United States Department of Education’s PT3 (Preparing Tomorrow’s Teachers to Use Technology) initiative. The grant, Developing an Ecology for Preparing Tomorrow’s Teachers to Use Technology, is administered by Spring Arbor University with substantive subcontracts at Merit Network, Michigan State University, and Eastern Michigan University. Funds from this grant will allow the organization to reach out to more pre-service teachers, increasing the scale of our
activities. The added resources will also allow us to better support portfolio creation through summer workshops, enhanced infrastructure, and increased on-line resources.

COATT’s PT3 Activities
Setting Standards
*Pre-service technology integration standards*

As part of the PT3 grant, COATT is leading an effort to update the state’s technology standard for pre-service teachers to bring an earlier version into alignment with the ISTE National Technology Standards for Teachers (International Society for Technology in Education, 2000). In October 2001 COATT, in cooperation with the Michigan Department of Education, established a committee to draft a revision of the state’s technology standard, known as the Seventh Standard. The draft of the revised standard has been developed and may be viewed as Table 1 at http://www.coatt.org/conferences/site2002/table1.pdf. The Michigan Department of Education hopes to present these revisions to the State Board of Education for formal review in spring 2002. The committee working on the revised standard includes COATT member representatives, educators and administrators from K-12 including representatives from the two major teacher unions, and a facilitator from the Michigan Department of Education.

In reviewing the earlier Seventh Standard, the committee found that the first committee had been ahead of its time, as the original Seventh Standard was more like the 2000 ISTE NETS-T than the 1997 ISTE version. While Michigan’s standard could be continued with some minor modifications, the new committee determined that a rewrite to bring wording in closer alignment with the national standard had advantages for both educators and students. For teacher candidates, similar wording makes it very clear how the state standard is similar to the national standard. The new standard also makes it easier to relate statewide initiatives to national ones, including the ability to readily adopt and modify curricular materials and assessments developed elsewhere. Additional implementation efforts through dissemination of best practices and incentives such as the MCOATT awards will continue in conjunction to encourage excellence in programs and outcomes.

Technology Training Workshops

Student teaching is a critical period in the training of teacher candidates, yet it is often the time when candidates find themselves looking to reduce risk in order to "survive", and are thus in the greatest need of an environment of technological entrepreneurship. The goal of the COATT Technology Training Workshops will be to help teacher preparation institutions partner with school districts to improve the potential for successful use of technology during the student teaching experience. Teams comprised of a student teacher, cooperating teacher, university supervisor or field instructor, and K-12 building technologist will form a “design community” to assist the student teacher in creating effective technology-infused lessons to be implemented during student teaching. The design team and community becomes a support system for the student throughout the design process and student teaching. The workshops will have both face-to-face and online components, extending over a yearlong training cycle.

A pervasive project objective is to build capacity in schools in low-income districts to provide technology-rich student teaching experiences. Low-income districts are defined as those with higher than 60% participation in the Federal School Lunch program. Over the three years of program activities, 30%, 40%, and 50% of the participating school districts will be low-income.

Summer Intensive Workshop

*Face-to-Face Design Community.* The training begins with a five-day summer intensive workshop that will include both training and design activities. Design teams work together to help the teacher candidate develop lesson and unit plans that make exemplary use of technology to achieve learning goals. Each COATT member institution is invited to select at least one design team to become part of the first face-to-face cohort of participants to pilot the initial training cycle. These groups will grow in size during the second and third years to four sets of 20 groups each year. As Consortium members assemble teams, their first priority will be to target
technologically underserved schools, such that a significant number of student teaching classrooms will come from these schools. The first workshop will begin in the summer of 2002.

Teams will develop learning activities that focus on strengthening standards-based practice by engaging members in authentic, problem-based activities aligned to Michigan curriculum and technology standards. Video case scenarios of effective teaching with technology will be incorporated as a basis for study and discussion. The workshop will conclude with presentations by the teacher candidates of a proposal and a thoughtful and workable draft set of lesson plans. This is a unique opportunity for pre-service teachers to enhance their teaching skill, and cooperating teachers to more effectively mentor student teachers by developing a collegial, collaborative relationship prior to their teaching placement.

Subsequent to the live component of the workshop, there will be online follow-up sessions, where the design community will gather to mark progress and continue the creative process. The online follow-up will last for a total of 30 hours per individual in a design group, and will conclude with the viewing of web pages that describe a final set of lesson plans.

**Online Design Community.** Beginning in the fall of 2002, monthly online sessions will be held for 250 teacher candidate/cooperating teacher teams (at least 500 people in all), with additional participation from the K-12 technologists or the faculty supervisors. This training will move the group members from more basic to more advanced understanding. The teams will participate in 10 monthly sessions consisting of two hours each. The curriculum will parallel that of the face-to-face workshop, but will also address any need for development of basic technology skills that is needed to be more inclusive of cooperating teachers districts that are technologically underserved.

**Implementation and Beyond.** The design team cohort groups will continue to meet on a monthly basis during the academic year, when the various teacher candidates undertake their student teaching. An important feature of their online gatherings will be to support the teacher candidates as they implement their teaching, and allow those who teach later to learn from those who go first. The teacher candidates will then be encouraged to submit an MCOATT portfolio for either the spring or summer round of awards, whichever is appropriate. In addition to meeting the requirements of the application, they will be asked to thoughtfully reflect upon and assess their experience as part of the design community. One of our key concerns is sustainability of our efforts, and to that end we are linking up with different State stakeholders to diffuse those efforts as broadly as possible.

**Conclusion**

The Consortium for Outstanding Achievement in Teaching with Technology (COATT) is, in its present form, the result of several years of intense work and close collaboration between entities that in the past have not had the opportunity to work closely together. Through organizational support from member institutions and United States Senator Carl Levin, COATT has created a means by which to encourage student teachers and practicing teachers in Michigan to integrate educational technology into their teaching practice in ways that reflect current thinking on best practices. With the increased capacity made possible by this Federal PT3 grant, COATT will support a larger number of pre-service teachers and the in-service teachers with whom they work.

As COATT moves into the future, we feel strongly that we have set a productive direction based on a solid standards-based foundation, working collaboratively to create a vision that will sustain us through growth and evolution yet to come.

Abstract: The purpose of this research project was to determine the impact of technology professional development on teacher preparation faculty in colleges of education, arts, sciences, and humanities at five universities in north Louisiana. Participants included 10 randomly selected university professors who attended 6 days of technology professional development. A 10 question structured interview was used for data collection. Interview transcripts were analyzed using case analysis and cross-interview analysis. Attending the technology professional development sessions provided professors with ideas, motivation, and the support needed to incorporate technology into their classroom curriculum.

Technology is a pervasive component of modern life. In order to prepare students to live in this highly technical society, they need opportunities to use technology as they explore and learn content area curriculum. To assure that students have these opportunities their teachers must be competent technology users who provide students with technology-rich meaningful learning environments. One way to assure that teachers model effective technology use is by providing them with technology-rich learning environments complete with technology proficient professors in their teacher preparation programs. Teacher preparation faculty in the colleges of arts, sciences, and humanities, many who do not recognize themselves as preparing future teachers, must model the integration of technology and curriculum (Beichner, 1993; White, 1994).

Dusick’s (1998) literature review indicated that faculty members’ use of technology depended on these factors: 1) administrative support, 2) computer availability, 3) resources, 4) support staff, and 5) training in the use of computers. Thompson, Schmidt, and Hadjiyianni (1995) in a three year study examining the infusion of technology into a teacher preparation program identified these essential factors for success: 1) easy access to technology; 2) allowing faculty to become personally comfortable with technology before using it for instructional purposes; 3) having technology integration as a department goal; 4) receiving strong support from the administration; 5) inviting participation in the program; and 6) one-on-one mentoring for faculty.

Faculty Development

Technology professional development is key in moving faculty toward successfully modeling the integration of technology in the preservice classroom. The professional development must incorporate technological and pedagogical components (Bullock & Schomberg, 2000) focusing on how to use technology to improve teaching and learning (Cottrell, 1999). Effective technology staff development requires, among other things, immersion in learning over extended periods of time, active involvement, a community of learners, a focus on the learners’ needs, and time for reflection (McKenzie, 1991). A learning environment based on adult learning theories with proper sequence and structure facilitates communication and learning (Mandefrot, 2001). The workshop facilitators must take into consideration the concerns and
feelings of the participants (Linnell, 1994). They must provide a friendly, comfortable, relaxed setting in which the professional development is viewed by the participants as an opportunity and not as a threat (Mandefrot). Workshop participants need the opportunity to meet and collaborate with others in ways to stimulate their thinking while building on their professional development experiences (Franke, Carpenter, Levi & Fennema, 2001). Learning to use technology and to infuse it into the curriculum in meaningful ways requires ongoing support from a connected community of learners who use technology. A community of learners provides not only the resources and technical support required to use technology but also the confidence to teach with technology (Ginns, McRobbie, & Stein, 1999; Hruskocy et al., 2000).

**Technology Integration in the Classroom**

Miller (1995) sees the current technological revolution as an opportunity to make profound changes in teaching that directly affect students' learning. In order for this to occur, faculty members must reflect on their teaching, master their anxieties, and learn to use technology in order to incorporate it into their teaching. Additionally, three conditions must be met for faculty to integrate technology into their teaching: they must believe that technology is more effective than what they are now using, they must believe that technology will not be disruptive, and they must believe that they have the technical skills and resources to achieve their goals (Zhao & Cziko, 2001). Infusing technology in the classroom requires that professors combine experiences with technology with the curriculum they are teaching. This requires faculty to re-examine what they teach and to change how they teach (Miller, Martineau, & Clark, 2000). Faculty who do not integrate technology in their teaching may find themselves overlooked and left behind as other faculty members revitalize their curriculum and the way it is taught (Baldwin, 1998).

Technology integration by faculty is neither spontaneous nor easy; it takes time and effort. Hord, Rutherford, Huling-Austin, and Hall (1987) developed the Levels of Use (LoU) to measure behaviors associated with the use of an innovation. These seven levels include: 1) non-use, 2) orientation, 3) preparation, 4) mechanical, 5) routine, 6) refinement, and 7) integration. Conversations, informal interviews, and observations can be used to assess levels of use to determine the impact of an innovation on the participants.

**Barriers to Technology Integration**

Barriers to technology integration include organizational ones and individual resistance to using technology (Miller, Martineau, & Clark, 2000). Many universities do not recognize faculty member’s use of technology for tenure and promotion decisions, hence, faculty members forego learning to use and integrate technology as they focus on research and publications which are considered in such decisions (Baldwin, 1998). Some faculty hope to reach emeritus before they are forced to change (Miller, 1995). Teacher preparation faculty members do not infuse technology in their classes in part because they lack professional development opportunities, proper equipment, administrative support, and technical support.

**Methodology**

**Participants and Setting**

The United States Department of Education’s Preparing Tomorrow’s Teachers to Use Technology (PT3) program has provided funding for grants to assist teacher preparation faculty as they learn to integrate technology into their teaching. One of these grants is the Technology in Higher Education | Quality Education for Students and Teachers (T.H.E.|QUEST) which provides intensive technology professional development for teacher preparation faculty at universities in Louisiana. Faculty teams from the universities work together as they develop methods of integrating technology into their curriculum. The purpose of this research project was to determine the impact of T.H.E.|QUEST technology professional development sessions on teacher preparation faculty in colleges of education, arts, sciences, and humanities at five universities in north Louisiana.
Sessions extended over 6 days for 7 hours a day totaling 42 hours and were attended by a total of 49 teacher preparation faculty. The professional development sessions provided extended opportunities for participants to work together as they experimented with a variety of hardware and software and discovered ways to use technology to enhance teaching. These sessions were held in T.HERQEST technology lab housed in the College of Education. For the purpose of this study 2 participants were randomly selected from each of the 6 professional development sessions held over the last 2 years for a total of 12 participants. Two participants were unavailable during the time the interviews were conducted, but participants from all sessions were included in the sample. Participants had been teaching at the university level from 3 to 33 years.

Data Collection

One way to determine the impact of technology professional development on teacher preparation faculty is to conduct structured interviews. Hence, ten interview questions were designed to help assess participants' levels of technology use, whether any changes were made in their teaching as a result of the professional development sessions, how they integrated technology in their teaching, whether they required their students to use technology, and whether they had encountered any barriers when integrating technology in their teaching. The researchers designed the questions, which were then reviewed and revised by a professor knowledgeable of the professional development sessions, but not directly involved in them. The interview questions were pilot tested on one of the session participants who was not among those randomly selected to participate in the study. The structured interviews were conducted in faculty members' offices over a period of three weeks by one of the workshop facilitators. Interviews lasted from 35 to 45 minutes and were conducted at the faculty members' convenience. The interviews were audio taped and transcribed by the researchers.

Data Analysis

When using structured interviews case analysis and cross-interview analysis are both appropriate (Patton, 1999). The transcripts were initially coded for case analysis, which provided vignettes of individual participants from which various patterns, categories, and themes emerged. The participants' responses were then grouped by questions and analyzed. This provided a clearer means of organizing the data and establishing linkages between the interviewees' comments. Initial coding and analysis was conducted independently by each of the researchers, providing triangulation (Patton). Researchers then compared and discussed their coding.

Effective professional development requires that the workshop facilitators establish rapport with the participants in a relaxed, comfortable environment conducive to establishing collaborative relationships among the participants (Mandefrot, 2001). The rapport that is established may prevent some participants from responding to interview questions in a forthright manner. Additionally, some teacher preparation faculty may be reluctant to disclose their limited use of technology. These factors may limit the generalizability of these findings.

Discussion and Interpretations

Interview transcripts were examined to determine if participants had made any changes in their teaching that could be attributed to attending the technology professional development sessions, to find examples of the integration of technology in their teaching, to establish whether or not they required their students to use technology, and to explore any barriers they encountered when using technology.

Changes in Teaching

After attending the sessions faculty members commented that they incorporated more technology in their teaching. During the sessions they discovered ways to integrate a variety of hardware and software in their teaching. The sessions provided them extended opportunities to experiment with software and discover ways to adapt it to their curriculum. Participants reported that they had written grants and
purchased additional hardware and software to use in their teaching. Some reported that the sessions had stimulated them to think about additional ways to use technology and had motivated them to use more technology. Others talked about the changes they had made in their teaching in order to effectively incorporate technology (Miller, Martineau, & Clark, 2000). Participants commented on the importance of modeling the integration of technology in their classes (Beichner, 1993; White, 1994). One change mentioned was that in order to integrate technology they had discovered that they needed to stop talking and give students control of their own learning. One participant commented, “I have to learn to talk less. ... we get very comfortable in talking rather than letting students explore and come to their own conclusions.”

No Changes in Teaching

A few participants reported that they had made no changes in their teaching since attending the technology professional development sessions. However, these participants reported that they had several ideas for using technology in their teaching and then elaborated on ways they could use technology. These faculty members reported using limited amounts of technology in their teaching. For example, two reported having some course materials posted in Blackboard. They did not, however, require their students to access the course materials. Some of these faculty members saw the benefits of technology, but lacked confidence in their ability to effectively use technology. One faculty member did not believe that using technology would be more effective than what was presently being done and believed that using technology would be disruptive (Zhao & Cziko, 2001).

Students’ Use of Technology

Faculty members who reported that they had not made changes in their teaching after attending the technology sessions also stated that they made allowances for students if they did not have access to technology or feel comfortable using technology. Some professors reported providing one-on-one assistance to students to assure that they could successfully complete assignments requiring them to use technology. Other professors simply required students to use technology to complete assignments and assumed the students either had the requisite skills or would acquire them in time to finish the assignment. One professor reported putting PowerPoint presentations on the web prior to class meetings and that even though it was not required, most students printed out the presentations and brought them to class to use as an outline while taking notes. Faculty members reported that students completed a variety of projects using different software packages, such as Microsoft Office, Inspiration, Netscape Composer, HyperStudio, iMovie, KidPix, and Blackboard.

Barriers to Using Technology

Barriers to using technology included lack of hardware and software and limited access to the hardware and the software that was available. Several participants noted the lack of technical support available on their campuses. Technology proficient professors reported being overwhelmed by requests to provide support for other faculty members, which often interfered with their own work. Several reported their biggest barrier was the lack of time to learn to use the available technology and to discover ways to integrate technology in their teaching. Some professors reported that not only was administrative support lacking, the administration impeded their efforts to acquire and use technology in their teaching (Dusick, 1998; Thompson, Schmidt, & Hadjiyianni, 1995).

Levels of Technology Use

Interviews with the participants and conversations and observations during professional development sessions were used to determine their Levels of Use (Hord, Rutherford, Huling-Austin, & Hall, 1987). Three participants were at the preparation level; they articulated definite plans for implementing what they learned in the sessions. One participant was at the mechanical level and was in the process of reorganizing her curriculum to make better use of technology. Three participants were at the routine level indicating that they were making few or no changes in their established pattern of use. Three participants were determined to be at the integration level as they actively worked to coordinate the use of
technology with other professors. Participants' comments on changes or lack of changes in their teaching reflected their levels of technology use. For example, participants who had not made changes in their teaching required only limited use of technology from their students and were at the preparation level of use. Overall attending the technology sessions had a positive impact on professors who were above the preparation level of use.

Conclusions

The technology professional development sessions provided participants with time to explore new technologies in a relaxed, comfortable working environment and to collaborate with their peers as they developed ways to integrate technology into their classrooms. This opportunity for extended exploration and collaboration provided participants with the motivation and stimulation to further refine and develop their technology expertise. Results of this research indicate that the technology professional development sessions enhanced professors' use of technology in their teaching to varying degrees depending on their level of use.

Designing Web-Based Modules to Assist Teachers with Teaching Mathematics to Minority Students

By

Carlous Caple, Ed.D.
North Carolina A&T State University

Abstract

Many teachers are faced with the dilemma of how to effectively bridge the gap in teaching minority students. Specifically, teachers are burdened with the content area of mathematics and communicating its concepts effectively.

A number of factors attribute to why minority students may have difficulty learning mathematic concepts. One factor would be that minority students might process information differently from their counterparts. Minority students tend to be concrete cognitive learners and thinkers, where they typically recall information, as opposed to the more analytical/linear learner and thinker, who has a greater ability to problem-solve. Another factor would be the absence of a technological presence either in the classroom and/or at home. The latter is a concern that has been addressed as a part of educational reform.

The design of a web-based mathematics module was developed to address the needs of teachers, and to bridge the gap with minority students and the learning of mathematical concepts. The module was developed to aid teachers in approaching the teaching of math to minority students in an uncommon way. Mathematic concepts focused upon the standards established by the National Council of Teachers of Mathematics. However, the instruction within each module was different from the standard way of teaching mathematics. Each mathematic concept focused upon integrating previously learned concepts such as addition, subtraction, multiplication, and division with new ways of approaching problem-solving skills. The web-based module allowed the learner to approach learning math concepts at his or her own pace. Also, the modules contained feedback during instruction, remedial instruction, and embedded testing to allow the learner to see where their problem areas exist. The teacher was also an integral part of the process. The goal of the web-based module was to aid in the teacher’s classroom delivery of mathematics instruction. Further, the goal of the web-based module was to improve instruction, and change the way that minority students process information. The module was established to aid in smaller classes, where students can interact more closely with teachers, enhance learning, for the benefit of increased time on task. Also, the development of learning activities that takes less time...
to master, and recontextualization, which often results in rapid learning, and allows more
time for mastery of additional material.

The following recommendations were made after piloting the web-based
mathematics module. The first recommendation was to update the module to effectively
reach students who use English as a second language. The second recommendation was
to duplicate the module for use with the National Science Standards. The third and final
recommendation was to introduce the module to in-service and pre-service teachers to
further bridge the gap with instruction for minority students.
Student Teaching Technology Sites: 
Creating Opportunities for Developing Technology-Using Educators

Abstract: Student teaching is the capstone experience in teacher education programs. Schools and departments of education try to place student teachers in classrooms where cooperating teachers model excellent practice and encourage student teachers to develop as innovative young educators. A dilemma arises when colleges try to help student teachers develop skill using technology. There simply are not enough P-12 classrooms where teachers provide good technology-using models. Moreover, for many reasons many cooperating teachers are reluctant to allow student teachers to use new technologies. This paper will present a solution for ensuring that preservice teacher candidates will have rich opportunities to use technology during their student teaching placements. We will describe the process of developing Student Teaching Technology Sites (STTS) and will report on the first semester of implementation.

At the end of September, just a month into student teaching, we were already hearing the rumblings. Cooperating teachers from several of the schools with whom we have long partnered were awed. “Wow! They can do that?” “Can you teach me?” “What will I do when you leave?” Student teachers were heard complaining: “We need more equipment.” “We HAVE to have another digital camera.” “Where can I get another copy of Timeliner?” “You should see the great presentations my fourth graders did!” “This is a great web site to help your kids do research!” The conversations were about teaching, but were peppered with comments and questions involving technology.

The School of Education at St. Bonaventure University was the recipient of a PT³ grant in the fall of 1999. PT³@SBU is a focusing on helping preservice teacher educators become excellent teachers. We are working primarily with elementary education majors as they learn about teaching and about learning but we are infusing all of our courses with technology experiences, exposing preservice teachers to situations where they are learning in technology-supported environments and helping them to design similar learning experiences for children. The foundational beliefs of our project are three:

- Excellent teachers are those who understand how children learn and who know how to plan for and support that learning.
- Technology in education is not important in and of itself; it should support and enhance learning and teaching.
- Learning how to use technology appropriately in the educational setting can only be successful as an integral aspect of learning how to teach in general. We do not teach technology. We teach about children; we teach about teaching; we teach about learning. We help our candidates focus on effective ways of helping children learn.

During the past two years, as we have been working with preservice teachers, we have been helping them use technology as a regular part of their repertoire and we scaffold their experiences as they began to work with children.
in learning environments enhanced by technology. The preservice teachers who were sophomores in 1999—when the PT3 grant was received—are now at the end of their undergraduate program, and ready for their capstone experience: a semester of full-time student teaching. These preservice teachers are the "products" of the curriculum and philosophical changes that have been fundamental to the work supported by PT3. The SBU School of Education faced a dilemma: during the past two years, we had implemented significant curriculum changes focusing on requiring our students to use technology for their own work and in their internships. As we looked at placing them for student teaching, we were concerned about how to ensure that they would be in classrooms where the cooperating P-12 teachers would welcome and encourage the use of technology. We were confident that our candidates could begin to use technology appropriately, but we had to find adequate placements.

The Challenges of Student Teaching: An Administrative View

Student teaching is the capstone experience, the time when candidates finally get to do what they have been learning about. Every program that prepares teachers wants to provide top-notch classroom placements for student teachers, but the challenges can be many. For Schools of Education located in rural areas, one of the most pressing is location. In rural areas, public schools are few and far between. They are often small, offering limited numbers of classrooms with tenured teachers willing and able to act as cooperating teachers. It is imperative that schools close to campus not be overwhelmed, and so in order to provide every student teacher with appropriate placements, candidates often have to travel considerable distances from the University campus—often requiring a 60 to 90 minute commute for the student teachers.

It should be the goal of placement offices to find classrooms with quality teachers "having some combination of the following attributes: pedagogical knowledge, subject area content knowledge, skills and attitudes necessary for effective teaching, strong understanding of human growth and child development, effective communication skills, strong sense of ethics, and capacity for renewal and ongoing learning" (Cobb, Darling-Hammond, & Murangi, 1995). The reality is that this is not always possible. When there are large numbers of student teachers, there is a limit to how "choosy" the placement office can be, and so student teachers are often assigned to classrooms where they will have adequate experiences, but in placements that may be less than ideal.

Another challenge is providing adequate supervision for student teachers, especially in rural areas. Supervisors often have responsibility for a number of student teachers in different schools—often at some distance from each other. Supervisors, consequently, have little freedom to spend extended time with student teachers and rarely can provide the just-in-time supervision that may help a student teacher succeed.

Enter technology—a factor that exacerbates the student teacher placement dilemma. One challenge of preparing technology-using new teachers is that there are currently not enough classrooms where quality, technology-using teachers can model appropriate use of technology to support teaching and learning. The ideal situation would be to place student teachers in classrooms where they are encouraged (or even required) to teach using technology. The CEO Forum argues that, "Wherever possible, student teaching and practicum experiences should be chosen for opportunities that will expose teacher candidates to: best practices in technology integration, a range of technology resources, and the design and delivery of instruction that incorporates technology as a learning and problem-solving tool" (CEO Forum, p. 10). As much as we would like to follow this advice, in many areas, it is still not possible. P-12 teachers who can expose their student teachers to high-quality technology integration remain rare.

The Challenges of Student Teaching: The Student Teacher’s View

Preservice teacher candidates see student teaching as the ultimate experience. Their expectations are high; their anxiety even higher. Student teachers want to prove themselves; they want to try all they have learned about. They want to launch their careers. However, they are generally realistic enough to recognize that there are serious challenges facing them:

- being welcomed into a classroom that is not theirs, with children who have already established allegiances to "the teacher;"
• having the freedom to try things that they have learned about, but that may be new to their cooperating teachers;
• working within an existing learning environment, with resources selected by others;
• and, in the case of technology, being allowed to try to use tools unfamiliar to their cooperating teachers – who often can provide little support and less guidance.

We send our student teachers out with an understanding that they are guests in their host school, and that while they should try to implement as many innovative learning experiences for the children with whom they will work, the student teachers must also cede ultimate decision making about the learning environment to the classroom teacher – the one ultimately responsible for the children’s learning. For example, while student teachers have been encouraged to use technology, it has been difficult to put into place requirements for the use of technology in environments where technology has rarely been used – and in schools where resources (both hardware and software) may be unavailable.

Meeting the Challenges: Our PT³ Response

During the first two years of our grant, the faculty redesigned curriculum, assignments and field experiences for preservice teachers. We created a wide range of opportunities for helping our teacher candidates learn about technology, gain experience using technology, and begin to develop learning experiences and lessons enhanced by technology. Our candidates complete a year-long internship, during which their courses and field experiences are infused with technology. During those internships, many candidates became enthusiastic users of technology, and developed a number of technology-enhanced learning experiences for the students in their internship classes. We wanted to find a way to ensure that they would have opportunities to continue growing and to demonstrate their technology competence during student teaching. Our solution was to invite a number of local elementary schools to become Student Teaching Technology Sites (STTS).

Our idea of an STTS is quite simple and straightforward. We approached a small number of school administrators and asked them if they would like to participate in a program that would help increase technology integration in their classrooms. We assured them that if they participated, we would assign to their schools only student teachers who were ready, willing and becoming able to use technology in their teaching. STTS student teachers would be expected to work with their cooperating teachers to develop technology-enhanced lessons and learning experiences. They would be expected to use technology regularly during their student teaching placement. They would be expected to provide some “backdoor in-service” for their cooperating teachers, helping them learn to use new technologies appropriate for their classrooms.

We approached a number of schools geographically close to our campus. We wanted our STTS schools to be close to campus for three reasons:

1. this would provide incentive for student teachers to apply for placement in those schools;
2. it would allow us to go to the schools more often, providing in-service to the student teachers and the cooperating teachers,
3. student teachers would be able to get back to campus to access technology support before offices closed.

In addition, a number of the schools closest to our campus were reluctant in recent years to host student teachers, and we hoped that the technology emphasis would be incentive for them to become involved again in our program.

We let the administrators know that through the PT³ project, the University would provide all STTS schools with access to:
• a mobile media cart – equipped with a high-end, internet ready laptop computer and a projector, a scanner, a color printer, a zip drive, an electronic microscope and a digital camera;
• licensed copies of a selection of software, to be selected in conjunction with the PT³ staff;
• training for faculty in the use of the media cart, software and Internet;
• availability of a graduate assistant for “just-in-time” support and troubleshooting;
• a student teacher supervisor who would spend at least one full day per week at the STTS.
We asked the STTS schools to provide:
• two half days of release time for a core group of teachers for training;
• time at two faculty meetings (or at an inservice day) for training for the full faculty;
• commitment to provide seven student teaching placements each semester;
• commitment from the cooperating teachers to allow – and, in fact encourage – the student teachers to use technology in a variety of ways.

Semester 1: STTS Success

Four local elementary schools enthusiastically signed up to become STTS sites. The administrators were enthusiastic and the teachers – although perhaps a bit more cautious – were willing to take on this new challenge. And, although this was something that we put into place rather quickly (and long after student teaching applications had been processed), more than 15% of our student teachers applied for placements in STTS schools. We configured the media carts, made sure that each student teacher knew how and where to get support, and kept in regular contact with them.

One graduate assistant took on the task of sending an email stream with suggestions for using different types of software. There were regular visits to the STTS schools. What we observed was that the student teachers saw this as an opportunity, a challenge and a reward. From the start, they were serious about their commitment.

The student teachers used technology as a teaching aid, but they also let children use a variety of tools. This is one of the most positive results: technology was not just in the teachers’ hands. They reported using an amazing array of technology applications – from using PowerPoint to play a Jeopardy-like game to helping 6th graders learn to take notes, having 5th graders do research on mammals using the Internet and then creating a presentation, using Inspiration for starting the writing process, using Kidspiration to help kindergarteners learn to categorize.

As exciting as the student teachers’ reports of their own successes were the reports the student teachers gave of the cooperating teachers’ reactions. We heard innumerable stories like these:

“"When I was teaching one day, I heard my teacher start giggling. She was at a computer in the back of the room playing with PowerPoint – and she was having such fun. I taught her the day before how to use sound. I think it was a mistake! I kept hearing strange noises and then she’d laugh!”

“I was in third grade. One day, all of the other third grade teachers came in to watch what I was doing. It was crazy having them all watch me!”

“Everyone fights over the media cart. Even the teachers who don’t have student teachers are using it!”

And in one STTS school, two student teachers were asked to plan and run an in-service day for the primary grade teachers teaching them to use the media cart and illustrating the kinds of technology-enhanced lessons they taught.

Looking Ahead

At the end of the semester, we asked the STTS student teachers for feedback. What should we do to improve this undertaking? Their responses came quickly. Some were not surprising:
• put another media cart in each school;
• give each school a second digital camera;
• add a video camera to the media cart;
• have software that was on loan only to STTS student teachers.

A few suggestions were so simple that we would never have predicted them:
• provide floppy disks – most of the STTS schools had used computers so infrequently with classes of children that there were not disks available for children to use;
...make sure that the Internet cables were really long - it was generally hard to position the media cart so that the cable reached the outlet and the projector was near a screen!

...find some way around the problems with the Internet filtering software (student teachers would prepare lessons when on campus - where there are no filters; when they got to their schools, what they thought were great Internet sites were often blocked).

**A Promising Model**

We believe that we have addressed one of the main criticisms voiced in the 1995 Office of Technology Assessment (OTA) report that "most technology instruction...is teaching about technology...not teaching with technology across the curriculum" (OTA, 1995, p. 165). We have simply required our students to use technology. It's not talked about a lot, it is just part and parcel of the everyday life in their education courses. They have to use a wide range of technology tools for their own work; if they are to be successful in their internships, they have to use technology as they teach and they have to involve children in the use of technology. As a result, we are beginning to see new teachers use technology as an everyday, non-intrusive tool. These young teachers have begun to internalize technology as a tool - it is not new, it is not unusual, it is just there...something to be used to support learning.

For a long time now we have been involved in helping practicing teachers become familiar with technology - from learning to use new tools themselves to learning about curriculum applications. During in-service workshops, graduate courses and other such sessions, teachers have argued that it is much harder to teach using technology. They do not usually deny the potential that new tools may have, but they invariably point out that it makes their day-to-day teaching harder. And so perhaps the biggest surprise of all came when we asked our SITS student teachers to reflect on how using technology had affected their teaching. "Is it harder to teach this way? Does it make your planning harder? Does it make the day more difficult?" "Of course not," replied one student teacher. And the others all agreed. "I can't imagine how hard teaching would be if I didn't have technology tools."

Perhaps the tide has begun to change.

Abstract: St. Bonaventure University was a 1999 recipient of a PT3 grant, and we have used the funds to support major changes in our curriculum. Specifically, we now require our preservice teachers to design and implement technology enhanced learning experiences for the students they work with during their internship year and during student teaching. This paper explains the process involved in curriculum change, and explores the success and problems we have encountered. It focuses on the kinds of technology-enhanced experiences our preservice teachers have designed and implemented. Project descriptions and sample lessons are discussed.

Introduction

Elementary teacher education at St Bonaventure University is based on a professional school model that places our undergraduates in local elementary schools for large blocks of time during their teacher preparation program. We believe that preservice teachers learn the art of teaching best through guided practice under the watchful supervision of both university and school-based faculty. Taking example from the medical and legal professions, the professions development school puts teacher interns in actual classrooms where they put the theory learned in university classrooms into practice with children. As we complete the fourth year of this field-based program, we are seeing that, indeed, our new graduates are better prepared to take on the job of teaching in classrooms of their own. This change is evident in our student teachers and in reports from student-teaching supervisors and from cooperating teachers. They report on more mature, confident and proactive student teachers. We are getting reports from school officials who have hired recent graduates and again the report is of confident and proactive new teachers. The implementation of this new program was difficult and required complete curriculum revision; the results, however, show that the effort was well worth it.

The core of our program is a two-semester internship (locally referred to as “Field Block 1 “and “Field Block 2”), during which a cohort of 15 to 20 preservice teachers and two university professors spend two days a week in a PDS site. During those days, students take a 9-credit hour block of theory and pedagogy courses and spend at least half of each day working in an elementary classroom — observing, planning, and teaching. While the interns are in the elementary classrooms, the university professors provide just-in-time supervision, helping the interns with the challenges they face as they learn to teach. This just-in-time approach to preservice supervision is proving to be very effective in all circumstances, but is especially crucial as we require that the interns become technology-using new educators.
Setting the Stage

Two years ago, when we were awarded a PT3 grant, it allowed us to act on what we knew was missing from our newly designed PDS-based program: proficiency in the use of technology. Our curriculum was designed to help our preservice candidates achieve the necessary competence to meet the INTASC standards. The PT3 initiative allowed us to again revise our curriculum, this time adding new experiences that would enable candidates to achieve the competence required by the ISTE standards for classroom teachers.

The redefined program goal was to help preservice teachers develop into excellent new teachers who would use technology as a standard part of their repertoire. For that to happen, they must be able to experiment with a variety of technology-enhanced teaching situations during their field experiences. They must participate in a learning environment where they and their students are using technology in a variety of ways to enhance the teaching and learning process. This might be easy if the classroom teachers with whom they would work during their field experiences were modeling such use for them, and if they could see lessons and activities that incorporated a range of technologies. However, in most cases that just was not happening. During their preservice field experiences, teacher education candidates typically have few role models in the public schools who use technology effectively to support children’s learning.

The PT3 grant gave us impetus to examine our program and identify an appropriate sequence of technology learning experiences for the preservice teachers with whom we worked. We began by requiring our students to become technology users themselves – users of basic technology tools for their own productivity. We then identified hardware and software appropriate for classroom use, and the PT3 grant provided the means to acquire those tools. At the same time, because our program was already field based, we were able to develop technology-rich experiences for our preservice teachers that they could then try out in real classrooms.

The PDS sites – our PT3 partners – have evolved into ideal laboratories where our preservice teachers can learn about technology. The schools were all in the very beginning stages of using technology, and there were few resources available for our students to use. We equipped each PDS with a media cart configured with a laptop, projector, printer, scanner, zip drive, and digital microscope. We also provided a digital still camera and a video camera. After one year, these media carts were getting such heavy use that we have now outfitted a second, “minor” cart – with laptop and projector – for each school and a second digital camera. On each laptop, we have installed a number of software packages appropriate to the courses the preservice teachers are taking (for example, they study language arts and social studies methods in Field Block 1 and science and math methods in Field Block 2). We also provided copies of a number of software programs that could be used on the increasingly available classroom computers.

Teaching as They Are Taught...and as They Are Taught to Teach

We want our interns to be teachers who will take advantage of new technology to make their practice as efficient and effective as possible. If we believe that teachers teach as they were taught, then we might be resigned to fighting the battle to change educational practice generation after generation. Most of today’s preservice teachers did not use technology when they were in elementary school – and did not see their teachers using it. We are convinced that we can create a sea change by combining the PDS approach to preservice education with an overt effort to model the use of technology in preservice courses. Our interns witness technology being used in instruction on an almost daily basis in their university classroom at the PDS.

During the Field Block semesters, university faculty model a variety of approaches to using technology in the classroom. For example, in the course on Developmental Reading, a professor might use Inspiration to model the use of character webs as a method to help children develop reading comprehension skills. During a science methods course, professors and candidates together might use a digital microscope to examine fruit and vegetable peels. During a Social Studies methods class, candidates use National Inspirer...
to enhance their own learning about US geography and resources, and then plan how best to use software of that genre as they study elements of cooperative learning.

As they take their methods courses where the professors model technology integration, during each of the two internship semesters the students are required to plan and implement a technology-enhanced learning experience for children. Each intern is assigned to a classroom for the whole semester, so as part of getting to know the curriculum, they are required to plan a project that is integrated with what the children are learning - finding a way to support and enhance children's learning by using technology. The project cannot be an "add-on" activity. The second requirement is that the children must be the users of the technology. Simply presenting a lesson where the teacher uses PowerPoint or Inspiration will not suffice.

Putting It into Practice

This is all not quite as easy as it sounds. It might be easier if we were teaching our methods courses in a traditional mode, where preservice students were in campus-based classes, carrying out peer-teaching lessons and designing activities and units that never really got tested in classrooms with children. But we were requiring interns in actual elementary school classrooms to negotiate with teachers so that they could use technology as they learned to teach. Most classroom teachers, if they are using technology at all, use it to support their own work, and have not ventured into designing learning experiences where children are using technology. Teachers in our partner schools do use email and word processing, and they are increasingly using digital cameras and printing out pictures for projects and bulletin boards. But they do not use technology as a regular tool to support and enhance teaching and children's learning. The children in many of our partner schools use Accelerated Reader and in some schools they are using courseware such as SuccessMaker. In most cases, however, children are working alone when using these applications. The teacher is rarely involved. More importantly, teachers rarely plan learning experiences where children use technology to construct knowledge in creative ways. If technology is used, it is used to enhance teaching rather than by students to create learning. Rarely do teachers and children use technology together to explore as they learn.

Curriculum-based Technology Projects

Among the many decisions we faced as we implemented this new approach was one of timing. Should we phase in new requirements or should we jump in, sometimes requiring our preservice students to do things with less than optimal preparation? We opted for the latter - believing that it was important for all of our candidates to get as much experience as we could give them before they graduated. Consequently, projects developed modestly in the first two semesters. During that time, interns with limited previous exposure to the use of technology in the classroom struggled with their own understanding of technology and its place in the teaching-learning dynamic. They were struggling with their vision of technology as tool for production and as tool for teaching and learning. They struggled with the decisions surrounding the scaffolding of children's use of new tools. These struggles were all colored by their own experience as learners and by their very limited experiences as teachers. As a result, most of the early projects might be considered "simple" applications of technology:

- Children created class yearbooks with digital pictures short stories about each other. These were printed using color printers and bound.
- Children used Inspiration to create character maps about the main characters in the novels they were reading.
- Kindergarteners used Kidspiration to create an "All About Me" bulletin board.
- Fourth graders created book-tape packages of popular stories and presented them to the school library.
- Third graders used Timeliner to create biographies – from the point of view of the year 2020.
- Fifth graders followed up the study of U.S. natural resources with a rousing game of National Inspirer.
- Fourth graders wrote letters to the editor of the local paper about Veterans' Day using a word processor.
Over the past year, the interns have been arriving in Field Block with a richer background — having completed the newly designed core courses in our program, now enriched with technology. The projects they design are showing more sophistication in terms of technology application and in terms of curriculum integrations. We believe that the latter is due to the fact that because they have more understanding of technology they can spend more time thinking about curriculum and less about technology. Typical projects now include:

- Children working in cooperative groups while studying Native Americans, with one writing the tribe’s history using Storybook Maker, another creating a timeline, a third creating a map of the tribe’s location and a fourth using Community Construction Kit to develop a scale model of the tribe’s village.
- Fifth graders developing a retrospective timeline of their journey through elementary school, to use at their “moving up ceremony.”
- Third graders interviewing each other, videotaping the video and then creating an interactive online yearbook using HyperStudio.
- Second graders using the Intel microscope to examine plants as part of a unit on plant growth.
- Fourth graders acting as roving photographers, capturing the daily life of their school with a digital camera and creating a hallway display — changed daily — illustrating the things that they think are important in their school.
- Third graders producing a HyperStudio stack for parents’ night that chronicles a day in their classroom. This presentation presents recorded sound interviews with teachers and students, digital photos, scanned images of student work, and digitized video.

Lessons Learned

If it can go wrong it will. Some days we think that should be the primary lesson we teach our preservice teachers — because when novices are using technology, inevitably things do go wrong. One of our goals is to get the focus away from the technology and on to the curriculum. In so doing, however, we run the risk of treating the technical aspect of using technology too lightly. What have we learned? A lot. We have learned (for the millionth time) that you can never assume that novices will test things out. We have learned that plugging in equipment is not intuitive. Here are a few lessons:

- Teach interns to always test all equipment before the children arrive in school. Then test it again.
- Test access to Internet sites in the classroom where you will be teaching (not from home, not from the teacher’s work room). Most schools use filtering programs; many have different levels of filtering set at different locations in the building.
- Don’t just test the hardware and software. Test locations! Make sure that you can locate the project close enough to the screen so that the image size is reasonable. Make sure your cables and electric cords are long enough.
- Test the actual program, application or presentation using the computer you will use during the lesson. A presentation prepared on a high-powered computer in the university lab may not run very effectively on a less powerful computer in the school!
- Plug in the equipment. Laptops run on battery, but nothing else does. After moving the media cart, plug it in and reboot the laptop (the zip drive will not be recognized if it is not powered at bootup).
- Try out the software. Use it extensively. Know how it works — you have to anticipate the questions children will ask and they things they will try to do.
- Know how to end the program. (Quitting is not always easy!)

Does It Work?

To help preservice teachers develop proficiency in the use of technology for teaching and learning, it was not sufficient to add course requirements to our program. Rather, we had to seek ways that required our interns to use technology in their professional practice. Those of us who work with new technologies know that proficiency with new tools is not gained solely from reading about their use or by hearing others talk
about the new tools. Therefore, simply adding a course in technology for teachers was not sufficient; we knew we had to add technology-enhanced experiences for our students. Real proficiency is gained when we begin to actually use the new tools for our own projects. Initially we added assignments at each level that required the active use of technology during fieldwork. We require candidates to do software reviews, to produce HyperStudio stacks, to use such programs as Inspiration and Timeliner during their teaching, to use digital photography and video for assignments, to use the Internet as part of lesson delivery, to submit assignments via email, and finally to develop an electronic portfolio during their internship and student-teaching semesters. All of these assignments have produced a growing expertise among our preservice teachers as users of technology for personal and professional work.

Comfort, however, often leads to complacency; when we found that the majority of our interns were comfortable with one set of new tools, we knew it was time to once again push the level of understanding by demanding more complex use of technology during their internship semesters. We wanted to move from the understanding of technology for teaching and learning at the knowledge and application levels of thinking to the higher levels of understanding required of those who analyze learning environments and then design new learning experiences. This would require interns to synthesize knowledge of learners, learning environments, and technology. The complex dynamism created as new teachers push their level of understanding on several dimensions at once is indeed a rich learning environment for both new teachers and the students with whom they are working. Just as these new teachers were feeling comfortable with their understanding of classrooms and the children in these classrooms, they were being pushed into disequilibrium by the requirement that they carry out a technology project that required them to involve children in the actual use of the technology. Even in times when children commonly interact with technology in their homes via computer games, DVD players and such, it is still not common to permit these same children to move into the world of technology in the classroom. As our interns began implementing newly designed projects that introduced children to new software and hardware, a wave of change has begun in our professional development schools. This change has gone beyond the interns and their students to their cooperating teachers, the teachers in classrooms nearby and to the administration of the schools in which they work.

The Clinical Faculty — the P-12 teachers with whom our interns work — are now suggesting new technology projects for the interns to take on. Many are trying some technology integration on their own — and are asking interns for help. The interns who are working with fourth graders this year have noticed that the many of children do not need to learn how to use the digital camera, for example, because the they learned from the interns who were in their classrooms last year. Children in the classrooms in our PDS sites have been exposed to a wide variety of hardware and software tools — and they are beginning to produce amazing products. Older children have produced book-tape packages for children in earlier grades; others have used video to produce school newscasts including local weather reports, producing town plans that include actual pictures of local business and buildings and eventually printing large-scale maps of their local communities. One multi-age first-second grade class adopted Engine Company #1 in New York City and produced a video and a book to send the firefighters. In every case, preservice interns have planned and developed these activities, have tied these activities to local and state standards and local curriculum, and have helped children create amazing products. The interns were learning to teach using technology and children were learning to read, write, compute or problem solve in technology enhanced learning environments.

This is appropriate use of technology in preservice education: mediating the learning of elementary students, preservice teacher candidates, elementary teachers, and college faculty, all at different but appropriate levels, creating true learning communities.

Acknowledgements

The work reported here was supported by a grant from the U.S. Department of Education's PT² program. In addition, it was supported by our public school partners in NY and PA: Coudersport Area Elementary School, Kane Area Elementary School, Cuba Elementary School, Wellsville Elementary School, Randolph Elementary School, and Olean Public Schools.
Valley City State University (VCSU) is a small, liberal arts campus in North Dakota. In 1996, the university became the second notebook campus in the nation. All students and faculty are issued a notebook computer and many of the classrooms on campus are networked for the use of computers and Internet connections. This technology literate campus provides an environment conducive to incorporating software programs into the teacher education methods courses. In addition, the University was awarded a PT3 grant further enabling the preparation of technology-proficient teachers.

This PT3 grant (Preparing Tomorrow’s Teachers to use Technology) was awarded during the 2000-2001 school year in order to train inservice and preservice teachers to use technology in their classrooms. Three goals of the grant are that preservice teachers will: 1) meet NETS and NCATE standards 2) be provided with technology experience in the K-6 classroom and 3) be able to use technology to help their future students improve learning by developing complex reasoning and problem solving skills.

Collaborative workshops are held to train in-service teachers in a variety of software programs and give ideas for their use in the classroom. Participants include VCSU’s Education Department faculty, in-service teachers from grant partner schools and technical support from a statewide Center for teacher training. This Center provides statewide training and consultation for teachers at all levels.

University courses provide students with an opportunity to utilize a variety of software programs and ideas for classroom use through various field experiences. Under the supervision of a University faculty member, the preservice teacher and the K-6 teacher participate in collaborative technology projects designed to develop higher order thinking skills in children. These projects reflect current best practices and VCSU’s Teacher Education model incorporating planning, implementing and evaluating. The software program is implemented into the methods courses followed by classroom application. Three specific software programs used are “Choices, Choices”, “Kid Pix Deluxe 3” and “Storybook Weaver”.

Elementary Science Methods provides an opportunity for preservice teachers to view a variety of materials. One of the commercial products previewed is the CD-Rom simulation “Choices, Choices – Kids & the Environment” and its’ accompanying handbook. Choices, Choices is based on an award winning series called Decisions, Decisions available from Tom Snyder Productions. Implementing the simulation aids the development of critical thinking skills through application, prediction, weighing options, and evaluation. Preservice teachers collaboratively develop a scoring rubric for reviewing all materials. Upon completion of the rubric the preservice teacher reflects on the application of the materials in an elementary classroom and considers the National Science Education Standards, inquiry, learner needs, planning and implementing. Knowing about various materials is useful, but knowing does not insure doing. Implementation is promoted through a tutorial developed to assist the preservice teacher in planning for the implementation of Choices, Choices – Kids & the Environment. The tutorial incorporates activities to prepare the teacher for the simulation, as well as possible activities to use with the K-6 student during the simulation. Templates for planning and student project scoring rubrics are also included in the tutorial to aid in evaluation. The preservice teacher acts as a bridge and provides assistance to the inservice teacher as they collaborate in delivering the Science based information.

In the field of Early Childhood Education, using computers in the classroom allows children the opportunity to gain experiences with technology as well as support the curriculum in a meaningful way. A challenge to the early childhood professional is finding software that promotes computer literacy without inhibiting creativity. Teachers seek materials that are developmentally appropriate and stimulate the young child’s ability to use higher order thinking skills of organizing, summarizing and responding. A software program that is frequently cited as meeting the above criteria is Kid Pix (available from The Learning Company), which has been part of early childhood programs since its release in 1991. The teaching possibilities are numerous and varied. Kid Pix helps the young child build self-confidence and cultivate their natural creativity. At Valley City State University, preservice teachers are introduced to the software
in methods courses and allowed opportunities in field experiences to work with multi-age children in a variety of classroom settings from kindergarten to fourth grade. With the introduction to the tools of Kid Pix, children and preservice teachers can create an array of projects that fit all areas of the curriculum. Preservice teachers act as mentors for the children in designing unique finished projects from original illustrated books to slide show presentations. Kid Pix Deluxe 3 is the newest edition of the software program. Valley City State University education students have access to this latest edition of software and work closely with inservice teachers in selecting projects, which would cultivate children's natural creativity and reach their creative potential. Preservice teachers, inservice teachers and university instructors collaborate on ways that the projects children create will be evaluated.

Valley City State University provides a number of opportunities for students to learn about teaching Language Arts. In Methods and Materials of Language Arts II students are provided with experiences to view and use the software program Storybook Weaver Deluxe, also available from The Learning Company. This software program allows students to be actively involved in the writing process. It includes a simplified word processing program and a variety of graphic features that make illustrating stories fun and easy. Storybook Weaver Deluxe can be used to provide an introduction to writing for some and an opportunity to express one self in an enriched environment for others. Preservice teachers view the software and brainstorm ways that this program can be implemented into the elementary classroom. They also evaluate how this software can be used with the Standards for Language Arts. Preservice teachers that are working in a field experience can use the software with elementary students, come back to the methods class to discuss how it was implemented and reflect on methods for improvement. The goal is for the preservice teacher to generate ideas for implementation of the software and leave the cooperating teacher with the ability to continue using these ideas in the future.

As a notebook campus, Valley City State University produces teachers who are technologically proficient. This alone, however, does not ensure that teachers are able to successfully implement these technology skills into a classroom setting. The methods courses and software mentioned allow the preservice teacher to make decisions for planning and to use reflective problem solving skills while implementing these projects in a classroom setting. The collaborative efforts provided in the PT3 grant workshops ensure that evaluation and revisions take place in a supervised setting. All participants addressing reflection and evaluation assist in improving utilization of software. The end product is a learner-centered environment where K-6 students and preservice teachers, as well as inservice teachers learn by doing.
A major challenge faced by teacher education faculty is the infusion of technology and creating the highest quality learning environment possible. The use of digital video case methodology is a viable instructional approach to meet the learning needs of tomorrow’s teachers. Inspired by the dedication to bridge the digital divide and provide high quality learning opportunities to preservice teachers, the National Educational Technology Standards (NETS) Digital Video Library (DVL) incorporated a digital equity expert commentary feature into its collection. A PT3 consortium led by Arizona State University is developing the NETS DVL. The online DVL shows video of teachers and teacher education faculty using technology in the classroom. The collection of digital video lessons are based on the NETS for Students: Connecting Curriculum and Technology (2000) and the forthcoming NETS for Teachers: Preparing Teachers to Use Technology. Carefully developed to address the NETS for students and teachers, the DVL lessons represent technology as an integrated component to reform-based curricula. PT3 community and digital equity leaders will provide expert commentary.

This presentation describes and demonstrates the possibilities of meeting the learning needs of preservice teachers by framing the infusion of technology into curriculum and instructional practices with a digital equity perspective. Members of the NETS DVL team will demonstrate and discuss the lesson commentary engine created to develop the collection of NETS-based lesson activities and demonstrate its use as a tool for digital video case-based instruction.
Two Perspectives on NETS as a Framework for Change in PT3

Abstract: Through the program Preparing Tomorrow's Teachers to Use Technology (PT3), teacher educators increase their understanding of the effectiveness of instructional technology and how best to prepare new teachers to be accomplished users of technology. This paper discusses two PT3 grantees' approaches to professional development, where each implementation uses the National Education Technology Standards (NETS) in different ways. The purpose of the discussion is to point out the role of NETS in guiding a PT3 implementation to conform to a set of nationally recognized standards, without constraining the teacher preparation program unduly or compromising its existing standards of excellence.

Introduction

The program Preparing Tomorrow's Teachers to Use Technology (PT3) is consistent with the belief that effective use of technology for teaching and learning should be an integral part of teacher preparation programs. Understanding the uses of various instructional technologies and their potential to transform teaching and learning requires modeling by teacher educators and guided practice by preservice teachers in classroom settings. The difficulty is that many teacher educators and mentor teachers have little or no understanding of the power of instructional technology and are themselves only novice users of technology for professional tasks. Professional development for integrating technology in the curriculum may begin with developing new skills, but much more is needed than offering inservice workshops and classes on how to manipulate a particular software application to produce a result (OTA 1994; LeBaron & Collier 2001). How can teacher education faculty acquire the expertise to prepare preservice teachers to use technology effectively; how can they insure that mentor teachers in their professional development schools are modeling technology effectively; and how can they assess their students' use of technology unless they know what "effective use of technology" looks like? PT3 provides funds and support to address that dilemma. The support includes a comprehensive, timely, and thoughtful set of standards for demonstrating effective use of technology in professional practice and in the classroom.

For those providing professional development to teacher educators and K-12 partners, the National Educational Technology Standards (NETS) represent a graphical organizer that summarizes the technological skills, tools and techniques deemed valuable in teaching and learning. NETS are the result of an ISTE initiative funded by the United States Department of Education's PT3 grant program, developed with contributions from Apple, Milken Exchange on Education Technology and a consortium of distinguished NETS and PT3 partners and contributors (ISTE 2000). Supplementary materials, including exemplary lesson plans, templates, and teaching strategies, are also available in materials like NETS/S/Connecting Curriculum and Technology (ISTE 2000). Significant acceptance of the NETS across the country is helping teacher preparation programs to focus their instructional technology efforts on those technologies and their uses that will most benefit the K-12 teachers as they integrate technology into their curricula.

Each PT3 grantee fosters a partnership between teacher education faculty and K-12 teachers and, in that context, decides how those standards can best be implemented. As a result of the partnership and its associated professional development, K-12 teachers come to understand what technologies can help their students improve their critical thinking and problem solving skills and best prepare them for the workplace and for lifelong learning; at the same time, teacher educators increase their understanding of the effectiveness of instructional technology and how best to prepare new teachers to be accomplished users of technology.
paper discusses two PT3 grantees’ approaches to professional development, where each implementation uses the NETS standards in very different ways. The purpose of the discussion it to point out the role of NETS in guiding an implementation to conform to a set of nationally recognized standards, without constraining the teacher preparation program unduly or compromising its existing standards of excellence.

Two Experiences with Implementation

The discussion focuses on two implementations of PT3 with the intention of showing how NETS can facilitate very different approaches to technology infusion in pre-service education. The first example is Notre Dame College in Manchester, NH, in its second year of a PT3 grant. The second is the Warner Graduate School of Education and Human Development at the University of Rochester, which is in its first year of implementation.

Notre Dame College in Manchester, New Hampshire, was invited by the New Hampshire State Department of Education (NHDoE) to participate in the three-year PT3 grant the state was awarded in the Fall of 2000. The timing was fortuitous, as Notre Dame had received a federal grant the year before that provided laptop computers to all faculty throughout the school. The Division of Education faculty were eager to begin serious investigations into how to use their new computers and how to apply them to their teaching. Partnered with Apple Corporation on the grant, the NHDoE supported the PT3 emphasis on the use of NETS as a guiding force. Notre Dame responded by revising their existing courses in instructional technology in line with the standards, and delivering professional development for faculty that also aligned with those standards. Faculty began modeling the use of technology in their instruction in existing education courses, and discussions are underway to revise the preservice teaching preparation program more fully into alignment with the NETS.

The University of Rochester’s Warner Graduate School of Education and Human Development applied for and was awarded a PT3 implementation grant in 2001. The Warner School’s approach to technology infusion is different from Notre Dame’s. In developing its PT3 proposal, the Warner School wanted to shape its PT3 implementation in line with its role as a research school of education. The Warner School, which had no existing courses in instructional technology, regarded technology infusion as a systemic reform effort. The Warner School’s instructional techniques emphasize inquiry and critical questioning, an excellent match for technology application (Jonassen 1999; Grabe 2000). In the Warner School implementation, each faculty member prepared an individual professional development plan for technology that addressed professional and research use of technology, integration in methods classes, and development of demonstration sites in area school where preservice teachers can observe exemplary application of instructional technology. Teacher education faculty committed to partnering with technology-using teachers in area schools to develop subject-specific courses on teaching and learning with technology. Warner School teacher education faculty benefited most from NETS as a framework that represents the “big picture” of technology and that articulates the national performance standards against which its preservice teachers and preservice program would be assessed.

Notre Dame College’s Use of NETS for PT3

When addressing increased use of computer technologies in the schools, Notre Dame College in Manchester, New Hampshire believes it is important to put their use into a context that brings understanding as to why those particular technologies are supporting education. The invitation by the New Hampshire State Department of Education (NHDoE) for Notre Dame to participate in the three-year statewide PT3 grant aligned with the readiness by the Division of Education faculty to begin serious investigations into how to use their new computers and how to apply them to their teaching. During the first year of the PT3 grant, five integration meetings with the faculty and K-12 partners were conducted by the NHDoE personnel and an Apple Corporation consultant, all of whom supported the PT3 emphasis on the use of NETS as a guiding force. Additionally, an introduction to Apple’s Evolution of Thought and Practice model (Sandholtz Ringstaff & Dwyer 1997) brought an appreciation that all participants were at different stages in their understanding of technology use for instruction. Faculty also saw that with each new technology addressed, the cycles of Entry Level, Adoption Level, Adaptation Level and Appropriation Level would be repeated. This reduced apprehension as colleagues recognized they were at the higher levels with some technologies and even the ‘experts’ were at entry levels with other technologies.
Participation in the PT3 grant by Notre Dame faculty was higher than most colleges statewide. Professional development meetings were hosted on campus once a month on Wednesdays, a day the faculty were already required to be on campus for late afternoon college meetings. All but one faculty member from the division were actively engaged in the grant; one member was on sabbatical.

Technology experience varied greatly across the twelve Notre Dame participants. Two had extensive backgrounds; two knew only word processing and electronic mail. To facilitate professional development, weekly sessions were offered. The instructor for the Technology Applications for Educators courses, who also served as the PT3 project liaison, offered two-hour work sessions for the faculty each week on Wednesday mornings. The initial technology stressed was Microsoft PowerPoint® and Inspiration®. The instructor also reviewed the remaining applications within Microsoft Office®, introduced faculty to Blackboard® and HTML, and provided consulting on any effort faculty members were engaged in with technology.

Attendance at professional development sessions the first year was strong. By the beginning of the second year of PT3 participation, the attention shifted from skills development to implementation. Faculty continued to increase their technology use, attending professional development workshops when they could, and engaged more actively in exploring changes within the preservice program to better equip the preservice teachers to use technology in their teaching.

Notre Dame consciously organized and delivered professional development for faculty that aligned with NETS-T and NETS-S. As a result, faculty became aware of the standards as they began modeling the use of technology in their instruction in existing education courses. At the same time, the Technology Applications for Educators courses, required of all preservice teachers, were reorganized around NETS, giving preservice students a thorough introduction to the standards. By year two, faculty began discussing the revision of the preservice teaching preparation courses more fully into alignment with NETS. The expectation is that syllabi will identify what technology modeling and student use will be taking place in each course, and all NETS standards will be addressed throughout the preservice preparation program.

Several ingredients contributed to success in the Notre Dame PT3 implementation:
- faculty ready to address technology integration
- common time available for workshops and discussions
- equipment and software available to each participant
- professional development opportunities in relevant tools and uses
- continual support from a technology-savvy individual working with faculty and encouraging new direction
- significant support from the division dean
- the PT3 grant to serve as catalyst and rallying point.

As with the University of Rochester implementation below, the PT3 grant itself brought focus and a sense of deadline, and the NETS documents provided the structure and criteria for assessment necessary for good course development.

University of Rochester's Use of NETS for PT3

The University of Rochester’s Warner Graduate School of Education and Human Development applied for a PT3 grant in 2001. The school felt compelled to infuse technology in all of its departments—Teaching and Curriculum, Educational Leadership, and Counseling and Human Development. Technology infusion represented systemic change for the school, driven by several external forces that demanded technology integration. These included New York State recertification of teacher preparation programs, NCATE accreditation, and CACREP accreditation.

A PT3 Implementation Grant was awarded in July 2001, and a doctoral-level instructional technology specialist was hired to facilitate the school's efforts with technology. A series of professional development offerings were planned, and relevant documents and resources were assembled, including copies of NETS-T and NETS-S for Teaching and Curriculum (ISTE 2000), the draft TSSA standards for Educational Leadership (ISTE 2001), and technology standards for Counseling and Human Development (CACREP 2001). At an all-day institute in September, faculty from the three departments viewed and discussed a variety of approaches to teaching and learning with technology. One structured discussion asked small, cross-department groups to focus on their respective technology standards, guided by the question, “What is a technology savvy educator by
Warner standards?" Faculty recognized the importance of technology skill mastery and embraced the use of technology to promote high-order thinking and a sense of professional community. They also insisted that professional preparation include grappling with the digital divide (PT3 2001), a serious concern in the high-needs Rochester City School District. Throughout the discussion, faculty referred to the standards for their own department and for the other departments, noting and reconciling differences. Faculty acknowledged that their respective programs would be assessed against the standards and agreed to incorporate the standards in their courses.

As a next step, each faculty member worked with the instructional technology specialist to develop a realistic, challenging technology plan, in which they committed to integrating technology in their courses, their research, and their professional/administrative role. Teaching and Curriculum faculty who taught methods classes also agreed to revise courses and develop new courses that highlighted the use of technology in content area teaching and learning. They further agreed to partner with technology-using educators in area schools to develop demonstration sites for preservice teachers to observe best practice with technology. “Best practice” was defined in terms of NETS and instructional innovation, in keeping with the Warner School’s emphasis on excellence in teaching.

It is expected that as new courses and course modules are rolled out, students will assess their knowledge and performance against the standards, cast a critical eye on technology implementation in schools, and reflect on teaching practices that incorporate technology.

Conclusion

NETS provides a framework for assessing preservice teachers and teacher preparation programs with regard to technology knowledge and integration. Each preservice program is free to use the standards in a manner consistent with its own emphasis. Notre Dame explicitly uses NETS-S and NETS-T in its course descriptions and syllabi. The University of Rochester uses NETS to guide student assessment and program development, while emphasizing innovative teaching, critical questioning, and social justice. In our experience, the standards provide a framework for technology infusion in complex, rigorous teacher preparation programs without constraining or compromising the excellence of the programs.

BRIDGING THE GAPS: USING TECHNOLOGY AND OTHER GRANTS TO HELP ENGLISH LEARNERS SUCCEED

Debra Lee Cook Hirai, Advanced Educational Studies, Bilingual and Multicultural Education, California State University, Bakersfield, USA, dhirai@csub.edu

Irene Borrego, Elementary/Secondary Education, California State University, Bakersfield, USA, iborrego@csub.edu

The California student population has recently become ethnic majority. For this reason, immediate steps need to be taken to improve delivery of instruction to EL's (English Learners). Now, if you take three parts ELDPI, two parts PROJECT TNT (a PT3 project which is partnered with StarTEC), one part PROJECT EXCEL, and one part PROYECTO ALIANZA, you have an incredibly effective staff development component (or recipe) to assist teachers who work with English learners and to ensure the success of those learners.

This article will discuss all four grants, their components, intended objectives, and how, in collaboration with one another, they provided teachers with instructional strategies, assessment strategies and technology to use in the classroom. The product of this collaboration effort assisted teachers to implement strategies which have effectively impacted the success of the English Learner. The "best practices" video clips, which are the culminating activity for this collaboration effort, are the most advanced form of professional development in the field at this time.

THE GRANTS:

ELDPI:

ELDPI (English Language Development Professional Institute) is a California state funded project from the University of California President's office, with collaboration from the California State University at Bakersfield (CSUB) and the Kern County Superintendent of Schools Office (KCSOS), along with various school districts. This Institute is held for one full week during the summer, along with five follow-up sessions during the school year. The purpose of this Institute is to educate teachers, administrators, and paraprofessionals in ELD (English Language Development) and SDAIE (Specially Designed Academic Instruction In English) instructional strategies, along with assessment techniques and instruments, and implementation of the California State English Language Development Standards (ELD standards) in their classrooms.

Participants are given an overview of the ELD standards, an overview of assessment techniques (in the ELD, Math, Science and Social Studies subject areas), and then many sessions on instructional strategies which they can use, all specific to grade levels 4-12 (4-6, 6-8, 9-12) and content areas, including ELD.

After the annual summer Institute week, follow-up sessions for the ELDPI include home to school partnerships, more strategies and a heavy emphasis on using technology; in particular, participants create personal electronic portfolios and reflect on the effectiveness of the instructional strategies used in their portfolios. The application of strategies learned, (electronic portfolios), is a crucial part of the staff development process, as school teams implement their instructional improvement plan (designed at the Summer Institute) and reflect on how well they are delivering instruction to English Learners (EL's), and how their students are performing in the class. The most effective electronic portfolios ("best practices" videos) are posted on the CSUB TNT website (http://www.projecttnt.com). By the end of the school year, participants have often reported a remarkable increase in student performance and in their ability to improve delivery of instruction to EL's.

Two of the project directors, Drs. Borrego and Hirai, from CSUB (California State University, Bakersfield), along with Javier Arreygui (an ALIANZA student), worked this past summer to encode some of the best practices displayed during the week-long Institute (2001). This includes video clips from keynote speakers, as well as teachers and consultants teaching effective instructional strategies to use with the EL student. These video clips can be viewed on the Project TNT (PT3) website, (see above), Learning Circle 3, “OLLE” (Online Language Learner Educators).

PROJECT TNT:
Project TNT (Teaching With New Technologies) is funded by the US Department of Education and it emphasizes “Creating a Technology-Friendly Culture in Today’s Schools.” StarTEC, Staff Teacher and Restructured Technology Education Consortium, another grant funded by the US Department of Education, is partnered with Project TNT and purchased training and equipment for TNT. Project TNT concentrates on developing “best practices” video cases which will showcase teachers using effective instructional strategies with EL students and with students in other content areas. Many of those teachers are participants of the ELDPI Institute. This project provides the equipment (cameras, lights, microphones and most importantly, “ibook” laptop computers with video editing equipment) which is used by participants to create and edit these videos. Also important to note is that Proyecto Alianza, a grant funded by the Kellog Foundation to assist certificated teachers from other countries (primarily Spanish speaking) obtain their California Teaching Credential, also collaborates with Project TNT.

PROJECT EXCEL:

Project EXCEL (Excellence in Curriculum for English Learners) is a partnership with the Kern High School District to assist in training high school teachers and CSUB faculty to work effectively with EL students. This project is funded by Title VII from the US Department of Education. Their first presentation involved Norm Gold and a discussion of Prop 227 mandates. Project EXCEL has not only provided many high school teachers with the ELDPI training, but also has paid to have many of the sessions videotaped, in addition to purchasing textbooks for them—Teacher’s Handbook, Contextualized Language Instruction by Judith L Shrum and Eileen W. Glisan.

THE RECIPE:

ELDPI provided the basic professional development for the participants. PROYECTO ALIANZA worked with ELDPI in offering the opportunity for teachers from other countries to also receive this training. Project EXCEL provided the videotaping, offered opportunities for high school teachers and CSUB instructors to participate in the Institute, in addition to purchasing textbooks. Dr. Borrego and Dr. Hirai worked with Project TNT and Javier Arreygui, to encode the video from the Summer Institute (2001). They are continuing to work on encoding individual teacher “best practice videos”, which all Institute participants are expected to produce by the end of the 2001-2002 school year.

The end product is an ongoing and ever increasing supply of teacher “best practice” videos which are organized according to ELD, SDAIE, Multicultural instructional strategies on our website, with open access to all teachers. The ELD, and SDAIE strategies are grouped according to grade levels. The Multicultural strategies are grouped according to content area (Math, Science, Social Studies and other core subjects). These video clips are an average of 2 to 5 minutes long and they focus on ELD, SDAIE or multicultural strategies. Each “best practice” will also include a reflection piece, done either by the participant, a college professor, or other well-known experts in the field.

This is the newest and most readily accessible form of “peer coaching” available. Peer coaching is very time consuming and requires reliance on release time and knowing that the showcased lesson will be effective, with no undue interruptions or discipline problems. With the best practices video clips, teachers can view them in the comfort of their own home, or at the school site with input and reflections from other teachers. If a teacher needs to teach a particular skill, for example, reading comprehension, grades K-2, for ELD, they can “click’ on ELD strategies, K-2 Reading, on the project TNT website and view numerous strategies demonstrated by consultants and/or teachers in the classroom. This is the most innovative, state of the art, type of professional development available for teachers.

EQUIPMENT NEEDS:

We began to test the editing process, by encoding video clips from the last ELDPI summer Institute, using all the technological equipment Project TNT had to offer. It became immediately apparent that we needed additional resources to complete our small project! What were we going to do for our 180 participants who were required to produce these “best practices” video?

First we needed lights and digital cameras (with firewires), cordless microphones, and “ibooks” (laptop computers produced by Apple) with firewire ports and loaded with “Quicktime” software for editing video. Then we discovered we needed headphones for the computers, a quiet place to videotape and edit, more hard drive space, a mouse for every computer we were using, a CD rom burner, lots of video tapes and a server big enough to hold all the videos!
In addition, we needed time—lots of it! And we needed training. Learning the program is not that difficult, but it does take time and dedication. We needed training in the editing process and in learning the fine art of videotaping.

Those hurdles overcome, we needed to think about how we would accommodate 80+ teachers and their equipment needs to videotape, edit and reflect on their lessons, in addition to providing time to train them in the videotaping and editing process. During each of the follow-up sessions for ELDPI, our Institute and Project TNT collaborated on providing the training. Each session contained a one and a half hour block of time for training on the portable “ibook” lab which was purchased through TNT. We discovered then that we did not have enough cameras to work with all the “ibooks” and videos the participants brought with them. With the help of Project Excel and the School of Education, we had barely enough cameras for the second session. The third session contained more time (two hours) for editing, more cameras and more “ibooks” (loaned to us by the Apple Corporation). By the end of the second session, participants were exceedingly excited about producing their “best practices” videos and extremely comfortable with using the “Quicktime” software for editing. We all witnessed the production of some very powerful electronic portfolios!

CONCLUSION:

Another project, SLICK (Second Language Institute for the County of Kern) has since joined us and will be encoding their videos and posting them to our website, also. The success of ELDPI is evident in the excitement created by the networking of teachers’ creative SDAIE and ELD instructional strategies, and the expertise generated by the participants as they learn to use the “imovie” equipment and software. This year we had different teams return to the Institute from the same schools as last year, and this summer we will hold two separate Institutes to accommodate the growing number of teachers, paraprofessionals, administrators, directors and other district and school personnel who desire this training.
Developing and Integrating Internet-2 video content into Teacher Education Programs

James.fouche@sonoma.edu

Abstract

Sonoma State University (SSU) is part of the California State University (CSU) system and has recently been awarded a substantial PT3 Federal catalyst grant over period 2001-2004 for project 'Light Bridge'. The Light Bridge project aims to develop video content resources for California’s Internet-2 network, the next and most powerful generation of today’s Internet. The project is both piloting and establishing revolutionary practices in preparing pre-service teachers to be adept and sophisticated in using technology in the classroom.

Overview of the Light Bridge project

The Light Bridge is a PT3 Catalyst project that aims to provide video content for California’s Internet-2 Broadband network. The project aims to pilot and establish revolutionary practices in preparing pre-service teachers to be adept and sophisticated in using technology in the classroom. The specific goals of the project are to:

1) Strengthen teacher education programs through the development of rich video content offered via the next generation of the Internet Broadband network;
2) Establish a student teacher support and supervision system that assures high quality support and assistance at a distance; and,
3) Disseminate teacher education video content, online resources, and student teacher support and supervision system.

Specific examples of Light Bridge activities include developing and maintaining rich visual teacher education content; piloting the use of video conferencing for teaching, supervision, and mentoring of pre-service teachers; and, capturing the classroom performance of pre-service teachers for analysis and criticism by mentor teachers and university supervisors over the network. While the Light Bridge project will initially be implemented at the Sonoma State University (SSU) campus (serving pre-service teachers and rural and low-income schools to which they are assigned), it will quickly be expanded to include pre-service teachers at California State University campuses all over the state. This represents a cohort of over 25,000 pre-service teachers per year. Light Bridge has the potential to revolutionize teacher preparation methodology nationally through SSU’s connections with nationwide teacher education reform organizations, such as the Renaissance Group and the National Network for Education Renewal.

This paper seeks to explore the pedagogical protocols of using video-based technology as an instructional medium for teacher training. We will consider the cautions of introducing video-based Internet instruction raised by Maddux (1998) and identify pros and cons between using video-based media compared to face-to-face learning environments. Consequently, we will be expanding upon the issues recently raised by Sipusic et al., (1999) in their research report for SUN Microsystems "Virtual collaborative learning: A comparison between 'Face-to-Face' Tutored Video Instruction (TVI) and Distributed Tutored Video Instruction (DTVI)." They reported findings indicating:

1. Most importantly, our research shows that video-mediated communication can in fact support both the content and relational components of discourse that are necessary for effective collaborative learning. The collaborative learning effect is fully intact with DTVI, opening the door to the widespread use of more effective distance learning models than the lecture-based model currently being used.
2. Furthermore, we have demonstrated that video-mediated collaboration can generate high levels of user satisfaction. While the DTVI students reported enjoying their experience slightly less than the TVI students, they reported enjoying it much more than a typical classroom lecture.
3. With DTVI generating higher academic performance and more enjoyment than classroom lecture, distance learning no longer need be considered a poor cousin to face-to-face instruction (page 45).

This PT3 catalyst project is also exploring how the use of video-technology pedagogical resources can be integrated into reforming the instructional design of higher education teacher education programs. A principle aim is to implement the joint Educational Technology teaching standards set by both the 'International Society for Technology in Education' (ISTE) and the 'National Council for the Accreditation of Teacher Education' (NCATE). Both ISTE and NCATE have jointly accredited National Educational Technology Standards for Teachers (NETS-T), which are aimed at reforming current practice within teacher preparation courses through the provision of a common set of performance indicators that lever Ed Tech integration. The Light Bridge project has adopted these ISTE Ed Tech teaching standards, as well as the Californian Standards for the Teaching Profession (CSTP), and has integrated them into several funded project areas that involve the following six curriculum development teams within SSU:

1. Classroom management;
2. Reading Language Arts and Second Language Acquisition;
3. Mathematics and Science;
4. Physical Education;
5. Video Case Studies; and,
6. Videoconferencing/Student Teaching

This PT3 catalyst project espouses Stenhouse's (1975) notion of achieving best practice curriculum development and reform of practice, through adopting his "teacher as experimenter" approach. Thus, we are funding reforms of authentic faculty programs and courses that require the key educational research and development tasks: video content development; course integration; and, obtaining feedback (task review) according to Elliot's (1991) action research reflection-upon-practice recursive cycle. We will be disseminating our first year pedagogical 'findings' of these research 'tasks' to this conference and will also be seeking to hold a video festival of exemplary video-clips that have been compiled from content sources developed by our project teams.

Conclusion

Light Bridge is an innovative Internet2-based development of video content for university teacher preparation programs. It relies upon the cooperation of a broad array of both public and private sector partners: school districts; county offices of education; universities; credential programs such as 'CalStateTEACH'; CENIC (Corporation for Education Network Initiatives in California)/DCP (Digital California Project); and, corporate partners such as Cisco Systems and Apple, Inc.

Abstract

Sonoma State University (SSU) is part of the California State University (CSU) system and has received a PT3 Federal catalyst grant over the period 2001-2004 for project 'Light Bridge'. The Light Bridge project aims to develop video content resources for California's Internet-2 network, the next and most powerful generation of today's Internet. The project is both piloting and establishing revolutionary practices in preparing pre-service teachers to be adept and sophisticated in using technology in the classroom.

Video Festival proposal for the Light Bridge project

The Light Bridge is a PT3 Catalyst project that aims to produce exemplary video content material for integration and experimentation into teacher preparation programs across the California State University system.

We aim to show a compendium of videoclip content material as exhibits that capture the classroom performance of pre-service teachers for analysis and criticism by mentor teachers and university supervisors. The following developmental curriculum areas are being 'captured':

1) Classroom management;
2) Reading Language Arts and Second Language Acquisition;
3) Mathematics and Science;
4) Physical Education;
5) Video Case Studies; and,
6) Videoconferencing/Student Teaching

Any video content that has been placed on an Internet-2 server and can be connected via a broadband Internet connection at the conference venue could also be demonstrated as
part of the 1 hour video festival demonstration session. We will produce an instructional handout for the delegates summarizing the project. This festival proposal represents the practical component to our proposed full paper on the topic, which has also been submitted to SITE 2002.

The Partnership to Infuse Technology into the Teacher Education Curriculum, a PT3 Implementation grant awarded in 2001, focuses on the simultaneous professional development of teacher education faculty and in-service teachers so that they will model meaningful implementation of technology and engage pre-service teachers in its use in university courses and clinical experiences. The primary goals of the project are that faculty and P-12 teachers will model the effective integration of technology for teaching and learning, and subsequently, graduates of the teacher education program will meet or exceed technology standards for first year teachers. The university’s Colleges of Education and Liberal Arts and Sciences, the university’s Faculty Development and Instructional Design Center, four school districts, two community colleges, and one business have partnered in this effort. The project components include: Integrating Technology in the Curriculum (ITC) course for faculty, the Engaging with Technology (EWT) on-line course for teachers, technology-rich clinical placements for pre-service teachers, technical support for pre-service teachers, a faculty/teacher exchange within ITC and EWT, the Summer Institute, and the establishment of a virtual learning community through the WebForum.

In fall term of each year of the grant, new faculty in the College of Education take the formal 16 week course, Integrating Technology in the Curriculum (ITC) while they are paired with teachers from the four partner districts taking the formal 16 week on-line course, Engaging with Technology (EWT). In spring term, continuing faculty in the university and community colleges take ITC and are paired with district teachers taking EWT. In both semesters, pre-service teachers in both third and fourth professional semesters, are paired, for their clinical experiences, with district teachers either taking or having completed EWT. Thus, active triads of faculty, teachers, and pre-service students are engaged in independent and collaborative efforts to effectively integrate technology into teaching at multiple levels.

Our most critical and fundamental component is ITC and, we have more experience with this component than any other. The ITC course was first delivered in fall 1999 as a mandatory course for new faculty hired by the College of Education. The College of Education has fully supported the delivery of the ITC course during the fall term of each of three years. In 1999, nine faculty completed the course, which met 3 hours per week for 16 weeks. New faculty were reassigned from teaching one course to take ITC. The original objectives were first, to rapidly improve the instructional skills of faculty in effectively integrating technology in their courses, and second, to facilitate the development of a cohort of faculty who were encouraged to work collaboratively in instruction and research using technology. The ITC course was again delivered in Fall 2000 under similar guidelines to 13 new faculty. During that term, new faculty in other colleges at NIU who taught preservice teachers were invited to attend. In Fall 2001, the 16-week, for-credit, ITC course is mandatory for 19 new COE faculty. Faculty were again reassigned from teaching a course to enroll in the course. The content of the course includes topics such as engaged learning with technology, ISTE and NCATE standards for technology, awareness of the technology available for instruction and research throughout the university, information tools, network tools, PC system maintenance, presentation tools, interactive multimedia (digital cameras and camcorders, working with graphics, etc.), distance education, BlackBoard, WebBoard, e-portfolios, assessment by and for technology, copyright and ethical issues, instructional video, and funding sources on-line.

During the spring term of each of the three years of the PT3 grant, 2002 to 2004, the ITC course will be offered to faculty in the partner colleges including College of Liberal Arts and Sciences, the College of Education, and the two community colleges on a competitive basis. Instead of providing a course reassignment, the faculty will be offered a stipend. Over the last two years, many senior faculty have requested the ITC course be offered to them. We anticipate more applications than we have room for in the course.

For the purpose of this paper, our research questions of interest are as follows:
(a) Does the ITC course, as currently configured, provide the framework for faculty to adopt the use of technology throughout their work as faculty, and particularly in their teaching?

(b) In the language of Rogers' Diffusion of Innovations (1995), who are the innovators, early adopters, early majority, late majority, and laggards with respect to adoption of technology?

(c) Using Roger's Model of the Innovation-Decision Process, can we determine the effect of the ITC course on the stages of the innovation-decision process: Knowledge: awareness of the innovation; Persuasion: attitude formation of the potential adopter; Decision: symbolic adoption; Implementation: trial or behavioral adoption of the innovation; and, Confirmation: seeking of reinforcement.

(d) Further, are modifications to the course structure needed to facilitate the adoption of change by the growing number of faculty who have completed the course so that we can observe movement toward the goals: modeling effective technology use in classroom, revising courses to include technology integration, requiring students to use technology in coursework, using new assessment models incorporating e-portfolios, and aligning curriculum with state and NCATE standards and our conceptual framework?

(e) Which faculty are most successful in moving toward the intermediate objectives as directed by the Logic Model based evaluation (McLaughlin and Jordan, 1999)?

Data that have been or will be collected, prior to March 2002, relevant to the project evaluation and decision-making in regard to the ITC course include:

1. Cohort studies of the classes of '99, '00, and '01 through focus group interviews, individual interviews and document reviews of syllabi and course materials, and, a survey of current skills and technology integration and needs for more training, information, and interaction with the technology and grant staff.

2. Pre and post measures of the '01 class of technology integration skills and use, and attitudes toward change in their teaching

3. Survey of undergraduate College of Education pre-service teachers on skills and attitudes related to their technology use, technology use by their instructors, and course requirements using technology; first conducted in Spring 2000 and to be repeated in January 2002.

4. Applications from faculty to take the spring '02 ITC course that will include statements of current competence, interests, needs, and plans for use.

5. Technology survey and needs assessment of regular continuing faculty in the partner university and community colleges

The Logic Model (McLaughlin and Jordan, 1999) "describes the logical linkages among program resources, activities, outputs, customers reached, and short, intermediate and longer term outcomes." This model provides the underlying framework for the project evaluation and therefore guides the collection of data for decision-making purposes. Underlying the evaluation of the grant activities is the Rogers' (1995) Diffusion of Innovations Model. The innovation-decision process is "the process through which an individual (or other decision-making unit) passes from first knowledge of an innovation, to forming an attitude toward the innovation, to a decision to adopt or reject, to implementation of the new idea, and to confirmation of this decision" (Rogers, 1995, p. 163). Within this framework, the data will be examined to answer the research questions noted above. The presentation at the SITE conference of this analysis of the ITC course would focus primarily on the issues of faculty development and change.

Integrating Technology Use in the Interning Experience

Marcia Cushall, Frostburg State University, US

The use of technology in the classroom can empower both teachers and students. However, its effectiveness in instruction depends on how teachers and teacher candidates use technology in their classrooms (Maddux, Johnson, & Willis, 2001). Teacher preparation programs should prepare candidates to integrate technology appropriately and effectively throughout the curriculum. This preparation must be achieved through instruction, field experiences, clinical practice, and assessments (NCATE 2000 Unit Standards). Assessment of candidates’ use of technology in the classroom is an important component part of their field experiences.

The assessment of the candidate’s performance should include assessment of the planning for appropriate use of technology, delivery of instruction, active involvement of the students in the use of technology and reflection about the process and the student learning. Performance assessments that include these elements have been developed by the Maryland Technology Consortium. The consortium evolved from a University System of Maryland (USM) task force convened in 1998 to define Maryland Teacher Technology Outcomes and performance assessment tasks for beginning teachers.

The task force consisted of K-12 teachers and coordinators, higher education faculty, Maryland State Department of Education (MSDE) personnel, and personnel from the Maryland Higher Education Commission (MHEC). During spring and fall of 1999, the draft outcomes developed by this task force were distributed to schools and professional organizations for feedback.

During this same time, the task force lead by MSDE applied for and received a PT3 Catalyst Grant to continue its work. The task force membership was then expanded to create the Maryland Technology Consortium. The consortium included the original task force members, representatives from additional institutions of higher education and additional local schools, more representatives from MHEC and MSDE, and representatives from the Human Resources Research Organization and from the Regional Technology in Education Consortium. The goals for the Maryland PT3 Catalyst Grant are 1.) curriculum redesign, 2.) development of performance assessments, and 3.) candidate development of electronic portfolios.

Supported by funding from the grant, the outcomes were revised and draft performance assessment tasks were developed for three of the seven outcomes. The revised outcomes address the following seven areas: 1.) information access, evaluation, processing, and application, 2.) technology communication, 3.) legal, social, and ethical issues, 4.) assessment for administration and instruction, 5.) technology integration, 6.) adaptive and assistive technology, and 7.) professional growth. In development of the performance assessment tasks, each task was to include the technology outcome, the technology indicators, the knowledge and skills needed to perform the task, a task summary, the scoring tool and criteria for evaluation, benchmarks, instructor notes, and curriculum connections.

In fall, 2000, the three performance tasks were piloted on several campuses and work began on the remaining four outcomes. In fall 2001 the outcomes became standards and the performance assessments were disseminated for full scale implementation of the standards and assessments within Maryland higher education. Standard V addresses integration of technology into the curriculum and instruction. Two performance assessments were developed for this standard and it is expected that these assessments will be completed during a candidate’s interning experience. The first assessment addresses the use of technology in the delivery of instruction; the second addresses student use of technology to support problem solving, communication and collaboration. Both assessments include evaluation of the planning for instruction, the delivery of the instruction, and reflections about the instruction.

The use of technology in the classroom can empower both teachers and students. However, its effectiveness in instruction depends on how teachers and teacher candidates use technology in their classrooms. Assessment of candidates’ use of technology in the classroom is an important component part of their field experiences. Performance assessments that include field-based components have been developed by Maryland Technology Consortium. The consortium evolved from a University System of Maryland (USM) task force convened in 1998 to define Maryland Teacher Technology Outcomes and performance assessment tasks for beginning teachers. To continue its work after the draft outcomes were developed, the task force applied for and received a PT3 Catalyst grant. Supported by the
grant, performance assessments were developed. One of the standards (formerly outcomes) addresses integration of
technology into the curriculum and instruction. Two performance assessments were developed for this standard and it
is expected that these assessments will be completed during a candidate's interning experience. These field-based
assessments will be shared and discussed. Participants will be encouraged to offer feedback on the content and form of
the assessments.
PT3: Preservice Teacher Education - How to integrate technology into teaching successfully using Intel's Teach to the Future

Shirley Davis, New Mexico State University, US
Susan Brown, New Mexico State University, US

New Mexico State University (NMSU) adopted a unique program to enhance their pre-service teachers program to integrate technology into teaching. This program meets the NCATE technology competency requirements and dovetails with what NMSU has been doing in the College of Education to integrate technology into teaching. Pre-service teachers are learning content knowledge about science, math, or early childhood education as well as the use of technological tools and how they enhance learning environments. Furthermore, these students are becoming technology savvy, more confident and better problem solvers in meeting the needs of the students of the 21st century or the digital generation.

Introducing the “Intel Teach to the Future Pre-Service Program”:

“Intel® Teach to the Future Pre-Service Program was designed to address the challenges that future teachers will face in effectively applying computer technology to enhance student learning. At the completion of the Intel Teach to the Future curriculum, pre-service teachers will have created a well-documented Unit Portfolio that engages students and helps them attain state and national standards.

The planning process begins with pre-service teachers determining what the K-12 student should be able to understand and achieve by the end of the unit. Next, pre-service teachers make decisions about what sort of evidence they would accept to prove that their students have developed this level of understanding and skill development. Throughout the Intel Teach to the Future curriculum, technology is used as a tool for K-12 students to create products that demonstrate their understanding and skills. As part of the Unit Portfolio, pre-service teachers create sample student products along with assessment tools to be examples and models for their future students. Once pre-service teachers have clearly outlined the desired results and created sample projects that demonstrate acceptable evidence of understanding, they then plan instructional activities and create teacher productivity products to support their unit.”

http://www.intel.com/education/teach/preservice.htm

We believe that the power of technology cannot be tapped unless it is grounded in new models of teaching and learning based on a student centered, project based curriculum, increased opportunities for active, hands-on learning, and respect for multicultural diversity. The goal of the “Teach to the Future” Program is to help pre-service teachers expand the boundaries of their creativity and the creativity of their students beyond the walls of the classroom. The modules provided by Intel are dedicated to actively engaging the pre-service teachers so that they construct knowledge through actions and interactions within their environment. The skills that the students learn are not isolated, but are integral parts of the classroom environment. With the help of the Intel modules, the NMSU team is helping the pre-service teachers become comfortable with the technological tools and become knowledgeable in using these technological tools to enrich the learning of all students in their future classrooms.

We tailor Intel’s “Teach to the Future” program to dovetail with NCATE technology competency requirements. Pre-service teachers will take a technology survey at the beginning of the semester with
questions coming from NCATE technology competency requirements. Students will create “technology badges” using MS Excel to see where their strengths and weaknesses are. The technology badge will provide the instructor a blueprint in tailoring students’ learning to meet the NCATE requirements. Students build “electronic portfolios” as they progress through the “Teach to the Future” program. At the end of the program students take the technology survey again and create a post “technology badge” to show progress. They will also have a collection of resources in their “electronic portfolio” to help them when go into the classrooms to teach.

Intel program allows instructors to select various modules for their students in the following classes: Language Arts and Social Studies, Methods of Teaching Elementary Science, Early Children Science and Math Methods, Integrating Technology into Teaching. All of them are required courses for Teacher Education Program (TEP) at NMSU. The modules include the following: copyright issues, creating unit lessons plans, locating resources for unit portfolios, creating student multimedia presentations, creating student publications, creating unit support materials, creating student web sites, teacher support materials, developing plans for implementation and showcasing unit portfolios.

The structure for implementing the Intel program is for pre-service students to take EDUC 368: Integrating Technology into Teaching (a pre-requisite course) before entering the TEP. Students taking this course cover 8-10 modules listed above. When these students enter the methods courses during TEP, they will already have the basic foundation of computer technology to allow the instructors to go right into content areas using the skills the students have learned.

The New Mexico State University College of Education is dedicated to the highest standards in our teacher preparation courses. These pre-service teachers will be shaping the future by teaching the students of the future. It is imperative that we keep up-to-date and using technology as the avenue to open wider the world of learning, the Intel modules will be a welcome addition to our curriculum. Dr. Brown, and Ms. Davis compose a team of faculty leaders who will guide others in this implementation of technology modules.
Sustainability of a PT3 Program: A Case Study

kajs@cl.uh.edu

Abstract: A key issue in educational change is the ability to sustain change related to educational innovation. Although vast numbers of educational innovations have been introduced into schools over the past 20 years, few have succeeded in effecting affective, behavioral, and cognitive student gains (Hord & Hall, 1986; Morris, 1997; Rubin, 1983). In 2000, the University of Houston-Clear Lake, in collaboration with eight school districts, DePaul University, and corporate sponsors received a three-year, one million dollar grant from the U.S. Department of Education to infuse technology into teacher preparation. Since programs tend not to be continued after federal funds terminate (McLaughlin and Berman, 1977), researchers with the UHCL collaborative studied factors related to the sustainability of innovations after grant’s end. This paper will discuss the factors that influence the successful sustainability of innovations in an educational environment and apply these factors to the UHCL PT3 program, using a case study format.

Introduction

A key aid in initiating school change, especially in the areas related to technology, is the acquisition and use of grants from both public and private sources. Essential in this process is the realization that grants function as temporary catalysts for meaningful change. Many of the attributes associated with sustaining educational programs or innovations need to be in place prior to and during implementation of the grant in order to sustain the program or innovation after grant funding ends. Researchers at the University of Houston-Clear Lake identified attributes that relate to the successful institutionalization and sustainability of educational innovations and incorporated findings into practices related to the Preparing Tomorrow’s Teachers to Use Technology (PT3) grant.

Overview of Sustainability

The concept of “sustainability” of any educational innovation is relative new to research and is equally as imprecise. Wormsley (1990) illustrated the ambiguity of the “sustainability” concept through a series of unanswered questions. Sustainability of a grant’s innovative process often collapses at the end of the funding period due to local causes including failure to continue financial support, lack of skilled manpower, and lack of interest (Wormsley, 1990). Consequently, decision-makers must be aware of these factors to ensure sustainability for the long-term success of innovations. Without sustainability, any innovation is likely to fail Curry (1992). While the use of the term “sustainability” is relatively new to research, Vaughn, Klingner and Hughes (2000) define sustainability as the extent to which it is reasonable to assume that educators will continue practices over time. This process, then, can be described as organizational change.

Miles’ (1983) work illustrated two cogent points about the process of organizational change. First, he pointed out that the majority of work on change stresses the “front end” of the process of change, or the adoption of the innovation. Second, he concluded that a helpful method of viewing the sustainability of change efforts is through a process of providing supports and overcoming obstacles. In addition to the support and obstacle approach, there is a general flow of the activities associated with sustainability that begins with the organization and flows through the users of the innovation to the innovation itself.

Bell (1983) approached the concept of sustainability by discussing the interaction between the innovation and organization, and four categories of factors. These factors, when applied to the context of an innovation, provide a method of assessing the likelihood of the sustainability of the innovation. The factors are those related to the (1) nature of an innovation, (2) nature of the organization, (3) external environment and needs of the external environment, and (4) granting agency. Researchers at UHCL used Miles’ (1983) and Bell’s (1983) approaches to guide the case study about the UHCL PT3 program. The following case study incorporates issues related to sustainability of educational innovations and discusses the implications of the findings.
Case Study

A key feature in providing organizational support to the innovation is the willingness of the organizational leadership to function proactively at three levels: (1) providing appropriate funding, and (2) supporting the innovation mandated use and rewarding of employees who contribute to the innovation, and (3) providing for staff development activities. The collaborative addressed these features through infrastructure and personnel. Leadership acquired a cold-fusion server for grant project’s use and supported professional development among faculty and staff, and helped implement the PT3 program objectives in the teacher preparation program.

A second area of influence on sustainability relates to the ability of the organization to support the users of the innovation through the change process. Particular emphases include activities related to user commitment and staff turnover. Through the grant, leaders provided resources, including release time, to assist users in implementing project objectives and in researching specific facets of the innovation. Additionally, the School of Education, through its own funds, invested in both hardware and personnel to assist in the creation and maintenance of a comprehensive website. The issue of staff turnover, in this particular case, was considerably more difficult to address as the concept of “soft money” could adversely impacted the continued employment of grant personnel.

A final key to sustainability lies in the quality of the innovation. In this area, the collaborative focused on two primary areas: (1) the mission of the School of Education, and (2) the requirements of the granting agency. Through this effort, the innovation became a comprehensive tool for the education of teacher candidates and the improvement of Pre-K to 12th grade education. Ongoing assessments have also been incorporated into the grant cycle and have been a stimulus to adapt professional development activities and to improve the content of the website. According to Stiggins (2001), two conditions underpin assessment success: (1) clear and appropriate achievement targets, and (2) an assessment-literate faculty. Consequently, educational leaders need to understand the issues, e.g., personnel, organizational environment, involved in the change process, particularly when attempting to sustain educational innovations.

Design Team Facilitator, Graduate School of Education
Patricia_Fontaine@uml.edu

John Wren, University of Massachusetts Lowell
Project Technology Assistant, Graduate School of Education
John_Wren@uml.edu

“Ready to Teach”, a Preparing Tomorrow’s Teachers to Use Technology project, provides training and support for higher education faculty who will model technology use in their classrooms. University faculty, K-12 cooperating teachers, and preservice teachers work together to fully integrate technology into classwork and curriculum.

In an effort to further the PT 3 initiative at the University of Massachusetts Lowell’s Graduate School of Education, we created six design teams. Each team consists of cooperating teachers from local public schools, preservice teachers in the Graduate Program of Teaching and faculty from the Graduate School of Education as well as the division of Arts and Sciences. During the first year of our Implementation grant, we supported these teams in a successful collaboration that cut across grade levels, elementary through graduate school. The ultimate outcome from each team was a curriculum unit infused with technology that can be taught in the region’s elementary schools. In addition, preservice, inservice and university faculty were exposed to the uses of multimedia equipment, software and other resources in order to become technology-proficient curriculum integrators.

Our poster presentation will highlight a successful collaboration among a second grade team from a local elementary school, an elementary social studies class of preservice students and their faculty advisor, and a university arts and sciences faculty member who is a specialist in Native American history and culture. The second grade team consisted of four classroom teachers, one special education teacher and the building technology specialist who is a certified teacher. The curriculum unit that is taught at this level is Native Americans in the Merrimack Valley.

We will present a poster of work that was produced as well as demonstrate on two laptops the lesson implementation at the school site and the projects completed by the preservice students. This work will exhibit the participants’ use of multimedia, Internet research and web design skills. Our presentation will walk the viewer through the entire design team process culminating in these finished products.

We consider year one to be a pilot year for the use of this design team format. We will share lessons learned that will make the process even stronger in the following years of the “Ready to Teach“ project. We have found that successful collaboration can occur among the constituents, that products can be disseminated across school districts, and that technology skills learned by students and faculty can be easily incorporated into university classes as models of teaching and learning.
Evaluating Web-based Environments for Teacher Professional Development on Technology Integration

Sara Dexter
sdexter@umn.edu

Christine Greenhow

Eric Riedel

Center for Applied Research and Educational Improvement (CAREI),
University of Minnesota
U.S.A

Abstract: Quality teacher professional development (TPD) for technology integration is especially needed. Online delivery methods offer much promise for anytime, anywhere teacher learning. Evaluation tools and methods can help designers of technology integration TPD sites meet their goals of providing quality learning opportunities for teachers. We developed and implemented a plan to evaluate issues of quality and quantity in web-based TPD sites. We present these methods and illustrate their application to a technology integration TPD site called Ed-U-Tech.

Introduction

Teacher professional development should support teachers' construction of new knowledge as well as connect with what teachers do everyday (Corcoran, Shields, & Zucker, 1998; Joyce & Showers, 1995; Loucks-Horsley, Hewson, Love & Stiles, 1998; Sparks & Hirsh, 1997). Quality professional development for technology integration is of special importance since as of last year, only 20% of our nation's teachers reported feeling well prepared to integrate any educational technology into classroom instruction (NCES, 2000). And new standards for teachers emphasize the importance of professional growth in technology integration competencies (ISTE, 2000; NCATE, 1997).

Many for-profit, school district, and higher education entities are looking to Web-based, technology-focused teacher professional development (TPD) sites to support teachers' expanding their pedagogical repertoire regarding integrating and implementing networked technologies (Goldman, 2001; Schlager & Schank, 1999). Although participating in networked communities, collaborating with peers and exchanging resources might facilitate teachers' development, most educators have not availed themselves of the Internet in these ways. According to Becker's national survey of Internet use by teachers (1999), web browsing and email were the Internet capabilities most often utilized by teachers and students.

For those seeking to offer Web-based learning environments to teachers, it is key they learn: What website characteristics are associated with a quality online learning environment? Which aspects of the site most engage teachers? Which teachers are drawn in to the site? We developed an evaluation plan to help us answer these issues of quality and quantity in web-based TPD sites. We will present these methods and instruments in this paper and illustrate their application to a technology integration TPD site called Ed-U-Tech.

Measuring the Quality of Teacher Professional Development Sites

Web-based teacher professional development sites are most likely to be effective when they are designed and utilized in ways consistent with the research on how people learn. In How People Learn: Brain, Mind,
Experience, and School, Bransford, Brown, and Cocking (1999) base the following key dimensions of effective learning environments upon current educational and cognitive neuroscience research.

Knowledge-centered environments focus on developing knowledge of the discipline and of teaching and learning. In a web-based environment, this might translate into digital content-area curriculum that is up-to-date, authentic, accessible and generative, and contains hyper-linked resource areas.

Community-centered environments evolve a community of practice among teachers where members develop common goals and collaboratively work toward achieving them. In a web-based environment, this could be expressed as Internet-based conferencing environments that assist communication over distances, or a repository of artifacts of each teacher’s practice.

Assessment-centered environments support teachers’ testing of ideas by promoting ongoing reflection and feedback on practice. Effective websites might include a design that use Internet-based networking to promote ongoing reflection and feedback on practice in a manner that is sustainable, wide reaching and affordable.

Learner-centered environments center on teachers as learners, building on their strengths, interests and needs. One of the most promising and under-appreciated qualities of new information technologies is their interactive capacity. This has special significance for judging the extent to which professional development websites provide learner-centered environments or otherwise are able to utilize users’ input to support their learning. Users can customize the site according to their preferences and level of knowledge as pedagogical designers.

The above conceptual framework was further developed and operationalized as a checklist of the desirable features of web-based environments for teacher professional development (see Table 1).

Measuring Quantitative Aspects of Teacher Professional Development Sites

In learning about the effectiveness of the website as a dynamic learning environment for teachers’ professional development, evaluators need to look carefully at its quantity of reach, or the number and frequency of users and how well this profile matches the intended audience.

To measure the reach, or “the who,” of a site, it should be backed by visitor traffic analysis software. Several commercial packages are available; we selected WebTrends for its good features-to-cost ratio. This traffic analysis package provides both summary and detailed statistics on visitor demographics, the site resources accessed, activity statistics (including visitor behavior in time increments), technical statistics (including server and client errors), as well as data on referrers (links) sending visitors to the site and analysis of keywords used in site searches.

These data allows site designers to: gauge the reliability of the website; triage which content areas to develop further, which areas to focus on less, and how to arrange content most effectively; decide how to optimize the architecture of the website based on where visitors are entering; determine which external links are most effective; and determine, to some degree, visitors’ satisfaction with their visits.

Evaluation Methods Applied to a Technology Integration TPD Website

We used qualitative and quantitative methods to help us answer questions concerning the Ed-U-Tech site’s quality (http://www.education.umn.edu/edutech), and the quantity of its users. Ed-U-Tech is a website that is designed to serve as a learning environment for teachers both during their licensure program at the University of Minnesota and after graduation. A PT3 implementation grant to the University of Minnesota provided the resources to develop the site. The authors of this paper represent, respectively, the PT3 project’s director, coordinator, and two evaluators. We sought to evaluate the project’s website to improve its functionality as a TPD environment. The results from our analysis are briefly summarized below.
A visual review and content analysis using a checklist of quality online learning environment characteristics allowed us to evaluate the Ed-U-Tech site in terms of how it mapped to knowledge-, assessment-, community-, and learner-centered standards (see Table 1).

### Possible Features of Knowledge-centered Online Learning Environment

<table>
<thead>
<tr>
<th>Feature</th>
<th>Ed-U-tech Site’s Knowledge-centered Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hyper-linked resource area (e.g. links to content area standards, current research on Methods and Learning Theory, etc.)</td>
<td>1. Hyper-linked Resource areas grouped according to content areas with links to content area standards, lesson plans, clearinghouse sites, professional associations, professional journals, professional development and/or college of education courses)</td>
</tr>
<tr>
<td>Digital content-area curriculum that is up-to-date, authentic, accessible and generative.</td>
<td>2. Resources in each content area provide links to reviewed sites and digital curriculum that is up-to-date, generative, and cutting edge.</td>
</tr>
<tr>
<td>Electronic networking forums to support knowledge sharing (e.g. web-based libraries of: videos of teachers and accompanying descriptions exchanged, reviewed, annotated, and linked to additional resources; lesson plans; journal entries; student work)</td>
<td>3. A series of interactive online case-based scenarios (IMMEX) with opportunity to practice curriculum design in content area and see exemplars</td>
</tr>
<tr>
<td>Interactive curriculum design tools with electronic prompts to scaffold thinking</td>
<td>4. A Discussion area where users can post a relevant article and start or join discussion threads focused around the integration of technology in education</td>
</tr>
<tr>
<td>Electronic notebooks encourage reflection in design process</td>
<td>5. Online Request forms ask educator’s to contribute their content area knowledge to the resource base.</td>
</tr>
<tr>
<td>Interactive survey instruments that encourage reflection on pedagogy</td>
<td>6. Introduces conceptual framework for thinking about technology integration (eTIPS)</td>
</tr>
<tr>
<td>1. Hyper-linked Resource areas grouped according to content areas with links to content area standards, lesson plans, clearinghouse sites, professional associations, professional journals, professional development and/or college of education courses)</td>
<td>7. Interactive forms ask users to reflect on eTIP principles and share their thinking</td>
</tr>
<tr>
<td>2. Resources in each content area provide links to reviewed sites and digital curriculum that is up-to-date, generative, and cutting edge.</td>
<td></td>
</tr>
</tbody>

### Possible Features of Community-centered Online Learning Environment

<table>
<thead>
<tr>
<th>Feature</th>
<th>Ed-U-tech Site’s Community-centered Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet-based conferencing environments that assist communication over distances</td>
<td>1. Electronic archives record discussion group history and provide a record of evolving ideas.</td>
</tr>
<tr>
<td>• Synchronous mechanisms (e.g. via “chat” rooms, multi-user virtual environments or asynchronous email, bulletin boards, threaded discussion forums)</td>
<td>2. Threaded discussion forums provide anytime-anywhere access to fellow educators</td>
</tr>
<tr>
<td>• Asynchronous mechanisms (e.g. email, bulletin boards, etc.) which allow anytime-anywhere communication and archiving of discussions to assist the development of a group understanding over time.</td>
<td>3. Electronic newsletter organizes community happenings and disseminates new information</td>
</tr>
<tr>
<td>Coherent human infrastructure (i.e. human facilitators who moderate online conferencing environments).</td>
<td>4. Discussions are moderated by an experienced educator and technology coordinator</td>
</tr>
<tr>
<td>Repository of artifacts of each teacher's practice (e.g. examples of students' work, collaboratively designed lesson plans, electronic records of previous online discussions, URLs to relevant information, etc.) that can be quickly retrieved, distributed, organized, and stored within the online community</td>
<td>5. Opportunity to share knowledge of subject area by posting to Resource area</td>
</tr>
</tbody>
</table>

### Possible Features of Assessment-centered Online Learning Environment

<table>
<thead>
<tr>
<th>Feature</th>
<th>Ed-U-tech Site’s Assessment-centered Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tools for or that encourage self-assessment, reflection, metacognition, feedback.</td>
<td>1. From the website, users can link to Ed-U-Tech-created online case-based scenarios designed to enhance their ability to make good instructional decisions about technology. They receive</td>
</tr>
</tbody>
</table>
summativ feedback on their performance, but the
software does not provide formative feedback,
such as electronic prompts, during performance.

<table>
<thead>
<tr>
<th>Possible Features of Learner-centered Online Learning Environment</th>
<th>Ed-U-tech Site's Learner-centered Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tools for or that encourage peer exchange, constructive critique, networking.</td>
<td>2. The site contains a web-based discussion area, but it is not moderated, and receives little traffic and use.</td>
</tr>
<tr>
<td>Data in graphical, text-based, and multimedia forms, acknowledging diverse learning styles</td>
<td>1. The Ed-U-tech website adequately presents information in graphical, text-based, and multimedia forms, acknowledging diverse learning styles.</td>
</tr>
<tr>
<td>Searchable online database through which users can search the site by a topic of interest to support teachers in important aspects of their daily work and let teachers easily and quickly find what is of interest to them</td>
<td>2. The site does contain a search engine through which users can search just that site by a topic of interest.</td>
</tr>
<tr>
<td>Customization according to user's preferences and knowledge as pedagogical designer (i.e. through web-based tools such as search engines, databases, conversation tools, simulations, visualizations, learning environments, initiate discussion strands, import objects, attach files, store work, download software, post notes to published work, or add sound and video to the online workspace).</td>
<td>3. The site does not allow for any customizable forms or features or personal work space for users. However, users may search the site and initiate discussion in an online forum. They are also invited to submit comments and URLs of sites to add to each learning area's resources section.</td>
</tr>
</tbody>
</table>

Table 1: Characteristics of quality teacher professional development Web sites derived from How People Learn framework (Bransford, et. al., 1999) and applied to the Ed-U-Tech web site.

The WebTrends software was useful in addressing the question: Which aspects of the site engages users? Eighty percent of the most viewed pages on the site are comprised of the standards-defined curricular areas (i.e. Read, View and Listen, Write and Speak, Mathematical Concepts and Applications, Inquiry and Research, Arts and Literature, etc. About half of the visits are used to look at just one, two or three pages, while only nine percent of the visits are used to look at 10 or more pages. The mean visit is 17.05 minutes long, but the median visit is much shorter, 3.77 minutes. That 76 percent of the visit last less than one minute and that the median is so far below the mean visit length, suggests a small number of core users.

The Ed-U-Tech website's newsletter subscription feature helps us to learn which teachers are drawn in to the site. Of the 146 subscribers to the newsletter, about half indicated they worked at a K-12 school, half of these at a high school. Of the 72 subscribers who indicated their interest in one of twelve content areas listed on the site, the “Read, View, and Listen section for Language Arts attracted the most attention (21%).

The WebTrends software further informs our examination of the reach of the site. During a recent quarter (from April 1 through June 20, 2001), there were 5,613 visits to the Ed-U-Tech website. This represents an average of 61 visits per day during, with each visitor viewing an average of nearly 7 pages. Of the 5,613 visits, 1,836 were unique visitors. Where the country of origin was known, 96 percent of the visits were from the United States. Sixty-eight percent (1,254) visited just once; 32 percent (582) accounted for the remaining 4,359 visits.

Summary
The Ed-U-Tech website is strongest on its knowledge-centered characteristics, featuring technology resources specific to over a dozen different content areas. The site links to online cases that prompt users to make decisions about the use of technology to support their pedagogy. These offer some unique assessment capabilities. However, they are not immediately available, requiring registration and log in at a separate website. The site has strong capabilities to support community, through “telementor”-hosted asynchronous discussion; this feature has been used effectively in the past, but is currently under-utilized. Finally, the site offers little customization capability, reflecting weak learner-centered design.
Conclusion

Evaluation methods such as a visual review with a checklist and web traffic analysis software are cost effective, in that they can be employed remotely or automatically. This paper illustrates the use of these evaluation methods in a case study of a technology integration TPD site. But such tools do not necessarily reveal the complete picture on what engages teachers and encourages them to return for additional learning. Further development or tools are needed, as are additional examples of their application. Interview or survey data could help to provide this information that would help designers of technology integration TPD websites meet their goals of providing quality learning opportunities for teachers anytime and anywhere.

Science Made for Teachers

Jan Downing, Eastern Kentucky University, US

As a result of this grant and the efforts of the faculty, preservice teachers at Eastern Kentucky University receive college science courses designed specifically with the needs of elementary and middle school teachers in mind. What is unique about the program is that arts and sciences faculty who have been trained in the area of state standards, and current, appropriate teachings strategies teaches the courses.

Most faculty involved with the project received one three hour course release time to work on the project. The team met regularly and consisted of a faculty member in science education, special education, physics, chemistry, biology, earth science, an elementary education undergraduate student and a classroom teacher within the district. The education faculty served as consultants; sharing education standards set by the Kentucky Department of Education, appropriate teaching strategies, and technologies that assist teachers in the classroom.

The project has opened communication between the College of Education and the College of Arts and Sciences. Professors from both colleges work side by side in an effort to understand and meet the needs of future teachers of Kentucky. Currently data is being collected to analyze the effectiveness of the new program.

This session will share ideas for others interested in improving science courses for preservice elementary and middle school teachers.
Preparing Tomorrow's Teachers to Use Technology (PT3): Applying the Technology Integration Model for School Success (TIMSS)

Trudy L. Driskell
School of Education
University of Houston-Clear Lake
United States
Driskell@cl.uh.edu

Abstract: The University of Houston-Clear Lake (UHCL) in partnership with eight school districts in the Houston, Texas area, called the UHCL Collaborative, has developed a successful, field-based teacher preparation program. The UHCL Collaborative in collaboration with DePaul University and corporate sponsors received a three-year PT3 (Preparing Tomorrow's Teachers to Use Technology) Implementation Grant from the United States Department of Education. The grant's purpose was to design a model to prepare teacher candidates to be proficient in developing and delivering classroom lessons that integrate technology within the curriculum. The organizational development of this PT3 grant incorporated components of the Technology Integration Model for School Success (TIMSS) described by Driskell (2001). This paper will describe the development of these components within the grant's operations.

Introduction

In 2000, the University of Houston-Clear Lake (UHCL) in partnership with eight regional and urban school districts in the Houston metropolitan area, DePaul University, and corporate sponsors, Microsoft, Apple, Inspiration, and Tom Snyder Productions received a three-year Preparing Tomorrow’s Teachers to Use Technology (PT3) implementation grant from the United States Department of Education. The focus of the grant was to prepare teacher candidates to become proficient in developing and delivering classroom lessons that effectively incorporate technology in the learning process so that all students (Pre-kindergarten to 12th grade) use technology in demonstrating mastery of lesson plan objectives. The program’s specialty is that the lesson plan format has both the teacher and the classroom students using technology in the learning process. The grant’s organizational development incorporated the components of the Technology Integration Model for School Success (TIMSS) as outlined by Driskell (2001). The TIMSS consists of four major components: (1) administrative support for technology initiatives; (2) foundations of understanding for campus teachers; (3) modeling and coaching for campus teachers; and (4) on-site campus technology support. This short paper will describe the development of the four components within the grant’s operations.

Administrative Support for Technology Initiatives

Administrative support is the first component for successful technology integration in classroom pedagogy. The UHCL PT3 grant proposal requested partnership with school administrators who recognized the necessity of technology in pedagogy, communicated the need for technology on their campuses, and, when possible, modeled technology use. Many of the campus administrators participated in the PT3 grant training sessions, which added understanding of and support for the grant. Grant support from university administrators was crucial, especially for implementation and sustainability of the grant’s objectives. Administrative support of technology in education is highlighted by the ISTE (International Standards of Technology Education) technology standards for school administrators (http://cnets.iste.org/tssa/view_standards.html). These standards require that superintendents, district curriculum specialist, and principals, among others, promote a school culture that encourages technology use in innovative ways. “Having a school climate that encourages the use of technology resources in innovative ways” is necessary to breakdown the barriers that prevent technology integration in today’s classrooms (U. S. Congress, Office of Technology Assessment, 1995, p. 162).
Foundations of Understanding for Campus Teachers

The second component for successful integration of technology in classroom instruction is the preparation of teachers. Typically, the teacher is faced with the lack of time to learn and experiment with technology (Strommen & Lincoln, 1992). While professional development may mean in-services training that usually last one day, this one-shot strategy is not effective (Benton Report, 1997). The UHCL PT3 grant (http://pt3.cl.uh.edu) provided to preservice teachers, mentor-teachers, and university faculty three days of hands-on technology training, addressing the use of relevant software for student learning and the integration of this technology within the classroom curriculum (i.e., lesson plans). Moreover, grant participants were provided ongoing support in developing and delivering lessons plans.

Modeling and Coaching for Campus Teachers

Classroom teachers need modeling and coaching, especially from mentor-teachers, to successfully integrate technology within the curriculum. A vital part of the UHCL PT3 Grant was to provide to mentor-teachers and university faculty, who are supervising preservice teachers, the three-days of technology training. Together, preservice teachers, mentor-teachers, and university faculty worked together as a team to develop and delivery technology integrated lesson plans, addressing specific grade level needs. Working on these lesson plans provided opportunities to discuss how people learn: actively, constructively, collaboratively, contextually and in a multisensory manner (Hunter, 1993).

On-Site Campus Technology Support

The fourth component for successful integration of technology in classroom curriculum is providing on-site technology support. While school districts have technology support personnel for classroom teachers, they may not have been prepared in professional development specifically focusing on technology integration of curriculum in lesson planning. The UHCL PT3 grant provided training and a website (http://pt3.cl.uh.edu) as a source of support. Many campus administrators, serving as instructional leaders, attended the PT3 grant training sessions to gain additional understanding on the use of technology in classroom lessons. Moreover, school district technology trainers participated in delivering the UHCL PT3 training sessions on technology integration. Campus and school district technology personnel, as well as technology-proficient mentor-teachers, need to coach and guide teachers in using technology software tools, and in successfully developing and delivering technology integrated lessons.

Conclusion

The Technology Integration Model for School Success (TIMSS) as outlined by (Driskell (2001) provides four key components for the successful development of classroom pedagogy that integrates technology within the curriculum. The UHCL PT3 grant operations incorporated TIMSS in assisting teachers to be successful in preparing classroom students (Pre-kindergarten to 12th grade) to use technology in their lifelong learning.

Technology Support in a School-University Partnership

Judith Duffield, University of Colorado at Denver, US
Geraldine (Geri) DiPalma, University of Colorado at Denver, US

This proposal describes a comprehensive effort to improve the Initial/Professional Teacher Education (IPTE) program in order to produce quality educators who will have the tools they need to meet the needs of their students. While technology is just one of those tools, it is one of the most powerful tools and has the capacity to positively influence the entire schooling experience. This project uses a combination of technology experts at the university and partner school levels and leadership academies to infuse technology into course syllabi, teaching activities and assignments for the programs teacher candidates.

The vision for the IPTE program with regard to technology is that our teacher candidates emerge with the skills, knowledge, and dispositions to enable them to use technology appropriately in every aspect of their teaching career. The goal of this PT3 project is to transform the IPTE program into one where teacher candidates are immersed in technology best practices, both at the university and in their clinical experiences.

The Initial/Professional Teacher Education program (IPTE) serves students seeking initial licensure in general and special education and advanced licensure in special education. Students are admitted to the program in the fall or spring and are assigned to a professional development school (PDS). They follow the school's schedule, returning when the teachers do in August or January. Their time in the PDS is divided into four internships. Elementary teacher candidates usually stay at one school for all four internships, while secondary teacher candidates have at least one internship in a middle school and another in a high school. The first three internships are for two days a week and the final internship is for four days a week. While in the first three internships, teacher candidates are enrolled in courses two days a week or evenings. Coursework takes place on the university campus and in the professional development schools. Individual student progress toward meeting the state licensure standards is measured by performance-based assessments that rely heavily on performance in the PDSs.

Once the teacher candidates complete their internships, they are eligible to apply for a teaching license, assuming all state standards and program expectations have been met. After the teacher candidates are licensed, they may choose a specialty, either a state endorsement or a School of Education certificate, and continue in the master's program.

Program governance. The IPTE program is lead by two councils. The Partner Principals Council consists of the sixteen PDS principals and two UCD faculty members who are responsible for communicating between the two councils. The IPTE Council consists of the sixteen site coordinators and site professors, and other IPTE course instructors. Each group meets at least monthly to make program and policy decisions. The IPTE Council is responsible for admitting students to the program and placing them in schools. Each PDS has its own leadership team, comprised of the principal, site coordinator, site professor, and four teachers, which is responsible for ensuring that the goals of the partnership and the school are met.

Initial/Professional Teacher Education Faculty
The members of the IPTE program faculty are defined as all those university and professional development school professionals who supervise the learning experiences of the teacher candidates. Site coordinators are K-12 teachers who have been released from their classrooms to work fulltime for the partnership. They supervise teacher candidates and coordinate professional development for the school. Site professors are university professors who spend at least one day a week at the PDS. Clinical teachers are K-12 teachers in professional development schools who supervise a teacher candidate in their classroom for any of the four internships.

The professional development school faculty serve as site coordinators, clinical teachers, and course instructors. The university faculty, serve as course instructors and site professors, and include instructors from two divisions in the School of Education and instructors from the College of Liberal Arts and Sciences. Faculty members often fill more than one role.

The Teacher Candidates
The School of Education only serves graduate students. A few of our students come to the university directly from an undergraduate institution, but most have had other careers, from homemaker to lawyer to business owner. All students are placed in professional development schools for four internships over a period of a year and go through the program as a cohort. After licensure, a majority of these students are employed in the metro area where the university is located, but others are employed throughout the state and in many other states.

Professional Development Schools
Sixteen professional development schools (PDSs) are located in six districts in the metro area, which ranges from inner city urban to industrial to rural. Their students represent a diverse population with many languages, ethnic groups and socioeconomic groups, but an overwhelming majority of the K-12 students are from low socioeconomic families.

The PT3 Grant Activities
The project consists of a team of support personnel. Site Techs are partner school teachers who spend the equivalent of one day a week working with the school, teachers, and teacher candidates to move the school forward on their use of technology. University Techs are mentors hired to work with faculty on revising their courses to infuse more technology, build their technology skills, and to work with teacher candidates on their technology skills. All of the Techs meet once a month to share successes and challenges and develop strategies for meeting those challenges. This Technology Council has the responsibility of planning and leading the semester's leadership academy based on the need of those they work with and shares a parallel role with the IPTE and Partner Principals' Councils.

The purpose of this short paper is to share the progress that we are making in the first year of this grant and discuss the successes and challenges we are encountering and how we are addressing those challenges.

Need for the Project
To determine the need for and the design of this project, data was collected from all partners in the IPTE program. Members of the IPTE Council were asked to describe the technology vision they wanted for their schools and classes and what it would take to get them there. Those working in PDSs were asked about the technology available in their school and the skill level of their teachers. Teacher candidates and course instructors were asked to fill out the Technology Prerequisite Skills Checklist. Course instructors and site professors were asked to complete a survey based on the Colorado Teacher Licensure Technology Standard 7 and report how able they were to meet the standard and to teach others to meet the standard. In addition, experiences from the current program redesign efforts to integrate technology across the IPTE program were a part of the data collected. The grant committee met to analyze the data and determine possible solutions. The resulting proposal was taken to the IPTE Council and Partner Principals Council for their approval. The needs described below and the proposal described in the project design are a result of this process.

Technology in IPTE
Since the first program redesign in 1994, infusing technology throughout the curriculum has been a stated goal. No separate technology course has been part of the course of study, though students were offered a technology course as an elective in the post-licensure portion of their program. While progress has been made, the IPTE program has yet to fully integrate technology across all courses and internships.

When we started, few of the instructors possessed the skills necessary to make this integrated curriculum a reality. During the first year, the courses included one or two guest lectures on technology. The second year, an instructor with technology expertise joined the elementary team and added lessons and assignments that required the teacher candidates to use technology. In the third year of the program, an instructor with technology expertise was hired to teach one section of one of the two general secondary methods courses. At this time, the program faculty also identified places in the entire curriculum where technology and other skills could be integrated, beyond the methods courses. During the fourth year of the program, all students were required to use the email system sponsored by the School of Education.

Beginning in January, 2000, all students entering the Initial/Professional Teacher Education (IPTE) program are required to have 24 hour access to a computer and modem. This past fall, we began distributing a technology prerequisite skills checklist to all applicants. The checklist contains basic technology skills that will be required of all teacher candidates when they enter the program, along with suggestions of opportunities available to the applicant for mastering these skills. Beginning in 2001, all teacher preparation programs in the state of Colorado will be required to verify that their candidates for teacher licensure have met eight new standards. Standard 7 requires that the teacher is skilled in technology and is knowledgeable about using technology to support instruction and
enhance student learning, and has five supporting elements: (a) apply technology to the delivery of standards-based
instruction, (b) use technology to increase student achievement, (c) utilize technology to manage and communicate
information, (d) apply technology to data-driven assessments of learning, and (e) instruct students in basic
technology skills (see: http://www.state.co.us/cche_dir/agenda/marivb2.html).

UCD Faculty Technology Use. The faculty have gradually increased their personal use of technology. They were
asked to fill out the same Technology Prerequisite Skills Checklist completed by all program applicants. Fewer than
half reported that they would be unable to complete any of the individual skills described. The range on each of the
skills was from 0 to 42%, with 15 of the 38 skills being met by all of the faculty. Only one or two faculty could not
complete an additional eleven skills. The areas most in need for training were in digital camera use, creating and
using spreadsheets, and setting their VCR clock.

Despite these personal skills, most faculty members lack the support and vision for how to apply that knowledge in
the courses they teach. During program redesign meetings, it was common for a faculty member to state that they
did not have to worry about technology because it didn’t fit into their course. This is not the case. In a survey of
those teaching IPTE courses and serving as site professors, no one felt that they were well enough prepared in the
state technology standard elements to be able to teach all of them to our teacher candidates. While all but three of
the nineteen surveyed had some idea of what the standard elements addressed, only three felt fully prepared to teach
any of the standard elements.

We are making improvements. Up until last fall, university classroom technology was inconvenient at best. Now,
with the addition of two upgraded computer labs and one technology rich classroom in the School of Education, and
the number of technology-equipped classrooms on campus, using technology while teaching is less of an ordeal.
Most faculty members have required some form of electronic communication as part of their classes, advising, and
professional interactions. Based on a previous and very successful faculty technology mentoring project, an
internally funded grant is being used this semester to proved assistance to course teaching teams to include at least
one technology-based activity or assignment. Most of the faculty are at the point where a program like the one
proposed here will be welcomed and effective, even without the current pressure to integrate technology coming
from the state.

Based on these results, some IPTE program faculty need assistance with basic technology skills, but all need
assistance to see how technology fits into their courses and then in making it happen. As stated earlier, faculty from
the College of Liberal Arts and Sciences are part of the IPTE program and will be included in all grant activities.

Technology in the PDSs
When the partnership began in 1994, most professional development schools (PDSs) had a computer lab, but few
had computers or other technologies available in their classrooms. During the past four years, the amount of
technology available in the PDSs has increased tremendously. Now, every PDS has between one and seven
computer labs, with seven of the sixteen schools having more than one. All but one have from one to five computers
and Internet access in every classroom. The remaining school has computers and Internet access in about 75% of its
classrooms. Every PDS has a technology plan that guides their technology acquisition and use. Each of the six
partner districts have district level technology teams that provide assistance to schools. This demonstrates a
commitment to the use of instructional technologies.

PDS Faculty Technology Use. In a survey of the PDSs, the school leadership team was asked to determine the
technology skill and use level of the teachers at their school. The ratings they used were: (1) Technology experts
who use technology in creative and innovative ways, (2) Teachers who regularly use technology in their classroom,
(3) Teachers who use just enough technology to meet school standards, (4) Reluctant users who need lots of
encouragement and assistance, and (5) Non-users who avoid using technology at all. While some schools had more
or less expertise, across the partnership, data indicate that 9% were considered to be experts, 21% regular users, 40%
using just enough to get by, 20% reluctant users, and 6% non-users.

One school in the partnership chose not to participate in this proposal. We believe their reasons are factors that
affect all schools and must be carefully considered when carrying out this proposal. The school’s reasons dealt
mainly with a feeling of overload. State-mandated, high-stakes, standardized testing, participation in a literacy grant,
and district-mandated inservice leave little time in a teacher’s day.

Based on these results, there is a need for teachers to be able to use the technology that is becoming more available
to them in better, more innovative ways. As with the UCD faculty, some skill building will be necessary, but using
inservice training is not likely to be successful. More creative ways must be found to work within the constraints of
a teacher’s day.

Teacher Candidate Technology Skills
During the first six years of the IPTE program, teacher candidates were asked to choose a leadership area to focus on while they obtained their license. One of the leadership areas was technology. While during the first few years of the program, nearly all students with any technology background chose technology, in the last cohort of teacher candidates in leadership areas, technology expertise is not a determining factor. Teacher candidates with technology skills are just as likely to be in technology as any other leadership area. The revised program eliminated leadership areas in favor of post-licensure endorsement and certificate programs.

The teacher candidates entering the Initial/Professional Teacher Education program were asked to complete the Technology Prerequisite Skills Checklist. While no one skill was mastered by all teacher candidates, fewer than 10% of the 118 teacher candidates indicated that they could not pass 25 of the 38 skills. The biggest need areas were in creating PowerPoint presentations, creating spreadsheets, downloading and using pictures from a digital camera, and setting their VCR clock. This indicates that teacher candidates are entering with a higher level of technology experience, a reflection of the change in society in general. Based on these results, teacher candidates will need some assistance with basic technology skills.

Summary
All members of the IPTE partnership need some assistance in developing basic skills. All IPTE faculty, in the university and the PDSs, will need help in developing technology best practices and carrying them out in their classrooms. Creative ways of facilitating these changes that build on successful IPTE program structures must be developed in such a way as to not overly burden the participants.

Project Design
This proposal is part of a comprehensive effort to improve the Initial/Professional Teacher Education program in order to produce quality educators who will have the tools they need to meet the needs of their students. While technology is just one of those tools, it is one of the power tools that has the capacity to positively influence the entire schooling experience.

Goals, Objectives and Outcomes
The vision for our program with regard to technology is that our teacher candidates emerge with the skills, knowledge, and dispositions to enable them to use technology appropriately in every aspect of their teaching career. The goal of this proposal is to transform the UCD Initial/Professional Teacher Education program into one where teacher candidates are immersed in technology best practices, both at the university and in their clinical experiences.
Michigan Teachers’ Technology Education Network

Abstract: The purpose of this paper is to describe Michigan Teachers’ Technology Education Network (MITTEN) project and some of the program’s early impact on the preservice teacher preparation at the University of Michigan-Dearborn. MITTEN is in its first year in a three-year award funded through the U. S. Department of Education's Preparing Tomorrow’s Teachers to use Technology (PT3) fund. The defining component of the MITTEN model is its creation of a networked learning community. The project's goal is preparing a cadre of future teachers with improved knowledge, skills, and confidence integrating information technology into the teaching and learning process in meaningful ways. The project will redesign computing, methods, and content courses, field experiences, and student teaching to ensure that students meet National Educational Technology Standards for Teachers (NETS*T) throughout their programs. A further intent is to form a self-sustaining development network among future teachers, faculty, and P-12 educators. MITTEN establishes networked learning circles (NLC)-comprised of student teachers, P-12 teachers, supervisors, technology specialists, and faculty-that focused on: a) early childhood, b) language arts, c) mathematics, d) science, and e) social studies.

Recent studies indicate that if future teachers are to effectively use technology their preservice preparation should employ multiple components. These components include course work in education computing, opportunities to observe faculty modeling the use of technology and the meaningful integration of technology into clinical field experiences (Duran, 2001; Moursund and Bielefeldt, 1999). Strategies for addressing each of these are becoming more common. But models for drawing all of the components coherently together are in short supply. This paper discusses the MITTEN project, which is aimed at tying all three components into preservice teacher preparation at the University of Michigan-Dearborn (UM-D).

MITTEN: A Networked Learning Community

MITTEN is designed to prepare a new generation of future educators with improved skills, knowledge, and confidence in integrating information technology into the teaching and learning process. MITTEN addresses this goal by creating a networked learning community dedicated to the transformation of teacher preparation at UM-D through integration of information technology throughout the entire educational experience of all prospective teachers.

The specific program objectives are:

- to prepare a new generation of P-12 teachers who are able to creatively and critically use technology to enhance student learning;
- to increase current teacher educators’ ability to use technology to better prepare tomorrow’s teachers and to model meaningful uses of technology in their professional practice;
- to increase inservice teachers’ ability to integrate information technology into their curriculum and to mentor student teachers to use technology in a technology-enriched environment.
to develop a series of technology learning resources (including software tools, Web-based curriculum materials, and hypermedia best practice cases) that model intelligent and powerful uses of information technology for future teachers, practicing teachers, and teacher educators; and
to form a self-sustaining professional development network among future teachers, practicing teachers, and teacher educators to reach and use technology resources for their further professional development.

Preparing Technology-Proficient Educators

MITTEN offers three types of interrelated professional development activities to preservice teachers, inservice teachers, and education faculty: a series of Capacity Building Activities, a sequence of meetings of the Networked Learning Circles (NLCs), and a pair of Seminar activities. The meetings of the NLCs and the work undertaken within them are of primary importance to the project. The other sorts of activities, however, constitute important sources of support for that work.

Capacity Building Activities

The Capacity Building Activities are part of preparatory activities geared toward enhancing the productivity of the NLCs. Capacity building activities are designed to increase the levels of confidence and competence with information technology tools. The format of the activities is as group workshops, working lunch sessions, and one-on-one mentoring sessions. The general scope of the activities encompasses three needs areas—telecommunication tools, productivity tools, and educational multimedia—while specific emphases correspond to the needs that participants identify on needs assessments surveys.

During the Fall 2001, the first cohort group participated in the capacity building activities. The researchers will present the implications of these activities at the time of the conference.

Networked Learning Circles

The Networked Learning Circles or NLCs will facilitate learning about content specific use of technology in the subject areas. The participants' work within NLCs constitutes the core activity of the project. Each consists of faculty members in content areas, in teaching methods, and in educational technology together with student teachers and their mentoring school teachers and field supervisors. This alignment parallels in small-scale Goodlad's center of pedagogy idea (Goodlad, 1994). As Figure 1 illustrates, Goodlad's contention is that effective interaction regarding teaching improvement calls for engagement among three entities: schools of education, school districts, and colleges of arts and sciences. Certainly, while each of these three participants has its own functions other business to attend to, Goodlad has stressed that each is an essential and equal player in a healthy teacher preparation "ecosystem" (p. 9). Specifically, each NLC consists of student teachers (4), cooperating teachers from P-12 schools (4), student teaching supervisors (1), educational technology specialists (1), methods courses faculty (1) and content courses faculty (2) from related schools and colleges. More than just a setting, then, the center of pedagogy "brings together simultaneously and integratively the commonly scattered pieces of the teacher education enterprise and embeds them in reflective attention to the art and science of teaching" (p. 10).

Figure 1. The "Networked Learning Circle": a structure for collaboration on technology integration, adapted from Goodlad (1994).
MITTEN creates five NLCs, each related to one of five fields of study: (a) early childhood, (b) language arts, (c) mathematics, (d) science, and (e) social studies. The overarching task of each NLC is to develop and field-test authentic projects in which technology enhances teaching and learning in specific subjects addressing National Educational Technology Standards for Students (NETS*S).

During the Winter 2002, an initial cohort group of NLCs has commenced. The researchers will present the implications of the NLCs at the time of the conference.

Technology Seminars

Technology seminars address the social and cultural implications of information technology for schools and society. MITTEN offers two technology seminars in a year focusing on different issues. The Seminar activities are designed to build awareness of broader social issues related to educational technology, with attention to topics such as the "digital divide."

The first technology seminar will take place in the Winter 2002 focusing on the "digital divide" and its implication on the Michigan schools. The researchers will present the implications of the technology seminar at the time of the conference.

Learning with P-12 Partners

The members of MITTEN view teacher preparation as a university and community-wide responsibility. In addition to the project's private sector partner, RWD Technologies, the MITTEN program is a collaborative effort of the UM-D's School of Education and College of Arts, Sciences, and Letters, the Henry Ford Community College, and the public school districts of Dearborn, Livonia, Westwood Community, West Bloomfield, Redford Union, and Jefferson.

MITTEN is a three-year program with expanding participation. In each year, the project participants will include additional cadres of student teachers, cooperating teachers from P-12 schools, student teaching supervisors, educational technology specialists, and methods and content courses faculty from related schools and colleges.

Abstract: An example of a content-area approach to technology infusion is presented. A physical science team helps pre-service teachers who have learned science in a traditional lecture setting develop the necessary skills to implement a discovery approach to learning in their own classrooms. Pre-service teachers use technology to follow the same inquiry-based model of experimentation that scientists employ in research. They observe phenomena that have been digitally recorded, slowing down the phenomena to collect data. They develop models to explain the data and test them by predicting unobserved phenomena, thereby constructing their understanding of physics concepts. The project has significant influence over abilities and attitudes of teaching candidates as they develop expertise in their disciplines.

Introduction

Science standards call for a discovery approach to learning but this method is hard to implement. One reason is that many teachers themselves learned science through a traditional lecture method and do not feel comfortable with a discovery approach (Tilgner, 1990). Science departments in the universities continue to deliver content in a traditional manner, so prospective teachers might only have the opportunity to learn science through discovery during teacher preparation courses in schools of education (McDermott, L.C., 1974, Zacos et.al. 2000). An inquiry approach to learning physics can be enhanced through the use of digital videos and Internet archival data bases (Etkina et. al. 2000).

The current project is part of a longitudinal study of a content area, team based approach to technology integration, where teams of professors, K-12 teachers, graduate students, and teaching candidates innovate and implement new technologies for learning (Barnhart, 2001). The Physical Science team focuses on using technology in real time data analysis. Data are collected by videotaping physical phenomena that happen so quickly, or on such a small scale, that naked eye observations are unreliable for data collection. Digitized videos allow students to slow down the phenomenon, see the details that go unnoticed in real time, and measure the position of an object at a given instant.

Experiments in Physics Instruction: a New Approach

Experiments are typically used in physical science instruction for two reasons: (1) To demonstrate a phenomenon, showing students what happened and why it happened, and (2) to test and verify a physical law taught in class (for example: students might conduct an experiment to verify Newton's second law). In both cases the instructor gives a lot of verbal and/or written guidance as students move through the procedures. Research has shown that such use of experiments has been ineffective in providing a context for meaningful learning (Roth et al, 1997). Instead, students learn much better when they construct their understanding, following a path like the one that physicists follow to construct new knowledge (Etkina & Van Heuvelen, 2001). This allows new roles for experiments in instruction.

Scientist’s use of experiments may be organized into observational experiments and testing or application experiments. These two types of experiments are used together to construct a coherent scientific theory. The cycle may be summarized as follows: (1) A physicist observes a physical phenomenon, and may invent physical quantities to describe what is seen, looking for patterns in the data. (2) If some interesting patterns are seen, she may propose a...
mathematical model to fit the patterns. (3) She then uses the model to predict new (unobserved) phenomena or devise a real world application. (4) She then designs an experiment to test the prediction or try out the application. (5) If the results of the experiment were contrary to expectations, the physicist may make more observations, or revise the initial model asking such questions as: What simplifying assumptions did I make? Is there a different model that would adequately describe the initial observations? Can I make a more accurate calculation? And so on.

Using this approach as a guideline, we made videos of more than 50 experiments in mechanics, molecular physics and static electricity. Each was digitized and put on the web as a clip. Prospective teachers download the clip (http://www.pt3.gse.rutgers.edu/physics/frontp.html) and watch the experiment either in real time or frame by frame. The videos are categorized as scientists would use them: (1) observational experiments, for the first stage of the cycle as students observe phenomena, collect data, learn to represent them in multiple ways (tables, graphs, etc.) and interpret them, and (2) testing experiments, used later to evaluate the models students develop to explain the phenomena.

The initial work is usually done at home as a home lab. The next day in class the instructor discusses the observations with the students. Students are encouraged to suggest different explanations for the patterns of data. Using the explanations, students predict the results of a number of digitized testing experiments. After making their predictions, students watch the testing videos in class and see if their predictions were correct. An example of this cycle is the “Motion” module, one of nine modules used in science methods classes for pre-service elementary teachers. First students observe a clip of two objects (one 200 g and the other 500 g) dropped from the same height. They record positions of the objects at each frame, and use the table of data to draw a graph of position versus time and velocity versus time. The next day, using graphs created at home, students discuss the data in class and come up with a model to describe it. For example, they may create a model showing that the objects fall in the same way and the acceleration of their motion is constant at about 9.5 m/s². They use the model to predict what will happen if two objects are not dropped simultaneously. If they are falling with acceleration (the proposed model), the distance will increase; if they are falling with constant speed, the distance between them will remain the same. They test their predictions with the video clip of two balls dropped with a time delay. In this case the experiment confirms the prediction based on their model.

In the process, the students are given little or no explanation for what they see. They construct their own knowledge of physics in the same way physicists do. As part of the project, pre-service high school teachers follow the same process but provide more quantitative analysis, using real time data available through the web, such as NASA X-ray archives of photon counts collected by satellites (Etkina et al. 2000).

Conclusion

Teachers who have learned science in a traditional lecture setting are hampered in their ability to encourage constructivist learning in their classes once they begin to teach. This weakness can be overcome by modeling the approach scientists take when observing and predicting phenomena. The current project demonstrates that pre-service teachers who work in a digital science lab setting, given minimal but important guidance as they observe time and other variables, develop more meaningful understandings of physics. They then are able to provide their own students more innovative and authentic technological support for learning. Continuing work shows that the project is having significant influence over the abilities and attitudes of teaching candidates as they develop expertise in their disciplines.

Abstract In June of 2000, the Department of Educational Technology at the University of Northern Colorado (UNC) received a PT3 grant to prepare teacher education graduates to use technology effectively in their K-12 classrooms. This paper focuses on the lessons learned by PT3 grant team members, while working collaboratively to redesign coursework in the department of Educational Technology, College of Education, and College of Arts and Sciences for undergraduate pre-service teachers.

Description of the Project

In June of 2000, the Department of Educational Technology at the University of Northern Colorado (UNC) received a PT3 grant (Preparing Tomorrow’s Teacher to use Technology). The grant, “Infusing Technology Use in the Preparation of Colorado Preservice Teachers,” proposes a plan for systematically changing the teacher education programs at UNC by infusing technology throughout the curriculum. The grant plan builds on the strengths of the existing UNC Partnership Schools and the internationally recognized graduate programs in educational technology. The project has three overarching goals: (1) graduates of the UNC teacher education programs will effectively utilize technology for instruction in their classrooms when employed as full-time teachers; (2) UNC student teachers will effectively utilize technology for instruction in the partner school classrooms; and (3) UNC faculty members will effectively utilize technology for instruction and model appropriate technology use for the preservice teacher education students.

We are making progress toward these goals through five specific initiatives: (1) enhance the required educational technology courses for students in the professional teacher education programs; (2) model appropriate technology use and integrate technology utilization into the professional teacher education program courses; (3) model appropriate technology use and integrate technology utilization in the general education and content area discipline courses; (4) integrate technology use by preservice teacher education students in partner schools; and (5) build a model for the effective use of technology in preservice teacher education programs. All grant activities are focused on one or more of these initiatives.

The UNC PT3 project is now in its second year of activities. To this point, the project team has primarily focused on two main activities. The first was to incorporate the expectations set forth in Colorado’s Standards-Based Teacher Act of 1999. This act requires a number of changes for the teacher preparation programs in the state, including the integration of technology across the PK-12 curriculum. The second area of focus has been with three cohorts of UNC faculty who have learned about and applied technology in new ways in their undergraduate preservice and general education courses.

Teacher Preparation Programs

Although there has been a major investment in technology for K-12 schools, the actual utilization and integration of this technology has been somewhat disappointing. A National Center for Educational Statistics (2000) study showed that 95% of public schools had Internet access in 1999. Although 65% of teachers had Internet access only 20% were using advanced telecommunications in their teaching (NCES, 1997). In 1997 and 1998, Persichitte, Tharp, and Caffarella completed studies commissioned by the American Association of Colleges of Teacher Education, which investigated student and faculty use of technology by colleges and departments of education. Both studies emphasize the importance of preservice teacher education students’ (a) ability to use technology and embed
it within their content areas and (b) exposure to effective models of technology use and integration throughout their preservice preparation programs.

UNC's PT3 team collected similar data during visits to the 21 partner schools (K-12) to speak with principals, teachers, and technology coordinators as well as observe each school's classroom uses of technology. The initial evaluation of the data collected have highlighted several key issues which are being addressed in redesign of the 200- and 300-level courses: (a) all schools visited have a fairly extensive infrastructure, both new and old machinery that is not being used to its fullest potential; (b) networks and file servers are playing a much greater role than could have been imagined; (c) the balance between platforms is shifting away from MAC and toward PC machines running the MS Windows platform and this is true across all grade levels; (d) teachers are not able to generalize how to use software outside of the way they have been originally instructed to either use it, or utilize it; (e) K-12 faculty want and need activities that they can integrate into their curriculum successfully; (f) student information management systems have become a critical component both in the individual schools, and in those schools' districts because state regulatory agencies demand extensive and comprehensive student data every year; and (g) with standards and assessments demanding more and more physical (time and energy) and financial (budgetary resource) support, technology facilitators (technology support personnel) have, as of late, become one of the lowest priorities on the K-12 personnel/time-allocation matrix.

Qualitative data gathered and analyzed by Lohr et al., that is significant to this project, found students felt the following about the introductory educational technology class: (a) the self-paced format was not only convenient, but gave freedom and flexibility; (b) the projects and rubrics were not as challenging as they could have been; (c) more examples and non-examples of each project would have been beneficial; and (d) fewer open laboratories would be preferable. The project team as a whole was disappointed the rapid application development (RAD) process and decided on implementing a full instructional design model for the PT3 redesign efforts of the ET department's undergraduate courses.

As a result of this study, the PT3 team decided that self-paced instruction should be created using a template that has been originally designed to deliver learner-friendly instruction. This template allows for continuity and uniformity of language and format. In the process of the Lohr et al., research study, the two educational technology courses it encompassed (a 200-level course for freshmen and sophomores, and a 300-level course for juniors and seniors) have been brought current not only in the knowledge and skills they taught and developed, but also in the utilization and implementation of latest in computer hard and software.

The team has also imposed a collaborative structure onto the process in order to efficiently and effectively redesign the undergraduate coursework in the department of Educational Technology at UNC. The graduate assistants were divided into three teams: design, development, and utilization. The design team was to conceptualize the assignments, rubrics, and tutorials, as well as complete a task analysis, identify standards, write objectives based on the standards, and create the assignments and rubrics. The design team components were given to the development to operationalize. They put the design into practice by creating the text, graphics, tutorials, and PowerPoint instruction. Once the pieces of each project was uploaded to the team website, the usability reviewed all components making suggestions for additions, changes and corrections.

Faculty Cohorts

Currently, fifteen UNC faculty fellows (8 from the College of Education & 7 from the College of Arts and Sciences) have redesigned at least one of their courses to effectively utilize and seamlessly integrate technology. An advanced doctoral student in Educational Technology who serves as an instructional designer has individually supported the professors in their efforts. The faculty fellows also participate in seminars on technology use in the classroom delivered by experienced technology integration specialists. The content for each seminar has varied slightly based on the needs of the participants each semester.

After having worked with two cohorts of faculty, the UNC PT3 team agreed structure as needed for the process of working with faculty fellows. A checklist of sorts was created so the graduate assistants could make the best use of their time and expertise. The graduate assistant, faculty team go through the process of reviewing the original faculty proposal, identifying goals, setting a schedule, deciding on project restraints, producing mid-term and final reports, equitable division of responsibilities, and identifying faculty needs.

Summary

The need for well-prepared, technology proficient teachers who know how to infuse technology into the curriculum has been identified at the national level and also exists at the state and university program levels. Many state legislatures have mandated appropriate technology training for preservice teachers. The Colorado state
The legislature has mandated appropriate technology training for preservice teachers and local school districts have previously identified a technology deficiency in the teacher education programs that the UNC administration is committed to enhance. The UNC PT3 team, through the initiatives described here, is committed to support and advance the integration of technology in classrooms at the local, university, state and national level.

**Abstract** Project: Partners is a collaborative PT3 grant between California State University, Hayward (CSUH) and the New Haven Unified School District in the San Francisco Bay Area. To achieve our goal of helping pre-service teachers learn to use technological tools in teaching and learning, we have matched technology-proficient K-12 teachers with CSUH Department of Teacher Education faculty. The K-12 Teacher-Partners model the use of technology as a learning tool in their classrooms, and they work with faculty members to integrate technology-based instruction into pre-service methods courses.

**Modeling Matters**

Project Partners was founded on the idea that modeling matters; when teacher education professors model technology for their candidates, pre-service teachers are more likely to use computers with their students. The articles in the *Journal on Computers in Teacher Education* and the *Information Technology for Teacher Education* report that teachers are more likely to use computers with their students when technology is infused into their methods courses, and when pre-service candidates see computers being modeled by their instructors.

For example, British researchers, Yell and, Rehabber, and Stokes (2000), argue that teaching candidates must learn to use computers in the context of the subject specific disciplines they are learning to teach. Central to their “permeation” model are university faculty who model instructional technology, and who assign tasks where candidates must use computers to complete their course work. (“Technology in Teacher Education: examples of integration and implementation in early childhood courses”, *Journal for Information Technology for Teacher Education*, Vol. 9, No 1, 2000, 95-109).

**K-12 Teachers Model for University Faculty**

To prepare University instructors to infuse technology into their courses, faculty members make monthly visits to the classrooms of NHUSD K-12 teachers who are expert in integrating computers in their curriculum. University instructors observe K-12 students working on computers and the management strategies employed in computer-based lessons. Professors post the practices and activities observed on a reflective journal page on the PT3 web site. In addition, they explain how technology enhanced student learning and discuss possible applications to their methods classes.

Not only do K-12 Teacher-Partners open their classrooms for observations to their Professor-Partners, but they also help education faculty infuse technology into their methods courses. Some K-12 partners visit the University methods classes to share a tech-integrated lesson with candidates. In other partnerships, K-12 teachers suggest ways that faculty can redesign their syllabi to include technology.
K-12 partners also submit the lesson the professor has observed to the K-12 Lesson Library. The Lesson Library contains over 300 technology inclusive K-12 lessons. These lessons all incorporate student use of computers to support teaching and learning core K-12 curriculum. Most of the lessons were designed by and used in classrooms of K-12 teachers from the New Haven Unified School District. Some Pre-service candidates contributed lessons as part of their credential preparation program; these lessons have been selected for inclusion through a juried process.

University Faculty Model for Candidates

In order to prepare University faculty to model technology with their candidates, Project Partners provides a variety of faculty development opportunities. On Friday mornings faculty attend Tech Tutelage sessions designed to improve instructors' technology skills. At these sessions professors learn to make PowerPoint slideshows and web pages for their courses. During the summer, twenty-seven CSUH professors attended the Summer Faculty Institute, which provided twenty hours of faculty training on educational hardware and software. In addition, professors received a laptop computer or stipend for attendance. During the school year, a full time PT3 staff member meets with professors to provide one on one tutoring, and help with curriculum redesign. As professors design tech-integrated activities for their teaching candidates, they post them in the PT3 Curriculum and Instruction Library.

The visits to K-12 schools, and the PT3 skill development activities, help professors redesign syllabi in their curriculum and instruction courses, and to deliver instruction in new ways. In addition to putting their syllabi on-line, and using PowerPoint for classroom presentations, professors also have candidates design instructional activities with computers. A mobile cart, with ten i-books purchased by the PT3 grant, is brought into methods classes, giving candidates hands-on experience using computers. Candidates are asked to design lessons, which incorporate technology. Pre-service teachers also have access to the K-12 Lesson Library where model lessons are available on the web.

Candidates Use Technology with Students

The modeling of educational technology in the University classroom helps teaching candidates to use computers with their students. For example, action research conducted in the CSUH single subject social science methods class confirmed that modeling instructional technology was the single most influential factor in candidates' use of computers with their students. In addition, modeling in the methods class positively influenced social studies candidates' attitudes regarding their future classroom uses of computers.

The PT3: Project Partners has made headway in helping teacher candidates use computers with their students. However, modeling is a necessary but not a sufficient condition for new teachers to feel confident about using computers in their first classroom experiences. New teachers must also have accessibility to computers, see good modeling at their school site from veteran teachers, and feel that they have sufficient competence in others area of their teaching to experiment with computer based instructional strategies.

Future Directions

Now in its third year, the PT3: Project Partners has expanded its K-12 University partnerships. The Lesson Library continues to grow. In addition, Project Partners is collaborating with another PT3 project to produce six videos of K-12 teachers effectively using computers with their students. These videos will provide visual materials for candidates and professors to discuss in methods courses. Project Partners is also helping professors to redesign their courses with technology inclusive lessons. The inclusion of these lessons into the Curriculum and Instruction Library will be a major focus this school year and next summer.

Our hope is that when PT3: Project Partners grant ends, the modeling of educational technology for candidates in methods courses will be a regular part of pre-service instruction, so that our new teachers will be prepared to use 21st century tools with their students.

Abstract: The College of Education at Pittsburg State University (PSU), Pittsburg, Kansas, is establishing, evaluating, and validating a comprehensive, standards-based technology professional development model for teachers and teacher candidates that can be customized for each local context. This model uses a computer-based performance assessment to allow teacher candidates, university faculty, and cooperating teachers to demonstrate their proficiency in technology use and integration. In partnership with an educational software company, Synergistic Systems, Inc., and the University of Kansas, PSU is designing and implementing a web-based performance assessment system for validation of technology outcomes.

Introduction

Research indicates that few teachers believe they are adequately prepared for the challenge of using technology (Northover, 1999). The leading obstacle to the implementation of technology in education is not a lack of hardware or software, but rather the fact that many teachers are not technologically fluent. National statistics have shown that teachers receive far less technology staff development than any other professional group.

According to the Office of Technology Assessment (1995), the lack of teacher training is one of the greatest roadblocks to integrating technology into a school's curriculum. "Most teachers have not had suitable training to prepare them to use technology in their teaching" (p. 43). A majority of teachers reported feeling inadequately trained to use technology resources, especially computer-based technologies. Only twenty percent of educators felt their technology skills were high enough to integrate technology into their lesson plans. Forty percent of all teachers have never received any kind of staff development regarding technology (OTA, 1995).

In a 1997 report for the Milken Family Foundation, Kathleen Fulton used the term "technological fluency" to describe the changing definition of what teachers need to know and do with technology. Technological fluency is a combination of the information skills and literacy, communications skills and literacy, and the technology skills necessary to function in a technological environment. For students to acquire technological fluency as a part of their educational experience, they must be taught by technologically fluent teachers. Faculty with technological fluency would be characterized by modeling technology use in the classroom, applying technology skills across the curriculum, and applying technology skills to problem solving and decision making in authentic learning environments. Brand (1997) stated, "If technology is to be used by students, then teachers must possess the confidence, understanding, and skills to effectively incorporate technology into their teaching practices" (p.11).
Overview

While most professional development models are based on teacher attendance or participation in a workshop or training activity, this project turned the model upside down and required in-service teachers to demonstrate technological proficiency through performance assessment rather than only attend workshops or courses. With this approach, learning expectations are expressed in advance and participants may use a variety of learning strategies to acquire the skills necessary for demonstrating their attainment of competency.

This project attempted to increase the quality and quantity of teacher interactions with technology by providing educational opportunities for college faculty and cooperating teachers through workshops, summer institutes, or small group and individualized learning experiences. The technological fluency of teachers was then validated through a performance assessment process related to relevant and authentic learning experiences. The PT3 grant, a three-year federal grant from the U.S. Department of Education’s Preparing Tomorrow’s Teachers to Use Technology program, provided the funding for this project.

Performance-Based Assessment

The role of assessment in many educational reform models or movements has taken on new meaning as reformers are finding that assessment standards and methods have considerable power as agents of change (Sheingold & Frederiksen, 2000). Although performance assessment can take many forms, it generally differs from the short answer or single problem approach of conventional assessment by focusing on the application of newly learned skills.

Performance assessment generally includes activities that could be called authentic activities similar to tasks a person performs in the real world. Performance assessment includes activities that accommodate multiple approaches and a range of acceptable products and results. Performance assessment activities may require learners to solve open-ended problems, create portfolios of products, or conduct experiments using computer simulations. The primary benefit of performance assessment is that it constitutes a measure of standards for performance of valued skills in a realistic situation and the performance task itself engenders a learning activity (Sheingold & Frederiksen, 2000).

Technological Fluency Standards for Teachers

Standards reflect shared values by identifying and describing those things that are important for a student to know and do. Sixteen technological fluency standards for teacher candidates, college faculty, and cooperating teachers were defined and established through a consensus process by the PT3 Steering Committee and were based on the PSU Technology Plan and the ISTE technology standards for students and teachers.

Technological fluency standards were organized into three phases: 1) technology operations, 2) technology management, and 3) technology integration. Each successive phase was intended to identify a set of technology skills and instructional strategies that exemplified increasing technology implementation and integration into classroom instruction and learning.

In our PT3 project we first established a set of technology standards and indicators that clearly described educational best practices for teaching and learning with technology that university faculty, cooperating teachers, and teacher candidates should implement in their classrooms. We defined teacher technological fluency as the integration of technology in the classroom by modeling technology use in the classroom, applying technology skills across the curriculum, and applying technology skills to problem-solving and decision-making in authentic learning environments. The technology standards and indicators were formulated by synthesizing national, state, and local technology standards and then identifying educational best practices that supported these standards within a local context. We then reinforced a pedagogy that enhanced and improved teaching and learning using technology tools and resources through performance assessment and financial incentives.

A technology standards integration matrix was established to serve as a basis or benchmark for performance assessment. The 16 technology standards comprised the main components of the matrix and then
variations for each standard or component were mapped. These variations attempted to identify the actual teaching practices and instructional strategies that classroom teachers employ when integrating technology in a classroom. Variations for each component consisted of discrete categorizations that described best teaching practices using technology. The variations were mapped along a continuum from unacceptable use to ideal use.

The final version of the matrix consisted of the 16 technological fluency standards and a set of variations (best practices) for each standard. Each successive variation indicated a level of use representing a closer approximation of ideal use (see Technological Fluency Standards Matrix). The technological fluency standards were organized into three phases: Technology Operations (standards 1-6), Technology Management (standards 7-11), and Technology Integration (standards 12-16). The technology standards and best teaching practices were construed to be a reasonable and appropriate set of the instructional practices of teachers integrating computer technology in a classroom and to reflect the actual and ideal practices of teachers integrating technology in classrooms. Although these technology standards and practices were developed and tested in a particular educational context, their application may be relevant for use in analyzing the integration of computer technology in other educational contexts as well.

**COOPERATING TEACHERS/TEACHER CANDIDATES:** Maintain, aggregate, and analyze student performance data using an electronic assessment tool

**FACULTY:** Teacher candidates use action research methods within methods and field experience course work to determine that technology or classroom teaching methods are impacting student learning

**COOPERATING TEACHERS/TEACHER CANDIDATES:** Teacher and students use action research methods to determine that technology or classroom teaching methods are impacting student learning

---

**Next Steps**

While the progress to date has met with substantial success, there is still much work to do. Currently, the project's corporate partner is converting the Phase I assessment instrument into a commercial product with March 1, 2002, selected as the product launch date. The overall instrument is now being extended and expanded to include Phases II (technology management) and III (technology integration). The management aspect of the instrument developed for Phase I will support implementation of the additional phases, but greater human intervention will be required for their full implementation. Participants will develop portfolios as directed by the software, submit the portfolios for review, and receive feedback as to the level of fluency the participant has demonstrated. While each participant will have the freedom to choose the context and content of his/her portfolio, the rubrics will ensure that the skill indicators related to specific standards are captured within the portfolio. Submission of the portfolio, review, and feedback will all be transacted through an online interface. The instrument's data management system will allow the project directors to track and direct the participants through the phases of technological fluency.

Abstract: Telecommunications offers the teacher candidates an environment through which to delve into higher order thinking skills within the methods coursework, student teaching internship experience as well as within the PreK-12 classroom environment. Modeling of appropriate uses of technology within the learning environment as the teacher candidate progresses through out their course of study emphasizes the numerous constructive opportunities to integrate telecommunications to reach the lesson objectives.

Introduction

Teachers desire numerous tools through which to communicate lesson objectives to the learners, opportunities to build communities of learners, as well as to focus efforts upon the unwritten curriculum that is of importance within all schools through out the nation and the world at large. Teacher candidates are novice instructional designers as well as instructors but the majority of teacher candidates, at this juncture within the history of educational training, are more comfortable with the idea of technological ideology. The philosophical as well as conceptual leap that must occur with the teacher candidates' use of technology within a learning environment is the instructional design and implementation of technologies. Further, modeling of such activities must be an objective of superior teacher education units.

The integration of technology within teacher candidate’s methods coursework offers the opportunity to communicate at numerous levels of understanding. Through the support of the United States of America’s Department of Education Preparing Tomorrow’s Teachers to Use Technology grant, the design and development of a World Wide Web site through which the teacher candidates, inservice educators associated with the professional development schools (PDSs) that support the training of teacher candidates, PreK-12 learners and university faculty have the opportunity to delve into the world of telecommunications. A supportive environment has been created through which access to telecommunicative environs is available to the teacher candidates, as well as faculty and learners whom support the teacher candidate’s professional learning opportunities.

Telecommunications encompasses several elements that can be positively modeled within a learning environment. listservs, chat sessions, bulletin boards, and electronic mail creates positive environments within a learning environment when focusing upon the scope and sequence of the instructional design process. Further, the instructor-centered and learner-centered focuses of telecommunicative uses are also elements that deserve further review.

Cognitive Flexibility

Cognitive flexibility offers further theoretical understanding concerning the nature of learning and the opportunities through which learning occurs within complex domains as well as ill-structured domains.
Spiro and Jeng state that, “By cognitive flexibility, we mean the ability to spontaneously restructure one’s knowledge, in many ways, in adaptive response to radically changing situational demands... This is a function of both the way knowledge is represented (e.g., along multiple rather single conceptual dimensions) and the processes that operate on those mental representations (e.g., processes of schema assembly rather than intact schema retrieval)” (1990, page 165). Additionally, cognitive flexibility “is largely concerned with transfer of knowledge and skills beyond their initial learning situation” (Kearsley, http://tip.psychology.org/spiro.html, paragraph 2). As such, cognitive flexibility is especially structured to support the integration and success of interactive technologies, such as telecommunications within the learning environment.

Telecommunications has the opportunity to reposition the learners beyond the mere obtainment of basic knowledge, towards opportunities through which the learners are enveloped within a world of understanding, analysis and evaluation of the knowledge they are integrating into a conceptual framework of understanding. The complex and ill-structured domains delineated within cognitive flexibility theory aptly describe the world of telecommunications, as well as the opportunities towards achieving higher order thinking skills within the learner’s conceptual framework of understanding.

### Bloom’s Taxonomy of the Cognitive Domain

As learners begin to obtain subject-specific knowledge, an emphasis must be placed upon the developing conceptual framework of understanding that is created. Bloom’s Taxonomy creates an appropriate format through which to view the developing levels of higher order thinking skills as the learner moves beyond basic knowledge levels of information towards a level at which the learner is comfortable analyzing the information and then, finally, synthesizing and evaluating the information that has been appropriately and successfully incorporated within the learner’s conceptual framework of understanding. Following is a brief explanation of the distinct levels of Bloom’s Taxonomy, with a short definition and sample learning objective verbs made available for review. Further, examples of behavior are presented to emphasize the specific levels of understanding.

</table>
The focus of the learning environment is to aid the learner in reaching the synthesis and evaluation stages of Bloom’s Taxonomy. The higher order thinking skills that the learner must reach are areas of further interest and discussion.

**Bloom’s Taxonomy of the Cognitive Domain and Higher Order Thinking Skills**

Achieving higher order thinking within the realm of a learner’s conceptual understanding of the subject matter under discussion is an art that teacher candidates must glean from inservice educators, university faculty and numerous other mentors. Higher order thinking skills provide opportunities to provide higher order thinking occurrences for learners within a learning environment supported by the further examination of Bloom’s Taxonomy. Further, broadening the focus of higher order thinking offers the opportunity to emphasize the creation and understanding of information beyond merely the knowledge level of comprehension. Thomas, Thorne and Small (2001) offer a brief description of what higher order thinking skills emphasize.

Higher Order Thinking, or HOT for short, takes thinking to higher levels than just restating the facts. HOT requires that we do something with the facts. We must understand them, connect them to each other, categorize them, manipulate them, put them together in new or novel ways, and apply them as we seek new solutions to new problems. (Thomas, Thorne & Small, 2001, paragraph 7)

Higher order thinking skills (HOTS) can be distributed into three main categories of understanding: content thinking; critical thinking; and, creative thinking. HOTS emphasize distinctly different levels within Bloom’s Taxonomy, which offers the range of simplistic knowledge attainment towards more complex levels of understanding and working with information. The complex levels of working with information and learner’s thinking processes and skills associated with HOTS parallels Bloom’s Taxonomy within the levels of the synthesis and evaluation. “As patterns of higher order thinking are emphasized in learners within all levels of the educational system, each subject area emphasizes the creation of innovative aspects that aid the learner towards the creation and reconceptualization of thought patterns; in other words, viewing the information from numerous perspectives and within real-world environments” (Brown & Crawford, 2001).

Therefore, there is a clear pattern towards Bloom’s Taxonomy of the cognitive domain and HOTS, which leads towards cognitive flexibility’s ill-structured domain that offers the learner the opportunity to create and delve into further understanding of subject matter through the appropriate and successful integration of telecommunications into the learning environment. The modeling of telecommunications within the learning environment is accomplished through the integration of specific available opportunities within the teacher candidates’ professional development. Following are specific telecommunicative opportunities that have been made available to teacher candidates, through the Preparing Tomorrow’s Teachers to Use Technology (PTTT) grant.

**Listservs**

Listservs have been integrated into the communicative levels of electronic discourse for numerous years. Such a telecommunication ally offers the ability to disperse information to numerous people within a simplistic mode of interaction and transmission. The listserv available through the PTTT grant maintains a bi-weekly message to all teacher candidates, university faculty, inservice educators and administrators who have become subscribers to the listserv community.

Digital newsletters offering updates on professional development opportunities, new technological innovations for the learning environment, useful Web sites for subject-specific or foundational knowledge are offered. Each digital newsletter is focused upon a specific topic, so as to offer significant information that will be useful to the subscribers. As well, a listserv is a simplistic format through which to disperse
important or useful information in an up-to-date, digital fashion. This ease of use maintains a one-way, asynchronous communication between the PTTT grant and the participants.

**Bulletin Boards**

Another asynchronous communication tool available for integration within learning environments is the bulletin board. The opportunity to create threaded discussions maintains a communicative quality to the learning environment, without hampering the learner's ability to create an “anytime, anywhere” attitude towards information attainment. The communication is occurring within a threaded discussion, yet the learner can access and respond to the discussion at any point within their busy daily schedule. Teacher candidates are expected to maintain a rigorous schedule within the PDS learning environment and may not have the opportunity to maintain designated time allocation towards telecommunicative activities at specific points throughout the day. Therefore, the ability to offer bulletin boards as a communicative activity maintains the thought pattern displayed within the discussion, but also maintains the freedom to review the discussion as an asynchronous entity. Further, the teacher candidate has the ability to develop and submit thoughtful responses to the discussion, without being hampered by time or keyboarding ability.

**Electronic Mail**

As a one-on-one asynchronous communicative tool, electronic mail (e-mail) is unsurpassed. Documentation concerning previous communications is easily obtainable within e-mail, due to the ability to archive email communications for future use. This is an important aspect for teacher candidates to consider, as documentation of learner and parental communications are important elements when issues arise. Further, the ability to maintain personal communication with parental figures is a lifesaving event, as telephone communications can be wrought with difficulty. E-mail has the ability to communicate with a parental figure, as well as document the communication attempts. As well, the ability to communicate with a learner who may have course difficulties is an important element to the success of the learner.

**Chat Sessions**

Synchronous telecommunication opportunities are also an important element within the learning environment. Teacher candidates maintain that a virtual office hour are useful during their plan of study, and maintains communication with their university faculty whenever questions arise concerning coursework issues. The positive element concerning chat sessions is the ability to communicate back and forth within a real-time setting; however, the negative elements associated with chat sessions are the designated date and time allocation as well as the keyboarding abilities of some teacher candidates.

**Integration of Telecommunications into the Learning Environment**

As stated by the International Society for Technology in Education (ISTE), “Technology must become an integral part of the teaching and learning process in every setting supporting the preparation of teachers” (International Society for Technology in Education, 2001, paragraph 2). Further, “A combination of essential conditions is required for teachers to create learning environments conducive to powerful uses of technology. The most effective learning environments meld traditional approaches and new approaches to facilitate learning of relevant content while addressing individual needs” (International Society for Technology in Education, 2001, paragraph 1). Therefore, ISTE supports the integration of technology into the learning environment so as to create a supportive environment that emphasizes effective learning and addressed the learner’s individual needs.

**Instructor-Focused Versus Learner-Focused Integration**

The implication for telecommunications modeling is that the ability to integrate telecommunications into the learning environment is simplistic; however, this is definitely not the case. Careful modeling of telecommunications integration into the learning environment must be created and supported by university faculty and inservice mentors. Only through this modeling of appropriate and
successful telecommunicative ventures will the teacher candidates expand their conceptual framework of understanding concerning the integration of technology into the learning environments. Emphasis must be placed upon the ability to integrate technology as an instructor-focused activity as well as a learner-focused activity. Telecommunications could easily be integrated as an instructor-focused activity through the support of a listserv environment; while a learner-focused activity could easily be designed and implemented through the support of bulletin boards and chat sessions.

Conclusion

With the inclusion of telecommunications throughout the learning environment, it remains that “The most obvious benefit of the electronic classroom is that it achieves what progressive educators could only dream of: a union of work and play…. There is no certainty that the electronic classroom will actually fulfill this promise, but it is this hope that makes the realization so attractive” (Ravitch, 1987, p. 28). The creation of learning environments that ready our learners for the complex, ill-structured world in which we live can only be appropriate towards the success of the future generations. Through the inclusion of technology, specifically telecommunications, the communicative nature of information and bonding has the opportunity to flourish.

A Journey through Learning with Technology

Sara Geith
School of Education
St. Bonaventure University
St. Bonaventure, NY 14778
geithse@sbu.edu

Abstract: This paper describes a preservice teacher's journey as she learns to use technology -- first for her own work and then as she learns to teach in elementary classrooms. Examples of lessons and projects in primary classrooms are discussed.

U.S. schools are adopting technology for instruction more than ever before. Certification programs are teaching and encouraging future teachers to integrate technology into their classrooms. The cohort of teachers graduating in the upcoming years will graduate with the knowledge of how to use technology to help them and how to integrate educational software into their lessons to benefit their students. Research shows that when teachers work together to make technology part of their classrooms their students learn more effectively and also prosper more in the world outside of their school. Studies conducted by the McRel organization show that students with access to technology in their classrooms perform better than their peers who do not have the same opportunity (McRel Products, 2000).

To fully appreciate the effect of technology one must look at the benefits technology has for teachers, how technology helps students learn, and how technology affects the students. During the first years of my college career I was introduced to technology. I learned how to use programs such as HyperStudio, Inspiration, and Microsoft PowerPoint. The university professors encouraged us to use these programs to organize our work and to help us during presentations. These programs, among others, are very helpful when teachers are organizing information for units or lessons plans. Programs such as PowerPoint can also be valuable for teachers if they need to put on a presentation for other school personnel or for parents who come to an open house or other meeting. For example, I created a PowerPoint presentation to encourage the parents in my community to accept Internet use in the classrooms. When I began using these programs another activity that I was working on was a unit on Alaska. We were focusing on how the position of Alaska in the United States helped promote explorers and travelers to populate America. First, I completed an Inspiration Web showing how I would integrate information about Alaska into each of the subjects that I was teaching. I have used this program for this purpose throughout my teaching career at Saint Bonaventure. I found that it was extremely helpful when planning my unit on the Healthy Body. I was able to brainstorm many ideas for each subject area and then I was able to create lesson plans and activities from there. It also helped because I was able to see the array of ideas that I wanted to cover and could then plan how long the unit would take to complete. Using the web as a guide for lesson planning is not the only benefit. You can use the web to help plan and create other activities. For example, when I created the web on Alaska, I was able to use it to help create a HyperStudio on Alaska. Having a base of the most important information I wanted to teach allowed me to create and interactive slide show to teach the children this information.

Another technological bonus for educators is the Internet. Once again, referring to the Alaska presentation, I was able to create the Inspiration web and the HyperStudio based on information I obtained from the Internet. Teachers learn that the way to succeed in their career is to utilize all of the resources that are available to them. And the Internet is one of the best teaching resources available. There are countless web sites with teaching ideas, and even more that have information that you can share with your students. Planning lessons used to take teachers days...the Internet really helps speed up and spice up this process. I am currently preparing to student teach next semester and the Internet has been one of my most important resources. I have been able to find many important facts that I can share with the children, interactive web sites that I can teach them through, and a tremendous assortment of activities the help my lessons to become more exciting. Teachers have told me, and I used to see, that planning lessons used to take teachers days. I think that the Internet has not only helped to speed up this process but has also helped spice up lessons, and made them fun not only for the children but the teachers too.

As my college years continued I became more involved in elementary school classrooms. In the past year I have started interning in primary level classrooms. This opportunity has broadened my perspective of how to use technology not only for my purposes but also when I am teaching the children. By taking this step and bringing technology into my
lessons, I have seen first hand what all of the research says. Technology is exceedingly effective when teaching children. Technology helps to draw the children into an activity, and because they are so intrigued by the new way of learning, technology helps keep them engaged in what they are doing, sometimes without even realizing that they are learning. I have taught the students in my classroom to make character and phonics webs using the program Kidspiration, and have also used Tom Snyder's Community Map Maker to teach the students characteristics of a community. Kidspiration is a program that helps children learn how to organize thoughts that they have and see the relationship between ideas they are being taught. For example, when I was teaching the children how to make a phonics web they learned about organization and relationship of a letter, to a word, to a picture. Each student chose a letter and then wrote three words in the connected bubbles that started with their letter. After this, they drew another bubble from each of their words and put a picture of the work they had chosen. When the students made character webs they put a picture of themselves as the main idea and branched five statements about themselves from the picture. From there they connected each bubble to one more to explain the idea they had previously stated. This helped them understand how to take their explanations to a higher level of thought.

Bringing a computer into a classroom is a wonderful anticipatory set. When I began my lesson I had the students' attention without using any words. When I began to explain what they were going to learn I did not lose their attention because they stayed focused on the technology that I was showing them. Children learn by doing, and part of that is visualizing. Technology allows you to show the children what they are learning, and then allows them to do what they have learned. Technology use supports greater learning because it allows students to immediately apply what they are learning. This is one reason that the community map-making lesson was extremely successful. The students enjoy drawing and if I had them create a map of their town on paper it would have showed them the same concept that the computer map showed them but by far the students learned more from taking their information and organizing it well enough to produce a replica map on the computer screen.

A final step in the learning process is excitement. Any teacher can tell you that children learn better when they are motivated and excited by what they are learning. Children love technology. My experience tells me that there is no other better way to motivate children than through the use of technology. When I taught the children in my second grade class how to use map making software to create a community it was one of the most successful lessons I taught all year. The students did not speak to their friends while I was talking, they worked in groups together to create a list of things that they wanted to put in their community, and when they had the chance to put their information on the computer they took turns with each other and worked together to make sure that their map was a replica of their real town. Finally, when the project was over and I printed them out a copy of their maps the delight in their eyes was astonishing!

As a teacher this is the factor that proves how important technology is to the children. The students looked at what was printed like it was a complete masterpiece. Technology helps children create pictures and write words in ways they never thought possible. Typically I see delight in the children's eyes when they realize that they have learned something new. When they learn something from technology this delight in insurmountable. The feeling that I get from seeing them happy makes the entire process worthwhile.

Technology can benefit all those that take time to use it in their classrooms. "Properly used, technology can enhance the achievement of all students, increase families' involvement in their children's schooling, improve teachers' skills and knowledge, and improve school administration and management" (U. S. Department of Education, 2000). My experience has also shown me that not only teachers and students benefit from technology use, but anyone that those teachers and students show the technology to also benefit. If all of these "players" join in the technological challenge, growth will occur, school systems will become more enriched, and together everyone will share the rewards of the new system they have created. During the presentation of this paper I will be able to introduce some of the technology that I have used with my students. I will be able to present some of the students' work and hopefully portray the feelings that the students had from participating in my technology lessons.

A Team Approach to Integrating Technology into the Teacher Education Program

Marsha A. Gladhart
College of Education
Wichita State University
Wichita, KS USA
marsha.gladhart@wichita.edu

Abstract: In the last decade, the College of Education (COE) at Wichita State University (WSU) has experienced the same challenge to better prepare teacher candidates to integrate technology that has been experienced by Schools, Colleges, Departments of Education (SCDE) throughout the United States. At WSU, the teacher education faculty decided to address this lack of teacher preparedness by adopting the ISTE NETS*T as technology standards for our graduating students. This presentation describes the three-layered approach used at WSU to integrate technology into the teacher education program to meet those standards. In the first layer, teams of teacher education faculty discussed, argued, collaborated, and finally developed a proposal to document how our teacher education students meet the ISTE NETS*T standards. The second layer involved student and faculty mentors who provided one-on-one assistance to faculty as they learned to use the technology in their instruction. The third level involved a series of faculty development workshops ranging from hands-on small group sessions to technology fairs open to the entire college. This presentation will share what our technology leaders learned from this process and the final integration proposal that resulted.

Layer One: Integration Teams

The process of integrating technology into teacher education courses presented a challenge to the faculty in the teacher education program at Wichita State University. The faculty in the COE had decided several years earlier that all technology should be integrated into undergraduate teacher education courses rather than covered in separate technology courses. Confident of having made a pedagogically sound decision to integrate, the faculty began exploring what integration really means and how it could be accomplished in our program. We discovered that this approach is simpler in theory than in practice. At first our attempts at integration were haphazard since faculty were already overloaded with goals and standards to be met and were not comfortable enough with technology to infuse it into their instruction. Our efforts focused on presentations to students in core courses, hands-on training in the computer lab when needed, and faculty development workshops and training to introduce new technologies to faculty.

In 2000, the Undergraduate Teaching Programs Committee adopted the ISTE standards (ISTE 2000) as our criteria for student proficiency in technology. The ISTE standards provided a starting point for structuring our technology integration. The Coordinator of Educational Computing distributed copies of the standards to all faculty in the teacher education program and began educating faculty about NETS*S and NETS*T standards and essential conditions for implementation. As faculty members discussed the standards, they began to question how the standards should be addressed in their courses. A number of issues arose as faculty attempted to integrate the technology to meet technology standards. Some of the more frequently voiced concerns and issues:

- Which standards should be addressed in what courses?
- What is my responsibility in teaching my students how to use the technology?
- I only have so much time to cover content, how will I manage to teach them how to use PowerPoint and other technologies without taking away?
- Should I require students to use technology to meet the course objectives or should I make technology optional?
The First Learning Experience

Our initial approach to supporting technology integration was to use the consultant model. WSU’s teacher education program is organized in 4 blocks of courses. Each block addresses major program goals and builds on a scaffolding set of experiences with extensive field experiences. Supported by a PT3 grant, a technology instructor and a curriculum specialist were given reduced loads to meet with each member of the first two blocks in the teacher education program and plan for technology integration. Faculty discussed the kinds of technology they required of their students, how they assessed student performance, and brainstormed new ways to use technology to help instructors meet the goals of their courses. This approach proved to be time-consuming and resulted in only marginal success in developing technology activities. Much time was lost trying to set up individual meetings with busy faculty. It also meant that dialog was only going on through the technology and curriculum specialists. The faculty members were not communicating with each other about their decisions on how to use technology, their concerns, or their successes. Some faculty members interpreted this consulting approach as an effort to tell them what to do in their classes. The difficulties with this approach reflect the necessity for change to be systemic if it is to be lasting and meaningful (Darling-Hammond & McLaughlin 1995; Kanter et al. 1992; Peterson 1995; Senge 1999). Instead of moving upward through levels of technology adoption (see Sandholz, Ringstaff, and Dwyer 1990), the faculty continued to rely on the “experts” and to wait for further instructions. It became apparent that we needed to change our strategy to a more collaborative approach. We had learned first hand that isolated efforts of change are not effective and are often short-lived. If we wanted programmatic changes that would have a lasting impact on our teacher education program, we obviously needed to change our strategy.

The Solution

In order to increase communication and collaboration among the teacher education faculty we decided to bring faculty together in ongoing dialog about technology integration. A pilot team of 4 instructors was brought together to discuss technology integration in Blocks 1 and 2. These instructors represented special education, educational psychology, secondary education, and elementary education. Their goals were to identify ways that technology could be modeled in their classes and to determine what technology skills their students needed to be successful in meeting the recently adopted standards. Lively discussions centered on what technology integration really means, what skills should be expected of students, what responsibility did the instructor have in providing instruction in using the technology, and how should students be assessed.

At the end of the semester, faculty members and the technology specialist had formed a cohort that had some common understandings of both the challenges and the benefits of integrating technology. When asked to describe their experience to the next integration team made up of methods instructors, the first team members were excited about sharing what they had accomplished. At the end of their presentation, members of Team 1 strongly recommended that the second team work toward a sequence of technology skills within the block classes. They even volunteered to continue to work with Team II to accomplish this on their own time!

A second integration team included 9 methods instructors in Blocks 3 and 4 of the program. This group was considerably larger than the first integration team and represented a variety of adoption levels, technology skills, and content areas. This team used an online rubric generator to create a rubric to set goals and to guide their work toward integrating technology into their classes. As they discussed technology integration, it became apparent that they needed more training in how to use the technologies. A list of topics of interest was drawn up and used to plan faculty development workshops. This list was further developed into a whole day of concurrent sessions for the entire College of Education faculty and teacher education faculty in Liberal and Fine Arts.

The second team was unable to agree on a sequence of skills or how they should hold students accountable for meeting the ISTE standards because they only represented 2 of the blocks and didn’t feel they could speak for the other blocks. Instead, they decided to focus on developing technology activities within their classes and sharing with each other. All technology activities were entered in a central database and a Web portal was set up so that faculty could view, edit, and search activities and technology tools for their classes. A grid of technology activities was designed that showed which classes were using technologies to meet their course objectives.

Again, the second team decided that the next integration team really needed to address issues related to student assessment in meeting the ISTE standards and to develop a plan for sequencing technology skills in order to scaffold student experiences in technology. Consequently a third team was developed with representatives from all blocks. A letter of invitation was sent out from the Dean inviting participants to engage in discussion with the end
result being a formal proposal to the teacher education program committee of how the program was going to ensure that students met the ISTE standards. This time the technology specialist served only as a facilitator, bringing supplies and setting up computers when needed and only occasionally offering suggestions or asking questions. The faculty members were told that they were to come up with their own proposal based on their own understandings and needs.

**Issues Addressed**

All three integration teams addressed basic issues related to technology integration. Questions addressed were: (a) Which technology skills must students have and at what point in their program? (b) Is it enough for students to see technologies modeled or must they be able to use the technologies to teach? (c) How do we determine if our teacher education students can actually affect their students' learning by integrating technology? (d) Since we don't offer a basic skills course in technology, whose responsibility is it to train students to use the technology? (e) Some of our older students are really stressed out by all the technology. What can we do to help them? (f) When do faculty members find time to learn about the technology? (g) When do faculty members find time to re-design their courses to include technology?

**The Final Proposal**

These questions were discussed and argued at length over several months. The final proposal described three levels of learning about technology: (a) seeing (instructor models), (b) doing (student learns how to use the technology), and (c) applying (student plans lessons and activities with integrated technology). Five technology themes were identified to be carried out throughout the Block program: (a) communication, (b) instructional strategies, (c) research tools, (d) assessment, and (e) ethical, social, and legal issues. These themes were based on the content within the teacher education courses, rather than an outside model. The technology specialist was delighted that the teacher education faculty were able to work through issues and concerns and to come to their own understanding of technology integration through dialog and collaboration.

This team also developed a sequence of technology activities in each block that was presented to their colleagues in each block for feedback and comment. Suggested technology tools or strategies were indicated but not required. For example, Block 2 instructors decided that students would be able to conduct a Web search to solve a problem and to evaluate Web resources for authenticity and credibility but they decided not to identify WebQuests by name. This allowed more flexibility for instructors to choose the strategy that best matched their teaching style. Each block identified technology skills that students would need to meet course requirements and published those in course syllabi. Students were encouraged to improve or acquire technology skills by attending mini-workshops provided by the Tech Center staff on a variety of productivity and instructional software, by enrolling in one of the computer workshops offered for both undergraduate and graduate credit, or by seeking help through online tutorials. The final proposal measured student competencies by assessing the ability to complete an assignment or project that required the use of technology. For example, students were not graded on their ability to use desktop publishing but rather on their ability to meet a course requirement for effectively communicating information to parents through a newsletter.

**Layer Two : Mentoring**

Funding by a PT3 grant provided student mentors for faculty. The student mentors were selected from undergraduate student applications and trained to meet faculty needs. The most popular requests were for assistance with setting up a Blackboard courses, creating Web sites, and media production. Our first mentoring efforts led us to conclude that student mentors could not produce work for faculty. They could only teach faculty how to produce their own instructional materials. Some faculty members resisted at first, saying they didn't have time to do the work for themselves. They really wanted a student assistant who would do the nitty-gritty work. However, the PT3 grant staff decided to encourage faculty to become independent of technology and instructional support as much as possible and to limit mentor assistance to teaching faculty rather than doing their work for them. Eventually, most faculty came to realize that they learned more and were able to use the technologies better if the mentor functioned as a guide rather than as an assistant. We also discovered that by involving student mentors in faculty development
activities, students learned more in order to be able to teach their instructors and that faculty members were impressed when students could use the technologies so expertly.

We also learned to limit the kinds of assistance offered to faculty. Instead of asking, "what do you need?" and then scrambling to train the student mentors to meet those needs, we decided to offer a menu of assistance from which faculty could choose. That decision allowed the staff to focus on training student mentors in depth and resulted in more independent mentors and mentees who required less supervision. Our student mentors began to be popular not only with faculty, but with their peers and college staff. We eventually had to develop guidelines to protect the mentors from all the demands on their time. We also discovered that increased technical assistance was necessary as faculty use of technology increased.

Layer Three: Faculty Development

We began our faculty development efforts with 2-day workshops led by outside consultants. These were minimally successful and involved only a few faculty members who were motivated to find two consecutive days they could devote to a workshop. Offering a variety of professional development opportunities has found to be more successful in both K-12 and higher education (Milone 1999, Rogers 2000). We finally developed an approach that provided this variety of experiences by including one-hour mini-sessions on topics requested by faculty, field trips to local schools and nearby Colleges of Education for inspiration, all-day technology fairs made up of concurrent sessions that faculty could select from to meet their needs, individual consulting by PT3 grant staff, and a network of model instructors we could refer faculty to when they had more questions.

The technology fair was one of our more popular efforts. Our partner K-12 schools requested we repeat the fairs at their schools with sessions designed to meet their teachers’ needs. Grant personnel were also asked to help design and participate in a university-wide technology fair as a result of faculty response to the college-wide events. For each fair, we selected a theme that was carried out in flyers, posters, signs, and the activities themselves. The excitement for our Dive into Technology event was heightened by lifesaver t-shirts, inflatable swim toys, ducks floating in the fountains, and a large seascape on a glass wall facing the computer center. Some faculty members ended up attending sessions all day, while others came and went according to their needs and schedules. The President of the University accepted our invitation to stop by one major event and even brought his wife to see what we were doing with technology.

Conclusion

Technology integration in the College of Education at WSU has evolved from sporadic efforts, one-shot workshops, and good intentions to an exciting program of activities. Technology is evident in teacher education courses, course syllabi have been revised to include technologies, faculty and students receive a variety of technical and instructional support, and excitement continues to build as the technologies become everyday tools for learning. A visit to the Technology Center may show students working on papers, completing online forms, developing instructional materials, and learning how to use HandSprings to track student progress. Students and faculty move between classrooms and the Technology Center with wireless laptops, digital cameras, and projectors. Technology is no longer confined to the Technology Center but is found where ever students and faculty are working together.

Arkansas Schools: Erasing the Digital Divide

Cheryl Grable, Teacher Education, University of Arkansas at Little Rock, USA ergrable@ualr.edu
Pat Laster, PT3 Grant, University of Arkansas at Little Rock, USA plaster@ualr.edu
Ashia Jackson, Social Studies Dept., JA Fair High School, USA adsjacks@swbell.net

Abstract: This paper is a report of a graduate action research project and a Preparing Tomorrow's Teachers to use Technology (PT3) digital equity study. The study looks at technology access and other barriers at a metropolitan high school. A survey based on the International Society for Technology in Education (ISTE) standards for students was conducted in the spring of 2001 and is compared to a survey conducted four years ago at the same high school to assess ways the digital divide is being erased.

Introduction
The digital divide is of particular concern in the Little Rock metropolitan area. According to a recent article in the Arkansas Democrat (2001) Arkansas' technology work force is growing at one of the slowest rates in the nation and is ranked 45th nationally. Another example of the divide is illustrated by the following demographics from an urban Little Rock high school. JA Fair has a population that is 80 percent African American; many of them coming from low-income homes. It also has a new high-tech computer lab that has a student enrollment of 52 percent white and 31 percent African American. This type of information confirms the digital divide. A plan to erase that divide led to the school receiving a grant to become an information systems and technology magnet school which means state of the art technology. This study is an assessment to determine current student and teacher use of technology that will act as a base line for future implementation and improvement.

The Study
This research compares student access and use of technology at J. A. Fair high school. A survey based on access issues and the International Society for Technology in Education (ISTE) standards for students was conducted in the spring of 2001 with 260 students from a variety of classes that can be considered representative of the student population. Students in English, science, social studies, business and a technology lab were asked to complete the survey. The results were tabulated and compared to a prior survey. The previous survey was conducted four years ago with 700 out of 930 surveys completed. Although the surveys differ, some of the data is similar and can be compared to look at issues of access and barriers to technology for students and teachers.

The Findings
After studying both surveys and interviewing a teacher at JA Fair, several observations were made. In 1998, 40% of the students reported having a computer at home, compared to 78% in 2001. Another interesting statistic is the number of students who used the computers in the library. The 1998 survey reported 70% use of the computers at the school library, compared to only 40% of the 2001 students. A teacher suggested that in 1998 there was a librarian who placed an emphasis on using the Internet to conduct research and the current librarian does not. Another reason may be due to the fact that the students now have access to an Environmental and Spatial Technology (EAST) lab, a Plato lab, which has grown from six to sixteen computers, and more access to computers at home. The EAST Lab is a high tech lab centered around problem-based learning and the Plato lab is designed around a courseware program based on skills acquisition in a variety of content areas. There were three business education
computer labs in '88 and four in 2001. In 1998, none of the Career and Technical classes had computers but now three are in home economics, seven in Marketing Education, and one in Coordinated Career Education. The Media Center has grown from four computers in 1998 to nine. In addition, the Little Rock School District now has its own technical support rather than using outside companies as it did in 1998. In 1998, the only department office/workroom that had a computer was the Science department and it was outdated. Presently, each department has a computer with Internet access. In 1998, the only classes that had a computer were the business education classes. The science classrooms now have at least one computer with Internet access, and every classroom is wired for the Internet with computers on the way.

The Future
Greater improvements should occur since J.A. Fair has been approved as an IS and Technology magnet high school. It is becoming a center for advanced scientific research and experimentation with an emphasis in the environmental sciences, engineering and information sciences, and medical sciences. A vital part of this program will be the close tie with University of Arkansas at Little Rock’s newly developed College of Information Science and Systems Engineering, as well as the Schools of Medicine and Life Science. A state of the art technology lab is in the works. One of the culminating experiences of the program will be a student operated and staffed business. “Connected Technologies”, the student business, will be implemented by eleventh and twelfth grade students proficient in information technologies. Students will research, plan, market, and manage a business that addresses the community’s technology needs. Teachers will mentor the activity and will establish collaborative partnerships with local businesses and technology professionals. Information technology professionals representing various ethnic and racial groups will be invited to collaborate and share their perspectives on this and other large projects. This will allow students the capability to communicate with the Little Rock Public Library, University of Arkansas Medical School, and University of Arkansas at Little Rock Library Systems. To access these databases, students will register with each system. Parents will be encouraged to communicate with teachers via e-mail.

Another series of important and motivating experiences will occur in the “Information Systems Management Center.” Activities in this area will train students in troubleshooting for the campus network and share information and software programs with all the computers on campus. These activities should excite students about Information Technology related careers while strengthening traditional academic programs with project-based learning experiences. This opportunity for entrepreneurship and small business management combined with Information Technology services will provide students with a meaningful “real world” understanding of the need for technology to ensure their success and advancement in the world of work.

It is evident that there are many hurdles to jump before the issues and concerns associated with bridging the digital divide to bring about digital equity are no longer concerns. JA Fair is in a unique position to help close the digital gap in this area. The success of this program will adequately prepare students for life in the 21st century. Student progress as they undergo this technological transformation will be tracked by keeping an on-going survey of students in the 9th grade as they progress to the 12th grade.

Abstract

The Nebraska Catalyst Project has sought to develop a convenient resource kit of educational technology assessments for the 17 teacher preparation programs within the state of Nebraska. Significant progress has been made in the range and quality of assessments being developed, which now encompass a variety of organizational approaches, including performance/portfolio, self-report, self-reflection, focus groups, surveys, and classroom observation strategies. Although these assessments are in various stages of development, they are beginning to be systematically available, and are starting to help the Nebraska teacher preparation institutions assess their individual progress in educational technology and teacher preparation. This paper provides a brief overview of each instrument under development by the project.

Introduction

It has been said that "You can't teach today's students with yesterday's materials, and expect them to have success tomorrow" (Teacher Librarian, March/April, 1999, p.34). It is indeed becoming a technological world, and the preparation of our pre-K – 12 students for the challenges of tomorrow no doubt demands a teacher preparation program that takes full advantage of educational technology. But how do we know when pre-service teachers are achieving the experiences that they need in educational technology through our programs? A good institutional linkage to teacher competencies in educational technology, and a good assessment process for those competencies, would seem to be two keys (Krueger, Hanson, and Smaldino, 2000; Smith, Harris, Simmons, Waters, Jordan, Martin, Cobb, 2000; Waugh, Levin, Buell, 1999). This paper overviews a variety of assessment strategies being tried at the 17 teacher preparation institutions participating in the Nebraska Catalyst Project.

The Nebraska Catalyst Project is funded by a grant from the U.S. Department of Education Preparing Tomorrow's Teachers to Teach with Technology (PT3) program and builds upon a strong partnership among the 17 Nebraska Teacher preparation institutions. This project is seeking to help create systemic improvements in the preparation of new teachers related to educational technology within Nebraska. This partnership also extends to various other Nebraska stakeholder institutions, including the Nebraska Department of Education, the Nebraska Association of Colleges of Teachers Education, the Nebraska Council of Teacher Education, the Educational...
Service Units, the Nebraska Distance Learning Association, the Nebraska Educational Telecommunications Commission, the Nebraska Educational Technology Association, and the Nebraska Distance Learning Association. Participants also include a newly organized group of Nebraska pre-service students called SETA (Students Educational Technology Association).

The overall focus of the Nebraska Catalyst project is to strengthen teacher education settings as they relate to training future teachers to use technology effectively in the classroom. Four task forces are operating aggressively within the project, including Task Force I—Assessment Development, Task Force II—Completion Requirements, Task Force III—K-12 Teacher Cadre Development, and Task Force IV—Distance Learning. Task Force I and II have worked together to undertake the development of various prototype instruments to help assess pre-service teachers classroom readiness in educational technology.

Across the country, there are already a considerable number of informal instruments in use by institutions of higher education (IHEs) that attempt to get a sense of the success of their educational technology preparation of pre-service teachers. However, somewhat more rare, are instruments that have been systematically developed and carefully refined, targeted at reliability in administration and validity in content, and based upon standards or competencies such as those from the International Society for Technology in Education (ISTE). During the last few years, institutions also appear to be moving more toward a wider variety of assessment strategies, or are targeting strategies that are generally more qualitative and hands-on in format, such as portfolios (Milman, 1999; Georgi & Crowe, 1998; McKinney, 1998; Petrakis, 1996).

The instruments that do exist are also fairly scattered across the institutional landscape, and thus sometimes not very convenient to interested institutions. To develop a locally convenient and multi-institutional resource kit of solid instrumentation was a major goal of the Nebraska Catalyst project. We believe that we have now made some strong progress in this effort, and the range of efforts and strategies undertaken is quite extensive. The efforts to date include a variety of organizational approaches, including performance/portfolio, self-report, self-reflection, focus groups, surveys, and classroom observation. These assessments are in various stages of development, but are even now becoming systematically available to help Nebraska institutions assess their progress in educational technology and teacher preparation.

The Instruments

The assessment instruments being developed are currently well within the refinement process, and within various pilot efforts by individual institutions. A brief narrative describing each of the instruments under development is provided below. More complete descriptions and background information can be found at the Nebraska Catalyst web-Site of http://www.necatalyst.org.

A Self-Report Instrument:

The Technology Ability Perception Self-Report Instrument (TAPSI) is an online survey that has been developed by administration to pre-service teachers at three IHEs in Nebraska. The Technology Ability Perception Self-Report Instrument (or TAPSI) has been developed as a general self-report instrument related to a pre-service teacher’s perceived educational technology skills and knowledge. This instrument is already examining pilot data from more than 150 pre-service teachers retrieved during the spring of 2001, and is in a formal refinement process based upon that data analysis. The instrument is currently available for interested institutions, and the Nebraska Catalyst Project is offering initial consultancy help.

A Classroom Observation Instrument:

The Classroom Technology Observation Instrument (CTOI) is an instrument that is primarily for supervisors of student teachers. This Classroom Observation Instrument was prepared for the Nebraska Catalyst Project and is currently under further refinement (prototype already completed), with the assistance of an assessment specialist at WestEd in San Francisco. This instrument has already been used during the fall of 2001, and is structured to formalize the identification of the classroom uses of educational technology by both teachers and
students. It includes an interpretive rubric for examining these various levels of educational technology (as well technology supportive constructs such as constructivism). Current conceptualization with the instrument are exploring its potential use on computer laptops or perhaps hand-held Palm devices, to make it more convenient to users.

A Web-Based Student Portfolio:

The development of a prototype for a web-based student portfolio has been underway through a direct collaboration between the Nebraska Catalyst project, and the two Nebraska PT3 Implementation projects (underway within the University of Nebraska system). The initial prototype of the student portfolio, which is currently "institution-based", now contains information from more than 500 students, across four different classes, and has been considered by NCATE (institutional visitation team) to be an evolving model that might be recommended to other institutions. The prototype is now available for more extensive use and refinement. In addition, the Catalyst project is also supporting a portfolio-developers special interest group, and is helping support various portfolio spin-off efforts at several of the partner institutions.

Pre-Service Teacher Focus Groups Protocol:

An initial focus group protocol was developed for use with pre-service teachers to support a group reflection process to examine pre-service teacher perceptions of how well Nebraska institutions are preparing their teacher candidates related to the use of educational technology for teaching and learning. To date, focus groups have been conducted at four representative institutions. The data from these focus groups has been carefully summarized, and is available on the project web site. In a follow-up process to the focus group effort (and based upon that protocol), a pilot web-based survey was also prepared for pre-service teachers. This web-based survey is expanding the input base of pre-service teachers, and provides valuable additional feedback on the perceived value and reform needs of their pre-service preparation programs.

Nebraska SnapShot Survey:

This web-based survey was conducted during February, 2000 and 2001, and focused upon determining the beliefs, use of technology, and the technology based needs of all Nebraska teachers, as connected to in-service education. A total of 4800 Nebraska teachers responded, providing a rich perspective on the current practices and needs of teachers in Nebraska, as it relates to educational technology in the classroom. The results have been disseminated to all Nebraska institutions of higher education, and the state legislature. Further information is available at the Nebraska Catalyst website or more directly at the URL of http://ois.unomaha.edu.

Faculty Survey:

A fairly extensive faculty member survey has now been piloted at one of the NE Catalyst’s institutions, and Likert scale self-assessment data has been collected on more than 90 participating faculty members. Survey questions focus on two main areas, including 1) faculty knowledge and experience related to educational technology, and 2) faculty attitudes related to educational technology. Interested institutions have the instrument freely available to them for potential revision and use with their own faculty.

Technology Skills Certificate:

The Technology Skills Certificate effort is underway at a NECatalyst participating institution (The University of Nebraska at Lincoln) and is being conceptualized as a "class-based" electronic portfolio for pre-service teachers. The students within the class undertake a variety of technology related assessments, which result in a certificate of successful completion. The effort is currently under development, and is targeted at being a model
for other interested institutions. Several institutions have benefited from periodic review of this effort, and from collaboration with the developers at the initiating institution.

**Profiler Basic Skills Checklist:**

Over 1200 pre-service teachers, at several Catalyst institutions have now taken this on-line self-assessment instrument. The data generated consisted of Likert scale responses to self-reflection based questions. Each individual pre-service teacher taking the on-line instrument receives both a response summary and a peer-based comparison diagram of their perceived strengths and weaknesses related to specific educational technology skills. The checklist prototype uses the popular Profiler web site and Internet data collection service, which can be contacted at [http://profiler.com/](http://profiler.com/).

**CEO Forum Institutional Self-Assessment:**

The Teacher STaR chart (School Technology and Readiness chart), established by the CEO Forum is also used by the Nebraska Catalyst project itself to provide an institutional profile for each of the 17 partner institutions regarding the status of educational technology within their teacher preparation programs. Questions provide feedback on technology integrated courses, faculty support, field experiences, and technology standards integration. Each institution receives an individual profile from the instrument web site for formative evaluation of the institution itself. It is also used for summary information on relative institutional progress across the project, which is being made available on the NECatalyst website. The Teacher STaR chart can be accessed from their web-site at [http://ceoforum.org](http://ceoforum.org).

**Stepping in the Right Direction**

Although there is still considerable work to do, the Nebraska Catalyst Project believes that it has made a solid start on providing an array of assessment instruments for interested institutions. The institutions themselves have been good partners in this effort, and are taking ownership of various pieces of the assessment puzzle. A real contribution to the success thus far has been the willingness for institutions to experiment a bit, and a genuine interest by the talented members of participating institutions to collaborate.

As you might surmise from the descriptions of the instruments themselves, there has also been a keen interest to try to do as much as possible, in an online format. The participating institutions are finding this online format to be very convenient, and such a format has been one of the key reasons that so many pre-service teachers and faculty have already participated thus far in the prototype and refinement process.

The Nebraska Catalyst Project has also been a strong believer in a development approach that also provides a careful linking and integration of the instruments to various standards for pre-service education, such as those from ISTE. Such a commitment is helping ensure that the instruments that are developed are indeed on-target, for what they need to help assess, and encourage, related to educational technology.

By striving to be both online and on-target, the Nebraska Catalyst assessment instruments are seeking to become model examples of using technology-based data collection to assess the educational technology preparation of pre-service teachers. The Nebraska Catalyst project is also hoping that such instruments become truly useful tools for helping Nebraska teacher preparation programs examine the technology preparedness of their pre-service teachers. In essence, these new instruments are beginning to help us ensure that Nebraska institutions themselves will indeed be "on-line" and "on target" as they strive to help teachers prepare students effectively for their educational futures.

This paper and the Nebraska Catalyst Project itself was made possible by a grant awarded through the Preparing Teachers to Teach with Technology Program (PT3), of the U.S. Department of Education. In addition, the Nebraska Catalyst Project has benefited from a strong base of creative and talented professionals who have worked on the various assessment strategies and prototypes, representing Task Force I and II within the project. Many colleagues have assisted in this daunting task, and have included individuals such as Mr. Paul Clark, Dr. Del Harnish, Ms. Ronda Littrel, Dr. Robert Mortenson, Mr. Bob Pawloski, Dr. Al Steckleberg, Mr. Mike Timms, Dr. Neal Topp, to name just a few of these innovative developers. More information about these individual assessments, and Task Force I and II, can be found at the Nebraska Catalyst web-site of http://www.necatalyst.org.
Technology Integration Best Practices: Multimedia Style

Michele Hardwick, University of New Mexico, US

Abstract

The University of New Mexico PT3 (Preparing Tomorrow's Teachers to Use Technology) Project entitled “Shared Visions” has developed Multimedia Lessons that provide examples of technology integration best practices. The lessons were created in collaboration with K-12 schools and are presented using a Cognitive Apprenticeship Model template developed by the University of New Mexico. The online lessons provide an interactive approach to teaching and an additional resource to College of Education faculty in the area of technology integration. Conference participants will have an opportunity to view the lessons and explore the application of the cognitive apprenticeship model. The session will cover both practical and theoretical issues encountered in identifying field practitioners, articulating the instructional design process, and creating meaningful video footage of best practices.
Technology That Works in the Classroom for PT3: From Low Tech to High Tech Mobile Computing

PT3 Management Team, Albany State University, USA
Betty Hatcher, PT3 Project Director, Department of Educational Leadership and Foundations; Gerald Burgess, Director of Educational Technology Training Center; K. C. Chan, Department of Natural Sciences; Rani George, Department of Educational Leadership and Foundations; Rosemarie, Department of English and Modern Languages; Sam Masih, Department of Mathematics and Computer Sciences

Abstract: The support of a U. S. Department of Education initiative, Preparing Tomorrow's Teachers to use Technology (PT3), has enabled a multidisciplinary faculty teaching strategy reform process using a mini grant proposal/award model. With this support, core faculty are revising course syllabi to incorporate technology-rich teaching, enabling all core students to experience a model teaching setting, beginning with their earliest college classes. As year three of the reform process begins, changes in teaching strategies indicate that faculty continue to add additional technology, incorporating the latest in handheld, wireless mobile technology applications.

Introduction

The PT3 project at Albany State University, the SOWEGA Project, is now in its third year and has expanding the strategies which has marked the initiative as a hallmark for faculty support in implementing change on a small, historically black campus. Through the activities of the SOWEGA (Southwest Georgia) Project, faculty are embracing new teaching strategies and providing models for technology rich instruction for all core course enrollees, including teacher education majors.

Each PT3 grantee has distinguishing characteristics and for the SOWEGA Project, a hallmark of its design is the involvement of all faculty disciplines represented in core subjects. This factor allows PT3, through a mini grant system that supports faculty from all core disciplines, to influence students enrolled in all core content courses. This project design targets students for exposure to faculty who are teaching with technology-rich strategies thus impacting future teachers from the time they begin their college career.

During year two, with some carryover funds approved, the SOWEGA project management team expanded the mini grant award system from the first year of seven awards, to 12 awards. The number of faculty who proposed to enrich their teaching expanded, and in some cases, they each worked with teams of faculty within their departments. The departments with participating faculty were teacher education (7), mathematics and computer science, science, fine arts, English and history.

The funded proposals in the College of Education included the following: The course called Prep for Teachers proposed to incorporate a multimedia portfolio component for the class. Student teachers complete their final product during the course, but until this year, it has been in a hard copy format. The project involved technical support from the Educational Technology Training Center on campus. Two other COE projects targeted a course revision that moved the course to an online course format, using Web CT. Two other faculty awardees revised methods courses in the area of social science and language arts in ways that promoted student interaction with multimedia assignments. In special education, two faculty teamed to revise courses to incorporate increased student access to assistive technology product knowledge.

One faculty person in English and Modern languages continued that department’s extensive adoption of revising teaching with technology, using student interactive assignments for the freshman core composition courses. In Fine Arts, the faculty teaching music appreciation explored software and Internet support and revised that core course with student-centered technology activity. In the natural sciences, a physics lab science course was converted to a web-based course delivery. In mathematics, an instructor with a research background and K-12 teacher training expertise used graphing calculators to provide workshops for math faculty and for K-12 teacher partner school faculty. Two courses in the social sciences (Georgia History and U. S. Government) were redesigned for content delivery via power point and Internet-based support, with a substantive assignment for student presentations. The student assignment supporting increasing writing skill development using technology resources and delivery.

One project goal that did not progress during year one was implemented with a mini grant this year, with multimedia portfolio production for students beginning with the existing course called Prep for Teachers. During this course, students begin their student teaching, with one day per week devoted to completing Intech training, a model for implementing technology for K-12 teachers. One outcome of the Intech training is putting their portfolio work into a multimedia format. The first of these portfolios was completed this summer (5), with the Fall class (which will more appropriately be in the year three annual report) reaching completion for the entire class.
A major finding or outcome from the multimedia project has been a new awareness concerning the quality of student writing in the portfolios. With the entire portfolio more readily available, education faculty are now addressing an improved system for monitoring student portfolio work, with grading and rewriting/correction built in to each course component. In the previous design, students turned in their portfolio work as hard copy at the ending of the semester, a timeline that did not support student rewriting and editing with faculty supervision.

Project dissemination continues to expand, with presentations via panels, papers and workshops presented at venues that are local, regional, national and international. Local dissemination is regularly scheduled with the SOWEGA Project Summer Seminar, and one-day event that combines area K-12 teachers, our students and mini grant faculty in a session where technology-rich teaching strategies are shared. These outcomes are also shared in settings (state meetings) with other University System of Georgia teacher educators. Presentations have been made concerning the project outcomes at national conferences, and one international conference. Presenting faculty have been members of the PT3 management team. Workshops have been offered by both the management team faculty and mini grant faculty on campus for students, faculty and for stipend-supported area K-12 partner teachers.

During the year two phase of the project, the project model continued in its primary goal to provide a mini grant award funding for faculty who proposed syllabi revisions, incorporating technology to demonstrate model instructional technology applications; to support teacher education students in an intensive technology training process (Intech) and to collaborate with system partner schools in supporting K-12 student teacher supervisors in technology training with Intech.

The scope of the mini grant activities has broadened, with increasingly strong development of technology applications, indicating a new willingness to adapt teaching for on-line learning and student interactions. As newer technology has emerged (hand-held computers), more faculty are seeking training to incorporate newer developments into their already revised strategies, one indication that the initial faculty proposals are indications of a long-term process of change.

Outcomes of faculty efforts, including both year two outcomes and highlights from the year three activity will be presented here, including evaluation outcomes. Using a continuation of the formative process, evaluation outcomes are guiding the successive focus of each year during the three-year process.

Results of the Evaluation

The second year of the PT3 SOWEGA project was a major success. We had more faculty receiving mini grants. Faculty from the Colleges of Education and Arts and Sciences were given up to $6000 to revise their courses by infusion technology in their teaching. Twelve faculty members were awarded mini grants. Of these 7 faculty were from the College of Education and five were from the College of Arts and Sciences. Four of the professors put their courses on WebCT, three of these four faculty had web-enhanced courses, while one of the faculty members one had a full-fledged online course. The other professors included more technology in their teaching. One of the professors had students in the Preparation for Teaching course do multimedia portfolios.

In addition to the revision of courses, SOWEGA PT3 Project also conducted Palm workshops, Graphing calculator workshops and a summer seminar for college students, faculty and school teachers from the two local school districts.

Evaluation data was collected from the students and professors. On the student side, the measures included projects, essays, extended performances, portfolios, student attitudes, morale, and satisfaction. On the teacher side, we evaluate had them provide evidence of infusion of technology in their courses. Professors also completed surveys that provided information about technology assignments and the type of software they had used in their classes.

Students completed a computer attitude survey that measured their attitudes toward the use of technology. About 288 undergraduate students from the Colleges of Education and Arts and Sciences students answered these surveys. More than 85% reported positive attitudes toward the use of computers and a high degree of comfort in using the computer. About 15 Professors in the two colleges answered a technology survey that asked them about their use of various software programs. This survey measures faculty use of basic technology in their teaching and regular daily activities. Based on the results it can be stated that competency with basic computer operations ranges from beginning to more advanced. A system wide survey is underway to get a better understanding of faculty's level of technology competence. The SOWEGA PT3 organized a one-day summer seminar in June 2001. Approximately 65 participants responded to a survey about the usefulness of the summer seminar. Of the 65 participants who attended the summer seminar 95% rated the seminar as an "outstanding activity" and stated that they received "ample information." About 10 of the mini grantees made presentations at the summer seminar.

The major aim of the SOWEGA PT3 project was to encourage professors to infuse technology into core Arts and Sciences courses and education courses. The pre- and post surveys were evaluated to see how many changes were made in the courses redesigned by the mini grantees. More than half of the twelve original syllabi had little or no
technology components. The findings related to the revised syllabi are complex. When judged against the National Education Technology Standards, the syllabi were found to echo strongly with the standard Technology Operations and Concepts and Teaching learning and Curriculum standard but weak in Social, Ethical, Legal, and Human Issues.

SOWEGA PT3 - Year Three Indications:

Many of the initial changes in teaching strategies in the SOWEGA Project focused on level one changes, with beginners adapting their lecture style to incorporate technology in very basic ways. As year two progressed and as campus-wide faculty interest expanded, faculty began to look toward newer applications, such as moving to web-based delivery for much of the course or using Palm technology to support class management.

One change from the core focus has been an award to two different faculty teams whose focus is directed more toward the school system partners. This supports the project’s goal for pairing student teachers with K-12 teachers who are both technology trained and practitioners. Dr. George Thomas teaches graduate courses in both statistics and Educational research, a course assignment that enrolls students from the K-12 classroom. His work with this population will expand that partner system’s awareness of the need for student teacher supervisors who can support student teachers who are using technology in teaching.

Another faculty team composed of Dr. K. C. Chan and Dr. Gerald Burgess is designing a system to support faculty who are seeking ways to incorporate the use of hand held computers in teaching. This team is developing a workshop delivery for training both K-12 and college faculty in applications of this technology to support and manage instruction.

SOWEGA PT3 - Core Faculty Mini Grants from Year Two: An Overview

1. Instructor: Zephyrinus Okonkwo - College of Arts and Sciences
Course: College Algebra

The purpose of this project is to infuse technology in the teaching of MATH 1111- College Algebra. The outline of the technology-enriched MATH 1111-College Algebra course includes objectives such as the use of graphing calculators, interactive mathematical software, mathematical software, web-based tutorials, and multi-media classroom presentations. The students enrolled in the course will be given workshops on the use of the Interactive College Algebra Software, Maple V mathematics software, and graphing calculators. A web-based computer resource will be provided for students and faculty. Homework assignments will be provided on the web and students will be able to solve problems and submit their solutions to their instructors online. The three principal participants, other faculty, and two pre-service interns will participate in workshops to be organized by INTEC and the Project Director. The interns will develop the materials to be posted on the web. The interns will also help develop power point presentations, web pages, and other mathematical documents for instructors of the course. An in-service teacher will facilitate the training of the interns. Dr. Samuel Masih and Mrs. Connie Leggett will be the principal consultants for this project.

Project Outcomes included: The course outline for MATH 1111-College Algebra has been revised to include the infusion of technology in the teaching-learning process, Dr. Okonkwo, Mr. Shelton, and Mr. Myricks have undergone extensive training on the use of the graphing calculator technology in the teaching of College Algebra, faculty are getting training on the use of MathType, EXP for Windows, web-based instructional materials and document preparation, and the MAPLE software. A website is being developed. Our temporary page is http://www.asuemath.asurams.edu/algebra

2. Instructor: Dr. Deborah Bembry
Course: Early Childhood Curriculum:

This course is being redesigned to become a Web CT enhanced class. Students’ syllabus and assignments were posted to the Web for easy access and retrieval. This format allowed the students to interact with the professor as well as each other.

Students still attended some classes since this is a web enhanced class rather than a strictly online course. Students presenting and demonstrating in class utilized more technology than previous classes. They searched the Internet for articles to critique, evaluated lesson plans for appropriateness for various ages and stages of development and brought in software and evaluated its ease of use and suitability for elementary and preschool children.

The following objectives directed the project: 1) Students will use a range of technology to demonstrate a comfort zone in locating, using and disseminating information. 2) Students will use a variety of technology and media to demonstrate a level of proficiency in use of technology in locating, using and disseminating information. 3) Students will interact with various technologies for the purpose of both transmitting and retrieving information. 4) Students will
use technology routinely to transmit messages to the professor, each other and other customers as needed. 5) Students will use technology to help redefine the role of the teacher form “presenter” of selected information to “manager” of active learning. 6) Students will have access to data, reports, curricula and other documents necessary for proper preparation to teach. 7) Students will collect and share information while actively engaged in the learning process. 8) Students will explore and evaluate technology resources as they relate to early childhood and developmentally appropriate practices. 9) Students will practice responsible, ethical and legal use of technology, information and software resources.

3. Instructor: Dr. Surendra Pandey
Course: PHYS1001 Physical Science

The purpose of the project is to develop and offer the Physical Science course online as well as in traditional format. Since the course will be offered during Fall 2001, the development of materials is in progress. A web site has been created for the above course PHYS1001 on the WebCT, http://webct.usg.edu/; a list of simulations using Java applets has been prepared that will include various topics covered in the course; a list of sites has been prepared that include data, graphics, virtual experiments on selected topics in physics; the syllabus is being modified to reflect the online offerings and necessary instructions for students and the PD and student assistant have registered for InTech training to be held on May 7-17, 2001.

A list of useful sites to be used by Physical Science students (online or traditional) include:

Physics tutorials & simulations: http://smet.asurams.edu/physicsweb/
Selected topics: http://www.glenbrook.k12.il.us/gbsci/physics/mmmedia/vectors/mzg.html
http://www.colorado.edu/physics/2000/waves_particles/wavpart2.html
Interactive: http://www.explorescience.com/activities/index.cfm
Periodic Table: http://trackstar.hprtec.org/main/display.php3?trackid
JAVA Graphic User Interface: http://www.scis.nova.edu/~venkata/CISC665/gui.html
Resources for teachers: http://www.4teachers.org/

4. Instructor: Mrs. Gina Harbor - College of Education
Course: Special Education 3306

The mini grant course revision proposed was for SPED 3306. In addition, I have completed 12 modules for an additional course, SPED 5501, and I designed a course that is being taught by adjunct faculty, SPED 5515 (15 modules)

All of the students in my courses are special education majors, and we meet class in a room equipped for teaching with technology. There are connections for the Internet and a projector. Student interaction is enabled through the use of such applications as WebCT, PowerPoint, Excel, IBM HotMedia, Netscape, Internet Explorer. Students use the discussion board and chat room features in Web CT to interact both in and out of class. Papers are graded and returned online, and grades are posted to an online grade book. Self tests online help students prepare for exams.

Sites such as PBS, CNN, and ABC help to keep students informed about current issues affecting special education. These sites usually require RealVideo Player. Students are then shown how to download and install the software. The objectives for my lessons focus on special education. The activities chosen to successfully meet the objective integrate technology. Students are taught the skills necessary to meet the objective on an as needed basis. I request that all of my classes be scheduled in the computer lab because I use the computer so frequently.

5. Instructor: Dr. Babatundi Abayomi - College of Education
Course: Measurement and Evaluation for Early Childhood Majors

Revisions for enhancing this course with technology will include moving toward more online interaction for students. This course is an introduction to the preparation, administration, and scoring of classroom assessments and tests. This course will also focus on the selection, administration, scoring and interpretation of standardized achievement and aptitude tests. The course will also address issues related to test norms and how to use test scores for effective guidance and evaluation. The course text has a companion website: A Virtual Learning Environment, and will utilize online information for review, student reporting and for accessing the syllabus and course assignments. The course includes four weeks of class meetings, with online instructional strategies composing the additional weeks of the semester.

6. Instructor: Mr. Michael Martin - College of Arts and Sciences
Course: Music Appreciation

The revision of the one of the core courses in fine arts, music appreciation, involved not only the addition of software and hardware, with some Intech training for the instructor. An additional need included a summer course in
learning applications of software especially designed for music appreciation instruction. The redesign of this course was more technology intensive than some, owing in part to the large class size typical of most semester enrollment. The scarcity of teaching space for large classes, and preference given usually to departmental major courses, created a teaching situation for this course in which the instructor taught the same course in several different classrooms. The challenge of this arrangement was creating a portable technology support setting.

The changes to this course have inspired other faculty in the fine arts to technology for instruction to the extent that one of the year three awardees is a fellow faculty, teaching art appreciation. The addition of technology rich applications in these areas has truly revived the departmental approach to technology. Since all freshmen rotate through these courses, this is a critical area to demonstrate a model approach to instructional technology applications for teaching.

7. English and Modern Languages – College of Arts and Sciences
Instructors: Mary Gervin and Gloria Ridgeway
Course: English Composition – a two-course sequence for core instruction

The course revisions accomplished by a team of English and modern language faculty produced an improved, web-interactive process for student learning. Using the increased access to web-based teaching settings, the instructional focus changed to allow increased student initiative for improving their writing skills. Via an on-line writing lab (OWL), students were able to monitor their own progress and access feedback beyond the traditional red ink, teacher-directed methods.

Hypertext resources were preferred over most other available software, as some of the limitations of software programs were prohibitive, including their expense, their hardware platform or specific network application limitations and the fact that they were time consuming.

The technology enhanced the writing process by empowering students to develop their writing skills. Instructors were able to achieve pedagogical goals while incorporating technology into the learning experience. The use of technology as complement to writing instruction can afford learners the opportunity to practice skills, promote self-direction, and meet individual needs without diminishing the learning experience.

The course revisions described are representative of the year two SOWEGA PT3 mini grants, and indicative of the broad range of both participation and variations of strategies employed by the mini grant faculty.
INTIME (Integrating Technologies into the Methods of Education): A PT3 Catalyst Grant

Doreen Hayek, University of Northern Iowa, US

Reports from the National Council for Accreditation of Teacher Education (NCATE) and the Office of Technology Assessment (OTA) have called attention to existing deficiencies in teacher preparation programs in preparing preservice teachers to use technology effectively in the PreK-12 classroom. Technology and the New Professional Teacher (NCATE, 1997) reports that preservice teachers should be required to apply technology in their courses and should see faculty model technology use in the classroom. In addition, Teachers and Technology: Making the Connection (OTA, 1995) suggests that in teacher preparation programs where faculty model technology use, students will adopt the use of educational technology in their instruction. The National Center for Education Statistics survey of 2001 points to the immense progress in computer and Internet accessibility made in U.S. public schools since 1994.

But in order for undergraduate students to learn to use technology when they teach, it is vital that university professors change the way they prepare teachers to use technology. According to conclusions drawn by the OTA, it is not enough to tell students about what is possible. "They must see technology used by their instructors, observe uses of technological tools in classrooms, and practice teaching with technologies themselves if they are to use these tools effectively in their own teaching" (OTA, 1995, p. 185). It is far more common, however, for education faculty to discuss technology, have students read about it or demonstrate technology, rather than model it or require students to incorporate technology use into their lessons or units (OTA, 1995, p. 185). The purpose of the INTIME project is to provide the necessary resources for methods faculty to revise their courses to model technology integration and require preservice teachers to apply technology, along with components of quality education, in their lessons and units.

The information presented in the National Center for Education Statistics survey (2001) makes the INTIME project even more relevant and necessary in the total picture of how preservice, inservice, and methods teachers can improve student learning at all levels through the use of technology presently available in U.S. educational institutions.

INTIME Goals:

INTIME (Integrating Technologies Into the Methods of Education) is a $2,397,594 Catalyst Grant to the University of Northern Iowa's College of Education from the U.S. Department of Education. The three-year INTIME project addresses deficiencies in teacher education programs in preparing preservice teachers to use technology effectively in the PreK-12 classroom. The purpose of INTIME is to provide the necessary resources for methods faculty to revise their courses to model technology integration and require preservice teachers to apply technology, along with components of quality education, in their lessons and units.

This session will show how the project is intended to produce change in teacher training programs in three ways: 1) The project provides web-based learning resources to support new teaching and learning processes in teacher training courses; 2) Teacher trainers can model technology integration in their classes and use the video scenarios and online discussion forum to discuss the technology-based learning process; and 3) INTIME provides a Faculty Online Discussion Forum through which teacher trainers can share strategies for integrating technology with other trainers.

Participants Involvement and Outcomes:

1) The participants will understand the "Technology as Facilitator of Quality Education Model". The model includes the following dimensions: students at the center of their own learning, principles of learning, content standards, teacher knowledge, information processing, democracy, teacher behavior, and
technology. Technology encompasses and permeates all the
"lenses" or elements of the model that involve interaction of
student learning elements.

The seven dimensions of the model provide a way for
educators to view the integration of technology related tools
into a robust educational environment. The materials the
project features include over 300 web-based video scenarios
of preK-12 teachers using technology as part of their daily
instructional activities. Each of these examples includes the
lesson plan, an interview with the teacher, a lesson overview, alignment with content standards, and a list of
technology tools and resources. Beyond providing the information necessary to recreate the lesson, the
activity is also viewed through the lenses of Technology and quality education elements.
The project sets up a framework for a robust educational environment and identifies key points at which
technology should be implemented and evaluated to determine its impact. The project also allows the
integration of new research findings into the appropriate segments of the model while maintaining the
structure to evaluate the impact of technology tools on these new findings as part of an ongoing evaluation
process.

2) The participants will view and critique online video vignettes of technology integration and
quality education in a PreK-12 setting via video streaming technology. They will consider what content
standards are addressed, how technology is integrated in the curriculum, and what other components of
quality education are implemented in the lesson.

3) The participants will discuss the project as well as share their ideas about its goals, applications,
strengths, and weaknesses.

ABSTRACT:
The purpose of InTime (Integrating Technologies into the Methods of Education) is to provide the
necessary resources for methods faculty to revise their courses, model technology integration, and require
preservice teachers to integrate technology, along with components of quality education, in their lessons
and units. The project develops online video vignettes to be utilized in methods courses that include videos
of best practices showing from PreK-12 classrooms where teachers are integrating technology in a robust
educational environment. The participants will view and critique one of the online case studies of best
practice in technology integration and quality integration via video streaming. The issues addressed in this
session will be interesting for deans, administrators, faculty, and decision-makers of all expertise levels.

National Council for Accreditation of Teacher Education. (1997). Technology and the new

Research and Improvement
Explorations in Modeling and Visualization in Mathematics and Science Immersed in Pre-service Teacher Education

Timothy Hendrix, University of Illinois at Urbana-Champaign/Office for MSTE, US

The National Council for Teachers of Mathematics has articulated in Principles & Standards 2000 (NCTM, 2000) the integral nature of the processes of doing mathematics. To know mathematics is more than recalling a loose-leaf notebook of facts—to know mathematics is to do mathematics. The Principles and Standards call for mathematics teaching to reflect these emphases in several ways. Mathematics learners should interact with mathematics concepts in multiple representations. Visual, numerical, and verbal means of viewing mathematical relationships should be employed as well as symbolic development. Viewing concepts from multiple perspectives promotes an environment conducive to making connections between mathematics concepts and phenomenon in real life, as well as to other mathematics concepts.

Today’s citizenry must make informed decisions daily that involve such an assumed understanding of mathematical and scientific relationships. NCTM (2000) refers to a ‘model’ as a “mathematical representation of the elements and relationship in an idealized version of a complex phenomenon” and urges educators that “students’ use of representations to model physical, social, and mathematical phenomena should grow through the years.” Similarly, the AAAS Benchmark science standards also point to the importance of modeling in the science curriculum. Students should be able to create models that reflect the nature of increasingly complex phenomena, understanding both the underlying assumptions of the model and the mathematical/scientific relationships between the elements of the model.

The national report Shaping the Future: New expectations for Undergraduate Education in Science, Mathematics, Engineering and Technology (NSF, 1996) strongly recommends that undergraduate programs “make creative uses of technology to promote modeling and visualization.” Technology enhances greatly the ability of students to explore models in mathematics and science. The types of representations and methods available to construct and manipulate different models allow students to explore many more interesting and realistic problems than traditionally experienced in high school classrooms. But the question remains as how to generate widespread implementation in the K-12 environment. The National Research Council (1989) makes the suggestion in the report Everybody Counts that “reform in undergraduate mathematics education is the linchpin for K-16 reform.” Furthermore, “college and university faculty [should] make introductory courses attractive and effective...lecture less; try other teaching methods...[and] link scholarship to teaching.”

As a component of the Ed Grid PT3 group, the Office for Mathematics, Science, and Technology Education at the University of Illinois at Urbana-Champaign works with the pre-service teacher education programs in mathematics and science to provide opportunities for modeling and visualization. In this panel presentation, faculty from the disciplines of science education and mathematics education will share this model for pre-service teacher education. Collaboration has been a theme that has contributed to the success of this model as science and mathematics education faculty work together to promote connections between the two disciplines. Different ways to implement visualization tools in pre-service coursework will be demonstrated and discussed. The panel presentation will provide a more detailed view and discussion of how various offices and grants within a college/university combine to support the integration of intensive technology tools in a pre-service teacher education program.

Within the pre-service teacher education program, there is an intentional recursive pattern of “immersion→reflection” that eventually leads to synthesis. We cannot expect beginning teachers (or any teachers) to use a tool for learning if they have not learned via those tools themselves. Learning about instructional technology is not sufficient; one must learn mathematics/science through the use of powerful technology to realize the power itself. Rather than teaching pre-service teachers about how to use the tool in mathematics and science, we have afforded them the opportunity to explore different representations of concepts via the use of powerful technology tools.
Throughout the teacher education programs in mathematics and science, pre-service teachers engage in multi-layered activities to enhance pedagogical content knowledge. In the first year of the two-year program, an emphasis is placed on engaging the pre-service teachers in activities that deepen their content knowledge of mathematics/science in an inquiry environment via the means of tools such as computer-based laboratories or Internet-based Java applets. Pre-service teachers are often unfamiliar with the use of these tools in secondary mathematics/science classrooms. Pre-service teachers in the cohorts are encouraged to reflect on how such inquiry and tools contribute to their deeper understanding of mathematics and science. At the end of the second year in the professional program, novice teachers who have completed 3 semesters of field experience, as well as a student teaching apprenticeship, are challenged to explore a wider array of instructional technology tools. The novice teachers are expected to synthesize two years of theory and practice to envision possible ways to implement computer-based laboratories and Internet tools in the classroom in order to promote inquiry in mathematics and science.

Field experiences and grants that involve local schools engage in-service teachers in faculty development as well as inclusion in the teacher education process. Analysis of student activities and reflections leads to further research about visualization and teacher development. The entire enterprise of theory, research, and teacher education becomes interwoven, thus creating a model for professional development and lifelong inquiry.

Implementing Change: Attitudinal Factors
Teaching Middle School Math/Science Teachers to Enhance Curriculum Using Technology
Project ImPACT at Farragut Middle School

Donna Henson-Boyers, doctoral candidate in Instructional Technology, Curriculum & Evaluation
University of Tennessee, Knoxville, United States, dhensonb@utk.edu

Susan Skuda, Project ImPACT Coordinator, University of Tennessee, Knoxville, United States
sskuda@utk.edu

Abstract: As part of a PT3 grant at the University of Tennessee, math and science teachers at Farragut Middle School are thinking about their teaching in new ways. A training model developed under Project ImPACT (Implementing Partnerships Across the Curriculum with Technology) partners interns with mentor teachers. These partnerships receive training that focuses on how technology can be used to support and enhance curriculum concepts in math and science.

The University of Tennessee is a recent recipient of a U.S. Department of Education PT3 (Preparing Tomorrow's Teachers to Use Technology) grant. Project ImPACT (Implementing Partnerships Across the Curriculum with Technology) is designed to work with some of the schools in the Professional Development Program, capitalizing on the partnerships of intern teachers and their mentoring classroom teachers. It has the dual focus of exposing professional teachers to technology that can be used to enhance their curriculum, and preparing preservice teachers to use technology for improved learning in their future classrooms. This paper will focus upon the effect of this technology training, resulting attitudinal changes, and their perceived impact upon the success of the program.

Farragut Middle School is the largest of 14 Knox County middle schools and the only middle school level Professional Development School site included in Project ImPACT. Students at FMS are grouped heterogeneously into teaching “teams” led by teachers who are specialists in language arts, mathematics, science or social studies. Six mentoring teachers, four in math and two in science, together with their intern teachers, participated in Project ImPACT technology training. Mentoring teachers received a stipend for their participation, and intern teachers were issued laptop computers and printers to use throughout the school year.

A major activity of Project ImPACT at Farragut Middle School included the creation of a learning strand model designed to help teachers develop applications of technology in the curriculum areas of math and science, with consideration of special education issues and needs addressed throughout the training. Through Project ImPACT, mentoring teachers, interns, the university faculty supervisor, and the school technology coordinator participated in training consisting of five weekly three-hour sessions, supplemented with matching support sessions of two hours each. Project participants also attend periodic team meetings.

The math and science learning strand was developed and delivered by a doctoral student in the field of Instructional Technology who has seventeen years' classroom experience. The trainer was supported by a staff member who was in the unique position of having served previously as Farragut Middle School's building level technology coordinator. The in-depth knowledge of the facility, equipment and the staff brought by this support person contributed to the effectiveness of the learning strands, team-building, and support at FMS.
An initial self-evaluation revealed that the mentoring teachers felt they had low to moderate technology skills, with most of their experience in electronic grading, word processing and email. All of the intern teachers had participated in at least one technology class as part of their required coursework, and most felt competent in their use of technology. One of the premises of Project ImPACT was that the interns' relative comfort and familiarity with technology, coupled with the mentoring teachers' classroom expertise would provide a fertile medium for infusing technology into the curriculum.

Training began with the introduction of Inspiration, software used for a variety of brainstorming and organizational tasks. The instructor modeled the use of the software as the teachers brainstormed their priorities and needs in topics to be covered during the 15 hours of training. Mentors and Interns then worked together to create an instructional unit, using the software as their organization tool. The next session focused on mechanical and technical aspects of setting up a class set of laptop computers, class management, and an exploration of online resources and lesson plans (http://web.utk.edu/~impact/teacherresources). The presentation software, PowerPoint, was introduced over the next two sessions, and teachers began creating lessons and resources to elaborate and enhance the curriculum they were covering. In that context, they learned to work with a variety of digital media, from digital cameras, to scanners, to capturing images from the Internet. Another session taught the creation of a webpage, using Netscape Composer, and the resulting pages provide another tool for teachers to use to maximize and focus student learning using the Internet. Woven throughout the training was the awareness of special needs students, and methods that could be used to support their learning, such as the use of text to speech, clear visuals, and enlarged text. Teachers also had the opportunity to explore and evaluate a variety of software and other technologies such as digital microscopes.

Perhaps the most powerful change that came about during the two months of training, however, was one of attitude. Teachers who began with an attitude of open skepticism ("I don't have time to do this," or "I don't see why I would use this in my classroom") found themselves eagerly creating PowerPoint presentations to add a visual component to their lessons. One teacher began as an absolute neophyte, very concerned about his lack of technology skills. After just a few sessions, he was not only using the technology, but combining several applications into lessons he will use later in the year. He is also eagerly planning ways for his students to work with classes of previous interns and teachers at other schools through the use of video conferencing. Another teacher observed that she had attended several workshops about PowerPoint and had never been able to use it. After completing her first PowerPoint project during a training session, her sense of accomplishment and empowerment was contagious. Still another's comment, "You know, the only reason anybody is doing this is for the stipend," later became "It's too bad every teacher at the school doesn't have the chance to learn this." Teachers who have worked alone within their own classroom found themselves collaborating and planning lessons together, and sharing units so that one unit could serve double-duty. They are beginning to see themselves as a community of educators, rather than as individuals teaching in isolation.

A key component to the changes coming about at Farragut Middle School is the teachers' sense of empowerment in the use of technology. At the beginning of the project, they were encouraged to identify their training needs and interests, and the training was tailored to meet these needs. This engendered an atmosphere of ownership and began a collaboration among teachers, interns, and Project staff. The competition associated with teaching in isolation is giving way to the trust and mutual support of community and a contagious enthusiasm that continues to grow. The sense of increased competence, coupled with new ideas and options for instructional dynamics have ignited a flame of learning for both the teachers and their students.

Acknowledgements

Project ImPACT was supported by a PT3 grant from the U.S. Department of Education, awarded to Blanche O'Bannon and Aileen Nonis, of the College of Education, University of Tennessee, Knoxville. The data presented, statements made and views expressed herein are solely the responsibility of the authors.
Recent studies have indicated that improving the capabilities of preservice teachers to integrate technology into teaching and learning requires systemic change within a teacher preparation institution (Cooper & Bull, 1997; International Society for Technology in Education, 1999; Mehlinger & Powers, 2002; National Center for Education Statistics, 1999; National Council for Accreditation of Teacher Education, 1997; Willis & Mehlinger, 1996). Based on this premise, the CEOForum on Education and Technology (2000) developed the Teacher Preparation StaR chart, an assessment tool designed to help institutions in systematically benchmarking their progress, with indicators ranging from "Early Tech" to "Target Tech."

Since the instrument's release, over 260 deans and directors of education schools and colleges signed a commitment letter indicating their support for assessing their progress and using the StaR chart in that process. The original StaR chart provided a good beginning but needed refinement. As a result, CATALISE (a PT3 catalyst partnership), after getting permission from the CEO Forum, has gone through a rigorous process to evaluate and refine the chart so that it can become a key component in technology planning for all SCDEs.

The PT3 catalyst grant program is designed to implement and improve the StaR chart as part of a larger program, CATALISE is assisting colleges and universities in technology planning, action, and results. CATALISE (Consortium for the Application of Technology and Learning Innovation in Schools of Education), is led by Western Illinois University bringing together four major teacher preparation institutions (Eastern Michigan University, California State University, Los Angeles, University of Alabama-Monticello, and Towson University), the Teacher Education Council of State Colleges and Universities (TECSCU), and partners NCATE, NCREL, the Metiri Group, and Apple Computer.

By working with TECSCU institutions, the project's goal is to significantly impact technology planning and policy for teacher education at participating colleges and universities. The project includes an online assessment tool based on the StaR chart which allows institutions to track their own progress as well as obtain comparisons with other institutions. Support is provided through mentoring, online resources, CD-ROM cases studies, and satellite and video broadcasts to assist participating colleges and universities.

In addition to providing the policy and research context for the new assessment tool, new research results developed through work by CATALISE on key issues facing SCDEs in assessing and improving technology integration will be presented as background. As a result of surveys and focus groups with SCDE leaders, issues identified include the need for standardized concepts, better measurement tools, and "gap" areas that were commonly identified among institutions as requiring assistance. The focus is on providing research results through a pragmatic lens to provide a framework that will benefit participants in their own institutional strategic planning.

The process and issues in creating the revised chart will be presented to illustrate the common concerns that arose through a piloting study of the chart and its features. The areas in which changes have been made will be described along with the rationale for these new features.

The revised chart has additional features that should enhance its usefulness:
- Determine progress in meeting NCATE 2000 technology standards
- Provide data for internal or external reviews
- Produce visual charts that can be used in institutional planning
- Relate institutional progress with other comparable institutions using standardized measures
- Assuring that technology decision-making is data driven
Providing evidence for needs that can be presented to higher level authorities as a priority for action.

When used for annual assessment, the tool presents a report that shows year-to-year progress.

The revised chart, now available to users on the World Wide Web, not only helps institutions assess their programs but provides feedback on the results in relation to others schools that have completed the questions. These results will be reviewed during the session to help participants understand the range and scope of technology programs among SCDEs. The results reveal the emerging strengths across programs as well as the ongoing issues facing institutions. The results include both quantitative findings as well as responses to open-ended questions that provide additional material that suggest both increasing sophistication and unintended consequences that require additional thought for future improvements to the instruments.

The chart will be distributed so that participants will have the opportunity to test and discuss the new assessment instrument and understand how to implement the chart in their institutional assessments. Test questions will be reviewed in a short interactive format to provide an opportunity for questions and feedback. The session will also introduce the CATALISE clearinghouse, a Web based resource designed to provide examples of program implementations that help illustrate the chart areas.

A Study of K-6/University Collaboration: Principles and Practices

Dale Hoskisson, Valley City State University, US
Gary Thompson, Valley City State University, US
Dave Bass, Valley City State University, US

Abstract

This paper will discuss the nature of collaboration and how it worked in practice for the participants in a PT3 grant. The collaboration takes the form of development teams consisting of the K-6 classroom teacher, at least one preservice teacher, and a university faculty member. The collaboration is funded through a PT3 grant. These teams gave the K-6 teacher extra support and expertise and the preservice teacher practical experience in integrating information technology into the curriculum. The participants in most teams were able to achieve a sense of equality among themselves. A student consultant protocol is being developed to address areas of concern after one year of experience with the teams.

A Study of K-6/University Collaboration: Principles and Practices

In the fall of 1996, in order to help preservice teachers achieve greater success in transforming education with the power of information technology, Valley City State University (VCSU) became a notebook campus. All faculty and students are issued a notebook computer for 24 hour use. Almost all classrooms are wired for student and faculty use of the internet and with large screen video projection capabilities. Information technology is ubiquitous and a normal part of daily life on the campus. Then, in 2000, the teacher education program developed a collaborative effort with K-6 classrooms. The heart of the effort is two-fold: 1) to provide in-service teachers with technology expertise and support for their efforts to integrate technology into their curriculum, and 2) to give preservice teachers practical classroom experience in integrating technology into the curriculum.

The collaboration takes the form of development teams consisting of the K-6 classroom teacher, at least one preservice teacher, and a university faculty member. The collaboration is funded through a PT3 grant. These teams gave the K-6 teacher extra support and expertise and the preservice teacher practical experience in integrating information technology into the curriculum.

This paper will discuss the nature of collaboration and how it worked in practice for the participants in the PT3 grant.

Principles of Collaboration

Lanier (1980) defined collaboration as "a complex interplay of talents and knowledge that come together at appropriate times to produce a commonly valued end result which no single party could have produced alone" (p. 409). Thomas (1972) described a continuum stretching from conflict through cooperation and coexistence to collaboration as the end point.

Generally, there are two conditions necessary for a successful collaboration. First, the participants should feel that they are equal in status. Second, they should have mutually agreed upon goals. A third quality that also plays an important role is equal participation in the decision-making process (Million and Vare, 1997) Friend and Cook (1996) believe that the necessary characteristics of collaboration are mutually agreed upon goals, voluntary participation, and equally valued professional resources to contribute to the goals. Cleveenger (1997) adds another element: the members need to believe that the collaboration serves their individual interests.

The Collaborative Projects

The teams select specific projects to work on and develop. To do this, typically, the university student would visit with the K-6 teacher and discuss what projects the teacher would like to do. The student would then discuss with the university faculty what would be the best way to accomplish the project. The dynamics of how this occurred varied...
greatly from project to project but there were always several face-to-face meetings with all three members to coordinate and evaluate.

A Sense of Equality

Successful collaborations involve a sense of equality among the participants. Each member needs to feel that she or he has value and is important to the effort. We were worried about helping the university students feel that they were an equal partner. This might seem difficult to achieve in a setting with one student and two teachers, one of whom would be grading the student. However, the students’ reports indicated a sense of equality. This was due in part to the fact that the students usually had much more experience with the technology than the K-6 teacher. Also, the university faculty was involved mostly as a consultant and provided ideas more than direction or evaluation so the students seldom felt the need to “please the teacher.” The following are typical comments from the students:

We worked side by side most of the time. After I showed the teacher how to use digital cameras, she took pictures while I helped students insert information into PowerPoint.
I showed the teacher how to use the technology. I also created instructional sheets so students could learn how to use the technology.
We were always working together. I would demonstrate how to use the technology, then we would both do it together.

The K-6 teachers had that same feeling of equality. They were the classroom experts. They knew what would fit into their classroom and what their students were ready to do. They perceived the university students as having valuable expertise in information technology and therefore as vital members of the team. The teachers made comments such as the following:

My practicum student was extremely dedicated and willing to share knowledge about technology.
I enjoyed the opportunity to work more closely with the practicum student—we approached the project as a team.

Initially, the university faculty were to be an integral part of the team. However, due to time restraints and the natural dynamics of the situation, we became outside consultants called in as needed. We usually ended up trouble shooting the problems that the students could not solve. As mentioned above, this turned out to be an advantage in helping the students feel more confidence in their value to the collaboration.

One area in which the projects did not meet the principles of effective collaboration was equal participation in the decision-making process (Million and Vare, 1997). This was by design. Because the ultimate responsibility for the success of the K-6 students rested on the K-6 teacher, so did the authority for the final decision in all matters. We felt that the classroom teacher needed to be comfortable with all activities. All team members had input in the decision making process but the K-6 teacher had the responsibility to make or approve all decisions.

Problems occurred with some teachers who were so unfamiliar with information technology that they did not feel equal or that they could really make the decisions. Also some students did not feel comfortable with going into a classroom and directing activities. To address these issues, we are currently developing a student consultant protocol. The protocol includes a set of interview questions for the student to ask the K-6 teacher about curriculum topics, available technology and software, and any specific needs. There will also be a process for contacting the teacher, gathering the information, consulting with the university teacher for ideas, then arranging a meeting with the three individuals to discuss possibilities and help the teacher make the decisions.

The Use of Multi-Media, Web-based Technology to Prepare Tomorrow's Teachers

Outline

Willis Copeland, Sarah Hough, David Pratt, Heidi Stevenson-Bagnall. University of California, Santa Barbara.

How can the multimedia and interactive capabilities of the World Wide Web be used to improve the professional preparation of teacher credential candidates? Surely, when a teacher education faculty member posts on a course website a syllabus and even a brief autobiography very little is added to the educational experience of students in that course. Yet such posting is typically the extent of use of the web by most teacher education faculty. What more is possible?

This proposed panel will discuss a series of web supported, multi-media modules that are being used with credential students at the University of California, Santa Barbara, in the context of a U.S. Department of Education-funded PT3 project. SITE 2002 attendees will have the opportunity to learn about how the thoughtful use of web-supported technology has been implemented in the program, and to hear about and discuss its possible impact on the development of the credential students that the program serves. Members of the panel will represent four perspectives: the Course Professor, the Technical Designer, the Teaching Assistant; and students in the course.

Theoretical Framework

The traditional model of learning assumes that knowledge of practice is easily transmitted from teacher education professor to student, the assumption being that the mind is representational, a mirror of some pre-defined ontological reality, and that once "transmitted" this knowledge is easily applied to real-life contexts (Cobb, 1994). Under this theory of learning there should be no conflict between what is learned in a lecture hall at the university and its application in a school classroom. A plethora of writings by a host of educational researchers tells us that this is not the case. For example, McDiarmid (1990), reminds us that "beginning teachers tend to believe that they were not taught essential knowledge, such as how to manage a classroom, regardless of whether or not they were exposed to such knowledge." (p12).

The development of credential students' technological expertise in UCSB's Teacher Education Program is largely based on a constructivist view of learning. This view sees knowledge as an adaptive function (Glasersfeld, 1990), in which a learner comes to know by responding to experience. According to Savery (1995), "we cannot talk about what is learned separately from how it is learned...rather, what we understand is a function of the content, the context, the activity of the learner" (p 31).

The web-supported materials discussed here have been designed to encourage credential students at UCSB to use their experience as a source of learning. While engaging in a series of activities which could not be undertaken without taking advantage of particular capabilities offered by the world wide web, credential students analyze and reflect upon their own experiences as they consider a variety of issues related to the use of technology to further educational purposes.

In our work thus far we have developed three types of activities:

Interactive multi-media assignments. We have constructed several web-based modules that require credential students to consider technological and pedagogical issues in light of their own experiences in classrooms. For example, a web page for a child development course presents streamed video recordings of three pupils, who are at different stages of logico-mathematical development, attempting to solve the same geometric problem. After credential students have viewed the videos on line, they are asked to type into the web page their responses to a series of questions designed to encourage their exploration of the differences and similarities that they see across the videos and, thus, to further their understanding of child development in mathematics. The students' responses, once submitted, go to a database that can be viewed through a web-based interface by the course instructor for grading purposes. Further, the instructor can identify interesting or irregular trends in students' responses and raise issues based on these for discussion in the next class meeting.

Online Video Cases. We have developed a series of on-line activities which present, on a course's website, exemplary video cases of technology use in classrooms. Students are first encouraged to view the
cases, repeatedly if necessary, until they feel that they “fully understand” what is occurring in the video. After this examination, students are asked to respond to a series of questions that elicit their analytical thoughts about the segments viewed. The responses of all students in the class are submitted to a database that is used by the course instructor to identify topics that will be used in the following class to challenge students’ thinking.

**Online examinations.** To give prospective teachers experience with a non-traditional testing environment, we have created examinations that offer “feedback” to the user as well as guided opportunities to correct their answers. This environment utilizes a combination of hypertext and Java programs to “branch” and thereby offer challenges to students’ responses that are most appropriate to those responses.

**Our Presentation**

Samples of the above will be presented and discussed from four perspectives:

*Course Professor’s Perspective:* Educational purposes and pedagogical techniques will be the focus of this part of the presentation. What are we trying to accomplish with these web-based tools? How are they used as part of the course?

*Technical Designer’s Perspective:* The use of video streaming technologies and hypermedia creates a powerful forum for offering working examples of classrooms in which technology is being applied appropriately. What were the technical difficulties that we encountered when attempting this use of the web? How were they overcome?

*Teaching Assistant’s Perspective:* Implementing interactive web-based learning modules with students enrolled in the technology course has not been flawless. As with implementing any new technology, we have had our share of technical, design, and pedagogical challenges. The perspective of the teaching assistant focuses on development, testing and implementation of the modules themselves, as well as overseeing their use by students. Sharing what went wrong and what can be improved in the creation and implementation of these modules will be valuable information for anyone looking to design and implement similar technology strategies.

*Credential Student’s Perspective:* Credential students have the opportunity to participate in learning activities that are entirely new to them. They cannot complete all requirements of the course without going on-line. The medium is the message. Is examination of video cases easier when one is less rushed, working at home rather than having to be immediately responsive in a live university class? Is the immediate feedback when they take the on-line examines more gratifying and in forming?

Redesigning Courses to infuse technology in a Pre-Service Teacher Education Program

Erin K. Hunt
Department of Educational Technology
University of Northern Colorado
United States
ehunt@coe.unco.edu

Manisha Javeri
Department of Educational Technology
University of Northern Colorado
United States
manisha_javeri@hotmail.com

In June of 2000, The Educational Technology Department at the University of Northern Colorado (UNC) was awarded a PT3 (Preparing Tomorrow's Teachers to use Technology) grant. The project includes five initiatives that are designed to bring about systematic change within the teacher education programs at UNC. The initiatives are enhance the Required Educational Technology Courses for Students in The Professional Teacher Education Programs, model Appropriate Technology Use and Integrate Technology Utilization Into the Professional Teacher Education Program Courses, Model Appropriate Technology Use and Integrate Technology Utilization in The General Education and Content Area Discipline Courses, Integrate Technology Use by Preservice Teacher Education Students in Partner Schools, Build a Model for the Effective Use of Technology in Preservice Teacher Education Programs.

This paper is solely concerned with initiatives two and three, or the initiatives regarding the modeling of appropriate technology use within courses at UNC. Thus far fifteen faculty members have been chosen from various disciplines within the university to redesign a course so that it incorporates technology in effective and appealing ways. These courses include PTEP (Professional Teacher Education Program) and general education/content courses, chosen each semester (fall, spring, and summer). Proposals are accepted from tenured, tenure track, and longstanding term appointment faculty for PTEP, general education, and content-area courses. The faculty members are selected each semester based on a proposal review process and the probable success of the project. All selected faculty members are already competent users of word processing, email, email attachments, and Internet browsing. The interested faculty member proposes the suggested changes for a particular course by indicating how technology will be used and modeled in the course. These changes may include content-specific materials and activities that utilize technologies such as Web-based learning environments, online forums, multimedia project-based learning activities, multimedia portfolios, modeling, and simulations. The project staff, the College of Education Leadership Council, the Arts & Sciences Administrators, and both college deans review the proposals.

Faculty members who are chosen to participate are released from one course and have access to a small budget, $500, for the purchase of software. Each faculty member who is accepted to participate redesigns and augments one course they currently teach. Along with the PT3 project staff, they identify appropriate places to infuse technology into the course, develop appropriate technology-based materials to be used in the course, and redesign the course to accommodate technology. Each faculty member is paired with an advanced student in Educational Technology who serves as the technology coach and instructional designer. This support averages four hours a week throughout the entire semester. The released instructors also participate in a faculty development seminar on technology use in the classroom.

A major focus of this effort is modeling by the selected faculty members, appropriate uses of technology in the various courses they teach, including the delivery of instruction, the faculty member's use of technology both in instruction and in course management and their students' use of technology both as a learning tool and as an aid to their future roles as teachers. All course materials are shared with all faculty members who teach the particular augmented course.

To expand on the current redesign efforts, four case studies have been chosen to relate in detail the redesign process. Each case study looks at one of the chosen faculty fellows and relates information regarding the redesign process, the end product, and the possible diffusion of technology integration to other courses and to fellow colleagues.
Faculty Fellow #1 is a Mathematics teacher for the preservice teacher-training program at UNC. Her previous technology experience included knowledge of Word and PowerPoint. Her main goal for becoming involved in the PT3 grant was to create a website for her methods course. Besides creating a website, she learned to use software tools like Dreamweaver, PowerPoint, Excel, Scanning and Photoshop. She also learned to download software from the Internet.

At the end of the semester this faculty fellow was able to create a website that had important components for her students to have an access to online resources, especially when they were out student teaching. The graduate assistant’s role in this process was to help her plan her project, make her feel comfortable with learning the software tools and their integration in her math class.

Faculty Fellow #2 was an expert in his technology skills previous to applying for the grant. He had worked as a graduate assistant for 3 years in creating online electronic portfolios at another University. He is well versed with many programming languages as well as HTML and JavaScript. His main goal for being a part of the PT3 grant was to be able to design an online class for the preservice teachers in the principles of scientific inquiry. This is the last class that the students are required to take before they go out for their student teaching. This class uses a multidisciplinary approach i.e., integration of chemistry, physics, earth science, and literature to develop scientific inquiry skills.

This faculty fellow used the Blackboard interface as a supplement for his class, instead of creating a website. This was mainly because UNC’s center for Professional development provided all the technical support in creating any class shell on use of Blackboard. The Graduate Assistant’s role was that of instructional designer, rather than a technology support person. The Graduate Assistant helped him find many articles related to scientific inquiry and online learning environments, some conceptual units form chemistry and physics that could be integrated in his class. This faculty fellow also decided to use visualization software called “World Watcher” as it is available for free online. Overall, his redesigned class focused on developing scientific inquiry skills using technology in a constructivist learning environment.

Faculty Fellow #3 teaches the Educational Psychology class for secondary pre-service teaching students. The course covers classroom management, theories of learning, etc. She currently uses PowerPoint and Digital Video to illustrate different lessons. However, these are limited to her laptop and cannot be accessed by students outside of the classroom. Once she began the project Fall 2001, she decided that it was imperative to place her materials online so her students could return to them for greater understanding. She also was leaving the University soon and wanted to leave the materials for the other faculty responsible for the course. This led to the creation of a class website, using Dreamweaver. It also put a focus on converting her iMovie’s into Quicktime video for use on the website. She found many other areas throughout her course to infuse technology. She enhanced assignments that were used every semester with technology. She also decided to look into websites and chat rooms that adolescents frequent in order to explore what kind of adolescent culture exists online. She hopes to bring this information to her preservice students.

The redesign efforts put forth by this faculty member are already diffusing to her other courses. She is finding that many of her online materials will be of use to the graduate courses she teaches. She is planning on constructing her materials in such a way that they are applicable to a variety of her classes. This faculty member has also already begun to be concerned with collaboration among her fellow colleagues. She is planning on launching a department-wide listserv that will be for use among both faculty and graduate students within her department.

Faculty Fellow #4 also redesigned his course Fall 2001. He teaches an educational foundation class that all preservice teaching students are required to take. Course topics include the history of education, multiculturalism, etc. Before the redesign, there was no technology use within his classroom. This professor chose to redesign his course by making the primary project a technology assignment. The primary project is to work collaboratively in groups and create the ideal school. In this case, generally a paper was turned in with information on it. He decided that it would enhance the assignment to have these schools represented virtually. This meant that each group would now create a website for their schools allowing not only the typical written content to be present but also to utilize pictures, graphics, and hyperlinks to give a better representation of those ideal schools.

The course to be redesigned was four credit hours and met four times a week. This allotted time to create a technology component into the course every week that would support their webdesign efforts. This faculty member is also creating the “shell” or interface that will hold all of his student’s projects and therefore will gain web development experience including basic graphic design that should lead him in his efforts to technically support his students next semester. Generally, this faculty member teaches at least two, if not more, of this course every semester. He feels that his ability to work with anywhere from 60-100 pre-service teacher candidates will have a wide spread affect. He is very willing to take some course time to ensure this occurs.
In June of 2000, The Educational Technology Department at the University of Northern Colorado (UNC) was awarded a PT3 (Preparing Tomorrow’s Teachers to use Technology) grant. The project includes five initiatives that are designed to bring about systematic change within the teacher education programs at UNC. The initiatives are to enhance the Required Educational Technology Courses for Students in The Professional Teacher Education Programs, model Appropriate Technology Use and Integrate Technology Utilization Into the Professional Teacher Education Program Courses, Model Appropriate Technology Use and Integrate Technology Utilization in The General Education and Content Area Discipline Courses, Integrate Technology Use by Preservice Teacher Education Students in Partner Schools, and Build a Model for the Effective Use of Technology in Preservice Teacher Education Programs.

This paper is solely concerned with initiative one, or the initiative regarding the redesign of the preservice educational technology courses at UNC. All elementary, middle grades, and secondary preservice education students are required to take two one credit courses throughout their teacher preparation at UNC. The goal behind the initiative was to redesign these to maximize their benefit to our students. The first year of the grant the PT3 team redesigned the 247, 248, and 249 classes. These courses had a distinct “tools” focus. Finally, the second year of the grant, we have worked to redesign the 347, 348, and 349 courses. Because of the tools focus in the 200 level courses, we wanted these to have a focus on integration. Between the two courses, the Colorado State Technology Standards and the NETS standards have been met for preservice teacher education students.

The 300 level undergraduate classes focus on the “Technology Integration” aspect. It is very important for the preservice teachers to understand the theory and practice of technology integration in their classrooms. Most students taking the Educational Technology classes associate the field with learning to use computers. This notion is carried over by them in their student teaching experience as well. The redesign of the educational technology classes was to make the students think, “Why are we required to take a Technology class in our curriculum?”, “What is my philosophy of the use of technology in education?”, How can technology utilize different learning
strategies?”, “What are some of the classroom management issues surrounding use of technology?”, etc.

All the above goals were achieved by redesigning the class that was formally tool based, in which only the different computer programs were taught. The new redesign look will have the following components

1. **Lesson Plans**
   
   A lesson plan is the backbone of a teacher’s instruction. Teachers that make time to create a lesson plan will greatly benefit from the process, implementation, and analysis. Students in 300 levels are familiar with the most productivity tools (like Word, Excel, Dreamweaver, and others) that they have learned in their 200 level classes. Students will now create lesson plans to integrate the tools with the content. They will also incorporate the state standards and teaching strategies to develop a lesson plan that effectively integrates technology. The scaffolding for this would be given by discussing the theory of technology integration, instructional design theories, instructional strategies, room design, and classroom management. Differences between the one computer classroom, multi-computer classroom, and utilizing a computer lab will also be discussed.

2. **Case Study**

   The final portion of the class will utilize a case study to create a problem-based scenario that is embedded in practice. The case study will last for a total of seven weeks. This case study will be delivered through a flash driven interface virtually. Students will meet every week for discussion regarding the case study and for help from the instructor.

   Throughout the case study, a scenario is developed in which the student has just gotten a new job that will fit both their particular age range of interest, i.e. elementary, middle-grades, or secondary. For the elementary preservice students, the content will be focused on literacy. For the secondary and middle-grade students, the content will focus on their particular content area. Within the case study scenario, the classroom the student is taking over was awarded a small technology grant the year before with specific equipment software provided as a result.

   The student is given the resources such as standardized test scores, grade reports, and Individualized Education Plans which model what teachers at our partner schools are given yearly. Other data will be presented via text, digitized video, and digitized audio. The students will be asked to create a needs analysis that is data driven from the available resources. They will then produce a lesson plan that seamlessly integrates technology to help solve the “gap” or problem arrived at in the needs analysis. Other “problems” come up throughout the case study such as technology and classroom management issues, room design issues, and equipment failures. This gives the students a place in which to apply the information that was gained at the beginning of the semester to solve a problem within a real world context.
Integrating Technology into Standards-Based Teacher Preparation
“Changing the Way We Do Business”

epcolem@isugw.indstate.edu

Abstract: Indiana State University (ISU) is working with students and faculty with support from the
Preparing Tomorrow's Teachers to Use Technology (PT3) initiative to create a teacher education
program that uses technology as a natural extension of the learning process. As students progress
through this program, they will experience technology-enhanced course instruction, develop a
technology-rich portfolio document, and engage in technology-rich field-based experiences. University
faculty members are actively involved in developing the types of technology-enhanced projects required
in the professional teacher education courses. Trainings focus on ensuring that the course requirements
meet the standards established by ISTE, NCATE 2000, and IPSB Content and Developmental
Standards, and the ISU Unit Assessment System.

Introduction

The key facilitator in this learning process and in the infusing of technology in the curriculum is the
classroom teacher. He/she affects student achievement by the instructional methods utilized, curriculum
presented, assignments given, and performance expectations. As noted in the Report of the National
Commission on Teaching and America’s Future, “What teachers know and can do is the most important
influence on what students learn” (p. 6). Therefore, it is imperative that teachers, with various levels of
experience, be prepared to meet the rising standards currently being placed on education.

National associations and organizations have outlined specific standards and performances for teacher
preparation. The National Council for Accreditation of Teacher Education (NCATE) developed a series of
six standards that will be used to assess the preparation of P-12 educators. According to the NCATE 2000
Board of Examiner’s documentation, “The conceptual framework(s) is knowledge-based, articulated,
shared, coherent, consistent with the unit and/or institutional mission, and continuously evaluated” (p. 2).
Indiana State University (ISU) has embraced the NCATE 2000 goals and aligned the teacher preparation
programs with these goals coupled with a commitment to performance-based assessment.

The Indiana Professional Standards Board (IPSB) has charged institutions of higher education in the
State of Indiana with creating an individual Unit Assessment System as a vehicle for documenting student
performances. This Unit Assessment System includes a series of performance indicators outlined by the
IPSB. The IPSB identified portfolio assessment as the key performance-based measure to be used in
reporting levels of achievement to the state for initial licensure. ISU and the School of Education (SOE)
have decided to use portfolio assessment as the vehicle for preservice teacher evaluation.

In addition to following the standards outlined by the NCATE 2000 and IPSB guidelines, ISU also
recognizes the standards prescribed by the International Society for Technology in Education (ISTE). Such
standards provide performance-based indicators that are used to assess the technology competencies of
teachers and preservice teacher candidates.
Project Implementation

Indiana State University is working with students and faculty with support from the Preparing Tomorrow’s Teachers to Use Technology (PT3) initiative to create a teacher education program that uses technology as a natural extension of the learning process. As students progress through this program, they experience technology-enhanced course instruction, develop a technology-rich portfolio document, and engage in technology-rich field based experiences.

University faculty members are actively involved in developing the types of technology-enhanced projects required in the professional teacher education courses. Frequent technology staff development trainings are provided to all faculty members involved in teacher preparation. Training focuses on ensuring that the course requirements meet the standards established by ISTE, NCATE 2000, and IPSB Content and Developmental Standards, and the ISU Unit Assessment System. Specific faculty members are directly responsible for ensuring that these technology standards are infused into the identified course curriculum.

Content area faculty members participating in this project are introduced to various technology possibilities that could be used to enhance classroom instruction. ISU students enrolled in the undergraduate preservice teacher preparation program are currently required to develop a paper portfolio demonstrating competence in the standards-guided program of study. Students are now being required to create and maintain a technology-enhanced portfolio that includes specific performance-based unit assessment requirements. In order to facilitate a common understanding of technology, ISU freshmen and transfer students are required to enroll in an information technology literacy course as part of their general education requirements. During this course students will be instructed on how to construct the portfolio. In addition to developing foundational skills, students enrolled in the teacher preparation program are required to demonstrate technology proficiency by creating various technology assignments. During the portfolio review process, students present and explain each artifact; the faculty members facilitate a reflective discussion regarding the students’ choice. This enables the student to verbalize the rationale for his or her selection.

Currently, the ISU teacher preparation program has embedded practicum experiences into each of the methods courses. Students are assigned to various classroom settings where they are responsible for the instruction, assessment, and management of classroom children. Students are expected to demonstrate their use of teaching skills with school-aged children. This experience provides an opportunity for undergraduate students to apply what they have learned in their course work to an authentically rich teaching situation. This is an invaluable experience for students as they are able to develop their own individual teaching style.

As part of the responsibilities of the field-based experience, students are required to develop an elaborate technology-enhanced project that reflects their progress toward becoming a professional educator. Students are assigned a project on such topics as parental involvement, classroom management, or service learning. The students are required to implement the project in his/her classroom setting. These extensive projects will enable the students to integrate technology into areas of teaching that are often missed in daily preparation. Students will then submit documentation of this in their technology-enhanced portfolio.

The ISU faculty member and the classroom teachers act as mentors who assist with the field experience technology project. During the field experience, both mentors will make frequent observations of teaching performance. The student teacher will demonstrate his/her competency in integrating technology into the classroom. The mentor teachers will then assist the student in carefully selecting artifacts and student examples to be used in the project documentation.

The entire field-based component reflects a strong commitment to best practices in education. ISU ensures that the graduates in education are prepared with the most current content knowledge and technology skills available. By integrating technology throughout the ISU teacher preparation program, students are exposed to increasingly complex applications of technology into the classroom.

References

The **Modeling Instruction with Modern Information and Communications**: the MIMIC Project, a U.S. Department of Education Implementation Grant, was designed to prepare pre-service teachers to integrate technology into teaching and learning. One of the goals of the MIMIC project is to create an online community to connect three populations: 1) teacher educators, 2) classroom teachers and 3) preservice teachers with the integration of technology in instruction. To achieve this goal, the MIMIC site was developed by a collaborative team including faculty in Educational Technology and students enrolled in a Master Degree program in Educational Technology at Cleveland State University. Since the Fall of 1999, the MIMIC site has been expanded as a key instructional resource for technology integration in teacher education program beyond a form of dissemination for the project.

The paper describes the findings of an evaluative study that examines the effectiveness of this MIMIC site and the key factors that promote more widespread effective uses of the MIMIC site. The evaluative study has being conducted in three phases: 1) self-evaluation, 2) team-evaluation, and 3) survey and interview to participants. In the self-evaluation phase, the developer reviewed a number of web sites related to PT3 projects and analyzed the strengths and weaknesses on each site. The findings of this inquiry were reflected in the revision process of the MIMIC site. For the team-evaluation, the leadership team provided the developer with comments on components to be updated or added/deleted. For the survey/interview phase, survey data will be collected from approximately 40 participant faculty members and mentors at Cleveland State University and five partner institutions of higher education. The survey questions will find out the following variables: participants' needs, interaction with online resource, access frequency of each component, adoption of online resources in their course, willingness of material submission, personal interests of the site, provision of feedback/suggestions, etc. During the Fall of 2001, semi-structured interviews will be conducted to approximately 10 volunteers who participate in this project.

The aim of this formative evaluation is to improve the usability and effectiveness of the MIMIC site based on participants' needs. The result of this study will produce a successful model of collaborative online resources that can be used as a primary teaching tool in teacher education programs.
PT3: Attitudes and Concerns of Preservice Teachers

Margaret Johnson, Southern Illinois University, Department of Curriculum and Instruction, US
Jennifer Earls, Southern Illinois University, Department of Curriculum and Instruction, US

Training future teachers to be tech users has become a priority for education departments in universities and colleges throughout the US. Graduates must be savvy in classroom climates where technology integration is the key. Introducing technology to novice instructors can cause anxiety. This paper explores the attitudes and concerns of pre-service teachers participating in classroom technology integration as part of the Southern Illinois University PT3 grant – Project LIFT-Off. Seventy-five teacher preparation undergraduate students enrolled in their first semester of the Teacher Education Program (TEP) completed pre- and post- surveys measuring concerns about technology and computer attitudes. The students participated in hands on training as well as workshops and in-class discussions of technology throughout the semester. The results showed that ...(The results are pending -December 2001- and will be reported in this paper). The concerns survey data was complemented by pre- and post- focus groups. These focus groups explored student concerns about using technology in instruction. Computer skills were also measured and used to help students choose professional development opportunities that helped to fill a gap in their skills.
Technology delivery using a flex cam to cross the digital divide in rural Tennessee schools

Pat Jordan, Tennessee Technological University, US
Margaret Phelps, Tennessee Technological University, US
Carl Owens, Tennessee Technological University, US

Tennessee Technological University in Cookeville, Tennessee is a recipient of one of the U.S. Department of Education's PT3 (Preparing Tomorrow's Teachers to use Technology) Grants. One of the primary components of the Tennessee Tech grant is to provide funds to place in each of the twenty-two partner schools a multimedia cart for their use. The partner schools, which are located in five sparsely populated rural Tennessee counties, are for the most part the schools where the field experience students and student teachers from the university are placed. The primary purpose of the cart is to provide state of the art technology that can be easily moved from room to room in the schools in order that the university students might have access to the same technology, which they experience in the methods classes they are required to take before they are placed out in the schools. The components of each cart, the total cost of which is approximately $5000, include either an Apple or PC platform desktop computer, a 32-inch TV, a focus box that allows the computer to "talk" to the TV, a VCR and a flex cam. During the course of the nearly three years that the carts have been in the schools, without a doubt, one of the most used and therefore most valuable pieces of technology on the cart has been the flex cam. Our experience with these carts shows that not only the student teachers but also their mentor teachers are using the flex cams more than any of the components on the cart. Many times the flex cam is removed from the cart and taken to a classroom where it is interfaced with the VCR and the TV in the room. A benefit that allows the remainder of the cart technology to be available for use by other teachers. Our presentation will focus on the flex cam as an application of technology that we have found "really does make a difference". The flex cam, more than any of the other cart components makes it possible for even an inexperienced teacher to use technology successfully. Once the teachers experience technology delivery via the flex cam, we have found they immediately begin to plan ways to procure one that they can keep in their classroom all the time.

The flex cam is a relatively uncomplicated piece of technological equipment that is used in conjunction with a VCR and a television to project items that are "seen" by the camera mounted on the end of the flexible neck of the equipment. The flex cam also has audio capability, which allows recording of a voice, or other audio cues through the use of the VCR. The flex cam as a technology application allows the teacher to effectively demonstrate or illustrate items to an entire class through the use of the VCR, which interfaces with the television. The objectives of the session are threefold: 1. To highlight a method of technology delivery through the use of a flex cam which we have found to be a very user friendly item for all the teachers who have been introduced to it through our grant; 2. To demonstrate the use of the flex cam to facilitate the integration of technology into sample lessons which have been developed by classroom teachers, student teachers and the PT3 staff; 3. To offer to the audience an opportunity to experience "hands-on" practice with the flex cams.

The audience who would benefit most from this presentation would be teacher education faculty, teacher education administrators, and elementary and secondary teachers. The level of experience necessary to successfully utilize the flex cam would be beginning to intermediate. There are no prerequisites.

We propose to bring with us three flex cams, which we will demonstrate to the audience. As the final part of our presentation the audience as a part of a "hands-on" exercise will then use the flex cams. The demonstration portion of the presentation will highlight lessons that have been developed by the PT3 staff for use in staff development sessions conducted in our partner schools. One such lesson uses the flex cam to project the pages of a book such as a primary teacher would do when reading to her students thus allowing each student to easily view the pages while not interrupting the flow of the lesson. Another lesson demonstrates the use of the flex cam to show bones of a frog, and other fragile objects, which do not easily lend themselves to handling by little learners but are excellent teaching aids for the elementary teachers. The flex cam allows for the learner to view objects from a multi-dimensional perspective that is useful in math lessons that use manipulatives. Other lessons will highlight areas such as music, physical education, mathematics, history, geography and art. There are an unlimited number of uses of the flex cam in the projection of small objects for ease of the entire class to view. Another use of the flex cam is to utilize the audio functions in conjunction with the camera to allow students to be taped and recorded such as we might do with a video camera. Teachers have used the flex cam in this manner to make video to be used in evaluation or for presentations and programs. The Interns will demonstrate the use of the
flex cam for such projects as student book reports where videotape can be made for the student to take home for the parents to view.

The flex cams that we will demonstrate will not be the models that can be interfaced with a computer. While we have used that model on the carts that we placed in our college level chemistry and biology departments, the higher cost of the software for the computer model flex cam is prohibitive for the carts which we placed in the elementary and secondary schools.

In the audience participation section of our presentation we will use our PT3 Grant Interns to assist those present who wish to experience the use of the flex cam. We will bring four flex cams so that we can offer three stations with flex cams and a fourth where we will demonstrate the connection requirements for the flex cam to the VCR and the TV. At the first station, because we have found that the neck of the flex cam is resistive enough that beginners hesitate to use the necessary force to place the flex cam on the object to be projected, we will assist with that aspect using the flex cam to view the participants and make a videotape which can be projected during the session. At a second station we will instruct the users in the proper way to orient and focus the flex cam for projection of books or other written material. At the third station we will demonstrate the attachments that fit on the head of the flex cam that allows the flex cam to be interfaced with a microscope and the one that will hold the forceps for the projection of very small objects or insects in the "bug box". We will demonstrate the use of the microscope with the flex cam at this station. At a fourth station the Interns will demonstrate the proper method for connecting the flex cam to a VCR that will be then hooked to a TV thus allowing the participants to practice the necessary adjustment to the VCR to cause the image to be projected on the TV.
Project START: Southeast Student Teachers Are Revitalizing Teaching Through Technology

Cheryl Lani Juarez
Miami Museum of Science
United States
cjuarez@miamisci.org

Abstract: Project START (http://start.miamisci.org), is a PT³ Catalyst grant that provides higher education arts and science and education faculty in six southeastern states (Alabama, Florida, Georgia, Mississippi, North Carolina, and South Carolina) with tools and training to help prepare tomorrow’s teachers to integrate technology-rich learning resources into the science curriculum and coursework. START activities and resources prepare technology-proficient facilitation teams to model technology integration in their teaching practice, facilitate the articulation between Arts and Science and School of Education faculty and school districts, and provide ongoing online and onsite dissemination support.

The Miami Museum of Science and the University of Miami School of Education and College of Arts and Sciences collaborated to adapt the Museum's teacher technology training model and materials. Partners included the Eisenhower Consortium for Mathematics and Science Education @ SERVE and the Smithsonian Institution's National Museum of Natural History.

Project Summary

Project START, a PT³ Catalyst grant, that provides higher education arts and science and education faculty in six southeastern states (Alabama, Florida, Georgia, Mississippi, North Carolina, and South Carolina) with tools and training to help prepare tomorrow's teachers to integrate technology-rich learning resources into the science curriculum and coursework. START activities and resources prepare technology-proficient facilitation teams to model technology integration in their teaching practice, facilitate the articulation between Arts and Science and School of Education faculty and school districts, and provide ongoing online and onsite dissemination support.

The Miami Museum of Science and the University of Miami School of Education and College of Arts and Sciences collaborated to adapt the Museum's teacher technology training model and materials to use with faculty responsible for preservice teacher preparation. The Eisenhower Consortium for Mathematics and Science Education @ SERVE assisted in the recruitment of cadres of key stakeholders committed to initiating reform in Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina to serve as START state facilitation teams. Each state team included six or seven three-member teams that consisted of one faculty member of the College of Arts and Sciences, one from the School of Education, and one district official responsible for technology training.

During the first two years of implementation (September 1999 through August 2001), each state team attended a four-day institute in Miami to prepare to adapt and replicate the modules relevant to their local needs. All costs for the Institute were covered by the grant. START Institutes provided participants with the tools to train others to: navigate the World Wide Web and to find science resources using effective search strategies; evaluate web sites that are valuable in addressing National Science Education Standards; discover a variety of available online courses, and how these materials can be used most effectively and the process for developing and applying criteria for evaluating online courses; explore mechanisms, strategies and resources for electronic collaboration; use videoconferencing to enhance teaching and learning; create professional portfolios using presentation software and web-based tools; create professional educator home pages on the World Wide Web; and replicate the strategies and materials provided at the START Institute.

During the third year, all state teams attended a regional conference, hosted by another project partner, the Smithsonian Institution's National Museum of Natural History (NMNH). Participants shared dissemination progress and challenges within and across states, refined their own state and local replication plans, and learn firsthand how Smithsonian scientists use technology in their work.
Each participant received a Trainer Toolkit that included a comprehensive Trainer Guide, set of Learning Cards, and a CD-ROM containing all presentations and training materials. As an incentive for replication, participants also receive digital cameras to facilitate the web page development workshop as well as to document their replication activities.

Throughout the project, START staff provides ongoing technical assistance, and continually updates the robust START web site - http://start.miamisci.org. The web site includes current data regarding replication activities carried out by the 120 START Master Trainers in the six southeast states.

Project START is funded under The Preparing Tomorrow's Teachers to Use Technology (PT3) Program, a competitive grant program authorized under Title III of the Improving America's Schools Act of 1994. Grants awarded under this program support innovative teacher preparation program improvements developed by the consortia composed of higher education institutions, state agencies, school districts, nonprofit organizations, and others who are joining forces to develop well-prepared, technology-proficient educators.

Abstract: Old Dominion University and Brunswick County Public School's PT3 partnership ACTT Now (Aligning Certification with Technology Training) provides technology training for pre-service and in-service teachers, university faculty, and the parents and students of a poverty-stricken rural school district in Southside Virginia. Results from the first year and a half of three grant programs are discussed: an internship program for pre-service teachers, a field-based masters degree program for in-service uncertified teachers, and technology training for university methods faculty. The initial findings from a new project initiative partnering pre-service and in-service teachers for collaborative lesson plan development are highlighted.

Introduction

Aligning Certification with Technology Training Now (ACTT Now) represents a unique partnership between Old Dominion University (ODU), in urban Norfolk, Virginia, and Brunswick County Public Schools (BCPS), a k-12 district in rural Southside Virginia. Over the past year and a half, the ACTT Now project has been working to create technology proficient teachers in both institutions and to counter the effects of the digital divide pervasive in poverty-stricken Brunswick County. ACTT Now's $1.3 million three-year grant is funded through the United States Department of Education's Preparing Tomorrow's Teachers to Use Technology (PT3) initiative and consists of five major components:

1. An internship program for Old Dominion's pre-service teachers
2. A field-based masters degree program for Brunswick's uncertified and provisionally certified teachers
3. Technology Opportunities for Parents and Students (TOPS): an evening technology-training program for Brunswick County community members
4. Student Technology Assistance Teams (STAT) and
5. Technology training for Old Dominion's methods faculty

During the summer of 2001, the ACTT Now grant team developed a new project element linking ODU's pre-service and Brunswick's in-service teachers. Starting fall 2001, in-service and pre-service teachers were paired to collaborate in the development of technology-infused lesson plans. This new initiative has dramatically enhanced three grant programs: the internship, the field-based masters program, and the technology training for methods faculty while building synergy within the project as a whole.

Grant Components

Internship

The typical ten-week student teaching placement in the final semester of a pre-service teacher's training provides at best a truncated, incomplete picture of the teaching process and the teaching profession. Student teachers begin their placements after the school year has started and complete their student teaching before the year ends. Student teachers often are not responsible for submitting grades and completing report cards nor do they meet with parents to discuss student progress. Much is left to learn during the first year of teaching. The ACTT Now internship program offers a more complete experience for pre-service teachers while also providing personalized technology training so graduating teachers will be well prepared to meet the needs of 21st century learners.

In lieu of the regular student teaching requirement, ODU pre-service teachers can elect to complete a one-year or one-semester paid internship in Brunswick County Public Schools. Interns begin their placement either during new teacher orientation in August, or during the in-service days at the start of the district's spring semester in January. Interns remain in their position until the end of the semester or year. Interns accept the same responsibilities as regular classroom teachers except that they are only required to teach half time. This leaves ample time for interns to meet with mentors, supervisors and technology specialists, and to observe and assist in other classrooms. Interns attend weekly technology workshops and receive personalized one-on-one technology assistance from Brunswick County's Instructional Technology Specialists.
ACTT Now’s partnership with Brunswick County enables ODU to provide a technology rich environment in which to prepare its pre-services teachers. Brunswick County Public Schools has emerged as a leader in technology despite the dismal statistics of its community, including one of the highest illiteracy rates in Virginia. Through the innovative leadership of its technology department, Brunswick County has acquired technology resources parallel to and in many cases often surpassing those in the wealthier districts surrounding the nation’s capital. Hardware resources include wireless mobile laptop labs, Intel microscopes, SmartBoards, Palm Pilots and probes, digital cameras, computer labs and projectors at each school and Internet accessible computers in every classroom. A bank of educational software such as the highly acclaimed Inspiration and Kidspiration and the latest Tom Snyder products are also available for teacher use. Four instructional technology specialists and the director of technology work to help teachers integrate these new tools into their classrooms and curricula. These resources provide ODU interns with cutting edge 21st century learning environments.

A unique funding mechanism allows the internship program to operate with minimal external funding. Brunswick County leaves one teaching position vacant for every three ODU interns it accepts. The money allocated to the teaching position is used to pay stipends to three year-long, or six semester-long, interns and their mentor teachers. Brunswick County, in effect, hires three teachers for the price of one.

In addition to a $8000 per year stipend, interns receive a laptop for use while they are involved in the internship program. Because Brunswick County is approximately 100 miles from Norfolk, the interns are provided with free housing or a housing stipend. Full year interns are eligible for health insurance coverage and will start at step two of the salary scale should they be hired the subsequent year. All interns are guaranteed a job interview upon completion of the program.

Dictated by the grant proposal, the goal of each intern is to find new ways to incorporate technology into the planning and preparation of lessons, to design lessons that utilize recent software applications, and to develop project-based lessons that require students to use a variety of technological media for both the construction and presentation of their work. Weekly technology workshops expose the interns to different technologies and model strategies for technology integration. Brunswick’s instructional technology specialists work one-on-one in the interns’ classrooms helping them transition the skills they learn in workshops into actual classroom implementation.

In the beginning of their internship, interns focus on technology as a tool for planning lessons, creating materials, or as a means to deliver instruction, for example, PowerPoint presentations. In the first semester of the program, most interns did not surpass this basic level. A few interns stall at this initial stage; but most are able to change their focus and embrace technology as a tool for their students to use by mid-way through their placement. At the end of the second semester of the program, the interns reported using technology both as a tool for themselves and their students.

Internet Resources
- Teacher used BrainPop.com movies and quizzes to teach the earth’s structure and plate tectonics
- Teacher led students in MayaQuest lessons
- Students interacted with digital models of portions of the sea floor
- Students viewed prehistoric marine animals
- Students manipulated ocean currents
- Teacher showed site devoted to runaway slaves—including original documents of advertisements for runaway slaves
- Class looked at indentured servants database to see if their relatives were indentured servants during the colonial times

Internet Research
- Students researched the scientific name and habitat of microorganisms
- Students researched the answers to photosynthesis and cellular respiration questions
- Students researched the geological process which led to the formation of sea floor
- Students used Internet to look up information on Vertebrates and invertebrates for a written and oral presentation

Presentations
- Students used the mobile lab to create webpages illustrating the major causes of WWII
- Teacher made presentations on a variety of topics: figurative language, prepositions, slavery, Monarch butterflies etc.
- Students made PowerPoint presentations on an author they researched

Hardware Applications
- Students observed microorganisms with Intel Computer microscopes and laptops
- Teacher used the SmartBoard for discussion/interactive activity on rainforest — students could draw rainforest animals over a picture of the rainforest

Table 1: Classroom activities using technology as reported by interns (spring, 2001)

As of Spring 2002, ACTT Now has had 36 interns participate in the program. Interns have reported beneficial but demanding experiences. They believe that their internship experience gave them a more realistic picture of teaching and thus better prepared them for teaching than a regular student-teaching placement. They felt they were completely immersed in the school culture and developed an authentic sense of the responsibilities a teacher has both inside and outside the classroom. Follow-up surveys and interviews during interns’ first year teaching placements will provide additional data on this and the internship’s impact generally. Interns indicate increased comfort levels with technology but a desire for more instructional assistance for seamlessly integrating technology into their instruction and more teaching strategies that will enable students to be fully engaged in the learning process.

Field-based Masters Degree Program

Old Dominion University’s Darden College of Education has been a leader in distance education for the past decade. Its Teletechnet program brings 4-year degree programs to students in remote areas throughout Virginia and the nation. Previously, its onsite courses served the urban population of Hampton Roads. Through ACTT Now, the Darden College of Education’s virtual hand materializes in a remote rural community greatly in need of educational and economic resources. ODU offers a three-year, 33-credit masters degree program in general elementary or general secondary education on-site in Brunswick County. And on the planning block for fall 2002, is an executive doctorate program for Brunswick’s interested teachers and administrators envisioned as a combination of on-site and Teletechnet courses.

Nearly one third of Brunswick’s teaching staff is currently enrolled in ODU’s field-based master’s program. Brunswick County has difficulty both recruiting and retaining teachers. Low teacher salaries and the remote location contribute to a near 20% turn-over rate. Brunswick County is able to market ODU’s field-based masters degree program as a means to both attract and keep good teachers. Through the use of grant
funding, Brunswick pays the fees, tuition and book costs for all of the teachers enrolled in the program. In return, teachers agree to teach in the district one year for every year they were enrolled in the program.

The main emphasis of the field-based master’s program is learning to improve instruction through technology. Teachers already certified complete a core of courses emphasizing curriculum development, instructional strategies, assessment techniques and the use of action research as a vehicle for self-reflection and instructional improvement. Uncertified teachers replace elective courses with state requirements such as Reading in the Content Area but otherwise complete the same core classes. All courses employ technology integration and require teachers to demonstrate the transfer of learned skills into the classroom environment. As with the internship component, the teachers’ initial forays into technology are teacher-centered. As teachers gain experience and confidence, the sophistication of their technology use improves. Teachers in the program fall along a continuum from novice to technology award winners. Starting in spring 2002, more experienced FBM teachers will serve as mentors to those less experienced.

An early finding severely altered the overall course content for the FBM. The majority of the teachers lacked a fundamental knowledge of instructional strategies. The most powerful applications of technology require students to be independent learners. A majority of Brunswick’s teachers were using teacher-centered lecture-based activities as their modus operandi. In October 2000, 83.3% of uncertified teachers reported that they were more inclined to lead a classroom discussion that was centered around simple questions that cover previously assigned material as opposed to a discussion generated by questions from students where the teacher’s role is to point students in directions that can assist them to find the best answers. Also 70.8% of uncertified teachers believe that students prefer to have this type of discussion. Before teachers could begin to use technology in ways that fully engaged the students, they needed to learn student-centered instructional strategies and believe that students can learn in that manner. Hank Becker’s research shows that teachers who exhibit more traditional teaching behaviors are far less likely than teachers embracing a constructivist approach to allow students to use new technologies even when the traditional teachers have five or more networked computers in their classroom (McKenzie, 2001). Instruction in the FBM program has since centered on student-centered instructional strategies and implementation.

Instructional Technology Specialists in Brunswick County Public Schools work directly with teachers including those individuals enrolled in the field-based masters degree program. They have several duties assigned to them but the most important is to assist teachers in the development of lessons and activities that infuse technology. Instructional technology specialists first help teachers learn to use hardware and software resources. Teachers select a resource to explore and then either schedule a series of appointments with an instructional technology specialist for one-on-one mini-workshops or attend an after-school professional development workshop. Following the skill development workshops, teachers collaborate with an instructional technology specialist to create a lesson, project, or activity in which the selected resource is infused into a classroom lesson. Brunswick County Instructional Technology Specialists spend the majority of their time in classrooms: modeling and co-teaching lessons using technology, observing lessons, and giving feedback to teachers. Brunswick’s four instructional technology specialists act as assistants in the field-based master’s class sessions and ensure tools and strategies introduced in class are implemented in teachers’ classrooms.

Technology Training for ODU Methods Faculty

An obvious method of producing technology proficient teachers is to provide teachers with technology training while they are enrolled in a teacher education program. The Preparing Tomorrow’s Teachers to use Technology (PT3) initiative was created to do just that. ACTT Now is fairly unique among PT3 projects in that many of its programs take place outside a school of education. The internship program offers intense technology training for pre-service teachers willing to live and teach in Brunswick County for at least a semester. The field-based masters program provides technology training and certification for Brunswick’s in-service teachers who lack licensure. The majority of Old Dominion’s pre-service teachers are not affected by these two initiatives. They receive technology instruction through one mandatory technology course and prior to ACTT Now, received little in the way of instruction for actually using technology in the classroom. Within the college of education, ACTT Now is providing training, resources and support to methods faculty. Members
of the methods faculty are encouraged to model technology-infused instruction in their courses so pre-service teachers learn not only to use technology, but learn how to teach with it.

A serious barrier to this goal was the lack of resources within the college. Methods faculty had limited access to computer labs and no access to recent software programs or small hardware devices such as PDAs, Palm Pilots, microscopes, and digital cameras. The purchase of a wireless mobile laptop lab allowed methods faculty to bring the technology into their regular classrooms. Faculty attended workshops using the mobile labs and were then able to use the same equipment and programs in their own classrooms. Brunswick County lends software and equipment not available at ODU. Graduate students and instructional technology specialists from Brunswick provided group and individual follow-up training sessions for faculty based on their expressed interests. An incentive program encourages participation among the staff: faculty who complete the two-part training sessions earn software packages of their choice.

**Linking Pre-Service and In-Service Teachers**

While the internship program, the field-based masters degree program and the technology training for the methods faculty were improving the proficiency of the teachers involved in the programs, the project as a whole lacked synergy. Nothing seemed to strongly link the separate components of the grant. In the summer of 2001, a new project element was conceived by Cathy Cheely, Brunswick’s Director of Technology. Cheely’s idea was to link the disparate elements in a manner not previously considered. ODU pre-service teachers enrolled in methods courses onsite at ODU would be paired with in-service teachers enrolled in Brunswick’s field-based master’s degree program. Together, the pre-service teachers and the in-service teachers would plan a technology-infused lesson.

Pre-service teachers are required to plan a lesson or a lesson unit in their methods classes. Normally, these lessons are designed for a hypothetical class and are never implemented. Symptomatic of the disconnect between higher education and secondary education, pre-service teachers plan lessons for ideal students in ideal classrooms that do not exist in real schools. Rarely do pre-service teachers consider SOL pacing guides, special education students, students who work at different rates or students performing dramatically above or below grade level when developing these lessons. By partnering with an in-service teacher, the pre-service teacher is provided with a real context in which to plan a realistic lesson. The Brunswick field-based masters teachers provide relevant information on their classrooms and curricula to the pre-service teachers via a monitored discussion board. The pre-service teachers then begin to develop lessons as assigned by their methods instructors. The collaborative process begins as the pre-service and in-service teachers negotiate the details of the lesson over the discussion board. When both parties are satisfied, the pre-service teacher submits the final lesson plan to be taught by the Brunswick teacher in his/her classroom. The lesson is videotaped and sent back to the pre-service teacher along with a written analysis. The videotaped lessons provide a wealth of instructional material for the individual methods students and for the methods classes at large.

The tool for collaboration during the first semester was a free online bulletin board service called EZBoard. A “community” was created for the field-based masters program which included a “forum” for the collaboration process. Within the collaboration forum, there was a “topic” area for each FBM student. All discussion between an ODU methods student and their FBM partner took place within the “topic” area for the FBM partner. Each participant had an individual login and password to enter the area but the dialogs could be viewed by all participants. This way the FBM instructors and the methods course instructors could monitor the online collaboration. During the second semester, grant staff member and FBM instructor, Patrick O’Shea, created a specialized database program to serve as the discussion board. This allowed all communication to be stored on Brunswick County’s servers and eliminated the commercial advertisements ubiquitous in EZBoard.

**First Semester Results**

The first semester of the collaboration project was completed in December 2001. Over one thousand communications were posted on the discussion board. There were sixty-three partnerships between sixty Brunswick field-based masters teachers and interns and seventy-seven ODU methods students. Forty-seven
lesson plans were delivered, performed and videotaped. These partnership was deemed successful. Sixteen partnerships did not yield a lesson plan and were therefore termed unsuccessful.

**Table 2:** First semester pre-service/in-service collaboration partnerships (December, 2001)

In successful partnerships, field-based masters teachers reported very positive experiences. Many said that they either learned a new idea or were reminded of a technique they had long forgotten. “It is always refreshing to read another teacher’s ideas. Sharing ideas is an excellent way to grow in our profession!” (Denise Painter, field-based master’s student).

Another student explained the benefit of “being open to creative teaching and learning, and the willingness to try something different - even if I thought it wasn’t going to work. Overall, I enjoyed the experience. It gave me a chance to, not only ‘think outside the box,’ but to actually ‘teach outside the box.”’(Ronald Thornhill, field-based master’s student).

Nearly all FBM teachers expressed a desire for their pre-service partners to come to Brunswick and teach or assist in the lesson personally. One FBM teachers indicated that she felt her partner was “cheated” out of the most important part of the lesson planning process: implementation.

The amount of collaboration varied even among successful partnerships. In some cases a partnership was labeled successful because it resulted in an implemented lesson plan, but the collaboration between the partners was minimal. In these cases, the field-based masters students reported experiencing frustration with the project. Many of their online postings went unanswered for weeks. Subsequent discussion with pre-service teachers revealed that some methods course students felt pressured to respond to postings and adhere to schedules dictated by their partner teachers.

Unsuccessful partnerships were victim to similar circumstances. In most cases, the fault was attributed to inconsistent expectations between ODU methods students and FBM collaboration partners or inconsistent expectations between ODU methods faculty and FBM instructional staff. In very few instances, “bad” matches between FBM and ODU students were made where pre-service teachers could not create lessons appropriate to their partner teacher’s subject or grade area. Additionally, both pre-service and in-service teachers identified concerns arising from asynchronous communication. The electronic environment prevented some partnerships from reaching a personalized level. Some partners used email or telephone conversations to establish initial rapport and used the electronic tools only after they had developed a relationship with their partner.

Other obstacles that hindered partnerships were variations in the lesson plan format used by the Brunswick teachers and those used by the methods faculty and students, the field-based masters teachers inexperience with peer-coaching techniques, and a general lack of understanding of the collaboration process by both parties. These issues are being addressed in the second semester of the project.

**Impact on Grant Components**

The ODU pre-service teachers who serve as interns also participate in the collaboration project. Because they recently completed methods course themselves, they are natural partners for the current methods students. Interns give presentations in methods courses and provide written feedback to methods instructors on the preparation they received in their methods courses as part of their internship responsibilities. So, interns already serve as a gateway between the two institutions. Involving them in the collaboration project intensifies the link and provides the grant leaders with a unique perspective. Since the interns are ODU students, they are privy to the pre-service teachers perspective yet, because they are immersed in Brunswick schools, they
understand the mentality of Brunswick teachers. This gives them the unique position of seeing the project from both sides.

Just as the interns are enhancing the collaboration project, the collaboration project is enhancing the internship program. All the methods students are either required to or have the option to participate in the collaboration project with Brunswick yielding increased visibility for ACTT Now. The collaboration project ensures all education students learn about the Internship option and thus serves as an automatic recruiting mechanism. Pre-service teachers involved in the collaboration project have several opportunities to visit their partner teachers in Brunswick County, and at the same time, observe the interns in action.

There are numerous benefits to participating field-based masters teachers. The collaboration project established peer coaching and peer review professional practices. Many teachers had not previously collaborated with other teachers, nor had they acted in a mentoring or peer-coaching role. Within these new roles, the teachers tutor their partners on instructional strategies and technology applications learned in class thereby strengthening their own understanding. They gain a new perspective on the teaching process and incorporate fresh ideas into their instruction. They are held accountable for their instruction via the videotaping process. And finally, they are required to thoroughly analyze the lessons prepared by the pre-service teachers forcing citing evidence for its success or failure. This analytical process helps the teachers learn to analyze the merits of their own lessons.

The collaboration project has direct benefits for both the methods students and the methods faculty. As a result of their one-on-one collaboration with in-service teachers, methods students will be more cognizant of the many issues involved in the lesson planning process and will have more realistic expectations when planning subsequent lessons. They will see first hand through the videotapes where their lessons succeeded and where they fell short, and they will receive the teachers' take on the lessons' strengths and weaknesses. Brunswick teachers help pre-service teachers plan lessons utilizing technological resources. A resource library including the instructional and technological resources available in Brunswick has been created at ODU so the pre-service teachers can peruse materials and experiment with hardware and software tools they may want to include in their lessons.

The collaboration project provides methods faculty with a reality check. Higher education has a reputation for being out of touch with current K-12 classrooms. The collaboration project ensures methods faculty are abreast of the realities facing today's teachers and are preparing their students adequately for the classrooms they will enter. Methods instructors are invited to visit Brunswick County to serve as guest lecturers in the field-based masters courses to share their expertise and model the methods they advocate for the pre-service teachers. While in Brunswick, they can observe first hand how Brunswick Instructional Technology Specialists are coaching teachers to use the latest technology resources. These resources can, in most cases, be borrowed so ODU faculty can receive individualized training on specific software programs and hardware devices they see in Brunswick. ACTT Now provides motivation for methods faculty to visit Brunswick and to use technology. Methods instructors who visit Brunswick receive a stipend and those who participate in the collaboration project earn a visit to a technology conference of their choice.

Conclusions

The ACTT Now project continues to impact both the pre-service teachers at Old Dominion University and the in-service teachers in Brunswick County. As more data is collected through the grant's external evaluation process, the extent of the impact will become clear. Already it is evident that the latest initiative of ACTT Now, the collaboration project, has had significant effect on three components of the grant project: the internship, the field-based masters degree program and the technology training for methods faculty. The partnering of pre-service teachers from an urban university and in-service teachers in a rural school district has led to increased technology proficiency for both groups.

The Millennium II consortium is implementing seven preservice teacher initiatives in the north Texas area. Technology-infusion activities are designed to continue the expansion of services to meet educator preparation needs of the state and nation. The emphasis for this three-year project is closing the digital divide. The key areas of quantity, quality and equity are addressed in the preparation of technology competent and confident new teachers. Major objectives in progress include:

- Increasing the quality and quantity of preservice technology integrating educators
- Expanding technology-infusing methods courses and instructor modeling of technology
Providing technology enriched assignments and assessment for special education preservice teachers
Establishing technology enhanced academic content courses for preservice teachers
Establishing fast track credentialing for technology aides to be degreed teachers
Developing Internet-based quality resources for preservice teacher courses
Recruiting new millennium teacher educators from technology infusing classroom teachers to work as technology fellows in the project.

The University of North Texas (UNT), seven K-12 school units, a multi-campus community college, and two professional associations have joined forces to implement project goals and objectives to achieve intended outcomes. The Millennium II consortium was awarded a U.S. Department of Education Preparing Tomorrow's Teachers to Use Technology Grant (PT3). The lead partner, the University of North Texas, contributed Higher Education Assistance Funds for in-kind hardware/software purchases for this effort, adding to the time and effort contributed by other partners. Approximately 700 new technology-infusing educators are targeted to be produced by the project over three years.

UNT includes one of the largest teacher education programs in Texas, preparing approximately 750 teachers each year in a variety of K-12 programs and all discipline areas including special education. The Professional Development School (PDS) model requires that the education of teachers be linked directly to learner-centered schools. Through alliances with schools throughout the Dallas-Fort Worth Metroplex, preservice teachers work directly with children for at least two semesters. From the beginning of the PDS efforts at UNT, technology has been a tool for acquiring information, increasing instructional options, individualizing assessment, accessing resources, and promoting communication. Both the College of Education and PD schools continue these efforts.

Full realization of learner-centered teacher education intertwined with learner-centered schools in which technology is being applied effectively and interactively requires three elements that are not fully in place. First, modeling and effective use of technology by faculty and students throughout their university and teacher education experience is required so that students "live with technology" rather than being told that they should integrate and infuse it in their teaching. As technology and its possibilities for improving education continue to change, faculty need time and support to learn to use the technologies and to demonstrate applications in the classroom.

The second needed element is continuous application of technology during preservice internship and practicum experiences. UNT works with schools, teachers, faculty and intern supervisors so that preservice teachers become leaders in modeling and using technology for assessment, instruction and equity. Third, the university needs vehicles for extending technology training to new groups of teacher candidates beyond those served directly on campus. By extending the opportunities for technological competence and confidence beyond the traditional boundaries of the campus, the College of Education seeks to bridge the digital divide in teacher education to rural and urban settings.

Each of these elements addresses the need for teachers who are better prepared in content, pedagogy, and technology. In addition, each of these elements requires that the College of Education faculty in teacher education and technology work with partners to achieve these goals: partners within the University who provide the content coursework for new teachers and partners who provide schools as living laboratories for students to develop their teaching skills.
Teaching Transformation Teams: Providing Face-to-Face and Virtual Teacher Preparation Experiences

Abstract: Faculty in The Graduate School of Teacher Preparation and Special Education at The George Washington University have benefited from participation in a Preparing Tomorrow's Teachers to use Technology (PT3) grant. Expanding beyond workshops and course releases to improve technology skills, faculty are teaming with public school teachers and graduate students as they redesign courses in the Master's degree program to reflect technology standards. This collaborative approach has complemented existing graduate school and public school partnerships and facilitated change in instructional practices and course content and modes of delivery.

Introduction

George Washington University's (GWU) vision for preparing tomorrow's teachers to be better users of technology in their teaching has not changed. However, its approach to making this happen has. The goal of GWU's PT3 Implementation Grant continues to be facilitating faculty members' improvement of their technology skills and their use of technology tools and strategies as a natural part of their methods and foundations courses. The project, Teacher Technology Leaders (TTL), is intent on keeping the focus on the course content and the ways in which technology use can enrich the curriculum. A study by Di, Dunn and Lee (2000) reveals that an integrated approach to instructional technology in foundations courses positively influences students' perceptions of technology use and enhances their abilities to use advanced technology for their teaching and learning. Through the TTL Project staff's support of faculty in changing instructional practices to utilize technology in meaningful ways, students in the teacher preparation programs are developing technology competencies. Additionally, the project has paved the way for faculty, graduate students and P12 teachers to work collaboratively in redesigning courses to better apply technology tools. Connections between the professional development of pre-service teachers, experienced teachers, and university faculty provide for what Lieberman and Miller (2000) refer to as the "rub between theory and practice" that is essential in educating professionals.

This paper describes two TTL Project components that demonstrate GWU's commitment to collaborative partnerships that focus on integrating technology in the teacher preparation programs. The aim of the first project was to utilize technology to expand and improve content in one of the foundations courses. The second was to create a "virtual space" to foster and support collaboration.

Teaching Transformation Teams

One of the greatest strengths of the PT3 grant program is its encouragement of grant recipients to make changes in their approaches as experience and collaboration with other grantees suggest. The TTL Project staff learned from the experiences of other grantees that having faculty work on teams is far more productive than providing them with course releases and expecting them to attend group workshops and other training opportunities. As a result, TTL reorganized its faculty involvement in project activities by encouraging faculty members to form Teaching Transformation Teams. Each team works together over the course of a semester and develops a final "product."

Each Teaching Transformation Team is made up of a faculty member, a P-12 classroom teacher, and a graduate student. This 3-person team works on a course development project to culminate in either a new course or a major redesign of an existing course with increased emphasis on the integration of the use of technology to deliver the course and the use of technology by participating students to complete course assignments. This work might, for example, result in the conversion of a course so it can be offered online. The team develops a detailed work plan delineating the milestones to be met throughout the semester. Team members meet at least once a month with a member of the TTL project staff to discuss tasks and identify project/partner or University resources. The development team is also expected to meet at least once or more between its meetings with the TTL staff member. Weekly status reports are entered into an online reporting system maintained in the TTL Prometheus (GWU's online course management tool) course set up to be used by all teams to share information. In our first semester (Fall 2001) not all teams were pure,
that is, some consisted of a faculty member and a classroom teacher, who also was enrolled in a GWU graduate program. One team was made up of two faculty members from a program and a graduate student from the program.

The faculty member is the lead member of the Teaching Transformation Team and responsible for planning team member assignments to achieve the desired outcomes of team activities. He/she is responsible for successful completion of all planned tasks and has total oversight responsibility of the participating P-12 teacher and graduate student. He/she sees that team meetings with the TTL staff are scheduled and that all reporting of team activities using the TTL online reporting tools is completed weekly. The participating faculty member receives supplemental compensation in a lump sum at the end of the semester of the team’s work.

The P-12 classroom teacher serves as a mentor on the Teaching Transformation Team to assist the faculty member with technology skill building and the development of meaningful technology-related activities related to the team’s content area. The teacher then assists the faculty member and the graduate student in the incorporation of these activities into the presentations or course on which the team is working. The graduate student provides clerical, research, and technology support to the team’s lead faculty member. The graduate student works with the classroom teacher to develop the team’s content area. The faculty member may direct the part-time graduate student to complete weekly reports using the TTL reporting tools. The participating classroom teacher and the graduate student are paid as part-time employees of GWU throughout the semester.

Six faculty members formed teams during the fall semester of 2001. One team worked collaboratively to redesign a foundations course in the teacher preparation program. This survey course addresses all issues of diversity including special education as well as human development. The team redesigned this course to utilize technology to facilitate opportunities for students to access credible web-based resources in the form of research, organizations, and teaching materials and to use those resources to expand their knowledge of development and diversity issues. All course materials were put online using Prometheus. Because team members felt the special education components of the course were not sufficiently addressed during class time, the team created webquests for seven special education topics. The idea was to a) increase students’ knowledge of particular disabilities, b) engage students in practically applying what they’d learn, c) encourage collaboration in conducting research and, d) increase discourse about the disability being studied. Webquests can be viewed at http://home.gwu.edu/~karenkor/tred208.

The Virtual Curriculum Laboratory

The TTL Project staff began using GWU’s online course management tool, Prometheus, during the first year of the Implementation grant to provide an easily accessible virtual space where participating faculty could share ideas and materials. Using Prometheus served three purposes: 1) to provide a necessary anytime/anywhere virtual space for sharing, 2) to encourage faculty to become familiar with this online tool that is freely available to them, and, 3) to serve as a model of how Prometheus could be used for a purpose other than a normal class. Although Prometheus was easy to use to facilitate online faculty dialog and resource sharing, project staff decided that some of its “course” features were unnecessary for our project purposes. In addition, work on another component of the TTL Project to be developed with one of its school district partners, Alexandria, Virginia, needed to begin. The main purpose of the component, Virtual Curriculum Laboratory, was to provide a collaborative workspace, so it was a natural tool to build for use with the project’s Teaching Transformation Teams.

The Ultimate VCL

The GWU/Alexandria City Public Schools Virtual Curriculum Laboratory component of the TTL Project is intended to serve as a community-building tool, as well as a resource development tool. It is a web site that provides access to built-in collaborative tools for small teams or “Labs.” The VCL differs from other such online collaborative spaces (e.g., University of Missouri’s Shadow netWorkspace, TAPPED IN, and MimerDesk) not only in the toolset it will ultimately provide, but also in its focus. In the initial development phase, VCL provides virtual collaborative workspace for teacher-to-teacher, IHE faculty-to-teacher, and in-service teacher-to-pre-service teacher-to-IHE faculty cooperation. In later phases, virtual workspace for some portion of the 6-12 population will be added.

The scope of the Virtual Curriculum Laboratory’s features originally defined by TTL Project partner Alexandria City Public Schools (Virginia) includes:

- A Collaborative planning “place”
- A library with
  - teaching resources
  - streaming video and data
  - actual resources or links to other site’s resources
- Online professional development “place” with access to
  - lesson plans, electronic texts, graphics
  - video library of “best practices”
what are now "normal" components of any online course delivery system

- An online course delivery and assessment tool for teachers to "teach" classes

The VCL Reality

One prerequisite that has stood out in discussions about what the TTL Project's VCL should look like is that the VCL interface should be uncluttered with limited items and choices. The VCL is public, however, all who want to use it must have an account to identify themselves and allow for differing levels of access. In doing this, the TTL Project staff rolled plans for a password-protected, database-driven intranet site into the VCL web site. The Virtual Curriculum Laboratory web site is a dynamic, database-driven site. A user's access level and group assignments determine what the user is able to see and do. For example, faculty level access means the faculty user will see a link to the TTL Project's equipment check-out page that other users will not see. Information in each user's database account record is used to determine to which Labs a logged-in user has access. Likewise, information in a group's ("Lab") database record allows members of that LAB to make the LAB private to only its members or public to others in the Virtual Curriculum Laboratory community.

Therefore, armed with an account ID and password, one logs into the Virtual Curriculum Laboratory web site and is immediately taken to a page that displays the threaded discussion of the user's default Lab. Each user can create or be a member of multiple Labs ("Lab" here is used to mean a "team" or "group"), but the user must identify one Lab to be his/her default. This default home page illustrates the development team's belief about the main purpose of the Lab: it is a place where two or more people work collaboratively and communicate primarily by posting messages to each other in a threaded discussion. So, that is what users will first see when they log in. One can switch to other Labs, to which one belongs, through a dropdown menu. Likewise, one can post to the discussion or send e-mail to individual Lab "partners" by clicking on the corresponding name on the left of the screen, or to the whole (current) group by clicking on "Lab Partners" heading. Menu links on the user's home page allow users to move to screens where they can collect URL links to share and look at as they develop their "product" (new course, course unit, presentation, etc.), post files to share with other Lab members (private team or "global"), or post research or idea notes to share with team members. The Reports feature of VCL allows participants to collaborate on the development of one or more reports of their work on their product. These ideas fit perfectly with what we see happening when several teachers collaborate on a project, as well as with the tasks of our Teaching Transformation Teams.

Conclusion

The team approach supported by a virtual workspace was highly effective in furthering the development of faculty members' technology skills. Team members commented that the collaborative approach of the transformation teams led to higher quality products and provided a supportive structure for achieving team goals. Each member increased her technology skills and sharpened her understanding of specific disabilities that impede learning. The evaluation of numerous web sites for possible inclusion in the webquests resulted in the creation of a databank of credible online sources now available to students. An added bonus to redesign of the course is that students will experience firsthand an instructional method that puts technology to good use in the classroom.

The work of the teams was greatly enhanced by the opportunity to communicate and share via the Virtual Curriculum Lab. Discussions occurred regularly but did not require face-to-face interactions. Works-in-progress were posted to a common space so that all team members could evaluate, comment and advise. Opportunities for cross-team communication encouraged participants to share what they were learning. The monthly face-to-face team meetings with a TTL Project staff member(s) helped to keep the team focused and the work on schedule. Overall, we find this supportive, collaborative approach to faculty development to be very promising.

Mentoring: Support and Reinforce Technology Infusion through Building Relationships

Jiang Lan, Southern Methodist University, US
Katie Sheridan, University Of Alabama At Birmingham, US
Betty Nelson, University Of Alabama At Birmingham, US
Lois Christensen, University Of Alabama At Birmingham, US

Abstract:

The University of Alabama PT3 team proposes a Panel Presentation to discuss lessons learned and best practices in establishing and fostering mentoring relationships as a mechanism in successful technology infusion in preparing future teachers. Drawn from our experience working with five higher education institutions and eleven P-12 school districts in the Birmingham area, the presentation will include 1) a brief introduction to the various mentoring initiatives; 2) the objectives and activities of each mentorship initiative; 3) positive outcomes as well as problems and solutions in building relationships for professional growth; and 4) management challenges. The panelists will discuss both theory and practice, and compare their experiences with each other and with interested audiences.

Mentoring: An Operational Definition

Mentorship is a label for a concept that connotes a “philetic” association, a relationship based on teaching through brotherly or sisterly love and dialogue (Broudy, 1972). The concept of mentoring has its root in the epic Greek myth, The Odyssey. In our project, this metaphor serves as an example for an ideal professional affiliation occurring among members of the university faculty and between university faculty and P-12 teachers, to provide each other with support, counsel, friendship, reinforcement and constructive models, for effective technology use in teacher development (Christensen, 1992).

Mentoring as a Mechanism for Technology Infusion

One of the problems associated with using technology is that, because it changes so quickly, one-shot development sessions are never sufficient (ISTE, 1998). A long-term solution is to develop self-sustaining users of technology. This is best accomplished through the development of learning communities. Through mentoring initiatives, the UAB PT3 project provides technological training as well as on-going support for teacher education faculty to infuse technology systematically throughout the curriculum. As an outcome of the mentorship, in a three-year period, the Mentors and Mentees reach a significant number to form a critical mass within the Partnership organizations. This critical mass will become the basis for the paradigm shift we have envisaged to support and sustain the significant technology infusion efforts.

The UAB PT3 Project

Led by the University of Alabama at Birmingham, the PT3 project is now well into its second year of operation. The project aims at infusing technology into the entire teaching/learning experiences of all prospective teachers in the Greater Birmingham Area Holmes Partnership organizations, composed of five colleges/universities and eleven P-12 school districts. Participating higher education institutions include public and private, small liberal arts colleges, a historically black institution, and a large comprehensive, research university. Participating school districts include urban and suburban, affluent as well as economically disadvantaged schools.

Central to our project is training and mentoring for faculty members to infuse technology into content/pedagogical courses and learning activities. Three mentorship groups have been formed to achieve the project goal: 1) The Technology Infusion Program (TIP), a mentorship initiative among higher education faculty; 2) Teaching + Technology Program (TTP), a mentorship initiative between P-12 teachers and higher education faculty; and 3) Assistive Technology Mentorship.

The Technology Infusion Program (TIP)

The Technology Infusion Program (TIP) is designed to build a learning community among higher education faculty. TIP focuses on 1) expanding the knowledge-base through incorporating dynamic and multimedia materials into the content area of learning; 2) empowering teaching and learning through introducing new paradigms made available by technology (e.g., visual learning, simulations, synchronized and asynchronized communications, etc.), and 3) enabling faculty to restructure their practice to reflect the successful application of National Educational Technology Standards and Alabama Courses of Study guidelines.
Teaching + Technology Program (TTP)

As research indicates, one of the significant problems in teacher education is the gap between theory and practice. For obvious reasons that most teacher education faculty went through their formal training without adequate exposure to and experience in technology (It did not exist at the time!). Yet some P-12 teachers, because of their professional belief, the need of the classroom, or pressure from society, peers, or home, have found ways to incorporate technology effectively into their teaching. The Teaching + Technology Program (TTP) has paired higher education and cooperating P-12 faculty together to model the use of technology. This includes, but is not limited to, practicum, field experiences, and student teaching.

Assistive Technology: Each One Teach One Model

The number of students with disabilities educated in inclusive classroom settings continues to grow. The education of these students is a collaborative effort and responsibility of regular and special educators. Assistive technology is a relatively new field to the vast majority of faculty in university settings. Very few teachers involved have experience or training in this area. As a result, very few students have had the opportunity to benefit from its potential. Currently, UAB offers the only course in assistive technology among the Partnership institutions.

The mentorship initiative for assistive technology connects together higher education faculty and P-12 teachers to explore options for field-based learning regarding assistive technology. The mentorship employs the Each-One-Teach-One Model to support the goal of disseminating knowledge of assistive technology. Training modules for assistive technology specific hardware/software have been developed and made available online. In addition, a webliography of assistive technology resources has been posted on the project web site.

Facilitating and Managing Mentoring Relationships

As with any complex endeavor, the success requires hard work from all parties, starting with the leadership. The leadership team of the PT3 project is composed of a Project Director, who, together with other members of the leadership team, sets the vision for the project. Mentorship is our means to successful project implementation. Each mentorship initiative is directed by an Activity Director, who communicates the vision of the project to participants, encourages and inspires innovation, and enables meaningful interactions among participants, groups, and between the participants and the project leadership team. In addition, a project coordinator provides essential administrative assistance to the mentorship, allowing activity directors to focus on fostering and nurturing the mentoring relationships without the burden of management details.

It is challenging to manage mentorship relationships across sixteen organizations with about a hundred participants. One of the lessons we have learned is that clear communication of expectations from the project to participants and vice versa is absolutely essential. To bring everyone, mentors, mentees, and activity directors and other project staff, on the same page, we have developed thoughtful and user-friendly management tools, e.g., learning agreement, checklist, project calendar, etc. At the presentation, we will share these tools with our audience and discuss their uses. Through the mentorship initiatives, we strive to cultivate groups of dedicated teacher educators who are not only instructional leaders in their respective discipline, but also confident and self-sustaining technology users.
What You See is What You Get: Virtual Field Trips and Pre-Service Teachers

Patty LeBlanc, Ph.D.
Department of Education, Stetson University USA
pleblanc@stetson.edu

Abstract: In June 2000, the Department of Education at Stetson University received notification of a grant awarded by the U.S. Department of Education to support the integration of technology into pre-service teacher education as a part of the national PT3 initiative. Located in central Florida, the T3 project is a consortium of five key partners: Stetson University (the fiscal agent), Bethune-Cookman College (an historically black college), Volusia County Public Schools, the Florida Independent College Fund, and Time Warner Communications. The purpose of the T3 project is to prepare pre-service teachers to effectively infuse technology across the curriculum to enhance teaching, learning, and student achievement. The focus of this presentation will be to describe the use of two-way interactive videoconferencing to enhance pre-service teacher education, to share preliminary results of our efforts, and to present lessons learned during the implementation process.

T3 and Virtual Field Trips

Virtual field trips were designed to enable pre-service teachers at BCC and Stetson to "peer into" an elementary classroom in order to unobtrusively observe real-time teaching. If the videoconference was held during normal school hours, the teacher education professor would facilitate discussion on methodologies, curriculum, classroom management, etc. If timed carefully so as not to interrupt the normal school day, pre-service students would also be able to ask questions of the classroom teacher. In this way, anyone at Stetson or Bethune-Cookman could take a virtual field trip to this classroom anytime during school hours.

Infrastructure, Support, and Costs

In order to implement virtual field trips for our pre-service students, a great deal of infrastructure had to be created and/or tapped into through grant partners. To put things simply: the PT3 grant enabled us to do things we could not possibly have done without external funding. Grant money was used to purchase a portable two-way interactive videoconferencing station with a SVHS video recorder and a tracking camera for SU, B-CC, and one of the grant's partner schools, Bonner Elementary. Bonner is an inner city school located in Daytona Beach, Florida, about 27 miles from Stetson and approximately 1 mile from Bethune-Cookman College. Bonner was chosen as the target school because most of our pre-service teachers are elementary majors and because Bonner is working hard to integrate technology effectively to improve student achievement.

Implementation

One of the T3 summer boot camp teachers, Ms. Carol Collucci, volunteered to be the videoconferencing queen at Bonner, and the equipment became a part of her tiny 4th grade classroom. The children in the class were so excited about "being on TV!" Ms. Collucci told me on numerous occasions that she was not going to sugarcoat anything. What our pre-service teachers would see would be the regular stuff of everyday classroom teaching—the good, bad, and indifferent.
Initially, the videoconferencing sessions were scheduled to coincide with elementary methods courses at SU and B-CC and were coordinated with Ms. Collucci, the project director, and the university tech support people. In the beginning, the project director facilitated the videoconferences at Bonner while the tech support people at Stetson and B-CC were in the room with the pre-service teachers and their professors. After a few successful videoconferences, the tech support people were no longer required in the room at the university and college, but were always on call during the scheduled videoconferencing sessions. The use of the equipment eventually became fairly transparent for both SU and B-CC, and Ms. Collucci and the children became accustomed to both literal and virtual visitors in their classroom. Much of the video transmitted during the videoconferences was recorded on SVHS tape to be compiled and edited during year 2 and 3 of the project to create case studies of technology integration.

The videoconferences began at the end of the fall 2001 term and continued throughout the school year. One of the project director’s goals during the implementation phase was for the systems to be used often in order to justify the tremendous costs involved. In most cases, we scheduled a virtual field trip at a specific time to view a specific lesson in a specific content area. Occasionally, we simply decided to "take a look" at what was happening with Ms. Collucci and her students.

Lessons Learned

The impact on pre-service teachers is still in the review stage, but some preliminary trends have been observed:

♦ Virtual field trips are pedagogically useful for pre-service teachers, and the model used here could be replicated at other universities, given the infrastructure required.
♦ Professors had to be led. They did not typically choose to videoconference unless the project director set it up. Professors, however, did respond positively to videoconferencing.
♦ Pre-service teachers were fascinated by the interpersonal communication that went on between students and teachers during class time. On the whole, comments and discussions tended to center around classroom management and the affective aspects of teaching more than on the content and teaching methodologies. Some typical reactions:
  o "I had no idea how much of the teaching day is spent managing behavior—at the expense of teaching content and/or skills."
  o "Teaching is exhausting work."
  o "Ms. Collucci is so patient."
  o "How will I ever be able to manage so many children with so many needs?"
♦ While pre-service teachers found the videoconferencing interesting and informative, they felt that they gained more when visiting/observing a classroom face-to-face. The project director theorizes that the "gestalt" of interpersonal dynamics in classroom interactions is more easily observed in person that in 2 dimensions.
♦ The equipment worked very well once everything was finally set up and tested. It was not, however, used as frequently as the project director would have liked.
♦ Many of the pre-service teachers wanted to meet Ms. Collucci and her students in person. Being relatively close geographically was a distinct advantage in that respect.
♦ The children responded positively to the school-wide attention they achieved on campus.

Virtual field trips have proven to be an interesting, but expensive way to examine and critique classroom teaching and to collect vast amounts of video data on teaching and learning. We believe that this highly collaborative technology shows a great deal of promise in teacher education.

Acknowledgements

The T3 project is funded by the U.S. Department of Education as part of Preparing Tomorrow’s Teachers to Use Technology Initiative (PT3). The project will receive $967,263 over three years, which is 42% of the total cost of the project. The T3 consortium will contribute $1,343,060 (58%) of the total project costs over three years.
Abstract: Clarke College, in partnership with the Catholic Archdiocesan Schools of Dubuque, is implementing a program to raise the technology learning curve of pre-service teachers, college faculty, and K-12 teachers and students. Our project aims to create a "school" environment in virtual space where teaching is transformed through technology. At this poster session project outcomes of PT3 grant goals are presented. These goals are to create: 1) innovative improvements in our existing liberal arts and teacher preparation program by enhancing coursework and student activities through transparent use of technology resources; 2) a learning exchange to facilitate digital connections between and among Clarke College faculty and K-12 teachers in our Archdiocesan Catholic Schools, and 3) an online graduate Alternative Teacher Preparation Program for re-entry teachers, mid-career adults and out-of-field teachers. Exemplary faculty/student projects are showcased to demonstrate learning outcomes resulting from integration of technology across the liberal arts and education curriculum.
Project activities include the following:

1. Providing a Technology Education Center equipped with state-of-the-art technology tools for teaching and learning.
2. Providing a Technology Integration Specialist to offer one-to-many and one-to-one workshops for developing technology-rich course projects.
3. Developing a Student Teaching Assistants Plus+ Program to provide students with technical training to support faculty.
4. Strategizing support for liberal arts and education faculty to integrate technology into coursework through WebCT.
5. Providing training for integration of ISTE/NETS standards into course syllabi of teacher education courses to promote a seamless integration of technology into course objectives and activities.
6. Creating an online community where students and teachers share technology-rich best practices with our K-12 Archdiocesan Partner schools.
7. Creating a telementoring program to support first-year teachers in the field.
8. Developing an online Alternative Teacher Preparation Program to meet the critical shortage of K-12 teachers in Iowa.
9. Developing a "telementoring program" as a vehicle to sustain support for first-year teachers during their critical first year of teaching.
10. Infusing Palm technologies and training into pre-service coursework, K-8 curriculum, and teacher field observation experiences.
11. Redesigning the current Master's Program in Educational Technology to include ISTE/NETS standards as well as the Technology School Standards for Administrators (TSSA), and
12. Creating a Digital Learning Exchange website to facilitate connections between and among Clarke College faculty and K-12 teachers and students in our Archdiocesan Catholic Partner Schools, the Internet, and Clarke's Intranet.

A "change of mindset" toward new and emerging technology integration is evident throughout the Clarke College culture. As a result of this grant, technology tools have been placed in the hands of users, hardware and software is available for transparent infusion into class environments, and training is available "Anytime, Anywhere". These three components add up to an overall increase of powerful uses of technology contributing to increased achievement in learning extending to all communities involved in our PT3 Implementation grant.

Throughout the two years of our grant, achievement of performance objectives has sustained a climate for Clarke College faculty, students, K-12 teachers and students to facilitate building collaborative models for exploring "learning how to learn" together through transparent use of information technologies. This poster session showcases best learning outcomes resulting from implementation of our PT3 grant goals.

Abstract

Abstract: Links to the Future is designed to increase our ability to address systematically our use of technology in the teaching/learning process. We are primarily committed to issues of educational equity: we see the digital divide as part of a much larger social justice issue that results from socio-economic differences. We address the integration of technology along multiple strands: 1) the redesign of the education curriculum to meet national technology standards, 2) the integration of technology into core and education courses, and 3) the development of technology-enhanced partnerships with K-12 faculty.

Introduction

Links to the Future begins with several key beliefs. The primary belief driving our project is the importance of addressing educational equity issues. We see the digital divide as part of a much larger social justice issue that results from socio-economic differences. We strive to achieve the goals of our project in such a way that it enhances educational equity for those students who frequently are on the short end of the educational receiving line. Because of this, we find that our technology resources are limited—so we need to do more with less. In addition to limited hardware resources, we often work with limited human resources, i.e., tech support. Therefore, we have to seriously address the issue of expertise—who knows what we need to know and how can we find them? Since we don't have large numbers of "techies" to help us meet the goals of the project, we need to work in active learning communities where expertise is shared and leadership roles shift according to the task at hand. This "limitation" thus works to support participant (including student) ownership of the project, as well as another key belief that we hold: that the infusion of technology is only of value if it supports effective teaching practices. Therefore, we emphasize the use of active learning, student collaboration, and project-based teaching and learning. In addition, we believe that technology is best used when it increases students' engagement and success with intellectually complex tasks. Finally, we recognize that students usually teach in the ways that they have been taught, so Links to the Future takes a systematic approach to the preparation of tomorrow's teachers to use technology through three strands: 1) the redesign of the education curriculum to meet national technology standards, 2) the integration of technology into core and education courses, and 3) the development of technology-enhanced partnerships with K-12 faculty.
Redesigning the Education Curriculum—Linda Lisowski & Diana Bohl

Links to the Future has responded to the evidence showing that new teachers are not being adequately prepared to use technology by initiating a revision of our Teacher Education curriculum at Mercyhurst, ensuring that ISTE/NCATE standards for teachers are demonstrated through our preservice teachers' coursework, field experiences, and portfolio. We recognize that stand-alone courses on computer applications will not give our students the capacity to integrate technology into their teaching; it is necessary to increase the level of technology integration in college education courses. Preservice teachers need to see and experience models of teaching with technology in order to use it effectively in their own classrooms.

At the start of the project, a faculty self-assessment (using the Teacher Preparation STaR Chart, http://www.ceoforum.org/sdce.cfm) indicated that our technology integration status was highly inconsistent. Because technology is a strand that runs throughout the curriculum, we found that most courses included some use of or instruction in technology. However, the extent to which technology was an integral tool supporting higher-order thinking and learning tasks varied. When we examined the ISTE/NCATE standards alongside course syllabi, we found that we already had in place the courses and learning outcomes necessary for our graduates to minimally meet the standards. What was missing was the consistent application of technology in the field. Our concerns now focus on exceeding the minimum standards and on providing high-quality field experiences where preservice teachers use technology not only to support their own productivity, but more importantly, to enhance the learning of their K-12 students.

We see several possible routes for exceeding the minimum competencies: 1) strengthening the technology component in all education courses; 2) strengthening the technology component in several key courses only, 3) encouraging that web-based course support be available for all education methods courses (e.g., BlackBoard); 4) requiring that students use e-mail and other electronic communications for all courses; and 5) requiring or supporting student completion of electronic portfolios. Each of these routes makes different demands on education faculty. A critical concern in the redesign of the curriculum is the capacity and willingness of faculty, who were hired for their very different areas of expertise, to provide high-quality instruction in technology and/or utilizing technology. Another issue here is the institutional capacity of a small, liberal arts college to handle significantly increased demands on the technology infrastructure. These are precisely the difficulties that face us as we focus on preservice teacher field experiences. The availability of mentoring teachers with pedagogical expertise is limited. When we also demand that mentoring teachers work in schools with an adequate technology infrastructure and demonstrate expertise in the integration of technology into the curriculum, we further limit the number of potential mentoring teachers to unacceptably low levels. In addition, we may limit ourselves to working with K-12 faculty in relatively well-off schools, rather than in the high-poverty schools that define our mission. Access to not only technological resources, but virtually all educational resources are impacted by ethnicity and class membership (Kozol 1991, Leigh 1999).

One way the project is addressing these concerns is through the development of active K-12 partnerships. Through project funds, K-12 teachers have the opportunity to take graduate courses in technology integration, borrow portable computers and peripheral equipment, receive mentoring support in their own classrooms from graduate assistants, and develop and participate in school-based technology seminars. Teachers who participate in the project agree to mentor preservice teachers in field experiences. In addition, Links to the Future addresses the computer competence of college faculty through the provision of training and supports, including stipends for redesigning courses to incorporate the use of technology. Five core and education faculty members have been awarded stipends this winter; 5 more will be awarded stipends in the spring. All stipend award winners teach courses taken by preservice teachers. It is the expectation of the curriculum redesign committee that project work in these areas will help us to make better decisions regarding routes to curricular redesign.

Effectively Integrating Technology into Courses—Joanne Carney

Improving the Computer Competency of All Faculty

We consider three aspects of our program to improve the computer competency of all faculty to be worthy of note. First, we have linked our efforts with two other on-going College initiatives, a faculty professional development committee that presents monthly seminars and a program of computer skills training sponsored by the director of information technology at the College. Second, we have set out to create "pockets of change" within as many departments as possible through our use of stipends and release time for faculty to revise course syllabi and infuse technology. Michael Fullan (1994) has pointed out that pockets of change reflecting new behaviors are what eventually
lead to more widespread change. We hope to make our new technology users models for other faculty in their departments. Finally, we are targeting faculty who are novices in technology use for particular assistance and inducements for change—for example, the core faculty representative on our management team is a self-described “Luddite.”

Because we have focused upon faculty who have limited technology skills and real anxiety about using computers, we have had to devise special project features to support them. These supports include a personal technology mentor assigned to each faculty member and efforts to promote networking among the target group members. I will elaborate upon these features of the program and give some anecdotal evidence that testifies as to the effectiveness of our approach.

Technology Mentors

The one feature that has proven most effective in supporting target faculty as they learn new technologies is the Graduate Assistant (GA) mentor assigned to each. The GA-mentor can provide private tutorials or assistance in the classroom when the technology-enhanced lesson is implemented. Though faculty may arrange for meeting time with their mentor whenever they wish—most of the first group of five faculty stipend winners are meeting with their GA’s on a regular basis, at least once a week. This regular meeting time has the effect of keeping the faculty member from forgetting what he or she has learned and minimizes the tendency for a busy professor to put all the technology work aside in the press of other responsibilities.

How effective has this GA technology mentoring been? In the words of one of our target faculty members: “You can keep the stipend money; I just want Chris!” For technology novices, the personal assistance and support of the GA mentor is crucial for learning. All of the faculty in our first target group have participated in various college technology workshops in the past; none were able to develop significant computer competencies on that basis alone. They need more personal assistance. Our Graduate Assistant mentors provide the support faculty technology novices need.

Networking

Another feature of our program is an active effort to promote networking among the five faculty members in our first group of stipend winners. Our core faculty representative (the “Luddite”), is one of the five; she is able to keep us informed about the needs of these neophytes and assist the others in a non-threatening way. Regular monthly meetings of the group give the stipend winners the opportunity both to share what they have learned with the others and get assistance from their peers.

Preliminary Results

How effective has our faculty development program been? Although this target group of faculty has only been engaged in course syllabi revision and technology instruction for two months, we already see signs of change in how these faculty members teach—technology is prompting a more student-centered, active learning pedagogy. In our last group meeting one faculty member shared what she termed a “marvelous experience.”:

I did not want to give them a traditional exam; I had instituted at the beginning of the term, a little ‘techy’ innovation I wanted to try. I gave them a list of about 10 different web sites...each day one of them was assigned to report something they learned ...from the website; the websites gave them broader knowledge of both issues ...and became for several a catalyst to "go deeper" so to speak. They even tracked some of these websites to help them respond creatively (i.e. two students wrote short stories dealing with justice issues; one wrote a poem)...Then they had to give a 5-7 minute (which usually went longer!) presentation on what they had discovered or created. I also gave them the option of working alone or with others; some chose the latter; others the former...It was a rich experience for them and for me. They knew it would be more work and they said they didn't care because they were learning so much and because they had the freedom to choose and shape how they expressed what they were learning.
Conclusion

Marjorie H. Dewert, former president of ISTE's SIG for Teacher Education spoke of the importance of providing professional development and support to all faculty who teach prospective teachers: "If I had to pick the area of work I believe to be most crucial to our success in ensuring that all new teachers are able to use technology effectively in their practice, it would be professional development and support for the teachers who teach the teachers (1999, p. 4). Mercyhurst College's Links to the Future has incorporated that work into our project.

The Pilot Year Project: Student Work—Joseph Lisowski & Linda Lisowski

In 1999, Mercyhurst College received a one-year PT3 capacity-building grant. The goals of that project were similar to the current Links to the Future goals. Education and core college faculty, and participating K-12 faculty worked together to effectively integrate technology into curriculum, using project-based learning to support intellectually complex learning and creating artifacts of student work. Two specific examples of student work completed during the pilot year include PowerPoint presentations created by students in a College Writing course who researched a component of local life; and barrier-free multi-media instructional units on CD-ROM created by graduate students in a special education methods course.

College Writing II

The first author worked to meet the project goals in his College Writing II course, taught at the branch campus. College policy requires all students who take College Writing II to complete several argumentative essays and an individual research paper. Whether a student matriculates at the main or the branch campus, the same standards and requirements apply. The differences between groups of students, however, are significant. On the main campus, students are "traditional," that is, young men and women from fairly affluent families, coming to college directly from high school. Their high school grades, rank in class, and SAT scores are above average. At the branch campus, on the other hand, are those students whose scores were not sufficiently high enough to win them admission to the main campus. These include many single-parent adult students, minorities, and re-entry women. In many cases, they have not done well in a "traditional" learning environment and harbor a distrust for the process of education. Significant attitudinal problems must be overcome; finding new, reliable learning strategies must be undertaken. In this regard, we considered what Paulo Freire (1999) has said: "to teach is not to transfer knowledge but to create the possibilities for the production or construction of knowledge." (p. 30)

After a high level of trust was established, the class turned its attention to research. Five groups of students were to research some very specific aspect of life in the college town. As is appropriate in constructivist classrooms, the students' interests and needs would be of primary concern in the development and evaluation of the project (Brooks & Brooks, 1993). Each group would decide what they wanted to know, how they would go about finding the information, how they would divide up the workload. The professor required that each group would publicly present their findings in a PowerPoint presentation utilizing graphics, sound, and text. After about ten minutes of distress, the class began to address the project constructively. Five students who had done PowerPoint previously felt comfortable being group leaders. Students determined to which group they wanted to belong with the stipulation that all groups needed 5-7 members. Class time was used to decide upon research topics.

Through PT3 grant resources, each group was able to borrow a digital camera for a "one day rental." The groups could "renew" the rental, if there wasn't a "hold" on it. Each week, groups reported their progress and used ten minutes of each scheduled class for group meetings. Although the computers on campus were inadequate for the tasks, in each group there was at least one student who had access to a computer adequate for the project needs. Within a month, each group was well on its way to producing a finished product; each was enthusiastic about what they were doing; and members of various groups often shared their "expertise" with others if they needed it. The class set a presentation date.

What remained was the determination of criteria to evaluate the end result. What specific items would be assessed? As a large group they brainstormed, coming up with about fifteen categories. Unanimous consent was required. No item would be part of the rubric unless everyone agreed on it. The class discussed and agreed upon 5 criteria—Clarity of Main Point (Focus); Composition—(Balance of text, graphics, & sound); Organization and Flow; Creativity; and Fitting Conclusion—to be accompanied by half a page of verbal comments. The two suggestions the professor made and put on the board for discussion were not accepted. Clearly, the students had taken full ownership of their work. To enhance their critical evaluation skills, all students would evaluate the other group presentations.
Student evaluations were used to determine a group project grade; however, the professor maintained final responsibility for the grading process.

As it turned out, the students' presentations were outstanding. The immediate effect of the project was that now each member of the class addressed the issue of research in a more personal and dynamic way. They had not been overcome by fear. They had used technology to take ownership of their learning, to commit themselves to an intellectually demanding and frustrating task, and to take justifiable pride in their efforts. They then were able to use this vital and interactive approach for the remaining classroom tasks.

Teaching Students with Physical Disabilities

The second author worked to meet the project goals in a required methods course for graduate special education and dual certification students. Teaching Students with Physical Disabilities is a course designed to insure that students who receive Pennsylvania's non-categorical special education certificate have experience and skills related to the needs of students with orthopedic and health impairments. The course uses Blackboard for posting course information and documents, linking to critical readings, and communicating among class members. At the time of this pilot project, the first author had a graduate assistant with a rare form of muscular dystrophy who served as a teaching assistant for the course. Because of her high level of independence and her limited movement abilities (she has use of 2 fingers in her right hand, along with adequate head control), this graduate assistant also provided the class members with a powerful example of the need for them to develop advanced computer skills if they were to teach young students with serious orthopedic impairments.

Students in the graduate program have widely varied backgrounds. They include certified special educators, certified elementary teachers, uncertified paraprofessionals in education and mental health fields, younger students straight from their undergraduate programs, and re-entry women with family and other work experiences. Planning and delivering instruction so that all students' strengths are utilized and all students' needs are met is often a significant challenge. Collaborative, project-based learning can be a way to utilize strengths and meet needs in this kind of diverse setting.

For their final project of the course, students were asked to work in self-selected small groups to develop either a web-based or PowerPoint instructional unit saved on a CD-ROM, and designed to meet the needs of students with average cognitive skills utilizing the principles of universal design. That is, the instructional unit needed to be barrier-free to meet the needs of students with physical impairments, but still had to be of interest to students with no visual, hearing, or physical impairments. The grading rubric included six areas upon which students work would be graded: 1) Learning objectives are clear, appropriate to the grade level and content area, and identified within the first two "pages" of the presentation; 2) Content is accurate and appropriately challenging; 3) Users can choose whether to access the unit visually and/or auditorily, and the unit is clear and cohesive in either modality; 4) There are at least 34 high-quality Internet links embedded in the unit; 5) The unit includes an assessment component that precisely matches learning objectives and content; and 6) The appearance and appeal of the unit are high. Students were free to select the grade level and content area of the unit. They were encouraged to work in groups in which at least one member had technological self-confidence and access to a good computer. However, Links to the Future provided two laptops for students to borrow (one PC and one Mac), if they needed. Students could also borrow portable zip drives (to facilitate working between computers), digital cameras and video cameras, microphones, and a rewritable CD burner. In addition, graduate assistants staffed a small lab that had two high performance computers, a scanner, and other peripheral equipment. The graduate assistants and professor were available to meet with students and provide technological support.

The major barrier to the successful completion of this project was attitudinal. It would not be too strong a statement to say that many students were horrified and angry when they first received the assignment. They had strong misgivings about their ability to complete the task, and many felt that it was an inappropriate task to be given in a non-computer course. However, they could clearly perceive that students with physical disabilities need excellent technology skills if they are to have access to educational resources and learning. The professor and graduate assistants listened carefully to student concerns and provided technological assistance. Nonetheless, during the time students were working on the assignment, there were many expressions of frustration and resistance; there were far fewer expressions of excitement and enthusiasm.

Students presented their projects during the final week of classes. They ranged from a simple math fact unit for first graders to an interactive intermediate grade unit on the Bill of Rights to a richly informative unit on Chinese life and culture. Some of the presentations were of outstanding quality—class members were astounded by the interesting presentations that the groups developed. In spite of the anxiety and dread the project engendered while students were
working on it, the end result was unquestionably positive. Students who had complained the loudest commented on what a powerful and positive learning experience this assignment had provided them.

Evaluation of the Links to the Future Project’s Effectiveness—Dawn Blasko, Kim Skarupski, & Michael Drabik

Penn State Erie’s Center for Organizational Research & Evaluation (CORE) is serving as the independent evaluator for this project. Researchers at CORE are conducting both formative and summative evaluations of the project objectives. A formative evaluation examines how a program is being implemented with the purpose of providing feedback for program improvement (Rossi, Freeman & Lipsey, 1999). The formative phases of this evaluation are ongoing via CORE’s continuous involvement on the executive team throughout the duration of the project. Summative evaluations are done at the conclusion of a project to determine its overall effectiveness (Rossi, et al., 1999). The first year project needs assessment will provide the baseline data to which subsequent improvements and project impacts will be compared. We used a combination of quantitative and qualitative methodologies to improve the validity and usefulness of our results (Berg, 1998).

The first step in meeting our objective was the development and implementation of a set of technology questionnaires for the three populations targeted in the grant: 1) K-12 teachers enrolled in a Links to the Future sponsored technology training course, 2) Mercyhurst College core faculty, and 3) Mercyhurst College education students. The instruments were designed to assess current technology utilization, technology knowledge, teaching characteristics, attitudes about computers, and other demographic characteristics. We decided to target the second-year students as the target student population, because they would be students during the entire three year PT3 project. CORE created an instrument tailored to each population and implemented it on a web site to simplify data collection and to enhance project sustainability in the future. The web site went on-line in October. Students were randomly assigned to receive either the online version or the paper and pencil version of the survey. Using a modified Dillman survey technique (Dillman, 2000) faculty and students received campus mail and e-mail reminders to improve response rates. Response rates for the K-12 teachers (100%), and students (87%), were quite high and the response rate for the faculty group was moderate (57%).

The surveys showed that the college faculty ranged widely in their use of technology. The percent of faculty who reported having computers at home was 90%. Twenty-four percent of faculty reported owning a Macintosh computer verses 76% who owned a Windows based PC. Relatively few faculty (10%) reported the use of complex technologies in their teaching (e.g., creating websites or multimedia development), and most of these were in technical fields such as computer science. Many more faculty reported using e-mail (67%) and word processing software (92%) on at least a weekly basis. Faculty also reported several barriers to the use of technology college-wide. The major barrier that they reported was having sufficient time, followed by obtaining sufficient software, and getting instructional technology support.

The education students surveyed were second-year students involved in the education program at Mercyhurst. Students were recruited during second term registration and via e-mail and campus mail. Many students (96%) reported owning a computer and the vast majority (97%) of those owned a Windows based PC. Over 94% of students reported having Email at home. Overall, most students report some familiarity with computers and nearly all realized that technology was vital to a career in education.

Turning now to the K-12 teachers, we found that most used e-mail frequently and 91% reported having a computer at home. As frequently noted (e.g., Anastasi, 1988), self-report measures can have limited validity, especially in cases where there appears to be an evaluative component. Therefore, in addition to the self-report survey, we have developed an observational coding scheme to assess the current use of technology in the K-12 classrooms. Observers were trained using COR (Courseware for Observational Research), software developed at Penn State Erie to teach observational research techniques, including coding methods, sampling techniques, and reliability analyses (Blasko et al 1998) All of the teachers that were observed were enrolled in the Links to the Future sponsored seminar, EDSP31, Technology in the Curriculum. This course includes three 2-credit courses that take place across a total of 30 weeks. We have now collected observational data in all 17 classrooms for a minimum of 60 minutes per classroom. After the observations, teachers completed a post-observation form that provided an opportunity via open-ended questions for them to add qualitative information about the class and their experience using technology.

Initial results suggest that, with a few exceptions, the self-report survey generally mirrors the teacher's actual behavior. Most teachers reported positive attitudes about computers and relatively high innovativeness scores. This is not surprising, given the considerable commitment that the course required. Even at this early stage of the project, technology was used 51% of the total time in the classrooms. For this group of teachers, technology use was primarily restricted to using educational software, searching the Internet for information, and using word processing software to
type assignments. The most frequently reported barriers to the use of technology included time for training and development and the lack of sufficient available hardware and software for teaching. Several teachers also mentioned that technical support in the schools was sometimes lacking. In some cases, the self-report survey did seem to overestimate the frequency of use of technology, for example teachers self-reported that they made heavy use of the Internet in their classes, but the classroom observations showed only 4% of the technology time was actually spent using the Internet, compared to the 16% of the time they used canned educational software. These data will serve as important baseline information for comparison to the observations collected in Spring 2002 at the end of the training course.

Another project objective was to redesign the education curriculum to integrate technology. At this point in the project, five faculty have been chosen to redesign courses and an additional five are being selected for the spring term. The faculty received funds that could be used for a course release or supplemental salary. Faculty were provided with consulting and technical support from the project team. Two weeks after the term, each faculty member will complete a project portfolio that will be the main source of evaluation data. It will include five sections: 1) New and old course syllabi, 2) Training efforts- What training have you gone to in the project period, on and off campus? 3) Sample project- a description and or demonstration of one learning project that you developed in the period of your course redesign. This can be on a CD, disk, video or the web, but must be available to the team to view. 4) Dissemination efforts- How have you shared your knowledge and skills with others, for example, through peer mentoring, conference presentations and publications, 5) Self-assessment- What did you learn? What do you still need to learn? What barriers did you identify to your integration of technology into your course? How might you overcome or cope with these barriers? How might we help and support your efforts? As a follow-up to the portfolio evaluation, classroom observations will be conducted the first time that the new course is offered.

The evaluation team is now planning for several upcoming project activities. We are fine-tuning our classroom observation techniques to simplify the criterion and improve reliability. We are developing an evaluation of the graduate students that were hired by the executive team to support the college faculty and K-12 teachers. Finally, plans are also underway for the development of a PT3 sponsored Links to the Future summer technology seminar.

Building a National PT3 Online Learning Community

Betsy Lowry
Program Director for Online Learning and Distance Education
Center for Technology in Education
Johns Hopkins University
410-312-3831
lowry@jhu.edu

Background

PT3 has the distinction of touching most major teacher education programs across the country. PT3’s national web site will serve a dissemination function, to share the wealth of research, program designs, evaluation findings, resources, and tools that are strengthening preservice teacher education through PT3 funds. To support the synergistic exchange between grantees, PT3 implemented a new intranet in August 2001 called the Electronic Learning Community (ELC), developed at Johns Hopkins University. This secure web space currently has over 800 registered members from the national teacher education community.

The ELC acts as a professional development resource for teacher educators by providing convenient channels of communication and increasing the opportunities for collaborative exchange of information and resources, improving the quality of interaction among community members. The structure of the ELC supports community involvement by integrating a decentralized approach to the development of site content, resulting in a web site that reflects the multitude of skills and expertise of the PT3 participant group. The ELC facilitates communication across geographic and professional boundaries, promoting continuous improvement and the generation of new knowledge. This web-based system enhances the learning and cohesiveness of the PT3 community by providing an open forum for the timely sharing of successes and a vehicle for “just in time, just for me” solutions.

Through a community-centered set of web-based tools and a strategic facilitation process, the ELC is being applied to meet the following needs identified by the PT3 community:

User Control

- Allow projects to contribute information regularly to the PT3 web site so that the increasing volume, depth, and sophistication of the program become evident over time.
- Provide a mechanism for all projects to share their products on the web site as they become available, with information about how the products can be accessed.
- Increase the opportunities for personal participation on the web site.
- Add an “upload” feature to allow all projects to continuously add new files and web sites (“artifacts”) to share with the larger PT3 community.
- Provide web-based interaction tools that can be user-controlled to allow any configuration of participants to meet online as needed. Provide facilitation support or mentoring for these groups as needed.

Community Building Processes

- Provide projects an opportunity to participate in identifying “best” or “promising” practices, models, and innovations within the PT3 community, and highlight what is selected on the web site in a searchable format. Allow projects to see the ongoing evaluative feedback, and provide a forum for public recognition of product development and other achievements.
- Build the PT3 community by providing a forum that allows projects to make ideas and accomplishments visible, and to receive validation from their peer group. Create a sense that this is an important place to be “seen.”
- Establish a mechanism to learn about learning communities from grantees who are doing work in this area.
- Establish a deliberate and effective mechanism for gathering information on the needs and wants of the PT3 community and other PT3 online presence clients continually.
Technical Integration

- Ensure that all interactive web-based systems that are a part of the PT3 program are smoothly integrated and seamless for users.
- Provide micro and macro spaces on the web for internal project work, for projects to move easily into larger program activities, and for cross-project collaboration.
- Provide a dynamic web-based calendar for users to record all project and program-related activities.
- Provide a mechanism for users to see what new content has been added to the site since their last visit.
- Offer an email alert system to draw users to the PT3 site when new content is added.

Purpose of the Poster Session

Multiple purposes will be achieved in this poster session:

1) PT3 grantees will have an opportunity to learn more about the Electronic Learning Community application, resources available through the ELC, its purposes and functions, and personal applicability. In addition, we can register anyone who has not yet become a member of the community.

2) We can use this face-to-face forum to foster collaborative exchange between and among PT3 grantees, and to encourage community members to participate in national PT3 initiatives currently facilitated through the ELC.

3) We can solicit feedback and input from PT3 grantees regarding the facilitation approaches used to grow and sustain this community, and effective strategies to make online community work.

4) Beyond the PT3 program we can discuss the role of online community in teacher education, sharing our experiences in applying this ELC web space and our facilitation strategies to over 50 communities of educators, and to three university-based preservice programs.

Comments Box on the Application:

We are supporting and facilitating the online community of all PT3 projects. A poster session will provide an opportunity to share the resources available on the Electronic Learning Community, discuss effective strategies for building and sustaining the community, and extend discussion to the role of online community in teacher education programs. However, it would be particularly beneficial to have a poster session type of presence throughout the conference, to engage more PT3 grantees in the discussion. We also want to ensure that all grantee participants are registered in the Electronic Learning Community. Is this a possibility?
Evaluating the Importance of Integrated Technology for Teaching and Learning Among Preservice Teachers

Dr. Linda Lynch
Department of Curriculum and Instruction
Southern Illinois University, Carbondale

Abstract
A valid and reliable instrument that measures the growing motivation to use integrated technology applications among preservice teachers was developed. Expectancy value theory provided the framework, for understanding the level of technology skill self-efficacy and value beliefs among preservice teachers.

Introduction
One major problem teacher educators face in an attempt to address the technology integration capability of preservice teachers, is measuring the level of motivation future teachers have to integrate technology in their future classrooms. Teacher educators want to know if the training and experiences they provide preservice teachers are ample enough to develop needed skills and a desire to use integrated technology as full-fledged teachers.

Preservice teachers experience a variety of opportunities to practice technology integrative activities in varying amounts. Given all the variables that occur in educating and training pre-service teachers, no two preservice teachers experience the same examples and practice associated with technology integration. By what method should preservice teachers be evaluated to give ample feedback to teacher educators, indicating success in the level of preparation to integrate technology given all the variation? Are preservice teachers motivated to use technology as teachers when they in fact graduate?

Instrument
The Technology Self-Assessment (Lynch, 2001) was developed to assist teacher development programs attempting to meet ISTE NETS standards to develop technology-using teachers. This valid and reliable instrument employs two meaningful constructs to demonstrate that preservice teachers are developing the motivation to use technology for learning and future teaching: technology skill self-efficacy and technology value beliefs. According to the expectancy value theory, motivation to take action is a result of the combination of skill self-efficacy and value-beliefs for the object of the motivation (Bandura, 1996).

The Technology Self-Assessment features the 13 technology applications that are described in the ISTE NETS literature. Each application explores four graduated levels of skill self-efficacy and value for each of the 13 applications. Additionally the instrument includes items that explore the effects of past experience, and integrated usage in project-based situations on skill self-efficacy and value-beliefs for each technology application.

Some of the proposed advantages of using this instrument over other known instruments are:
- Specifically designed to represent the ISTE NETS standards for preservice teachers
- Supported by meaningful theories that are particularly valuable to demonstrate motivation to use various integrated technology applications preservice teachers
- Measure detailed technology skill self-efficacy of preservice teachers for a number of technology innovations
- Measures past experience and integrated usage of each technology application which is known to have affects on technology skill self-efficacy in preservice teachers
- Instrument was valid and reliable when used with two groups of preservice teachers
• Instrument is well suited for longitudinal studies
• Instrument is well suited to provide information to assist teacher development programs in their self-evaluation
• Instrument is easy to administer.

Conclusion

It is important that preservice teacher institutions assist their graduates in acquiring needed skills, methods and motivation to use integrated technology in their learning and future classrooms upon graduating as teachers. Accurately measuring elevating technology skill self-efficacy and value-beliefs with a reliable instrument is also important to preservice teacher institutions who are developing future technology using teachers. The Technology Self-Assessment measures technology skill self-efficacy and value-beliefs, and should be a valuable aid in demonstrating the growing motivation to use integrated technology among future teachers.
Teaching with Technology

Kristi Maier
School of Education
St. Bonaventure University
St. Bonaventure, NY 14778
maierkm@sbu.edu
716-373-7679

Abstract: "Are we going to use the computer?" This is what my students ask me all of the time. I am currently a senior elementary education major at St. Bonaventure University and concluding my student teaching. I am student teaching in a STTS -- Student Teaching Technology Site -- where I am required to incorporate technology into lesson plans and daily activities. This presentation will describe my efforts and successes. I will discuss the effects this program has on student teachers, children and K-12 cooperating teachers.

"This is great!"
"Wonderful!"
"Are we going to use the computer?"

These are just some of the quotes that I hear daily from second graders in my class and my cooperating teacher at Allegany Elementary School.

I am currently a senior elementary education major at St. Bonaventure University and concluding my student teaching. In conjunction with St. Bonaventure University, Allegany Elementary School has a special program, which enables (and requires) student teachers to incorporate technology into lesson plans and daily activities. This is part of a new program at St. Bonaventure in which student teachers were selected to be placed in schools that have "technology tools" available and accessible. As the use of technology increases in schools, I could not miss the opportunity. As I finish my professional semester as a student teacher, I feel that being placed in this position is one of the best opportunities that an aspiring professional teacher can have.

I am currently teaching a unit on communities and neighborhoods. Throughout this unit, I have incorporated different types of technology to enhance student learning. One example of technology that I have utilized is a program called Inspiration. This program allows users to create a graphic organizer with colorful graphics and pictures. The particular Inspiration web that the students in my second grade class created was one that focused on "things that you may find in a neighborhood." I think that this was a really great way for the students to begin to grasp the concepts of communities and neighborhoods. Instead of just discussing the topic, it was interesting to have the students come up with suggestions and insert them into the Inspiration web. This was one of the very first technology projects that I introduced to the second graders and their faces just "lit up" as soon as they realized they were using the computer. Often, just setting up the computer and projector is an anticipatory set in itself. It "grabs the student’s attention" and that is so very important in creating a classroom atmosphere that is effective and creative.

Another very effective use of technology that I have used in my teaching experience is the use of educational software. Educational software can be a very powerful and interactive tool that brings learning to children in a different way. Software allows children to explore opportunities and become familiar with current technology trends. In the communities and neighborhoods unit, I thought that it would be a positive learning experience to have the students create their own map of a neighborhood. With the technology equipment available, I chose to use a software program called Neighborhood Map Machine. This program
allows students to create and design their own neighborhoods. As a class, the students developed their own neighborhood incorporating various aspects of neighborhoods and communities that we explored throughout the unit. The students really became interested and involved with the lesson and were learning while having fun at the same time. Each student participated in developing the neighborhood and as a result of teaching this lesson, the students were always eager to find out when they will be using the computer again and what other activities they can do with other technological equipment.

In conjunction with my cooperating teacher, I am in the process of developing a computer center in the classroom. Before I arrived at Allegany Elementary School the computers located in the classroom were not being used. Due to the fact that the students took such great interest in the technology that I have started incorporating into my teaching, I’m confident that it will be very beneficial for the students to have access to technology in the classroom everyday. In order to make this a success, I will choose software programs appropriate for my students. This will increase their development in technological skills as well as the subject matter.

With the help of St. Bonaventure University and Allegany Elementary School, I have been able to incorporate different types of technology to enhance student learning. I should also note that not only has the use of technology in the schools enhanced student learning, but also it has affected the student teachers and professional teachers that I have been working with. It is not uncommon for other teachers in the building to ask me how to use technology in different situations. Thus far, I have truly enjoyed using technology in a classroom situation and I feel that my abilities will be very effective and beneficial in future classes that I teach.
The Tech Mentor Project: Technology and the Student Teaching Experience

Susan Malone
Department of English
University of Southern Mississippi
United States
s.malone@usm.edu

Abstract: This presentation will share the results of three semesters of the Tech Mentor Project, one of the activities of USM's PT3 Initiative. Selected Tech Mentors work with student teacher volunteers on focused technology-related projects during the student teaching placement, connected through WebCT to a virtual community of other Tech Mentor teams and the PT3 team.

Introduction

As part of USM's PT3 project, student teachers are placed with trained Tech Mentors who have agreed to collaborate with the student teacher on technology projects during their placements. Tech Mentor teams participate in a virtual community supported by WebCT and collaborate to create a model lesson plan based on the NETS for Teachers and the NETS for Students, as well as appropriate state curriculum standards. Tech Mentors are recruited from among our regular pool of mentor teachers, focusing on those teachers who are already doing exemplary things with technology in their classroom or on teachers who are interested in learning more about using technology. For this second group, a special summer training session improves their technology skills and prepares them for their roles as Tech Mentors. Student teachers apply for the special designation of Tech Student Teacher. In the first year of the program, ten of our school district partners were involved in the Tech Mentor program; during the second year, we have expanded to include fourteen districts; next year, we will incorporate all nineteen of our PT3 consortium school district partners. In addition to working together on the model lesson plan and communicating regularly with other Tech Mentor teams on the WebCT bulletin board, Tech Mentor pairs work with the PT3 team to help develop strategies for extending the expectations of NETS for Teachers compliance to all student teacher placements at our University. Also, in Fall '01 we added an additional requirement for select teams who will develop and submit a portfolio of all the technology-related activities they completed during the placement. This presentation will share some of the results of the last three semesters of the Tech Mentor project. Student teachers and mentor teachers who have participated agree that the experience has improved their ability to use technology in their instruction and increased their students’ learning. We will also share some of the challenges we have faced in developing and supporting this virtual community, which covers half of our state.

Over the three semesters we have conducted the Tech Mentor Project, 52 teams have participated, representing nine of our school district consortium partners. Our goal was to place Tech Mentor teams in ten districts during the first year of the project, in fourteen districts during the second year, and in all nineteen districts in our final year, with one elementary and one secondary team in the targeted districts each semester. Because of the difficulties involved in coordinating student teacher placements with our Office of Educational Field Experiences, their district contacts for student teaching placements, our district contacts for PT3 activities, student teacher applicants for the Tech Student Teacher slots, and the relatively short list of trained Tech Mentors, we have not always reached these target numbers. We hope to involve enough regular mentor teachers over the life of the three-year project to build up the pool of technologically-proficient mentors so that all student teachers will eventually have an opportunity to work with one during their placements.

Tech Mentors and Tech Student Teachers sign commitment forms agreeing to do the following: (1) attend two required meetings during the semester; (2) make weekly postings to the WebCT bulletin board discussions; (3) develop a model lesson plan correlated to the NETS for Students and Teachers and to the appropriate state content standards; (4) complete required surveys (two Profiler surveys on their perceived technology skill level and one end-of-term feedback survey); (5) work with the PT3 team to develop ways the
new ISTE NETS for Teachers can be used in evaluating student teachers; and (6) after participation in the project, serve as district resources/trainers for other mentor teachers on the role of the NETS in student teacher evaluation.

Challenges of the Virtual Community

We use several of the WebCT tools to support this project. In the Course Content section, we provide links to extensive online resources, including relevant standards, ideas for using particular software (Inspiration, PowerPoint), support for the one-computer classroom, netiquette resources, software evaluation resources, web evaluation resources, free online tools (Filamentality, TrackStar, RubiStar, QuizStar, etc.), project-based learning resources, and web quest resources. We also provide project-specific information and forms, including the lesson plan template, the contract and commitment forms, reflection guidelines, and portfolio guidelines. We provide a direct link to our Profiler surveys, to make them easier for participants to access; we post specific discussion prompts, assignments, milestones, and due dates on the calendar tool, to help participants stay on track; and we use the private email and bulletin board tools.

Even though participants sign a contract saying they will participate regularly in the bulletin board discussions, we find that they often do not follow through on this. For most of the teachers, this is their first experience with WebCT, though more of the student teachers have been exposed to it. They have never participated in a virtual community like the one we have tried to develop and have difficulty making it a part of their routine. Based on the end-of-semester survey, 11% of the respondents said they never knew they were expected to post regularly (despite the contract and the discussion at the first meeting); only about 32% did regularly join in the conversation; 39% said they didn't have time; 11% said they didn't know how to say; and 7% said they forgot about that commitment. Most of us on the PT3 team have had great success using the WebCT bulletin board as supplements to our university classes; however, the participants in the Tech Mentor project meet each other only once, at the beginning of the semester, and do not have time to develop relationships that make the online discussions comfortable for them -- they never really feel like they are in conversation or in community. When asked if they would have preferred more face-to-face meetings, 89% said yes, suggesting they are more comfortable with the more familiar setting.

Tech Mentor Successes

Despite some disappointment in the online virtual community, our Tech Mentor project has proved successful. Though 40% said they would have used just as much technology in their instruction even if they had not participated in the project, 60% said they used more than they would have had they not been involved. Though a few (7%) participants reported that they had to strain to find ways to use technology, 74% found a natural fit between technology tools and the objectives of their curricula; 77% believed that their new technology lesson more effectively supported student learning than what they had done in the past (none thought it was less effective), and 95% said the use of technology improved students' motivation and engagement. District support and expectations regarding technology use will determine how likely 23% of the participants are to continue to use the strategies they developed during the project, but 77% reported that they were very likely to continue with their use of technology, because it had become integral to the way they think about teaching their subject matter.

Abstract: This paper describes a project integrating technology into a reading methods course. Part of a faculty development program of a PT3 grant, this was a cooperative effort, where the class was co-taught by the Reading Faculty instructor and an Instructional Designer working with the grant. WebQuests were integrated into the regular curriculum, with groups of students creating a WebQuest as their major class project. The genesis, planning, implementation, and evaluation of this project are discussed. Successes included large percentages of participants approving of the integration of technology into the course and students who felt the technology was well integrated into the course. Many students saw limitations in this connection, and the time involved in the project was also seen as a negative by some students. Suggestions are offered for those working to integrate technology into the content and methods courses of their teacher education programs.

Introduction

Over the last 15 years, as computers and the Internet have become a greater part of schooling, criticism has been leveled at teacher education programs for failing to educate new teachers effectively in technology use (CEO Forum, 2000; Office of Technology Assessment, 1995). The continuing failure of our K-12 schools to use technology to increase student performance in a widespread way is one result of this failure. While much attention has been paid to the role of instructional technology classes in alleviating this problem, a much more problematic issue is the integration of technology into content area and methods courses. Until technology is an integrated and natural part of the whole teacher education program, it is likely to continue to be viewed as an add-on or separate subject. This paper looks at a recent effort to integrate technology into a reading methods course.

This effort came about as a result of several factors. The Department of Education at Eastern Washington University (EWU) received a PT3 grant in 2000. Part of this grant provides for faculty development in technology. The focus of the grant in this, its second year, is one-on-one mentoring for faculty, with stipends available for those with specific plans for integrating technology into their courses. This gave the co-author of this paper the incentive to begin integrating technology into one of her courses in the Fall of 2000, something she had been thinking about, but hadn’t felt the support or self-skills to do so prior to that quarter.

The author was hired by the College of Education and Human Development, of which the Department of Education is a part, to help coordinate the various technology efforts of the college. A major aspect of his position was intended to assist faculty to be more effective users of technology both for themselves and in their courses. Serendipitously, more money became available through the PT3 grant for the year, and the author was formally assigned to work with the PT3 grant, assisting with their various efforts. As the author and co-author are husband and wife, it was natural for them to work together on these already existing plans.

Course Background
During the summer of 2001 the reading faculty at Eastern spent a week revisiting and updating the first three required classes for Reading majors in the department. While discussing the needs of the students, community and state requirements, it became clear that few of the faculty were integrating technology into these three courses. While two professors were using Blackboard to support class projects, when the co-author brought up the need for students to use technology for curriculum design, the general consensus was the classes had too much to cover, and that adding technology would be impossible.

Education 410, Student Centered Reading, the course which the authors selected to use for integration of technology, is the third core reading methods course for the reading major at EWU. This class was seen as a good place to try to integrate technology for several reasons. First, students majoring in reading compromise the largest group of students enrolled in the department, and as this is a required course, a large number of students could be introduced to the use of technology in the classroom in a hands-on way. Second, as EDUC 410 is the third core class, the students enrolled will already have been exposed to the broad range of topics offered in the first two readings methods courses. This background would give them a grounding in reading development, methods and materials as well as lesson planning and some field work in public school classrooms. Third, as the title of the course suggests, the content of the EDUC 410 focuses on student centered learning techniques. These techniques include such things as Literature Focus Groups, Literature Circles and Cooperative Learning. Thus, the development and use of WebQuests as discussed below, with their focus on the participatory nature of the students involved, worked well with the goals of this course.

Rationale for the use of Technology in Education 410

As we began planning the best way to integrate a technology component into the course, we had to look at several factors. These included a desire for technology to be an integrated component of the course and not an add-on, making the technology student-centered, and having the university students actively participate in using the technology as they or their students might in a K-12 classroom. Looking at these and other factors, we decided WebQuests would be a good and valuable way to integrate technology into the course.

WebQuests are an inquiry-orient, student-centered activity invented by Bernie Dodge and Tom March at San Diego State University (for more information on WebQuests see the San Diego State University WebQuest page at http://edweb.sdsu.edu/webquest/webquest.html). They are designed to use students' time well when they are on the Internet, rather than just having them spend unguided, and often unproductive, time surfing the web trying to find useful information. When designing a WebQuest, teachers find the appropriate web sites first, and design an activity using those sites and other resources. A well designed WebQuest enables students who use it to be active participants in their learning by making choices, working cooperatively and often creating one or more products as a result of their WebQuest activities.

WebQuests appeared to be a good technology project for this reading methods course for several reasons. First, the students would be active participants in designing a WebQuest. As a result of this course activity, they would learn web page creation skills in the context of developing reading curriculum rather than as separate skills. Second, WebQuests are focused on both content and process, thus modeling good classroom technology use rather than simply reading and talking about such use as is often seen in teacher preparation courses. Third, WebQuests encourage cooperative group work, again providing an opportunity for modeling in the university classroom the types of activities and behaviors we hope the future teachers will implement in the K-12 classroom. Finally, because the teaching of cooperative learning techniques was already a component of the course in which the WebQuest project was planned, this could be seen as an incorporation of technology into the course, rather than a time consuming add-on.

The Planning Phase

Once we had decided on WebQuests as our means of integrating technology into this course, we then needed to determine how best to implement the use of this technology into the existing course structure. While we had originally thought to focus on WebQuests during the second half of the class, we decided it made more sense to try and integrate the activities throughout the course. This was partly motivated by the knowledge that the students in the program, almost all elementary reading majors, had received little or no technology use in the
classroom to this point in their program. Thus we planned to integrate technology activities and demonstrations into the class from the start. By using this approach, we hoped the students would not only get paced instruction in this area (alleviating 'technology frustration'), but would also come to understand that technology can and should be integrated into the curriculum. Therefore, we also planned whenever possible, for the technology activities to have connections to the other activities being done in class on any given week.

By following the outcomes of the course as mentioned in the Course Background section above, we maintained the objectives of the class while still being able to integrate, rather than ‘add on’ another component, thus avoiding a common complaint of university faculty: that the integration of technology into existing courses is too difficult, time consuming and results in the need to drop some course content in order to accommodate the technology component.

Before discussing the implementation and results of this project, some information on the setup of the classroom is important. This course was a night class which met once a week for four hours at the university’s off campus downtown education center. No technology is available in the classrooms, although each has an Ethernet port for Internet access. The building also has an open lab available for student use. However, this lab cannot be used for teaching, thus without bringing in some outside technology, this project would have been difficult or impossible.

Fortunately, the Department of Education has a set of iBooks®, and we were able to check out six of them for the quarter. To maximize the available technology, a wireless Airport® network was set up in the classroom; each group had one iBook®, and all groups were able to share the single network connection and be online together. Additionally, a digital projector was brought in for teaching and student presentations. While the technology limitations presented some problems, (discussed later), this setup did allow at least the minimum necessary access for groups to work on their projects, and might be considered a reasonable model of what teachers might face in attempting a similar project in a K-12 setting.

Implementation of the Project

The technology activities in this class started the first night, with a brief introduction to WebQuests. The students were shown the San Diego State WebQuest site, given a handout with URLs designed to help them get started finding out about WebQuests, and a WebQuest treasure hunt worksheet. Finally, we went to the lab and our students were given basic instructions on lab use. Two weeks later, we went over the first assignment and began the next, which was having the students plan the outline of their WebQuests.

Because we had a large classroom with a divider, we were easily able to split the class into two groups for separate activities. On this evening, one half of the class worked on a hands-on book-making activity, based on the text reading for that week, while the other half began their WebQuest plan. By dividing the class in this way, more individualized assistance was provided that third week at the beginning of the planning phase. Final plans were evaluated and adjusted the next week. We reasoned that with a solid plan in place, groups would be able to work on their own WebQuests with an understanding of the basic parts of a WebQuest and the responsibilities of each group member.

In the fifth week, again splitting the class in two, students were able to not only work at various learning stations based on the text reading, but were able to devote half of the class time to learning the rudiments of web page creation. This included the fundamentals of creating and saving pages, putting graphics and links on the pages, and design issues such as use of color, white space, and the appropriate use and crediting of graphics. Because of the overwhelming amount of information in this one session, additional time was spent the next week on some of these components. After that, in-class WebQuest time was mostly devoted to having groups work on their projects, sometimes as a whole class, sometimes split and always with a chance for groups to work on their own. Finished WebQuests were upload to the College server and presented during the last two class sessions.

Data & Analysis

To determine the effectiveness of integrating technology into this course, we gave the students a separate evaluation in addition to the department course assessment. We asked how useful they found the technology component to be, whether they felt it connected well with the reading curriculum, and the relevance of the
project to the reading program and their future teaching. They were also asked to discuss their other technology experiences at the university and whether they would like to see other classes implement similar technology projects. These questions were asked anonymously in an open-ended format, allowing students to raise other factors they felt to be relevant. Nineteen out of twenty-two students (86%) filled out the survey, given during the final class (two students were absent the final class night).

Coding of the surveys was done one respondent at a time, question by question. After a first reading when no coding was done, and initial set of codes was created and applied during the second reading. These codes were further refined and reapplied where appropriate, until all data were coded with one set of codes. Results were then put in a spreadsheet so the data could be viewed both by respondent and by question, to look for overall trends and to ensure that each individual's line of codes reflected their answers.

The first question asked students how well they felt the WebQuest project fit the course curriculum. Responses were coded into five categories ranging from a good fit to not fitting and students not liking the projects. Table 1 shows the results from this coding, with 8 of 18 (44%) students who responded saying the fit was good or moderate, 6 (33%) saying they liked the project but didn't see a good fit, and 4 (22%) students seeing no fit. The responses to Question 2, on whether the students felt the technology was a valuable addition to the course, sheds some additional light on this issue of the technology fit.

Table 1: Technology/Curriculum Fit

Sixteen out of 19 (84%) students responded that they felt the technology was a valuable addition to the course. This included three students who felt there was no fit in Question 1. In responding to why they felt the technology was valuable, 8 students felt the skills they learned or were learning about WebQuests gave them valuable resources for the K-12 classroom. Five additional students saw learning and using the technology more generally as important for teachers. On the negative side, four students felt that the time spent on the WebQuests took away from time they would have preferred to spend on the reading curriculum. Thus while many students may not have seen the connection between the reading curriculum and the technology, an overwhelming majority did think the technology was a valuable addition to the class.

Question 3 asked students if they would like to see similar technology projects integrated into their other courses. Thirteen out of 19 (68%) said yes, with one additional student answering both yes and no, with reasons given on each side. Three of the six students who answered no mentioned a lack of experience or skills with the computer as a factor in not wanting to see similar projects in other classes. Five students said that if similar projects were done, they should be better connected to the curriculum, echoing results from Question 1.

Question 5 asked students about their other technology experiences. This question was added because we knew that the university in general and the Education department specifically are somewhat weak in this area. Twelve out of 19 (63%) students said they had had few or no technology experiences at EWU, they had had a bad technology class or two, or they had a lack of computer experience. Again, this mirrored what we suspected, and implications of this will be discussed below.

Other comments that came up in Question 4 or throughout the survey included 5 students mentioning the use of iBooks® instead of PCs as an inhibiting factor, and 7 mentioning time as a factor making the integration of the technology difficult. The relatively low number of students complaining about the iBooks® was something of a surprise for us, as this was an issue that came up repeatedly in class.

Recommendations & Conclusions

We were frustrated with the number of students who saw little or no connection between the technology and the curriculum. Several possible factors may account for this. Responses indicated that two of
the students may not have understood the purpose of the course as stated in the course objectives in the syllabus. Additionally, some students who liked the technology but saw no fit, gave responses that indicated that they did see some connection, if not in the course, at least in their future classroom practice.

But finally we must conclude that one suggestion for those integrating technology projects into methods courses is to make this connection explicit. In EDUC 410, student-centered reading methods were read about, discussed and modeled. While we would prefer to leave the students free to choose their own WebQuest topic, in the future we may instead require one of these methods be incorporated into their WebQuest plan.

In contrast to the responses to Question 1, we were heartened that so many students felt the technology was a valuable addition and would like to see similar projects integrated into other courses. However, for those instructors who know their students may be lacking in technology skills and experience, less intensive projects may be a better way to start. A WebQuest requires considerable time: learning about them, planning, researching appropriate sites, and learning web page creation skills. This is quite a lot to ask of students who may be barely computer literate.

Regarding time, a factor specific to this class was the quarter system that the university follows. Classes are only eleven weeks, and because of vacation and weather there were only 9 required meetings. In this light, the accomplishments of the students are even more impressive. We felt this was a valid project that related directly to the course goals and content, and feel the resulting WebQuests were in large measure very good first efforts given the time and technology constraints. However, student concerns over the time involved and the dominance this project took during the last part of the course must be taken into account in future planning.

While the students had mixed opinions on how well the technology fit with the course content, the authors felt this connection was made. Suggestions for others interested in implementing similar projects include gaining knowledge of the technology abilities of students, being aware of the time required for intensive, innovative technology projects, and making explicit connections between the course curriculum and the technology project.

Teacher education programs need to do a better job of preparing new teachers who can use technology in effective, innovative ways in their classrooms. For this to happen, the technology must be integrated into the methods courses teacher candidates take, so that they have practice using technology with the subject matter they will be teaching. By integrating the use and design of WebQuests into a reading methods course for elementary reading majors, the students in this class had the opportunity to learn technology, use technology for a specific educational purpose, and make a technology-based product that may be useful to them in the K-12 classroom.

Change Continues as UAA School of Education Moves Forward

Ann McCoy, University of Alaska Anchorage, US

During the second year of a PT3 Implementation Grant, we are continuing our work with integration of technology into our teacher preparation programs. In addition, as a result of our Title II Partnership for Teacher Enhancement grant we have been redesigning our teacher education program. The PT3 grant support this effort. Big changes are occurring including the addition of new faculty, the development of several new teacher education programs, and the restructuring of our school.

Our PT3 grant addresses four specific goal areas: Program Development, Faculty Development, Student Development, and K-12 Partnerships. They are part of a systemic change in teacher education and linked to each other and to other projects and programs within the SOE. These are the goals of the PT3 grant.

STUDENT DEVELOPMENT: SOE GRADUATES will be well prepared, technology proficient educators.

FACULTY DEVELOPMENT: SCHOOL OF EDUCATION AND CONTENT AREA FACULTY will be knowledgeable about current practice related to the use of computers and technology and integrate them in their teaching and scholarship.

PROGRAM DEVELOPMENT: SCHOOL OF EDUCATION PRESERVICE TEACHER EDUCATION PROGRAMS will reflect best practice including the integration and modeling of technology in all courses, using distance technologies to erase the differences between urban campus-based and rural programs.

K-12 PARTNERSHIPS: SCHOOL DISTRICTS WILL BECOME FULL PARTNERS in new teacher preparation through mentor teachers modeling best practice supporting pre-service year-long internships and shared training activities.

Changes continue to occur at our university. New faculty are joining our ranks and new programs are being developed and implemented. A panel of university faculty will interact with the audience as they share their experiences on lessons learned and the continuous assessment that is occurring during this period of change.
Abstract. The University of Texas at San Antonio's Preparing Tomorrow's Teachers to Use Technology (PT3) project uses a collaborative approach designed to achieve systemic change resulting in an improved teacher preparation program. The Tech*Connect Project engages university faculty, pre-service teachers, and field-based supervisors in joint activities that deliberate issues related to teaching with and about technology. Most members of the target population are below the level of "early technology" proficiency. The project goal is to establish a fundamental level of understanding about appropriate practices in technology use across learning populations. This model program aligns the teacher certification curriculum with state-mandated content and technology standards and infuses technology into field-based experiences in partnership with local schools.

The increasingly presence and use of technology in PK-12 classrooms is in contradiction with teacher preparation programs that have historically provided insufficient training to enable practitioners to use technology effectively. Many teacher education programs tend to teach about technology rather than with technology. Such programs seldom provide many examples of faculty modeling how to teach with technology and give pre-service teachers little variety of technology experiences in their field experience classes. Often there is little quality control over the experiences they have because strategic planning for technology infusion has not occurred.

In response to these conditions, a recent study by the International Society for Technology in Education (ISTE), commissioned by the Milken Exchange (Moursand & Bielfeldt, 1999), recommends that: (1) technology should be integrated across the teacher preparation curriculum rather than limited to stand-alone courses; (2) institutional planning is required to integrate educational technology into teaching and learning; (3) increased opportunities should be provided for student teachers to use technology during field experiences; and (4) faculty should be given support and training so that they can model appropriate technology uses in their courses.

At the same time, evidence indicates that many university faculty members involved in teacher preparation have little proficiency in technology use themselves. Moore (1991) believes that a critical difference in the ability to adopt technology exists between those who know what technology can do and use it and those who do not like to take risks, but are willing to have someone or something prove to them that the risk is worthwhile. The "chasm" between these two groups, as Moore calls it, accurately describes differences in attitude expressed by many University of Texas at San Antonio (UTSA) teacher education faculty. Although they may acknowledge that they need to incorporate technology into their teaching, models for its use and incentives to use it have not been readily available. In addition, many faculty members are unaware of resources available to them and, given their busy schedules, do not find time to seek them out. The way to achieve successful technology adoption, according to Moore, is to combine faculty and pre-service teachers in situations designed to create an irresistible reason to adopt technology. He suggests that such situations should make learning easier, more productive, or more enjoyable.

Other studies show that getting faculty to use technology not only takes access, but also involves developing a variety of strategies to offer support for faculty while they are training to use it. Brown, Demao, Forsyth, Godwin-Jones, Keller, Pelfrey, Price, and Shumard have identified five components of successful professional development to achieve technology infusion, including:

- **Collaborative mentoring**: coordinating the development of small, cooperative learning networks centered around "early adopters" who will act as mentors;
• **Networking:** creating a network of interconnected faculty interested in teaching and technology through email and other technologies;

• **Structured training:** offering faculty specialized learning experiences that are carefully designed to fit their unique needs as learners;

• **Model projects:** supporting projects by faculty that will encourage the dissemination of technology innovations to less-skilled faculty;

• **Consultation:** offering specialized technical support to faculty on demand

Cooley and Johnson (2000) indicate that successful professional development must overcome barriers such as lack of support, incentives and rewards, and just-in-time training, as well as respond to faculty perceptions of infringement on academic freedom. The dynamic nature of technology development necessitates a culture that supports continual learning and provides immediate access to resources for improvement and a greater likelihood of success.

The 21st Century Workforce Commission concludes that the current and future health of America’s 21st Century Economy depends directly on how broadly and deeply Americans reach a new level of literacy that includes strong academic skills, thinking, reasoning, teamwork skills, and proficiency in using technology. Both university faculty and pre-service teachers acknowledge the lack of systemic requirements to demonstrate technology proficiencies in teacher preparation programs. Willis (2001) notes that in efforts to reform programs effectively, all stakeholders must be engaged in determining needs and processes and strategies must reflect the nature of the populations to be served. In response to this need, the UTSA Tech*Connect project represents a systemic response to the national call by the U.S. Department of Education for increased technology training in teacher preparation programs.

**Project Overview**

The Tech*Connect project represents the combined resources of UTSA, corporate and nonprofit educational institutions, and three local school districts and will target pre-service teachers, and UTSA teacher education faculty members. The project seeks to help participants acquire the skills to build effective technology applications in PK-8 learning environments and model technology practices that augment learning.

Tech*Connect activities were derived from a needs assessment that indicated what the service populations both wanted and needed. Program activities are divided into four components: program improvement, training, support and communication and dissemination.

Program Improvement is a major project activity and is on-going. To ensure that all teachers certified through UTSA leave the program with appropriate technology skills, successful technology infusion must occur in all teacher preparation program areas. This process will be implemented by making structural changes to incorporate technology standards, beginning with the courses in the certification programs used to prepare teachers for positions in Early Childhood through grade 8 (monolingual and bilingual). The process of program improvement involves systematic analysis of existing course syllabi for (a) current applications of technology and (b) logical infusion of the Texas State Board of Educator Certification beginning teacher technology standards. Tech*Connect consultants who are knowledgeable in technology-based pedagogy work with each of the teacher preparation program areas: early childhood/elementary; instructional technology, secondary, and special education. The consultants analyze syllabi, interview instructors and make a variety of suggestions about how standards can most appropriately be integrated into specific courses. Program area facilitators then work with course instructors to devise most appropriate activities for content. Once standards have been assigned to all course and activities finalized, Tech*Connect staff work with individual faculty for one-on-one training and support as well as make themselves available for demonstrating and modeling technology in actual class meetings.

Training is the second and most pervasive project activity. Faculty profiles serve as a baseline for individual faculty development over the grant period and serve as a map for Tech*Connect initiatives. Training is offered in a variety of venues to provide a smorgasbord of choices that can best meet the needs and wants of the population being served.

A main training activity involves cohorts of preservice teachers, faculty and field-based supervisors as they participate in a year-long course based on Southwest Educational Development Laboratory’s *Active Learning with Technology* curriculum. Preservice teachers are placed with field-based teachers for one year in their last semester of coursework followed by a semester of student teaching. Training is conducted in district computer labs and technology-supported classrooms to provide an authentic learning environment and trainees will be allowed to use campus equipment for the training. Since the training spans two semesters, participants have the opportunity to reflect upon, practice, and master the skills they have acquired in actual classroom situations.

There are many other opportunities for the project community to participate in training. Cutting edge technologies are demonstrated from sole source vendors such as Apple, Casio, LeapFrog, and Lexia. Additionally, project participants may attend videoconferences on topics of relevance to courses, attend small group training sessions, or utilize Star Online tutorials. The UTSA Teaching and Learning Center offers sessions in which faculty from across the university demonstrate technology-assisted lessons, allowing COEHD faculty to experience what it is like to be learners in college level courses in which technology is effectively used. The session presenters are recruited from non-education disciplines, including art, math, science, humanities, and business.

A third program activity is Mentoring and Support. Tech*Connect provides just-in-time learning and optional support services to UTSA faculty and field-based supervisors. We know that without supports that provide one-on-one and timely services, educators are less likely to adopt technology into their practice. These activities will include: technology mentoring by undergraduate students, just-in-time support, inter-district activities and demonstrations, specialized training upon request, and Tech*Connect Technology Kits that can be checked out for use by project partners.
The final project activity is Communication and Dissemination. To support individualized learning through anywhere, anytime access to resources, the project provides 1) videoconferencing, and 2) a Web site designed to meet the specific needs of consortium members. The Tech*Connect Web Site is being developed in stages beginning with focus groups to discuss needs and wants for online resources and tools. Eventually, online resources will include a comprehensive database that will facilitate the location of resources of interest to preservice teachers, UTSA faculty, and field-based supervisors.

The first year of the Tech*Connect implementation has inspired much support and excitement in the project community. The project activities evolve when initial plans do not work out in reality as they were intended and with reflection and determination new strategies are uncovered. For example, project consultants “adopt-a-class” and work with faculty to analyze their current practices and devise effective ways to integrate technology supported student activities. Consultants and graduate students then attend class sessions and support technology activities or model appropriate practices. In this way, preservice teachers get hands-on experiences while faculty learn how and when to use technology within the context of their own classroom. Approaching technology training from the needs and wants of target populations promises success and sustained momentum for the continued development of a technology savvy group of educators.

Abstract: Currently, the main focus of PT3 funded projects across the country is the meaningful integration of technology into the teacher preparation classroom settings. One component of the PT3 grant project at the University of Houston is that pre-service teachers experience educational applications of technology through a series of three educational technology courses prior to entering the classroom. While we recognize that this step is necessary, we know we must look further to enrich our students' learning experiences. Allowing the PT3 team to use technology tools to bring the school experience to our on-campus students is a continuing building process. As part of this process, the PT3 team has established a Virtual Classroom (VC) committee. The sole purpose of the committee is to come up with various ways in which video cameras can be used to enhance learning.

Introduction

Pre-service teachers at University of Houston have many opportunities to utilize technology while they are completing their coursework; however it is difficult for these students to obtain a full understanding of how technology can realistically assist them in a classroom environment. An idea that piqued our interest was to videotape actual educators demonstrating exemplary integration of technology, using the applications that are included in the undergraduate educational technology courses. These are the same applications that the pre-service teachers are expected to explore as classroom tools. This idea is being explored by the PT3 Virtual Classroom committee at both the local and community level.

Local Beginnings

Before approaching the learning community outside the PT3 grant, the Virtual Classroom committee decided to take advantage of the resources already available on campus. While not representative of the k-12 student populations, the preservice technology classes provide a valid educational setting for exploring the potential of videotaped technology-rich lessons. In this learning-conducive environment, the VC committee set out to videotape technological interaction in our own preservice classrooms. Technology-enhanced lessons were prepared by the tech fellows for each content area and demonstrated to the preservice students during the videotaping. Team members collaborated in the planning, videotaping, and final editing. The purpose of taping our own team was twofold: to create technology-rich demonstration videotapes, and to go prototype the entire process before moving into local schools. We plan on extending the number of these university classroom examples as well as continuing with the plan for k-12 campus lessons to show exemplary integration to future pre-service teachers.
Community Plans

The main goal of this project is to provide students with a model of how to teach specific content area with technology rather than just how to use technology (Francis-Pelton, Farragher, & Riecken 2000). The first step is to acquire the assistance of community educators who are willing to demonstrate classroom techniques for videotaping. The VC team will conduct the videotaping in the teacher’s regular classroom to preserve normal interaction, as much as possible. Teacher demonstration and student response will be included in the videotaping.

When all of the shooting for the video is completed on location in the schools, the VC team will then edit the video to an appropriate presentation length and format. Once they are integrated into our method courses, the videos will allow pre-service students to observe how integration of technological applications is actually being utilized by educators. In addition, pre-service teachers will note the difference between teachers who use computers in traditional ways and those that use it as a tool to solve problems or improve students’ critical thinking (Yildirim, 2000). It will give the students a sense that they can make technology work when they move into the classroom.

Videotaping exemplary use of technological integration in a classroom setting will also provide a chance for pre-service students to examine samples of student involvement and reaction. Pre-service teachers will have an opportunity to view multiple tapes and can compare and contrast the differences that they see regarding student behavior. In addition, Preservice teachers also need opportunities to examine learning under different instructional conditions if they are to understand the relationships among teaching and learning (Neiderhauser, Salem, & Fields, 1999). Again, the videotapes will provide an opportunity for pre-service teachers to observe circumstances where students are engaged and learning is enhanced due to technology integration.

Conclusion

Through observations, students may be able to acquire some excellent strategies for use within their own classrooms when it is time for them to make the transition. The opportunity to view a variety of classroom integration techniques will provide a foundation for the effective use of technology in the classroom.

Abstract: This session describes the dissemination of PT3 Grant – Project Mimic on the Baldwin-Wallace College campus. The Collaboration of the Americas expands the MIMIC model through the use of desktop videoconferencing as well as into Internet 2 for distance mentoring....whether that is from within US (university to university) and/or in collaboration with foreign colleges and universities, (Argentina and Chile). This session will discuss the progress made in the use of desktop videoconferencing, streaming of musical concerts, tutoring and the use of Internete2 for videoconferencing.

Introduction

The Collaboration of the Americas grew out of the original PT3 Project MIMIC grant. Project MIMIC's addresses the problem that only a small number of higher education faculty in this country actually model good practice integration of technology for pre-service teacher education. Few education students encounter experiences and role models that will prepare them to create and support technology-rich classrooms. To address this, the MIMIC Project provides technology mentoring for higher education faculty so faculty can, in-turn, and appropriately model current educational technology.

The Collaboration of the Americas expands the MIMIC model through the use of desktop videoconferencing as well as into Internet 2 for distance mentoring....whether that is from within US (university to university) and/or in collaboration with foreign colleges and universities, (Argentina and Chile).

Collaboration of the America’s Project

The project has expanded into three sub-projects:

- One education faculty member is a MIMIC participant working in the area of early childhood teacher preparation. She will have a mentor who is a current 3rd grade teacher in a local school district. Her mentor is also finishing her Master’s Degree in Educational Technology this spring. In addition to these two folks working together, a third tutor is being arranged at a distant University and the plan is to connect these people via Internet2 with distance videoconferencing. This professor works in the area of educational technology but is also interested in early childhood computer literacy. Most of this project will be involved with the software iVisit and NetMeeting.

- Two professors from the Instituto Superior de Formacion in Patagonia, Argentina, have formed a collaboration with Baldwin-Wallace College for Spanish audio files in exchange for technology skills for their teachers in training. Where videoconferencing will take place with this project the use of the software iVisit and NetMeeting will be the software of choice. The goals of this project are:
  - to actively collaborate with other teachers in a distant environment via email, discussion board, virtual classroom and hopefully live teleconference (iVisit and NetMeeting) on various teacher classroom methods. In the past the professors have used chatrooms with their students located throughout the country. We are planning the extension of these chatrooms to both audio and video (conferencing and streaming) file exchange.
  - to receive, from Argentina, Spanish audio files (male, female, teenager, different dialects) to assist our Spanish Department on the Baldwin-Wallace College campus in helping future Spanish K-12 teachers. (This is a problem we are experiencing on our campus with the PRAXIS II language test).
  - to actively assist the Argentina teachers in the English as a Second language classes in developing comfort in the use of educational technology in their classroom environment. This will include the use of all parts of Blackboard as well as some CALL (Computer Assisted Language Learning).
  - to achieve cross-cultural pollination of teaching methods and ideas as well as other cultural variations between our two countries.
A BW music education faculty member has been fortunate to be involved in three Artist Residencies sponsored through the Ohio Arts Council and the Chilean North American Cultural Institute in Chile, South America. Her target projects have been focused in the Chilean cities of Copiapo and La Serena.

- Her work in Copiapo has been at the Liceo Experimental de Musica de Copiapo which is a grade three through twelve school of the arts in the middle of the Atacama Desert. The Chilean government has declared this Liceo as the model arts school for the country in the development of curriculum, scheduling and programming. Her residencies there have been multifaceted. In addition to guest conducting the bands, orchestras and choirs, she have been charged with assessing and evaluating all perspectives of the school from teacher and student performance in the classroom to scheduling, materials, teacher education, inventory and the coordination of the writing of the National Chilean Music Education Curriculum. It is her hope that the development of her technology skills will enable her to develop a web site that will support sharing web stream broadcasts of quality teaching and performance examples and professional development information. Through the use of video conferencing, she hopes to be able to maintain an ongoing dialogue throughout the year so that she is able to support her Chilean colleagues on a daily basis as they work to further music education in their country.

- Her second project is in La Serena, Chile, at the Universidad de La Serena and Escuela Experimental de Musica "Jorge Pena Hen." This past August, she spent a week at the University de La Serena leading the "Encuentro de Directores de Bandas de Concierto Escuelas Artisticas del Norte Chileno." This was a weeklong convention for all of the band directors in the north of Chile. She presented clinics on numerous subjects such as conducting, rehearsal techniques, repertoire, and singing in the instrumental classroom. This was the first time that an event of this type had been presented in Chile and the first time that these thirty music educators had ever met! It was an extraordinarily successful event that ended with a commitment on the part of the teachers to attend every year. The opportunity presented itself to start the very first Chilean Music Education Association. She is committed to working with these dedicated music educators to help them continue their professional growth through the year. She hopes to experiment with distance learning through the use of Internet2, video conferencing and web stream broadcasting to share what she can with her new colleagues.

- Time during the visitation to the BW campus in January by the Universidad de La Serena and Escuela Experimental de Musica participants will be used to train them in desktop video teleconferencing software as well as in Real Producer and file transfer for streaming their future concerts. On Feb. 22nd BW will stream a live concert especially for these two intuitions. This is in preparation for their institution doing a stream back to BW. This maintains the dialogue of the instructors involved in the collaboration from the conferencing and the performance level.

- Final exchange of dialogue and conferencing will take place this academic year over Internet 2. On October 2, 2001 the authors and this music educator participated in the Internet 2 Megaconference where we explained how Baldwin-Wallace would be using this technology to further enhance this cultural exchange experience. Questions we fielded from colleges and universities around the world on the approach to our campus wide approach to experimental foreign study.

We at Baldwin-Wallace College, Division of Education have attempted to disseminate the goals and object of Project MIMIC beyond the scope of the original grant. Our purpose is to further experiment with the new frontiers of Internet 2 and the use of desktop videoconferencing to enhance the tutorial process.

Abstract: The faculty of the NC State College of Education (CED) is in the process of transforming its organizational culture to better support educators as they deal with a changing technological landscape. We are developing and refining a model for change that will help twenty-first century teachers understand both the use and the potential of instructional technologies. Our panel (comprised of the CED Dean, the IT Director, and four CED faculty members) will describe the creation of a fertile landscape for change within our college that has resulted, in part, from our PT3 Grant, MentorNet. We believe there is a direct
relationship between identifying the force vectors of our model and building order out of what, at times, appears to be organizational chaos.

Introduction

Twenty-first century teachers face challenges that stretch beyond what was expected of their counterparts only a few decades ago. It is now necessary for teachers to develop a critical understanding of the use and potential of instructional technologies along with a lifelong capacity to refine that understanding in the face of ongoing technological innovations. Simultaneously, today's teachers must blend these innovations with rapidly changing class content. Finally, and perhaps most importantly, they must cultivate a similar capacity to accommodate to change in their students. With all of this in mind, the faculty of the NC State College of Education is transforming its organizational culture to better support teachers as they grapple with education's changing technological landscape. As we articulate our evolving model for change, we hope to turn a lens on ourselves to better examine what we are about so that we can provide experiential information to colleagues attempting similar transformations. We believe there is a direct relationship between identifying the force vectors of our model and building order out of what, at times, appears to be organizational chaos (Fullan, 2001). These vectors include relationships and collaborations, autonomy and individual degrees of freedom for programs and faculty in approaching our vision, participatory information interpretation and creation or the organization members, and openness to energy changes.

In an effort to describe the creation of a fertile landscape for change within the NC State College of Education (CED), we present the perspectives of the CED College Dean, the CED IT Director, and four of our CED faculty members. The creation of our new landscape is, in part, a result of our PT3 grant, MentorNet (Preparing Tomorrow's Teachers to Use Technology, U.S. Department of Education).

Leadership through Collaboration

The administration of a college of education must make choices about the leadership framework it will use. At NC State's CED, we have chosen a culture of collaboration that includes visioning, building organizational capacity, and sustaining strong yet flexible programs. First, we identified relationships as a force vector in our change model to be a source of strength in the midst of change. It is important to examine the structures that support these relationships. Relationships between faculty in the same departments, across departments, and within the wider university are key factors in the implementation of change. Collaboration releases excitement and energy that can be a primary source of creativity for new work. Our PT3 grant pushed us to work in teams of faculty from three of our college departments. Arts and science faculty joined with teacher preparation faculty from neighboring institutions to forge new ways of teaching in technology-enabled environments. For these partnerships and relationships to work and make sense we need information and interpretations to come from a wide group of constituents. These include recognized experts in technology and learning, research support, publications by our faculty, and invited presentations from professional associations (Berger, Casey, Belzer, & Voss, 1994; National Middle School Association, 2001).

Our second identified force vector is degrees of freedom in approaching the organization's vision. The vision for an organization focused on such relationships needs to involve everyone and be a strand (or force vector) that works throughout the college. The NC State CED vision states: "The College of Education is committed to being a leader and innovator in research, application and dissemination of effective strategies for teaching and learning through technology-enabled environments with the ultimate aim of preparing educators who foster high achievement for all students." This vision is aligned with issues facing both our state and our nation as we prepare for the opportunities inherent in an emerging knowledge-age economy. This vision must be available to everyone in our college, whether they are in Adult and Community College Education, Educational Research and Leadership and Counselor Education, Mathematics, Science and Technology Education, or Curriculum and Instruction. When we allow for individual freedom in ways of approaching the vision, the overall identity of our organization will be sustained.

Our change model includes a third force vector, information interpretation and creation. To build ownership of our vision and its implications for future practice, we must share the information creation process with the people who will implement the vision. We firmly believe that the best way to prepare our students, tomorrow's classroom teachers,
is to create a climate that includes exemplary teaching with a variety of technologies and materials they will be expected to use when they graduate (Quinn & Valentine, 2001; Weller, 1996). This is a source of energy for doing work towards having all our faculty routinely work with cutting-edge technologies in their teaching and research.

The fourth force vector is openness to energy changes. We believe we have an opportunity to focus the power of current and emerging technologies to transform the way we teach and learn. But as Margaret Wheatley reminds us, the issues that trouble organizations most are chaos, order, control, autonomy, structure, information, participation, planning, and prediction (Wheatley, 1992). A college of education is not exempt from these issues. The NC State College of Education is setting forth on a path of change and transformation that will give our faculty the opportunity to innovate in the face of educational issues and challenges. By taking this opportunity to change, grow and remain open to energy changes, we plan to be a viable and dynamic system that will welcome the challenges of the future.

**Capacity Building through Adaptation and Adoption**

The introduction of technology into any organization -- whether it is business or education -- is directed in part by the dynamic forces of the potential of change through technology and the inertia of established practices (Bruce, 1993; Cuban, 1986). Successful integration of any new technology involves a number of changes (Casson et al., 1997). The process usually starts with a few early adopters who are willing to work on changing larger organizational attitudes towards the technology (Rogers, 1995). Change needs to happen in a number of ways to make this conversion successful. It means changes budgetary policy to make way for purchasing of the technology and setting up the infrastructure. It means budgetary and organizational change to make way for adequate service and support staff. And it means changes in work habits so that the technology is adapted and integrated into the mainstream activities of the organization. While businesses and educational institutions share this same basic evolutionary process, primary, secondary, and higher education all have unique characteristics that shape and influence the introduction of new technologies.

Through a slow evolution during the 1980's and 1990's, the College of Education at NC State University has grown from a single small lab of Apple IIe's to five labs each having between 15-25 student computers, computer-interfaced ('smart') marker boards, an instructor's computer, and a projector. These desktop computers -- both Macintosh and PCs -- are arranged in a variety of row configurations, with the instructor's computer at the front of the room. These labs are reserved for classes and otherwise available for open lab use. This computer resource model is not only typical of undergraduate education, it is also reflects the model used by many of the elementary and secondary schools in NC and the rest of the nation: classrooms with minimal computer infrastructure and a few (or one) fixed computer labs and media center.

Growth in computer facilities at the College of Education was hampered for many years by the lack of a continuing budget for computing resources. With computers treated as a capital expense, funding was low, uneven, and unreliable. The instituting of a university-wide student fee for computing meant both the establishment of a steady revenue stream and a larger change in organizational attitude that led to the funding of infrastructure improvements and paid support staff from other budgetary sources. Public schools in NC, however, continue to lack reliable funding sources in many counties, leading to uneven support for continued upgrades of computing technology and paid staff to maintain it.

Even with a generous level of funding for computer technology in the College of Education, integration into the core activities of the College continues to be an ongoing challenge. While administrative and research activities readily moved to the use of desktop computers for word processing, spreadsheet, and database management, integration into instructional activities has been slower. In institutions of higher education, the traditional lack of central authority means that this conversion typically happens one on one with individual faculty. There is the added fact that for most faculty there is no compelling and obvious reason why desktop computers would be particularly useful in a traditional classroom setting. Not surprisingly, the biggest use of the computer labs is by those instructors and curricula that were already heavily lab-based and teach activities centered on the development of computing skills. These same patterns can be seen played out in public schools for many of the same reasons.

Rapid advances in mobile computing technology has meant that laptop computers no longer are substantially more expensive with less computing power. Larger, higher quality screens, large hard drives and plug and play capabilities with numerous peripherals have made laptops near equal in quality to similarly priced desktop computers. Better battery life and wireless networking technology means that mobility no longer has significant disadvantages in these areas. While the technological hurdles for mobile computing has largely been overcome, the organizational barriers mentioned earlier are still there. Effective use of mobile computing means shifting from College-owned, fixed computer labs to student-owned, mobile computing. This shift means a change in budgeting that requires students to
come to school owning their own computers. Current College funding would then go into increased staff support, enhanced wireless networking, and more specialized computing peripherals. While the technical barriers for bringing computers into a traditional classroom setting have been largely removed, there is still the need to develop compelling models for how computing can be used in instructional settings other than traditional labs (e.g., Griffioen, Seales & Lummep Jr., 1999). Public schools, which has never been able to fully fund traditional computer labs and an adequately trained staff, face stiff hurdles in adopting new mobile computing technologies. Unlike institutions of higher education, they cannot mandate that students purchase laptop computers. They also have weaker networking infrastructure to build upon and less paid technical staff available for support.

Many of these issues came into play in a pilot project with sophomore and senior science education students the author participated in. These classes made use of wireless networked laptop computers owned by the College and brought into the class on a daily basis on a specially designed cart. The students were instructed on how animated graphics could be used to support science instruction. Students then created their own animations using Flash software for use in clinical teaching experiences out in secondary schools.

Because the students did not own their own laptops, the process of bringing the laptop cart down to the classroom, setting it up and having students take and set up their computers used up valuable time in the classroom. The use of laptops without a full range of removable media options also added to the difficulties of transferring files to the computers at the beginning of class. While the instructors of the class had considerable experience in teaching in traditional computer labs, there were many lessons learned about the instructional possibilities when computers are no longer rigidly fixed and dominating the classroom environment. These changes altered the ebb and flow between whole class instruction and individual work and the interactions between instructors and individual students and pairs and triads of students working together.

When it came time for students to take their projects out to their sponsoring secondary school, there were a number of factors that complicated their novice teaching experiences (Parkinson, 1998). The lack of computing infrastructure at the sponsoring schools made it mandatory students bring the College’s laptops out to the schools for their lesson. While many schools had a projector the students were supposed to be able to use, access issues often made it difficult for the sponsoring teacher to borrow the projector for the presentation. Students who were already nervous about teaching their lesson now had the added burden of setting up and troubleshooting a laptop and projector in a classroom where the sponsoring teacher often had little experience with this equipment. In some classrooms, there was the added difficulty that the sponsoring teacher was either indifferent or mildly hostile to the use of computing technology in his or her classroom.

As with desktop computing, the integration of mobile computing into institutions of higher education will be a long-term evolution (Carlson, 2001). While computing is well established in many aspects of college and university life, faculty will need to be convinced on a one-on-one basis that mobile computing can be an effective tool in both the classroom and the lab. Colleges of education have the added burden of helping to facilitate the integration and coordination of this technology into both its institution and in the primary and secondary schools. Reflection and lessons learned from the integration of desktop computing into organizations will provide valuable guidance as we move through the integration of this new generation of technology.

Creating a Collective Faculty Research Agenda

Research initiatives within the CED faculty are varied, reflecting a wide range of professional contributions and interests. Currently, approximately 35% of the faculty are engaged in research involving some aspect of the impact of instructional technology on education. These CED research agendas are aligned predominantly with specific discipline areas; however, collaborative, interdisciplinary research teams are emerging. For example, a team of faculty from three discipline areas, (i.e., social studies, science, and IT) within the College are studying the use of GIS on student learning. Additionally, a team of educators from three separate schools, (i.e., Computer Science, Design, and Education) are teaming to examine the effects of animated pedagogical agents on science and literacy learning. As our research agenda evolves and as we continue to build our College infrastructure for external funding, we anticipate that our capacity to support more complex interdisciplinary research agendas will increase.

In an attempt to recognize existing research on instructional technology within our College, we have synthesized particular lines of inquiry into the following broad-based questions.

- How can instructional technologies lead to students' understandings of math and science concepts? (Specific lines of inquiry include: scientific visualization, geometric and algebraic transformations, probability software, web tutorials for environmental science, animated pedagogical agents for botany concepts, technology beliefs and practices of math educators (Berger, et al, 1994; Weller, 1996).)
• How can instructional technologies enhance reading and language arts teaching and learning? (Specific lines of inquiry include: developing phonological awareness through computer software, technology infusion in LA methods classes and teacher prep programs, literacy and web-based instruction, animated pedagogical agents for narrative learning.)
• How can instructional technologies enhance the school counseling process? (Specific lines of inquiry include: research and development on Career Key, a web-based career counseling tool [English and Chinese translation]; IT and elementary and middle school counseling.)
• How do new IT pedagogies enhance the learning of culturally, economically, and academically diverse students?
• How can instructional technologies enhance Technology Education? (Specific lines of inquiry include: Internet learning systems, spatial visualizations, and computer-aided drawing and assessment.)
• How can middle school teaching and learning be augmented through a technology-enabled curriculum integration model (National Middle School Association, 2001)?

Synthesizing the current research within our College serves a twofold purpose: 1) to recognize, articulate, and validate strands of current and projected research interests, and 2) to use this existing research platform as a catalyst for developing a more synergistic community of researchers. We believe that moving from disparate, individual lines of inquiry to a unified, college-wide research agenda has the potential to enact a sense of collective human agency. Such agency through community building can create what Sergiovanni (1994) refers to as "a community mind," which exists when people feel connected to each other and work together for common goals.

Our goal is to create research-based models that lead to instructional practices that address both the efficacy of technology-enabled environments for teaching and learning and critically examine the impact of emerging technologies on contemporary educational practice. Ultimately, such a goal has the potential to yield a more equitable and excellent education for all children.

Facilitating Technological Change in the Classroom

Two CED faculty members have been caught up in the transformations that go along with technological innovations, changing class content, and change in students. We present their stories as examplars of reflective practice by faculty members within our changing organizational climate.

Middle School Teacher Preparation

At times my efforts to integrate technology in my own teaching career, infuse it in the courses that I teach in middle grades teacher education and balance its use with what I know to be good teaching and learning practices for students, has me flying by the seat of my pants. I seem to be always in a state of development, designing and implementing lessons and projects with my colleagues and students that finish with a BANG, after having grown like Topsy during implementation.

Teacher education in a technology enabled environment is dynamic, exciting and places you in a continuous state of flux. When you are in the thick of discovery you and the students move from one “Ah ha” moment to the next. Like any good teaching, you learn as much as you teach, that is if you can stop the action research long enough to do the necessary follow-up reflection. Ask me where I am going with my curriculum development and the signpost on the MASH television show springs to mind, arrows pointing in every direction. Recently, I paused to examine what my students, colleagues and I had accomplished. I knew we weren’t off course, but we needed to determine which of the many courses we were on was proving to be the most valuable for our teaching and learning. Here’s what I found:

• an early case study using my undergraduate Foundations of Middle Level Education class showed that students felt better about learning and using technology if a risk free environment existed in the classroom, if there was an abundance of user friendly technology support staff to trouble-shoot and help students and if the project in which they engaged was meaningful and allowed them to work in partner teams to develop collaborative websites.

• a service learning curriculum integration project replete with GIS, PowerPoint, internet research, spread sheets, streaming video and digital photography that was undertaken with preservice teachers and a team of eighth
graders and their teachers was rich beyond belief because of the opportunities technology enabled. Students addressed important community issues, researched environmental problems, all while teachers orchestrated differentiated instruction opportunities that were a click away with the mouse. The project was showcased at a university symposium. Spit and polished eighth graders who were dressed for success "taught" an audience of doctorates and Deans how the bonds of class-bound lessons can be broken with the use of technology. Later, the project became a "how-to"model for using curriculum integration in a technology enabled environment. It was featured in a website built by graduate education students to promote curriculum integration as a teaching and learning approach that best meets the needs of early adolescents. Amazingly, by logging on to technology we had spiraled our curriculum work across two semesters and 130 learners.

- a virtual field trip lesson that started small as an after-the-fact website about a real trip to Russia, actually prompted a return trip during which student teachers journaled back in real time from Russia to their students and colleagues. This follow-up trip activity was so popular with scores of teachers and students, that the project has now grown into a technology enhanced year-long study of Russia. The project, dubbed Russia NC-6, will culminate with a virtual field trip for thousands who will be able to participate because technology will enable them to make the trip to Russia with us. Our traveling university research team will interview and gather research about questions asked by the sixth graders. We will send back information and digital pictures to supplement the sixth graders home-based research efforts. The research team will be examining the effectiveness of teaching using curriculum integration in a technology enabled environment.

These are a few of the examples that show that some of the best teaching and learning in a technology enabled environment demands flexibility, imagination and the ability to be a risk taker. My colleagues and I have found that you might not be able to always chart a straight course, but with technology you can go anywhere.

Social Studies Teacher Preparation

Driven by a new technology portfolio requirement for initial teacher licensure, methods classes for social studies—already pressed for time—now expanded to include a computer lab component. Over the three years that the requirement has been in effect, we have responded by creating a computer lab component in Social Studies Methods. Based in an undergraduate fall course divided into two main components; the first eight weeks of Methods and the second eight weeks of full time student teaching, a Friday computer lab has become an exciting component. I do not use the term exciting lightly—students are happily attending a 3:30-5:30 computer lab session. The hours are strange, but that was originally when the lab was free, and oddly enough, it’s a time that has stuck and become very workable.

We designed modules and tutorials to set students onto tasks that were directly related to their student teaching practica. As a former Social Studies teacher who often used the computer lab (even in the 80s), this was not a foreign concept, and for future Social Studies teachers, computer integration cannot be. I describe this approach as expanding the landscapes of learning; that is, expanding to other parts of the school building, of the world (virtually) and into the greater community. The landscapes of teaching Social Studies should be broad, not isolated. The Internet helps to facilitate that expansion.

While I am expanding the landscapes, however, the time constraints remain the same, so the labs I designed had to be extremely time efficient. The syllabus includes: searching for lesson plans, WebQuests, Power Point, constructing class Web sites, and building a technology teaching portfolio. After the second week of the computer lab sessions, I asked students to reflect on their learning about instructional technology integration. Some of their comments are very telling about the level at which they had ever considered integrating technology into their teaching practice. This should be prefaced by the fact that this particular undergraduate program is housed not in the College of Education, but in the College of Humanities and Social Science. Students take their ‘professional’ education classes in our college, but for the most part are educated as History department majors. These comments come from a group of thirteen students, ten of whom were placed in practicum settings. Most of the students were unfamiliar with the concept of a Boolean search. Our first lesson was how to find teaching resources on the web to support Social Studies topics.

“Prior to this class I was still somewhat [computer] illiterate ...I have learned how to set up a webquest, which is pretty amazing to me and is baffling to my parents ...I have not seen a lesson that directly brought the kids into a lab [at my practicum site]”*

“ I found out about lesson plans, student activities, role plays, simulations and webquests in my two lab sessions.”

“I've only had one lab session so far, but already I came out of it with a little more confidence about where on the web I can find SS lesson plans, info, databases, etc...It's nice to know with google, PBS, etc that I can pull up
opinion pieces or factual info ad nauseam. I also learned how to pull up two pages at the same time and how to cut and paste websites [URLs into a webquest]."

"I had no training in incorporating technology into a class...what have I learned? How to build a web page for a class."

"I’ve learned several good methods of searching for good activities & lesson plans on the net...The webquest using Filamentality really helped me get a strong idea of how to build a web page that will contain several web pages with the same major content area ... The only SSIT that I have seen in my setting is the showing of a video." [x 6 students]*

"I feel I have learned so much about technology in the few sessions we have had so far. First, I never knew lesson plans could be found on the internet...The webquest was a new animal to me as well...This is wonderful because teachers can construct such great assignments using new technology."

These comments typify those from the remainder of the group. The two respondents * asterisked presented technology portfolio products to a group of professional IT educators in a partnership (MentorNet, PT3) workshop after five weeks of computer lab sessions. All of the students presented their technology portfolios at a reception at the end of their eight weeks of student teaching and each had implemented at least one of the products into their practice during those eight weeks.

**Conclusion**

We have explored solutions to complex challenges related to organizational and technological changes. This exploration and examination is an ongoing process. The vectors for technological change include the relationships and collaboration between faculty, the autonomy and individual degrees of freedom for programs and faculty in approaching our vision, participatory information and interpretation of the organization members, and openness to energy changes. Our leadership framework is based on a culture of collaboration that includes visioning, building organizational capacity, and sustaining strong yet flexible programs. We are continuing to build technological capacity through adaptation and adoption. Creating a collective research agenda will help create community and enhance the participatory nature of information in our organization. All of this cultural change will require faculty members who are open to energy changes in the system and will do the reflecting and growing necessary to build from the chaos.

Electronic Mentoring of Career-change, Adult Learners in Pre-service Teacher Training

Maryanne Murach
Consultant & Lead Researcher
Upper Valley Teacher Institute
United States
Maryannem@mediaone.net

Abstract: This paper discusses whether electronic mentoring is a viable method of providing collegial support and guided reflection for career-change, adult learners during their pre-service teacher training internships. These interns spend the majority of their time isolated from their peers, their supervisors and their faculty as a result of program design and geography of the region. The paper covers literature review, methodology, obstacles encountered, and project results.

Introduction

The Upper Valley Teacher Institute (UVTI) specializes in preparing mature, well-educated people from other professions to teach, and develops strong collegial support for teachers so that they will remain in the profession. UVTI reverses the percentage of time typically allotted to academic theory and classroom practice. In the pre-service training program, each intern works full-time in a classroom under the supervision of a 'best practice' professional teacher chosen from several states. This practical experience is reinforced by weekly seminars and support from UVTI supervisors, who are highly, experienced educators.

At the end of the 10-month training period, graduates have demonstrated competency in all of the areas covered in conventional academic programs, and they have also acquired a full year of teaching experience. UVTI's geographical location and unique weather patterns make it very difficult for supervisors to meet with interns more than once every 10 days. Also, the internships are conducted at schools that span three states. The purpose of this study was to determine if electronic mentoring by supervisors and peers improves the practicum experience of career-change adult learners during their pre-service teacher training.

The literature review focused on three main areas: computer-mediated communication and email, teacher isolation and adult learning, and mentoring pre-service teachers. The conclusion was that technology now exists to facilitate communication across geographical distances. Even though adults may be intimidated initially, many are eager to learn these new methods of communication.

The methodology section covers how the supervisors were trained prior to being expected to use technology. It also covers some of the obstacles that needed to be overcome before a successful implementation could take place.

The results section focuses on positive aspects and developmental opportunities from the supervisor/mentor and the intern/mentee perspectives. This is followed by recommendations for next steps and overall conclusions regarding the appropriateness of technology use for teacher preparation.

Computer-mediated Communication and E-mail

According to Gresham (1994), the invisible college is a social network that operates informally through traditional methods of telephone conversations, postal mail, and print within an area of specialization, with contacts made through conferences and other forums. The informal network provides a forum for sharing new ideas and research through discussion and feedback. As a result of delays caused by publication processes in the formal presentation of ideas, these invisible colleges are frequently on the cutting edge of information in a given area of specialization. With the emergence of computers and the ease of networking, the invisible college moved to cyberspace through computer-mediated communication.

Computer-mediated communication brings us a step closer to the interactivity of face-to-face communication with the added benefit of permanency through textual communication. Gresham (1994) noted that the textual basis for e-conferencing coupled with the speed and interactivity of electronic communication created a hybrid form of communication known as media communication. Email is an asynchronous form of computer conferencing in which messages are transmitted instantaneously but recipients can read and respond to the message at their convenience. Scholars participating in electronic conferences care most about the content of the discussion, and are less concerned with the technology that supports it. However, it is the computer technology that makes this type of communication possible.
Teacher Isolation and Adult Learning

Teachers have been the primary information source and the solitary supervisors of their classrooms. They usually work alone behind the closed doors of their classrooms with little interaction with other teachers to plan, teach or evaluate together. Very little time is allowed during the day for such activities. Even during pre- and in-service teacher training, the emphasis is on bringing new content and/or pedagogy to individual teachers, which tends to reinforce a main factor in resistance to change, teacher isolation (Tye, 1999). For hundreds of years, the school organization has been hierarchical by design. Those at the top of the pyramid are the privileged, with power, prestige and access to information; while those at the bottom, traditionally teachers, have low pay, little prestige, and no formal autonomy. Once they accept a position, teachers are relegated to their classroom where they are expected to conform to directives given by central offices and be content to use the tools of their trade. Common to most classrooms are the blackboard, the overhead projector, and the duplicating machine which help the teacher maintain their position as an information authority while alleviating writing to allow time for class management, arbitration and supervision (Hodas, 1993).

Cultural changes are causing changes in classroom practice. Until recently, there has been little incentive to change. Unlike most bureaucracies, school systems reward time-in-grade and academic credentials rather than performance. Teachers and administrators with a need for authority feel they must appear competent to their students, and in the case of administrators, to their subordinates (Hodas, 1993). The widespread student use of home Personal Computers (PCs) and the Internet is forcing teachers to be interested in the technology. Students who have been weaned on technology expect their teachers to be comfortable using computers, networks, and databases with the same facility as they now use textbooks, chalk and blackboards (Hodas, 1993). Other factors are also operating to bring about change.

In response to national and state initiatives regarding standards and technology integration, the roles of teachers are changing. In order to raise the perception of teacher from nonprofessional, bureaucratic worker to 'professional' status, the teacher is now expected to function as a member of a team (McGe & Boyd, 1995). New behaviors involving collaboration, problem-solving, inquiry and general sharing are required, and a different type of professional development is needed to promote these behaviors. There is much more information that needs to be grasped and shared. Working across disciplines, like combining math and science, is becoming the norm. Many of these changes require the implementation of technology as an integral part of the teacher's toolkit. However, many entry-level teachers are not comfortable using technology because they fear either their own or their students' inability to correct errors (Rein, 1995).

Adult learners have different needs and learning styles than children. Malcolm Knowles popularized the term 'androgogy' and presented the basic principles for teaching adults. His model included:

1. Setting the climate so the environment is conducive to learning;
2. Involving the learner in the following tasks: planning the course design and learning activities, diagnosing their own learning needs, formulating their own learning objectives, designing their learning plans, and evaluating their learning (Lee, 1998, p. 47).

Knowles felt that the major distinction between adult learners and children was that life experiences, not teachers, were the main resource for learning (Lee, 1998). To elaborate on this view and further define how adults learn, Mezirow (1997) described transformative learning as the process of changing one's frame of reference. In order to achieve that type of transformation, educators must establish objectives that promote critical reflection and provide opportunity for discourse. Experiences that meet those requirements and involve group deliberation and problem-solving are described as "learner-centered, participatory and interactive " (Mezirow, 1997, p.8). Computer technology, including the internet and computer-mediated communication, are conducive to these types of learning and experiences.

Research regarding technology use by older learners indicates that first and foremost, they need experiences that will help them build their self-confidence and feel good about the experience (Timmermann, 1998). Some barriers that need to be considered, but are often easily remedied, include computer anxiety, embarrassment, slower response time, dexterity and physical discomfort. Once these hurdles are overcome and the basics have been mastered, the adult learners become empowered, partially because they have conquered a domain thought to belong only to the young (Timmermann, 1998). The opportunity to bridge two wide gaps: intergenerational and geographical distance, is a great motivator for older learners to use technology. According to Timmermann (1998), using electronic forms of
communication like e-mail allows contact with family and friends as frequently as the older adult learner would like, in their own time and at their own pace, without having to travel or incur large phone bills.

**Mentoring Pre-service Teachers**

Mentoring has successfully been used as an organizational and professional development tool to orient people to systems or cultures, provide leadership opportunities and support individual development. The origins of mentoring lie in Greek mythology, when Odysseus left his son's education to a friend and advisor named Mentor. Since that event over three thousand years ago, the concept has grown and flourished within academia (Janas, 1996). Mentoring in the United States has been used for quality improvement in both business and education for many years. Janas (1996) and Luna & Cullen (1995) indicate the all-around benefits that can be derived from successful mentoring programs. Mentors, proteges, staff developers and the organization benefit in many ways, both directly and indirectly, from successful mentoring programs.

Key to a program's success is planning, with the overall process resembling the model described by Knowles. According to Janas (1996), the physical environment and scheduling provide the foundation for supporting mentors and reducing isolation, as well as determining formal and informal contacts, identifying common tasks to be worked on and allowing for group interaction. The hallmark of effective mentoring programs is often the emotional and social aspects of the process, with the staff developer serving as the pathfinder on a personal and professional journey of discovery. An example of a successful program is the Peer Assistance and Review (PAR) mentoring program in Columbus, Ohio (Stedman & Stroot, 1998). The program purpose is to help the interns become effective teachers, and all interns are required to participate and pass the one-year program to have their contract renewed. Interns rate the program highly, citing emotional support, teaching guidance and professional development as indicators for the program's success. Through this program, the school district has been able to retain talented, enthusiastic and dedicated teachers (Stedman & Stroot, 1998).

Students in teacher preparation courses in many institutions of higher education are now required to integrate technology into their lesson plans, but many faculty members are still not technologically literate. Smith & O'Bannon (1999) cite many successful research projects that provided both technology training and mentor support to faculty during and following their training. Sometimes the mentors were faculty members, other times they were graduate students. Common elements of successful programs used the model: multiple session, demonstration, practice, critical feedback. Mentors provided the teachers/interns with ongoing support. Surprisingly, technical competency of the mentors was less important than the regularity of weekly contact and the collaborative environment where software was explored together (Smith & O'Bannon, 1999). Teaching the faculty with a demonstration-practice model provided them competence, self-confidence and an additional tool to use with their students.

Mentor teachers must reflect the ways of thinking and acting associated with new kinds of teaching, either leading reform or developing collaborative experiences where mentors and novices can explore new approaches together (Feiman-Nemser, 1996). Mentor teachers, as facilitators of learning, must have their own teaching characterized by practicing reflection, active learning and inquiry, in order to assist students in becoming active participants in their own intellectual growth (Wigle & White, 1998). In this way, they are more prepared to mentor collaboratively versus supportively. According to Evertson & Smithey (2000), mentors need to help new teachers more systematically, through dialogue and reflection, moving beyond merely providing emotional support.

When faculty focus on learning outcomes and presenting the learner with many opportunities to practice and improve, then encourage student reflection and self-evaluation, their role changes from coach to mentor. Mullen (2000) describes her model of collaborative mentoring as different from traditional mentoring. Typically, when dealing with university faculty and school faculty, the former is grounded in theory and the latter in practice. The collaborative model provided a process to integrate educational theory and practice by providing for secondary and peer mentors and facilitating team-oriented projects. Participants in general felt their lives had been enhanced; they learned from others, found their attitudes improved, and benefited from the continued professional development the project provided. In addition, they experienced an increased ability to rethink and solve classroom problems.

**Methodology**

**Introduction**

During the 2000/2001 school year, the supervisors at UVTI participated with other Preparing Tomorrow’s Teachers in Technology (PT3) grant participants in several integration sessions sponsored by the New Hampshire Department of Education and Apple Computer. A typical session consisted of an
introduction and demo of some technology piece, either software or hardware, followed by a practice period. Participants were often asked to work on a problem or situation typical of one they might encounter back in their schools. A representative from Apple would offer hands-on assistance, make recommendations and provide immediate feedback. The sessions started with simple presentations like an introduction to the PT3 Intranet site and logging on for email, then progressed to more complex assignments like creating a PowerPoint presentation and Inspiration diagrams. Following the practice period, there was a time for questions and a time to reflect on how the 'new' technology could be used back in the classroom.

Implementation

In order to provide an immediate opportunity to practice using the Internet and email, UVTI decided to use a 'free' intranet option, for the short term, to create the UVTI web site. The UVTI site was modeled after the NH PT3 site and proved to be a familiar location for the supervisors. UVTI also investigated the feasibility of partnering with the Vermont Institute of Science, Math and Technology (another PT3 grant recipient), and use their site then being developed specifically for educators. Travel, health problems and weather, caused several months to pass before site visits and demos could be arranged. It was not until late spring that we had access to the National Institute for Community Involvement (NICI) site. Initially UVTI felt that since NICI provided 40 hours of technical support, and the 'free' intranet site would soon start charging a fee for use, that NICI was the way to go. However, it proved to be both difficult to get everyone's accounts established and cumbersome to move around the site. By the time everything was "up and running," there was little time for mentoring; however, the obstacles that we encountered during the process provided some important lessons. Basically, implementation plans must factor-in time for unforeseen delays.

Results

Technology in general and the Internet specifically hold great promise for teaching. From anecdotal comments received about the process, the following trends were noted.

Supervisors/mentors enjoyed:
- Experiential aspect
- Potential of the medium
- Email as popular form of communication due to asynchronous nature: it was convenient, kept an electronic log of interactions, and provided samples of the interns writing skill
- Additional compensation made them feel like valued professionals

They also indicated that significant personal and professional growth and learning took place.

Developmental opportunities:
- Need more consistent and frequent use
- Need help in guided reflection format and expectations
- Need a mechanism on the site to clearly indicate when and what 'new' information is posted
- Need more support back at UVTI because several supervisors required individual sessions

Interns observations:
- This group more technically proficient than supervisors
- Several regularly checked intranet site and email
- Liked the asynchronous nature of the tool, so they could view presentations, information and mail at their own convenience
- See the potential for the technology to be used as a professional development tool

Developmental opportunities:
- Need more consistent participation by all: no dialogues took place on the threaded discussions because too few participated
- Need reasonable minimum hardware configurations defined: speed and capability make a difference

Those who were technologically literate became discouraged when so few participated in on-line interactions.

Next Steps

It appears that several changes are needed before the technology can make a significant difference. Administrative mentors need more time to practice and use the technology. Building the site use into everyday routine may give them a reason to consistently log-in and check for email, messages and 'new' information. Teachers who mentor also need to know about and practice using new technologies in their classrooms so the interns see its value beyond 'a professional development tool'. Mentors and interns need
to set goals and establish minimum participation requirements that account for part of their grade so everyone uses the technology at a required level. Mentors also need to define reflection on practice for the interns, and share their own reflections with each other in order to experience the process and capitalize on the professional growth the role of 'mentor' provides.

Conclusion

The technology, in the form of the Internet and electronic conferencing methods, now exists to allow communication across geographical distances. Even though adults may initially be intimidated, many are eager to learn this new method of communication. Training should consist of basic instruction and time to practice, with technical support provided. Collaborative mentoring is a way of bridging the distance between educational theory and practice, provided the mentors focus on dialogue and reflection as opposed to merely providing emotional support to pre-service teachers.

Abstract: Louisiana State University, Southern University, and the East Baton Rouge Parish Schools have developed a strong, cohesive partnership through their joint PT3 Implementation Grant, PT.NET (Pre-service Teachers Networking Environments Through Technology). Now in the third year, all grant activities have been directed toward teacher education program reform at both universities. Much has changed in regard to technology integration within both programs and several of the strongest components are highlighted and shared. Three specific initiatives are addressed as providing a “winning combination” for the grant participants: Student Teacher Laptop Loan Program, Student Teacher Technology Conferences and other training, and Teachers-in-Residence.

Introduction

Seeking to ensure that current and future educators are prepared to integrate technology into instructional methodologies, Louisiana State University’s College of Education facilitates a multi-faceted program for faculty, classroom, and pre-service teachers. The comprehensive program, built upon the results of state grants and a PT3 Implementation Grant, assists in implementing a full-scale improved teacher education program benefiting PK-16 students and faculties. With the primary purpose of PT.NET being to assure that all elementary education graduates are competent and confident in integrating appropriate technologies in inclusive classrooms to improve children’s achievement, the programmatic goals continue to guide the Colleges of Education in their quest for program strengthening, effect upon teaching and learning, and the nurturing of pre-service and faculty professional growth.

Objectives

Entering the third year of our PT3 Implementation Grant, PT.NET (Pre-service Teachers Networking Environments Through Technology), the College of Education has met and exceeded original expectations of the grant’s four programmatic goals. A summary of the goals and indicators of goal completion provides a concise overview of the successes and subsequent strengthening of the College of Education.
Goal 1
University faculty in the arts and sciences and in professional education in both universities will model appropriate use of technology in their instruction.

The Colleges of Education and Arts & Sciences have strengthened their relationship through the auspices of several joint grant activities funded at both the state and national levels. As the participatory number of Arts & Sciences faculty members increases, the mutual respect between the colleges expands. In sharing a common goal of being “teachers of teachers”, faculty members are drawn into this circle of scholars and the lines of communication widen. The ever-broadening effect of this camaraderie continues to encompass additional faculty from other disciplines across the university.

Goal 2
Post-secondary educators involved in elementary teacher education programs will engage in cross-disciplinary collaboration.

A variety of program implementations have contributed to the establishment of cross-disciplinary collaboration among the university teacher education faculty. With the defining of additional Professional Development Schools combined with the strong grant component of the Teacher-in-Residence program, the College is assuring that classroom teachers, university faculty and pre-service students are afforded opportunities for true collaboration and planning. These programs are foremost in the College of Education sustainability plan for positive systemic change.

Goal 3
Pre-service teachers will systematically integrate technology to support and enhance student learning and achievement.

In meeting this goal, the College strives to provide opportunities and support for the application of technology in culturally diverse classrooms. All student teachers have mandatory experiences in both high and low SES identified schools. With the expansion of our program focus, the College is sponsoring the first annual State Student Teacher Technology Conference and a subsequent New Teacher Workshop for those hired by the State of Louisiana. The anticipation of continued professional development and training opportunities for pre-service teachers abounds.

Goal 4
University faculty and pre-service teachers will participate in hands-on learning experiences with modern technology in elementary schools.

University faculty is provided technology-rich instruction in elementary school classrooms. Pre-service teachers are required to make use of technology-enhanced activities in classrooms with diverse learning needs are two strong aspects of this program. Primary technology integration training has taken place in the PT.NET Summer Institutes, which are designed to bring together faculty, teachers, and student teachers. Follow-up technology integration sessions are planned by the three Teachers-in-Residence during their weekly visits to their assigned schools. In-classroom mentoring has and is supporting the hands-on training experiences of both faculty and pre-service teachers.

Components
Through the auspices of several state and university technology grants within the LSU College of Education, thirty-six laptop computers have been purchased for use by the student teacher program. An application process allows student teachers to write a summary of personal technology skills, depth of preparation to use technology in the classroom, knowledge of technology integration activities, and intent of use of the laptop during the student teaching experience. The testimonials and documentation from laptop users from the last four semesters have provided affirming validation to the program and its continuance within the LSU College of Education Teacher Preparation Program.
Student teachers have been participants in a number of technology integration training opportunities. These include Laptop Orientation Workshops, Summer Institutes designed to place university faculty, classroom teachers, and student teachers within the same training experience, one-on-one assistance from the Teachers-in-Residence, and workshops for student teacher/supervising K-12 classroom teacher teams to train and plan together technology-rich lessons for their classrooms. Two hundred and fifty-two (252) classroom teachers, pre-service students, and university faculty members have received training and the opportunity for follow-up support since the inception of the Summer Institutes. Student teacher/faculty teams have presented the results of their technology integration efforts at the state LACUE Conference and the local Pre-service Teacher Conference held last year. The 2002 State Student Teacher Technology Conference will provide an additional means for faculty and students to offer professional presentations illustrating their skills and team approach to classroom planning. The design, implementation, and successes of these training opportunities will be shared with SITE International Conference participants.

The three Teachers-in-Residence, hired by PT.NET, work daily with university faculty members, classroom teachers who supervise student teachers, and with the student teachers themselves in planning and implementing standards-based technology integrated lessons. These master teachers work on a rotating and as-needed basis within their assigned schools and universities providing a successful mentoring experience for all involved.

The Teachers-in-Residence are a cohesive force within the technology thrust of the universities. They have proven to be an invaluable asset in establishing and maintaining a link between the university approach to teaching technology integration and the classroom implementation of these strategies. Realizing the importance of this phase of PT.NET, the grant partners are formulating sustainability plans for this and other “winning combination” programs.

Outcome

The Colleges of Education at Louisiana State University and Southern University are determined to continue building upon these successes, thus sustaining the key components to institutionalize changes necessary to integrate technology in teaching and learning. The foundational support of our PT3 grant and other College programs are contributing to the development and technological growth of K-12 students as the ultimate beneficiaries.

The inclusion of our PT3 Implementation Grant (one of four selected from 253 Implementation Grants nationwide) in the USDOE video, "The Challenge to Change", allowed LSU’s College of Education to share successes in implementing change and program reform. Our PT.NET grant was also selected as one of eight to be included in a research case study sponsored by the USDOE highlighting successful programs forming strong partnerships and initiating teacher preparation program changes. This national attention, along with more than twenty (20) conference presentations, have provided a means for a spotlight, but more importantly, have provided a means for self-reflection on our goals, achievements, and future needs for the College of Education.

The College is determined to continue building upon these successes thus sustaining the key components to institutionalize the change necessary to integrate technology in teaching and learning. The foundational support of this grant and the other College programs are contributing to the development and technological growth of K-12 students as the ultimate beneficiaries. Louisiana State University seeks to continue its influence among current and future educators.
Faculty Development: Inter-Institutional Collaboration

Abstract: The Technology Leadership Academy has established an environment which fosters the sharing of innovative strategies and best practices in helping to prepare a new generation of teachers who are comfortable and competent in using the new technological tools for learning. This session will highlight the Academy’s approach to developing this environment, including the following activities related to the Fall Institute, Regional Conferences, “Faculty Mentor,” Consultants Database, Professional Development Task Force, and Digital Equity Task Group.

Introduction

The Technology Leadership Academy is a project funded by the U. S. Department of Education’s Preparing Tomorrow’s Teachers to Use Technology Initiative. The mission of the Academy is to develop a collegial network for the infusion of technology into teacher preparation programs within the four-state area of Kansas, New Mexico, Oklahoma, and Texas. Academy partners include the higher education community, state agencies involved in teacher education, and the corporate sector. This presentation will showcase online tutorials for faculty development, how the Academy has developed an online learning community for technology infusion, and how faculty members can create this collaborate environment at their universities and in their regional areas to elevate faculty teaching and improve adult learning.

The mission of the Technology Leadership Academy, a component of the Technology Leadership Institute, is to develop a learning community among teacher preparation programs. During the past year it has grown from an abstract concept to an organization with over 395 individual and 115 institutional members. From its inception, the goal was to build a collegial and collaborative organization to provide mutual support and sharing of resources in the challenging task of infusing technology into teacher preparation. The first organizational meeting, hosted by the University of Texas in January, 2000, was attended by key officials from universities and state educational agencies from the four states. Activities included: finalizing the Academy’s organizational structure; establishing priorities; dividing into task groups (each concentrating on one aspect of the Academy’s mission); nominating chairs of each Task Group (to serve on the Steering Committee and oversee the Task Group’s functioning); and identifying a set of directives and recommendations for the Task Groups. The Steering Committee, comprised of deans, faculty and technology directors, provides direction and oversight of the Academy’s activities and meets several times a year to review progress and discuss future plans. There has been a shared responsibility in development of the Academy, even though the distance across these institutions makes this task even more challenging (and yet so rewarding).
Review of Related Literature

"The notions of classrooms as communities of learners is no longer restricted to the four walls of the classroom" (Norton & Wiburg, 1998, p. 210). The implications of this finding are twofold: (1) pre-service teacher educators should move beyond the walls of the classroom to prepare their students for the teaching field and (2) pre-service teacher educators should use this opportunity to explore online professional development opportunities which are outside the boundaries of their own campuses. One of the barriers for faculty members in finding online professional development resources is the time. There are so many resources on the Internet that faculty members may feel a sense of information overload. Faculty members may become overwhelmed with trying to find quality resources in a short time span. However, online tutorials offer a number of advantages. Faculty members are able to find tools that fit their specific needs. Also, time can be viewed as a benefit. Faculty members are able to find professional development opportunities on their own time—late at night, as soon as a question/problem arises, etc. Online professional development experiences offer faculty members across numerous institutions the opportunity to stay in frequent communication with one another. This sharing of expertise can facilitate a supportive environment in which faculty members can grow together as they build upon their technological abilities.

"The ability to use and teach with technology has become a requirement for pre-service teachers" (Davison, Burr, Eberlein, Fuchs, Saucedo, & Steffen, 2000, p. 11). Therefore, it is imperative that faculty members serve as role models for their pre-service educators in how to effectively infuse technology into the curriculum. Otherwise, our emerging teachers and the next generation of students may become victims of our technologically dynamic society.

References

Academy Structure

As shown in Figure 1, the organizational structure of the Academy is designed to assure that it is responsive to the needs of the member institutions. The Steering Committee provides leadership for the Academy and consists of 14 individuals who represent the member post-secondary institutions. The Academy has nine task groups, and each task group is chaired by a Steering Committee member.

The Task Groups consist of volunteer faculty or staff from the member institutions and state educational agencies. Each Task Group is responsible for determining and coordinating its specific part of the Academy’s functioning. Eight Task Groups emerged from the organizational meeting of the Academy. These include: Assessment and Planning, Academy Web Community, Consultants Database, Fall Institute, Policy and Leadership, Professional Development, Regional Conferences, and Technology Integration. Recently the Academy formed a ninth committee, the Digital Equity Task Group.
Academy Activities

Online Tutorials

The Academy is facilitating an online tutorial process for faculty members in working with pre-service teachers to educate students of culturally and linguistically diverse backgrounds, given the changing social context. The Academy Web Community Task Group has developed a Faculty Mentor and Faculty Subject-Area Mentor. These projects are unique resources that use a question and answer format to allow faculty members access to relevant online faculty technology professional development resources, models, and research. The Faculty Subject-Area Mentor focuses on the following content areas: Math, Science, Social Studies, English-as-a-Second Language, and General Education Development.

Educational Technology Coordinating Council

Academy members are represented on the Educational Technology Coordinating Council to develop the State of Texas Master Plan for Educational Technology 2000-2003. The mission of the ETCC is to ensure the cooperation and coordination of the state's efforts to implement education technology initiatives. The State of Texas Master Plan for Educational Technology is aimed at pre-service and in-service training in technology integration for teachers and librarians. The Master Plan includes eight goals and objectives which identify the organizational infrastructure and data requirements necessary to measure successful implementation. Included in the goal descriptions are definitions, level of impact, lead agency and participating agency information, objectives, limitations, and due dates. One of the most significant sections in the Master Plan is focused on the 12 Recommendations which serve as an implementation plan for achieving statewide collaboration in educational technology.
Fall Institute

Although competition within universities can be used in a positive manner, the focus of the Academy is to instill close, working relationships among and across institutions. The Fall Institute, the Academy's annual conference, is a strategy used to accomplish this goal. Teams of 3-5 individuals from member institutions participate in a 3-day conference focused on infusing technology into teacher preparation programs. Academy members also participate in organizing Regional Conferences on member campuses to strengthen the face-to-face component of the continued attempted by the Academy to provide a structure that fosters community and resource sharing within the four-state area. Written evaluations, collected at the end of the Fall Institute, have been compiled, analyzed, and available for review on our website. The data will be used to determine the thrust of future Fall Institutes and Regional Conferences.

Consultants Database

The Academy has devised a project to recognize outstanding faculty members who are infusing technology into the curriculum. The Chair of the Consultants Database is in consultation with the Institutional Representatives of all member institutions with the aim of developing a comprehensive listing of faculty with expertise in various areas who would agree to be featured on the Academy website in a biweekly segment and to be part of a database of resources.

Participant Outcomes

This session will be an interactive experience, whereby mutual benefit will exist between participants, between the participant and the presenter, and vice versa. The following are the objectives of this session: learn more about the PT3 program; become familiar with the mission, goals and objectives, and components of the Technology Leadership Academy; participate in a discussion about accountability issues involved in building an online learning community; learn about the process that the Academy took to develop this community—discuss benefits and challenges of certain strategies taken; contribute ideas on how the Academy can reach more faculty members. Our goal is for the participants to share ideas with the presenters on how to encourage more faculty members to become involved in the Academy and be held accountable for their participation.

Conclusion

The Academy has found that although virtual environments can powerfully support the development of learning communities, extensive face-to-face interaction and opportunities to participate are also essential. It is the membership and interactions within that membership that provide the definition, the direction, and the power of the community. The Academy is a learning community with potential to have significant impact on teacher education. Although it is the individuals from the member institutions that provide the talent and resources, these resources gain strength and vision through the collaboration and support within the learning community.

Facilitating Systematic Change in Teacher Education: A Model for Technology Infusion

Blanche O'Bannon, The University of Tennessee, US
Aileen Nonis, The University of Tennessee, US
Susan Skuda, The University of Tennessee, US
Kathy Puckett, The University of Tennessee, US

Teachers that are capable of preparing technology proficient students for the 21st century is notably one of the most critical needs in public schools today. This need has challenged teacher preparation programs to produce teachers that are able to infuse technology and curriculum. A recent response to this challenge is Project ImPACT (Implementing Partnerships Across the Curriculum with Technology), an implementation project recently funded by the U.S. Department of Education, as part of the Preparing Tomorrow's Teachers to Use Technology Program. This project employs a team approach to facilitate the infusion of technology in the teacher education program at the University of Tennessee and K-8 curricula. The ultimate goal of Project ImPACT is to provide prospective teachers with the ability to use technology to enhance teaching and learning. To assist in the accomplishment of this goal, a model was developed which establishes collaborative teams of university faculty, mentor teachers, and preservice interns. This model, designed in keeping with research findings on effective technology training and implementation, is designed to facilitate the infusion of national technology standards for teachers in university classes and national technology standards for students in K-8 schools.

A panel that is representative of participants in Project ImPACT will present an overview of the project, snapshots of the training/implementation model used, curriculum restructure activities at the university level, and prospects regarding resulting changes from university faculty, mentor teachers and preservice interns.
Experience Counts: Comparing Inservice and Preservice Teachers
Technology-Integration Decisions

Abstract: A study of 67 preservice and 67 inservice teachers' performances on online classroom technology-integration simulations demonstrates how computer-based, decision-making scenarios with embedded assessment are utilized to identify key considerations preservice and inservice teachers use when infusing technology. Three major findings emerged from the analysis of computer-generated maps of teachers' step-by-step decisions and accompanying written essays: (1) Although inservice and preservice teachers accessed similar data, the teaching experiences of inservice teachers appeared to influence their perception of the simulations which is reflected in the differential quality of their written justifications. (2) Inservice teachers addressed significantly more key elements of educational technology integration and implementation principles in their essays. (3) In decision making, inservice teachers focused measurably more on the use of technology as a learning tool and the importance of professional development while preservice teachers emphasized neutral topics such as the ubiquitous nature of computers and access to hardware and software.

Introduction

Selecting the most effective instructional approach, including teaching with technology, is a challenging task for many teachers. A deeper understanding of how teachers prioritize issues and make decisions about their instructional programs is crucial in developing professional development in technology for classroom teachers and future teachers. This paper will present data on how experienced and novice teachers differentially make technology integration decisions. To enhance future teachers' conceptual foundations and decision-making skills on infusing technology into the curriculum, two PT3 grant recipients have co-developed simulations of technology implementation scenarios commonly encountered in K-12 classrooms.
These computer-based simulations span a range of technology infrastructure, curricular content, school systems and instructional issues. An opening scenario is first presented providing a problem context. Then teachers select menu items and analyze data to reach their decisions and concurrently the IMMEX problem-solving assessment system records each menu-item selection in chronological order. Additionally, the software generates a map that illustrates teachers’ step-by-step problem-solving approach, which guide assessment and metacognitive development (Underdahl, Palacio-Cayetano, & Stevens, 2001). Upon completion, teachers compose a written justification online for their decision to integrate or not integrate technology. Teachers’ essays are scored based on the number of educational technology integration and implementation principles—eTIPs—addressed (Dexter, 2002).

Purpose and Objectives

While the eTIPs-IMMEX simulations have been primarily used as an instructional aid in preservice curricula, we conducted a comparative analysis of preservice and inservice teachers’ decision-making strategies on eTIPs computer-based simulations to examine the impact of experience on technology integration and implementation. The following two questions guided this investigation.

1. What are the primary considerations of both experienced and novice teachers when deciding whether or not, or to what extent, to integrate technology into instruction?
2. How do experienced and novice teachers differentially make technology integration decisions?

Theoretical Framework

While rapid advances in technology and the proliferation of computers in school have expanded pedagogical options for educators, teachers continue to struggle with how and when to integrate and implement technology effectively into instruction. According to Pierson (2001), schools are so eager to purchase and have teachers begin using technology, that they mistake simply having and turning on a computer as integration. However, merely knowing how to use a computer is not sufficient to ensure that teachers will effectively integrate technology into the learning curriculum. Instead, a teacher who effectively integrates technology is able to draw on extensive content knowledge and pedagogical knowledge, in combination with technological knowledge, when using technology in the classroom (Pierson, 2001).

One challenge facing teacher education programs today is preparing teachers to use technology effectively in schools (Wedman & Diggs, 2001). Using problem-solving scenarios such as the IMMEX software program can provide pre-service teachers with an appropriate context in which to construct knowledge about technology integration. The IMMEX scenarios allow students adequate opportunities to learn to teach with, not just operate, educational technology (Dexter, 2002). The eTIPs IMMEX-powered cases challenge teachers to apply their knowledge of the following six principles when integrating technology.

Educational Technology Integration and Implementation Principles: eTIPs

- **eTIP 1**: Learning outcomes drive the selection of technology.
- **eTIP 2**: Technology use provides added value to teaching and learning.
- **eTIP 3**: Technology assists in the assessment of the learning outcomes.
- **eTIP 4**: Ready access to supported hardware/software resources is provided.
- **eTIP 5**: Professional development is targeted at successful technology integration.
- **eTIP 6**: Teachers reflect on, discuss, and provide feedback about the role of and support for educational technology.

Data Sources

Data was collected from 134 written responses from a random sample of a combination of 67 credential candidates and 67 inservice teachers were analyzed. Preservice teachers solved the eTIPs cases as part of a Technology in Education course assignment at a university in California. Similarly, inservice teachers...
performed the eTIPs cases as a requirement for a 120-hour educational technology professional development program.

**Methods**

**eTIPs IMMEX-Powered Cases**

As part of a Department of Education grant, two PT³ investigators have co-developed computer simulations of typical classroom technology implementation scenarios to enhance future teachers' conceptual foundations and decision-making skills on infusing technology into the curriculum. The eTIPs Cases IMMEX-powered simulations are an expansion of the case-based problem solving in content-specific disciplines continuum developed at the UCLA School of Medicine in the mid 1980's (Stevens, Lopo, & Wang, 1996). The eTIPs IMMEX-powered cases span grade levels, curricular content, and technology readiness. Using online instructional cases can provide preservice teachers with an appropriate context in which to construct knowledge, providing multiple opportunities to practice their instructional decision making about technology integration. These simulations are meant to supplement, not supplant, teachers' classroom-based integration experiences. Using these scenarios as exercises provides a common point of experience that allows discussion about goals and approaches for technology integration. Intrinsic to IMMEX problem solving is the concurrent tracking of menu-item selections as users research data to solve problems posed in the prologue. Below is a representative sample of a prologue that introduces teachers to the technology integration dilemma.

"You are in your second year teaching English at West Bend Junior High School, a grade 7/8 school that features "looping." That is, you, and the other three members of your interdisciplinary team work with the same group of students during both of their years at the school. A special grant the school received has provided new technology resources for you and your students. You are in the process of planning units on persuasive writing and informative writing for second quarter and want to consider how this technology might best support teaching and learning in your classroom. For end of the unit assignments your students are expected to complete authentic writing projects that can demonstrate their progress toward the State's content standards. You need to make a decision this week about when and how, or even whether, to integrate educational technology resources into one or both of these two writing units. After you have used the menu items to explore the information provided in this case, state your decision about whether or not to integrate educational technology resources into your classroom in the "Solve" menu item. If your decision is to integrate, also describe how you would do so. Use information from the case to explain and justify the answer you submit."

**Scoring of Teachers' Essays**

Teachers' essays were scored based on the number of educational technology integration and implementation principles—eTIPs—addressed (Dexter, 2002). We examined the quantity and quality of information written by the two groups of teachers. Each sentence in the essays was tagged for key elements of eTIPs incorporated. Depending on the depth of the answer, an essay can receive a maximum 12 points, receiving up to two points for each of the six eTIPs. We used the following criteria to determine the essay's score on each of the six eTIPs.

Zero-- when the teacher makes no reference at all to the substance of the eTIP;
One-- when the teacher makes a general reference to the substance of the eTIP, or implies consideration of the eTIP; and
Two-- when the teacher discusses a specific eTIP comprehensively and provides supporting details from the information presented in the case.

The following is a sample essay written by a teacher that was assessed using the above scoring guide.

"The technology assignment to support the authentic writing English projects should be integrated starting in the Fall (Technology Implementation/Planning = eTIP 1). The teachers have time in their schedules to implement the program. They also have enough technology (Hardware Access = eTIP 4) shared or otherwise to support the English project. Furthermore, the students seem well prepared to focus their assignment on the computer. All students have had computer software and training since seventh grade (Prerequisite Skills = eTIP..."
2). This will ensure a first year success on the project in the classroom. Next, administration, colleagues, teachers, and the community really seem to support the technology assignment. (Administrative Support = eTIP 4) In-services, activities, and mentor programs are all available to new and veteran teachers (Professional Development = eTIP 5). Last, the resource information supports the standards component for integrating technology into the English curriculum (Standards = eTIP 1). Research findings, complex reasoning, mind tools, and software reviews are all available to lend a helping hand to new programs that these English teachers may want to integrate (Reflective Teaching = eTIP 6). I say yes to the integration. I say have a meeting in the summer before school starts and get this curriculum up and running.”

This essay was assigned a score of ten. The teacher addressed eTIPs one, two, four, five and six that are indicated in parentheses. Since the teacher included one key element for five eTIPs and provided supporting details from data presented in the simulation, the teacher was awarded the full two points for five out of six eTIPs. However, like most teachers, this teacher did not address the use of technology for assessment, eTIP three.

Results

IMMEX-generated maps of decision-making strategies by preservice and inservice educators indicated that most teachers examined the majority of the information in the problem space and most appeared to do so in a sequential manner through the menus. While there were few item-selection differences between the groups, inservice teachers addressed significantly (p < .05) more eTIPs in their essays than preservice teachers. Preservice teachers were also more likely to mention more neutral topics such as the ubiquitous nature of computers, impact of technology on teaching, etc., than were inservice teachers. There was an equal frequency of mention of hardware, software and standards. The listing of most frequently mentioned issues collected from the essays is shown in Table 1. These data indicate that although the two groups accessed the same data from the simulations, the experiences of the inservice teachers influenced the perception of the simulations and the decision justifications.

Table 1: Preservice vs. Inservice Teachers Differential Emphases on Key Elements of eTIPs

Importance of the Study

Despite the significant investment in technology and professional development in recent years, it is still uncertain how teachers make the decision to integrate technology or not and to what extent (Zhao & Cziko, 2001). What are the primary considerations experienced and novice teachers use when deciding whether or not, or to what extent, to integrate technology into instruction? We pursued this question by examining experienced and future teachers' written reflective analyses of decision making in conjunction with IMMEX search-path maps of step-by-step decision-making approaches on computer-based simulations that span a range of
classroom scenarios. The observation that preservice teachers are inclined to focus on access to technology and marginally consider crucial dimensions of learning with technology such as technology implementation planning, prerequisite skills, and characteristics of learners suggests curricular areas in need of increased emphases in educational technology curricula. Instructors can utilize data attained from teachers' performances on eTIPs IMMEX-powered cases to design instructional interventions and refine curricular content for future educational technology courses.

Inventing New Strategies for Integrating Technology into Education

Anthony Petrosino, The University of Texas, US
Jere Confrey, The University of Texas, US
Paul Resta, The University of Texas, US
Melissa Tothero, Project INSITE, US

The purpose of the PT3 grant Inventing New Strategies for Integrating Technology into Education (INSITE) is to develop a scalable model of a technology-infused educational program for the next generation of middle and high school teachers of mathematics and science. INSITE brings together key players from the core content courses, professional sequence courses, and field experiences; facilitates collaboration among these key players; and provides the technology-related expertise they need to model exemplary educational technology in science and mathematics. The graduates of the program have internalized a vision of mathematics and science education in which technology is an integral part of the teaching and learning process. They have seen the critical role technology can have in shaping all aspects of scientific and mathematical thinking: its conduct, methods, records, evidence, collaboration and dissemination. INSITE represents a commitment to systemic change, initiated by a consortium from the Colleges of Education and Natural Sciences of the University of Texas and the Austin Independent School District (AISD).

Research shows that new teachers will not be able to initiate or sustain the use of technologies in schools unless it is a critical and enduring part of their preparation (President’s Committee of Advisors on Science and Technology, 1997; Office of Technology Assessment, 1995). They will not develop critical capacities to evaluate effective and ineffective uses, nor to learn efficient techniques of integration, unless their university experience integrates in all aspects of their preparation. They will not understand the pernicious effects of the Digital Divide on access to technological careers, unless the witness effective programs to be the needs of the children of the working poor. To meet these challenges, INSITE has partnered with UTeach (http://www.uteach.utexas.edu), a highly successful secondary preparation program, to create a seamless teacher preparation program to span all four years of the students’ undergraduate experience. It will include the implementation of a digital portfolio assessment and institution of an annual evaluation and planning cycle by a Technology Leadership Team.

The UTeach program has been immensely successful. Currently there are 230 students in the UTeach Program, with an overall retention rate of 72.6%. In Fall 1999, 40 new students entered the UTeach Program. Of these new students, 80% continued on to the next courses in the program for Spring 2000. The first cohort of 28 students was selected for UTeach in the fall semester, 1997. By the spring of 2000, UTeach enrollment has grown to more than 200 with 40-60 new students being accepted into the program each semester. Retention rates for UTeach students have been far better than for their undergraduate peer group in the College of Natural Sciences. This success is due to aggressive recruitment of students at all levels, financial benefits, pervasive field experiences, one-on-one interactions with master and mentor teachers and a revised, enhanced sequence of education courses directed at math and science teaching. We expect UTeach to grow to 500 students by the 2002-2003 academic year.

Although the UTeach program has experienced marked success, its integration of technology was not originally as effective or ubiquitous as desired. We have been hampered in finding school-based sites that reliably use a broad array of technologies in creative and resourceful ways. Faculty in the sciences still question technologies use in developing basic concepts with students and thus use it sporadically. While technology has been integrated in the initial pedagogical courses, growth in the program has threatened the continued and enhanced use of technology as it is embedded in curricular initiatives. Because these courses and student teaching depend on field components, prospective teachers must be given the opportunity to observe and to practice integrated technology in their field experience. These sites of practice must include contrasting types of schools to ensure that technological disparities do not continue among poorer children.

To this end, INSITE has provided support for faculty in the colleges together with cooperating teachers to plan a technology-rich teacher preparation program. With the assistance of PT3, UTeach has become an exemplary model program of teacher preparation in science and mathematics. UTeach is now poised to have a major impact for the country.

INSITE has four major goals to help facilitate technology infusion within an exemplary teachers development program:
1. To intensify, extend and enrich the use of technology as a modeling, visualization, data representation, symbol manipulation and collaborative tool in introductory courses for mathematics and science majors.
2. To institutionalize and fully implement the integration of technology in the three mathematics and science education professional development courses
3. To establish an expanding cadre of mentor teachers who can provide our students access and experience in multiple sites of best practice using exemplary technology, particularly with urban and rural populations

4. To establish an intensive collaborative Technology Leadership Learning Community among all teacher-educators in the UTeach program, to plan for technology infusion, establish an integrated program, and share expertise.

Evaluation

The evaluation plan for the INSITE project is based on the Goals and Objectives of the total scope of the project. A brief description of the Evaluation Design as it relates to each of the project goals. Full results will be presented at the Conference Meeting.

**Goal I: To intensify, extend and enrich the use of technology as a modeling, visualization, data representation, symbol manipulation and collaborative tool in introductory courses for mathematics and science majors**

The course syllabi for every content and methods course in the teacher-preparation sequence will be examined as a means of documenting instructional and course activities and requirements for technology integration. Student products will also be examined to determine if students are learning to integrate technology with the teaching and learning process. Both completion of projects and types of technology featured in the projects will be monitored. Formative and summative course evaluations by students will provide additional data.

Every preservice teacher candidate will have a Student Portfolio in digital format. These portfolios will examined to ensure each contains designated technology components. A panel of experts comprised of Methods and Content Instructors and Technology Integration Specialists from both UT and AISD will use a Delphi-voting process to reach consensus on the content of a performance-based student assessment drawing from the NETS, TEKS, and SBEC requirements for preservice

**Goal II: To institutionalize and fully implement the integration of technology in the three mathematics and science education professional development courses**

The influence of course instructors on their students will be measured by how well preservice teacher candidates perform on the Student Teacher Final Evaluation process on the section related to technology integration. Also, by the end of the Professional Development Sequence, preservice teachers will be required to complete technology-enhanced lesson plans. Completion of these and their descriptions will be documented in the Student Portfolios (digital format).

**Goal III: To establish an expanding cadre of mentor teachers who can provide our students access and experience in multiple sites of best practice using exemplary technology, particularly with urban and rural populations**

Focus groups of mentor teachers will be formed to aid in the development of a top-quality teacher preparation program in integration technology. School district records will also be kept and monitored to document the number of mentor teachers prepared and the number of teacher candidates being served. Evaluation data will be collected from semi-structured interviews with mentor teachers, UT faculty, student-teaching supervisor, and the students themselves. As a means of providing follow-up information about these teacher candidates and whether they continue to use technology integration in their teaching, an electronic survey will be conducted via the on-line conferencing system. The quality of the Units of Practice and the structure of the portfolio design and assessment will provide additional data.

**Goal IV: To establish an intensive collaborative Technology Leadership Learning Community among all teacher-educators in the UTeach program, to plan for technology infusion, establish an integrated program, and share expertise.**

Outside reviewers will examine samples of student portfolios blindly and compare their evaluations. A rubric, currently under development, will be utilized to incorporate aspects of content domain, educational technology and learning theory in order to provide needed feedback to the students. The portfolios will become objects of reflection and revision by the participating UTeach students as they receive feedback from UTeach faculty and staff. The portfolio will serve both a formative as well as summative assessment component. We will make the rubric available at our proposed website in order to assist other universities in assessing their own use of multimedia portfolios.

Our intent is to present the results of project INSITE through the Fall 2001 semester. In addition to the four goals we will also present the results of extensive clinical interviews with our PT3 Fellows as they engage in their first full semester of incorporating technology into their existing practice.
Transforming Activities with Technology: Professional Development in Preservice Education

Abstract: In professional development work with preservice teacher educators at the university, we have tried to take seriously the constructivist notion of beginning from where the faculty are, and building towards more and more sophisticated and elaborate possibilities for integrating technology. The teaching practices and activities faculty have been using represent important aspects of their knowledge and capabilities, as well as a tangible foundation on which to build. Focusing on the activities and practices with which faculty begin offers us the opportunity to develop new practices that those faculty take ownership of, while transforming the activities to include technology as a tool. In this paper, we focus on productive processes of change from our faculty’s existing teaching and learning activities and practices toward activities enhanced by technology. These models of the transformation of teaching practice are meant as examples of how meaningful change can successfully be undertaken.

Educators generally agree with the constructivist notion that schoolchildren learn through the active construction of knowledge, based on their present understandings, rather than simply absorbing whole ideas transmitted to them. Too often, professional development efforts with faculty of education ignore this truism. In the Preparing Tomorrow’s Teachers to Use Technology (PT3) project at the University of Missouri-St. Louis, we have tried to take seriously the notion of beginning from where the faculty are, and building towards more and more sophisticated and elaborate possibilities for integrating technology.

Researchers in the cognitive and learning sciences differ to some degree in their ideas about the mechanisms of learning, but a common recommendation to foster learning is a process of inquiry, including planning, action, and reflection (e.g., Bransford, Brown, & Cocking, 1999; Brue, 1993; Polman, 2000). Researchers in the sociocultural tradition (e.g., Wertsch, 1998) built upon the work of Vygotsky (e.g., 1978) and Bakhtin (1981) have stressed the notion that learning occurs through action carried out in the world, with the social support of other individuals and the support of cultural tools such as language, the practices that have been handed down, and other mediating artifacts like books and computers. In our professional development work with preservice teacher educators, the teaching practices and activities they have been using represent important aspects of their knowledge and capabilities, as well as a tangible foundation on which to build. Focusing on the activities and practices with which faculty begin offers us the opportunity to develop new practices that those faculty take ownership of, while transforming the activities to include technology as a tool.
During an early meeting in the 1999-2000 school year, our first group of participating full-time and adjunct university faculty began developing a “Technology Integration Menu” with the support of PT3 staff. In the group meeting, examples of activities and practices incorporating technology were brainstormed. A set of five broad emergent categories of activities was determined from the brainstorming, and after the meeting a written checklist of activities was created for use by each faculty member in the project. The written menu has been modified and expanded over the past two and a half years, but the basic structure has remained. Table 1 summarizes the categories and gives an example from each:

<table>
<thead>
<tr>
<th>“Menu” category</th>
<th>Example “menu” item</th>

<td>I will research the internet for web sites for my students to use</td>
</tr>
</tbody>
</table>

**Table 1:** Summary of “Technology Integration Menu”

In subsequent individual meetings, PT3 staff used the technology integration menu as a starting point for discussions with faculty members on ways they could take what they are already doing and, by using technology, enhance it. That process has continued with new groups of 5 to 9 participating full-time and adjunct faculty joining us as a cadre each fall and winter semester. Each semester, we have several meetings with the participating faculty, including some opportunity to check in on progress and share ideas.

Table 2 summarizes a number of the possibilities for the transformation of existing practices of our university faculty to technology-enhanced practice. Some of the items, including putting syllabi online (Table 2, item 3) and converting lecture overheads to a computer-based medium (Table 2, item 1), are relatively easy for faculty to undertake, and relatively common. They result in little substantive change in opportunities for the learning of students, although they do provide a context for some faculty to familiarize themselves with a technology they have never used, and a flexibility in access to information for students in the class. A few instructors who take these steps are uncomfortable or unwilling to move beyond them to more ambitious change.

Table 2: Transformations of practice

The instructor who has replaced multiple choice tests given during class time with equivalent online tests (Table 2, item 4) has not changed that pedagogical event itself drastically, but his purpose in doing so is to free up class meeting time in an introductory course for more active learning strategies.

My students won't be doing anything but online testing from now on. I'm trying to move lower level information to technology so I have more time in class. The tests are timed... honor system... over several chapters at once. (The program) draws from a pool of questions so every student gets a random set of different questions.

(Evaluator notes, Fall PT3 Faculty mtg., 2001)

Online discussions taking place between class meeting times (Table 2, item 2) have taken a number of specific forms within our faculty, but have a number of attractive features in common. In contrast to in-class face-to-face discussion, the asynchronous nature of online discussion allows for greater participation by all members of the class. One faculty member commented that students are less inhibited and more direct and honest in their questioning online, echoing the findings from communications research (e.g., Sproull & Kiesler, 1991). Several instructors use class time after the online discussion to summarize the ideas presented, and address any issues that might need clarification. Despite the overall popularity of online discussions, several of our more reluctant faculty, particularly those with large classes, had concerns with keeping track of online discussions. Other faculty in large classes chose to limit the requirements for numbers of posts by rotating student involvement, and also devised means of students monitoring one another and reporting back to the instructor, rather than requiring in depth monitoring of all posts by faculty.

The PE instructor (Table 2, item 6) became interested in using online resources after our Director sent her a number of URLs of sites directly pertaining to her field of expertise. Some of those sites included WebQuests and units from a web site called “Filamentality.” At a PT3 meeting soon after, some of our technology-using partner teachers from 4-6 classrooms talked about WebQuests and suggested that each instructor and preservice teacher should write one. These 4-6 classroom teachers were sold on the use and effectiveness of WebQuests and they passed on their enthusiasm to our faculty members at the meeting. That little push was all the instructor needed. She wrote a WebQuest that incorporated a number of activities that her students used to do out of context, into an interesting, scenario-based WebQuest.

Another instructor (Table 2, item 7) presented oral reviews and held class discussions toward the end of each semester to serve as a semester review. She decided that her students would retain more information if she had them create their own reviews in PowerPoint. The students prepare their presentation outside of the classroom, thoughtfully and actively processing information from the semester. They return to class and share their presentations with the rest of the students, teaching them what they have learned, thus making the information their own. A discussion ensues. Students also have an artifact that they have produced which could become part of their portfolio.

It is a culminating activity which they synthesize in a powerpoint presentation (what they have learned). Even novices seem to be able to do this in about three hours of work. Students have surpassed the teacher. One student has a clip for cultural diversity. To me it is magic. Very nice and very professional.

(Evaluator notes, Fall PT3 Faculty mtg., 2001)
One instructor (Table 2, item 8) inherited a class that previously had students compose papers on school philosophy, investigate a school setting and study the issues surrounding a school’s curriculum. This instructor decided to write a WebQuest to incorporate all those things. Now, instead of having a number of somewhat disjointed assignments, the students are approaching a problem as if they were on a committee coming together to start a new charter school. All of the above mentioned issues are addressed in the WebQuest, in an interesting, real-world approach to school site issues and philosophy. These ideas found their origin in a fall PT3 faculty meeting after an initial discussion with one of the PT3 staff.

1st Instructor: I could do “Designing A School” (WebQuest), in a social reconstructivist manner. (The program) could approach each of the core philosophies and how would you approach this from an existentialist perspective or . . .

2nd Instructor: Each group could do a different one . . . use the PBS series for informing school design or curriculum . . .

1st Instructor: They use Ed Week, NEA abd AFT sites, and the ASCD site . . . Is it possible to design a WebQuest that could be done simultaneously with different levels of students? It would be a neat group portfolio piece.

(Evaluator notes, Fall, 2001)

Several instructors enhanced assignments by providing the opportunity for publishing the resources. The instructor of the developmental psychology class (Table 2, item 9) transformed a paper assignment written for grading by the instructor into a web research assignment resulting in a networked resource for the students own and others’ future use. The secondary social studies methods instructor (Table 2, item 10) enhanced a local history project with digital photography as well as the opportunity to post materials online for later reference and use.

Finally, a number of instructors (Table 2, item 5) in advanced courses have students develop lesson and unit plans, and increasingly these must include web resources. These may be further enhanced by technological scaffolding built into document and presentation templates.

Best experiences so far have been to go onto the internet and find a good lesson plan and find a unit with lesson plans. They were shocked at what they found. They found incoherent units and lesson plans. This was a good experience because they are always looking for an easy answer.

(Evaluator notes, PT3 Faculty Mtg., Spring 2001)

In previous work presented at SITE (Polman, Mastin, Beyer, & Navarro, 2001), we described our efforts at systemic reform to support technology integration by preservice teacher educators. In this paper, we focus more specifically on productive processes of change from our faculty’s existing teaching and learning activities and practices toward activities enhanced by technology. These models of the transformation of teaching practice are meant as examples of how meaningful change can successfully be undertaken.

Abstract: This study looks at a different approach to professional development of higher education faculty. Faculty members were asked to participate in a preservice technology course. Forty-nine faculty members accepted the invitation and took the course during Fall Semester 2001 or will take the course during Winter Semester 2002. Interviews and focus groups were used to find the impact participation in this technology course had on the faculty members’ attitudes toward technology integration in teacher preparation courses as well as their use of technology in their own teacher preparation courses. Our preliminary study found that faculty members are accepting of and will excel in this model of professional development.

Introduction

This pilot study reports on one component of a larger PT3 grant project focused on the integration of technology into the teacher education program at a large western university. One goal of the PT3 grant is to help teacher education faculty develop skills in technology use, model the proper use of those skills to preservice teachers, and implement technology assignments in their courses. Over the past year, as the faculty worked together on committees, participated in workshops or talked informally, the topic of technology integration became a common conversation. Faculty wanted to know what their students knew, what technology skills they had, how to gain these skills themselves, how to change their curriculum and how to create meaningful assignments that used technology. Over and over again, the instructors for the IP&T 286 course were approached with questions, suggestions, and requests for help. On a whim, one instructor said, “I think everyone should take the technology course along with the students.” As we thought about this idea and discussed the possible ramifications, it seemed like a great possibility. With the support of the IP&T 286 course instructors, the PT3 project directors, and with minor adjustments to the course curriculum the idea blossomed into a viable plan. As part of their professional development faculty were invited to complete the technology course required for all pre-service teachers. Participants agreed to:

- Complete course assignments and develop “products” for use in the pre-service courses they teach.
- Model the use of these “products” in pre-service courses.
- Create assignments for their students in their pre-service courses during Winter Semester 2002 that use the skills gained in the technology course.
- Participate in focus groups to share their experiences in learning and then in using technology in their courses.

Data Collection
The data collection for this pilot study has been qualitative in nature. Focus group interviews, classroom observations, and examination of course syllabi were used as tools. Comments to PT3 grant leaders from the faculty during the course have been reviewed and reported. While the larger study is focused on the process of change for the entire teacher education program, this study reports on the faculty who volunteered to complete the technology course required for all preservice teachers in the current program. The primary research questions include:

I. Is the faculty-as-student taking the technology service course model effective for professional development of higher education faculty in a teacher preparation program?

II. Does it promote change in the use of technology in participants’ course syllabi and assignments?

III. Is this model more effective than traditional workshops and seminars in helping faculty integrate technology into their courses?

The following is a list of questions developed for the focus group and individual interviews.

Group A: Questions Regarding the Technology Course Curriculum

1. What are your feelings and observations regarding the curriculum in the IPT 286, preservice technology course?
2. What are some of your successes with the content/curriculum?
3. What are some of your failures/frustrations with the content/curriculum?
4. Are the skills taught/gained relevant to the McKay School of Education pre-service teacher preparation program?
5. Are the skills taught/gained relevant to your course(s)?

Group B: Questions Regarding Personal Change

1. How have your ideas/thought processes regarding the use of technology changed due to your experiences in IP&T 286?
2. Are you or have you changed your teaching and content delivery methods in any way because of your IP&T 286 experiences?
3. Has being in the same classroom as your students allowed you to better relate to them?
4. Has having the shared IP&T 286 experience started new conversations between you and your colleagues?
5. Have you worked with other colleagues while completing assignments?
6. Are you discussing curricular and/or program changes?
7. What have you learned together?

Group C: Questions Regarding Curricular Changes

1. Do you feel you can change your curriculum to use the skills/knowledge/understanding you have gained?
2. Are you going to change your curriculum to use the skills/knowledge/understanding you have gained?
3. What are you or have you changed in your curriculum and/or assignments because of your IP&T 286 experiences?
4. Do you feel you better know what you can expect from your students in their use of technology?

Group D: Questions Regarding Program Changes and the Faculty-as-Students Model

1. Do you see the potential for program changes based on your IP&T 286 experiences?
2. What kind of program changes would you propose based on your IP&T 286 experiences?
3. Do you think that the faculty-as-students taking the technology services course model is a good one?
4. If you participated in last years traditional workshop training, compare and contrast the differences.
5. Is the faculty-as-students taking the technology service course model better? Why?
6. Is the traditional workshop model better? Why?
7. Why do you feel one is better that the other?
8. Which do you feel you learned the most in? Why?
9. Which has had or do you think will have a greater impact on your teaching methods and curriculum?

Group E: Questions Regarding Miscellaneous Ideas

1. What were you hoping to learn? And have you?
2. What were you expecting the course to be like? And was it?
3. What roadblocks have you run up against? What were your greatest successes?
4. What kind of preparation do you recommend for faculty-as-students prior to taking IP&T 286?

Results

Forty-nine faculty members have agreed to complete the technology course; 28 Fall Semester, 14 with a possibility of 4 more Winter Semester for a total of 18, and 3 more have committed for later semesters. Seven percent of the faculty members who enrolled Fall Semester have dropped from the program; one left the faculty and returned to the K-12 arena full-time and the second retires in a year and felt the work was not worth his time. Sixty-one percent of the faculty members, who enrolled Fall Semester, have completed the course with 25-30 percent completing the assignment on time. Thirty-two percent of the faculty have felt a time crunch and are spreading the course over the duration of both Fall Semester 2001 and Winter Semesters 2002. From the interviews and focus groups it was found that 64 percent of the faculty felt that the course should be spread over a period of two semesters for faculty. The course work was too demanding with their existing teaching and research responsibilities. The faculty members suggested that having an optional weekly seminar would be helpful. This would allow them to meet with the course instructor or a teaching assistant to ask questions and get additional help with assignments. This would also create an atmosphere of communication and collaboration with the group. A natural peer lead support system would also be created.

Results of the Focus Group and Individual Interviews:

Twenty-two of the 28 faculty members enrolled in Fall Semester participated in an interview or focus group. One faculty member missed her focus group, the two that dropped opted not to participate, and the last three didn’t have enough of an experience to warrant comment.

Group A:

From this group of questions the focus was on questions four and five that concentrate on the relevance of the technology course’s curriculum to the pre-service preparation program and the faculty member’s course in general. The feeling was that the course has great relevance as a whole. There was concern regarding two of the modules; those being HTML coding and HyperStudio. Many faculty members didn’t feel there was any relevance for HTML coding to their courses in particular. Of the 22 interviewed 17 struggled with the HTML module to the point of wanting to give up the project. On the other hand all 22 found the Microsoft Office module extremely relevant, most particularly PowerPoint.

Group B:

From this group of questions the focus was on questions one and two that concentrate on the changes in individual faculty members’ thought processes regarding the use of technology and their teaching methods. It was found that most of the faculty had already begun to rethink their uses of technology in their courses prior to this experience. However, participation in this course solidified their resolve to make changes to their own courses. It also gave them the confidence and the needed technology skills to make the desired changes. Sixteen of the 22 plan on adding or expanding the use of PowerPoint in their course, either for personal use or as assignments for their students. The entire group is considering some type of electronic communication.

Group C:

The primary focus in this group of questions was on whether or not the faculty members better understood the knowledge and skills their students brought to their courses. This was a resounding yes. All of the faculty felt they could hold their students to a higher standard and ask more of them with regards to technology use and integration. They felt they could include more technology requirements in various assignments. Many didn’t feel that they would change their present curriculum significantly to better take advantage of their newfound skills nor the skills the students bring to the table.
Group D:
This group of questions received a lot of time in the interviews and focus groups and was thoroughly explored. Twenty of the 22 felt participation in the pre-service technology course was an excellent form of professional development. Over all, this was an extremely positive experience for the faculty with very few frustrations.

The faculty were asked to compare this experience with other traditional workshops/seminars they had participated in. They felt that the traditional model (workshop/seminars) heightened their awareness of available technologies and possible uses but didn't allow them the time to learn the skills needed to incorporate the use of these products into their courses. Many times following a traditional workshop/seminar they felt frustrated as they returned to their offices to try and use what they had seen. For most, they couldn't make the technology work as they had seen it demonstrated. Many of them abandoned trying to use technology because they didn't have the time nor the patience to figure it out.

The faculty found participation in the pre-service technology course a wonderful experience because they could learn at their own pace with the guided tutorials and help from computer lab assistants. The tutorials gave them something to refer back to and they had constant teaching assistant help when questions or problems arose. They have been able to generalize the skills gained to their everyday lives. One faculty member learned how to use several software packages that he had at home and had no idea previously how to use them. Learning how to use them made him extremely happy. The faculty member had bought the computer so he could work from home but was unable to use the technology; now he has the skills and confidence to succeed.

Group E:
This group of questions concentrated on the learning desires of the participants and whether or not they were met. The first and foremost goal of all the faculty members was to better understand the technology skills their students would bring to their course. They wanted to know if they could make changes to their courses and if the students could meet the expectations of those changes. They all feel they now know what to expect from their students. They can now say, “I know what is taught in the technology course and you can do this assignment.” Some feel that they could make many small changes to assignments because they know their students should be able to do the work. From there the learning desires greatly deviated by individual. Power Point was the most desired technology skill wanted. The PowerPoint module gave them a basic knowledge, but some felt they needed more advanced applications to better use this tool. The greatest disappointment came for those seeking web design skills. Many felt the HTML coding module was too difficult and had no relevance because there are so many web-editors available for use.

Some comments made to the PT3 project director(s) and/or IP&T 286 class instructors as email messages are:

- The class has been very interesting and beneficial for me. (I have substituted many of the lab assignments to meet my personal interests and needs - but the lab assistants have no way of signing off on these - any suggestions?) Yes, it is difficult to be a student again especially meeting deadlines. (I haven't done so well here - certainly I wouldn't get an "A".)

- I've been grateful for the accommodations Becky (the instructor) has made for us. She's allowed us to put HyperStudio on our laptops, which will be a great blessing as we're off campus for four weeks during the time those assignments are due. The lab aides have been very polite in my experience with them.

- Thanks for helping set this up for the faculty. (I think it would be helpful if the deadlines could be adjusted for faculty—possibly extending through two semesters rather than one. I know Roger has felt overwhelmed, but would be able to succeed if the time constraints weren't a factor.)

- I'm slowly making progress -- I just need time, doesn't everyone? I heard we could have HyperStudio put on our laptop -- so we can work at home. Who do I talk to about that?

- I have learned a bunch and want to finish up Winter. I would like to learn all that the course has to offer. I will be in touch with you after the first of the year. Thanks for the opportunity.
• Enjoyed the class on Wednesday. The timeline was great. The first assignments are helpful. I look forward to the rest.

• Thank you for your wonderful class. I have loved learning from you. I feel like you have become my treasured and respected friend. I can’t believe how much I have learned in such a short time.

• I have some concerns about being able to finish this in one semester. Is it possible to extend it through next semester or do I need to just suck in up and finish it this semester?

• Well, I will tell you that I've decided not to do the class. From the packet and zip that was given to me, it seems that the information is presented for Apple/Mac, but I am a PC person, so I'm not doing the assignments. I admit that I did not take the time to find out if the assignments were also written for PC platforms. The reasons I didn't do this was most of the things that were part of the syllabus I already know how to do—I am very competent with word processing, clipart, word art, tables, formatting, etc.; I can use spreadsheets and databases, I can merge; I use PowerPoint for every class I teach; I've scanned documents; my family Christmas newsletter includes multiple columns, photos, clip art, calendar, etc.; so, I'm pretty technologically with it. I was hoping to learn about video editing and html—but not with a Mac. So, again, it might sound like I am whining and complaining—and in fact I might be. But the course is not going so well for me.

After receiving the last email above, a project member sat down with the faculty member and discussed her concerns. She was about to be the first dropout. The project member, with permission from the course instructor, restructured the assignments to better meet the needs of the faculty member. She was shown how to use the existing tutorials and class materials with her PC technology, which completely changed her outlook. The faculty member will focus on HTML and video editing. She will start producing her own class web site, which will take advantage of effective teaching videos she has produced with her video editing skills.

Conclusion

We have found in this pilot study that the faculty-as-students taking the technology service course model is an effective form of professional development for higher education faculty in a teacher preparation program. The faculty has found that they have been able to better learn the technology skills presented to them and that they have found ways to better generalize those skills to their own courses and research. The traditional conference/workshop model opens their eyes to possible uses of technology, while the faculty-as-student model gives them the skills needed to produce technology enhanced products, model those products, and write meaningful assignments for their students. Twenty of the 22 participants in focus group and individual interviews recommended the continual use of this model and would recommend the model for use at other institutions of higher learning. Some modest changes have been planned for Winter Semester courses and assignments by faculty who participated in the technology course. One of the most valuable outcomes of this project has been the open communication between faculty members across several departments. As they have worked on assignments together and met with the course instructors, students, and each other many barriers have been removed and they look forward to a continuation of learning and working together. The IP&T 286 course instructors as well as the teaching and learning support center director and teaching assistants are more open to faculty suggestions and the faculty are more willing to try new technology in their own courses. More time will be needed to measure the extent of the impact this experience will have on the faculty members as they continue to revise their curriculum and assignments to include technology. The positive response to the faculty-as-students model shows the need for further research in this area and further development of this model for faculty development.
Infusing Technology into Preservice Teacher Education: An Evolution in Methodology

Margaret A. Price, College of Education, Texas Tech University, USA, Peggy.price@ttu.edu

Patricia Herrera, PT3 Technology Specialist, Texas Tech University, USA, Patrici.Herrera@ttu.edu

Abstract: A teacher educator and technology specialist explore different methods of infusing technology into a secondary teacher education program over a four-semester time frame. They hoped to determine if preservice teachers' self-awareness of classroom computer application was raised and if strategies of how they might apply technology skills within their future classrooms were valued. They found preservice teachers had varying levels of technological competency and their level of value for the strategies introduced in their teacher education course differed according to their self-identified competency levels. Implications for practice included implementing technology components on-site at technology rich public schools and allowing preservice teachers to apply computer application skills within the classroom.

Introduction
Technology and its classroom use has been a primary focus of education reform. National technology goals have been developed and continuously revised to meet accountability standards of various federal, state, and local governing groups (NCATE, 1997), ITSE (2000), Texas Education Agency (1995), and others. As states and local districts implement standards-based initiatives to bring veteran teachers into the information age, future teachers must be able to show evidence of their technological skills. Teacher preparation programs address the call for instructional technology in various ways. Whether requiring stand-alone courses within programs or infusion of use throughout regular course work, teacher educators are obligated to prepare students for classrooms they will soon enter. (Gillingham & Topper, 1999), NCATE (1997), TEA (1995).

The Problem
Texas secondary teacher preparation programs are limited in the number of education classes required by the state governing board (Texas Higher Education Coordinating Board, 2000); therefore, many variations of “technology” coursework are accepted as meeting program requirements. In essence, secondary preparation students fulfill university technology criteria prior to entering certification programs. Students’ experience of computer usage focuses on fulfilling course work requirements within their major college and rarely on applications classroom use.

The Purpose
Primarily the purpose of this study was formulation and implementation of an infused technology component into secondary teacher preparation courses. We also hoped to determine if preservice teachers’ self-awareness of classroom computer application was raised and if strategies of how they might apply technology skills within their future classrooms were valued. The research questions guiding the study were:

1. What was the level of self-claimed educational technology competency of preservice teachers at the beginning of the semester?
2. How might the teaching team formulate lessons and activities, which might heighten preservice teachers’ awareness of various technology usage as a planning/instructional tool?
3. How did the technology component within the class influence how preservice teachers might use technology in future classroom situations?
4. What was the level of self-perceived educational technology competency of the preservice teachers at the end of semester?

Contextual Setting
Over four semesters the teaching team (the teacher educator and technology specialist) conducted various activities with preservice teachers. The technology specialist designed and conducted a variety of self-perceived technology competencies. Throughout each semester the teaching team participated in five technology lessons (hands-on, interactive instruction). Course requirements identified the submission of technology-informational and instructional activities for evaluation and inclusion on class web sites. The technology specialist conducted a post-test of self-perceived technology competencies. The teacher educator asked each class participant to address the value/non-value and possible future applications of the technology component in the students’ final self-assessment of the class.

Methodology and Data Sources
The teaching team used a mixed methodology to analyze data collected from four semesters in which the technology component was infused into preservice teacher education classes (Miller & Crabtree, 2000). Simple descriptive statistics were used to analyze the demographic, pre and post-test data, as well as described on technology related assignments. Qualitative methodologies were used to derive emerging themes of individuals’ perceptions of value/non-value of the technology component within the framework of the teacher education class. Pre- and post-tests on self-perceived computer skills were taken each semester. Computer skill activities were designated as part of course curriculum and competency was assessed by the teaching team. Students also had the opportunity to specifically address aspects of the technology component, which they deemed valuable/non-valuable in their final self-assessment of the course.

Results
Collectively, the demographic data revealed a typical population of preservice teachers: a majority were Anglo, female, middle class, and from within local geographic rural, urban areas (Lortie, 1975; Howey & Zimpfer, 1989; Darlings-Hammard, 1990). On the pre-test, 75% of the students identified their level of competency as computer literate. 11.2% selected “true beginners”, 2.9% identified themselves “experts”, and 10.2% were unsure of their ability level. Post-test results saw a slight increase in self-perceived upper levels of competency, with a decrease in the “true beginner” category. Of the 68 students participating in the study, 54.4% did not participate in any field experiences 13.2% had 40 or more hours, and 32.3% had less than 25 hours.

From the preliminary qualitative data analyses, several predominant themes emerged. Flexibility for individual students and classes and a difference in perceived needs between students and the teaching team emerged as a strong theme for consideration. Changes were made to address needs of...
preservice teachers and to better utilize available technology resources within the university. We made adjustments in the curriculum to be more open for preservice teacher input of particular needs, eliminating some activities and adding others. The teaching team identified themes of value/non-value which were particular to the self-perceived computer abilities of the preservice teachers. Of those who categorized themselves as computer "experts" the technology component had two reactions: non-value and less than valuable in terms of skills, yet valuable in terms of educational application. Of those who identified themselves as computer "literate", the theme of awareness emerged of how technology can be used in the classroom. Frustration, gratitude and application knowledge emerged as preliminary themes from the true beginners.

Implications and Suggestions for Our Own Practice

One obvious implication gleaned from the preliminary data is modification of expectations and requirements for a heterogeneous classroom, where differing levels of competency require differing levels of assignments. Secondly, we must provide opportunities in the field for preservice teachers to experiment with, explore options, and apply the lessons and activities they are asked to complete. Perhaps what the teaching team has actually done is create a "stand-alone" set of lessons infused within a course. While the preservice teachers profess to "see" the need for and use of technology within the classroom, they will not entirely value it until they can apply it. Preliminary data will guide and direct the development of an instructional plan to present the ITPTE model (Infusing Technology into Preservice Teacher Education). In spring 2002 a cohort of undergraduates will be placed at a technology-rich middle school for blocked methods classes and 30 hours of observation, teaching and classroom interaction. The availability of adequate technology resources for instruction, plus the possible opportunity to implement technology applications within field experiences may give us a clearer direction on how better to infuse technology into teacher preparation classes.

Results of a Study on Developing Learner-Centered Technology Assignments with Student Teachers

Joyce A. Rademacher, Jane B. Pemberton, & Tandra Tyler-Wood

Carefully designed infusion of technology into field experiences for preservice teachers can provide a formal teaching and learning approach that encourages future teachers to demonstrate and model proficiency in technology applications and usage. Thus, novice teachers will develop the ability to use available technology as a tool to enhance the learner’s experience.

Ideally, appropriate technology infusion should give preservice teachers the opportunity to learn how to structure lessons, student projects, and student activities that are motivational, involve active participation, permit collaboration, emphasize content mastery, and individualize instruction. As these teachers enter the profession, they will have a unique set of skills and technology-related experiences that will empower them to be adept in their classroom environment. Additionally, these new teachers will know how to plan the equitable use of technology-related resources and build a dynamically networked learning community based on curricular needs and goals.

Using technology to enhance pedagogy is necessary in a Professional Development School (PDS) model where universities and school district personnel work in partnership to prepare technology-competent teachers. Learning how to infuse technology into lessons and assignments that will meet the needs of all members of the learning community requires explicit planning in order to be effective. Nothing can be more important for the student teaching experience than mutually shared goals between university faculty and district practitioners in regard to technology-related experiences that will benefit public school students.

As a result of a Preparing Tomorrow’s Teachers in Technology grant (The Millennium Project, 1999), a district team teacher worked with university faculty in a PDS partnership to assist student teachers in the development of learner-centered assignments.

A learner-centered assignment is defined as an assignment that ensures equity in excellence for all learners (Texas State Board of Education, 1994) by including the characteristics of a high-quality assignment that is respectful of the needs of all learners while encouraging the use of their skills and talents (Rademacher, J.A., Deshler, D.D., Schumaker, J.B., & Lenz, B.K. (1998).

Team teacher planning and development activities that facilitated successful completion of assignments by the student teachers and their students were as follows: (1) The team teacher consulted faculty who taught content courses and helped them locate high-quality lesson plan sites, identify technology resources in the schools, and design the assignment completion guidelines the student teachers were expected to follow; and (2) Planning guidelines for the assignment were explained in the curriculum class and student teachers were taught how to use two planning forms entitled the Student Intern Planning Sheet and Approval Form and the Self-Evaluation of Student Choice Assignment form. These guidelines helped the student teachers design their assignments check their final product for quality.

Team teacher support activities that ensured student teachers were successful in the design and implementation of assignments with their students were as follows: (1) Student teachers were instructed to consult their mentor teachers for ideas and approval of assignments that were relevant to their particular student teaching setting; (2) District curriculum coordinators were invited to share ideas and resources with the student teachers; (3) Two days of “hands on” technology training was provided in the district technology lab to brainstorm project ideas; and (4) The team teacher provided ongoing assistance to the student teachers as needed while they developed their assignments. Student teachers were required to share their assignments during the last student teaching seminar.

Types of assignments varied according to student/mentor needs and interests. Example assignments included web pages, power-point presentations, Internet research projects, learning center assignments, brochures, and pet care guides. Student teachers and mentor teachers were very pleased with the final products and attributed their assignment completion success to the support provided to them by the
team teacher. Students in mentor teachers' classrooms were also quite pleased with what they had learned as a result of the student teachers' assignment planning and implementation process.

A survey based on technology standards as defined by The International Society for Technology in Education (ISTE) was administered to these 31 preservice teachers three times over the course of the student teaching year. One part of the survey, Stages of Adoption of Technology (Christensen, 1997), asked student teachers to circle the stage that best described where they were in their use of technology at the beginning of the year before they completed their student teaching assignments. They were also asked to complete the survey mid-way through the year, and again at the end of the year after they had used technology in their student teaching placements. The scale was as follows: Stage 1 = Awareness; Stage 2 = Learning the Process; Stage 3 = Understanding and application of the process; Stage 4 = Familiarity; Stage 5 = Adaptation to other contexts; and, Stage 6 = Creative application to new contexts.

Results were analyzed to determine if there was a change in the student teachers' attitudes toward technology and their level of confidence in using technology to enhance teaching and learning for their students. Survey results indicated that student teachers' felt more confident at the end of the student teaching year in contrast to the beginning of the year as to their level of confidence in adopting technology. Mean scores were calculated to show how perceptions had changed from the beginning of the year to the end of the year as follows. The differences in mean scores and how they changed from the beginning to the end of the year are as follows: Stage 1 Awareness = 4.0 to 6.0; Stage 2 Learning Processes = 4.4 to 4.8; Stage 3 Understanding and application of the process = 4.3 to 5.0; Stage 5 Adaptation to other contexts = 2.9 to 4.5; and, Stage 6 Creative application to new contexts = 3.3 to 4.5.

Conclusions from this research are as follows: (1) Opportunities for enriching technology experiences are possible for everyone during a PDS experience; (2) The assignment completion planning forms were helpful in designing and evaluating the components of a learner-centered assignment; (3) District support is needed and necessary in order to facilitate rich technology assignments for student teachers; and (4) Team teacher support should be expanded to increase technology integration opportunities for both faculty and students in the field.

Note: For a detailed explanation of the methods, procedures, and planning forms employed to develop and implement learner-centered technology assignments in a field-based setting, see the following reference: Radmacher, J, Tyler-Wood, T, Doclar, J., & Pemberton, J. (2001). Developing learner-centered technology assignments with student teachers, Journal of computing in teacher education. 17(3), 18-25.

Abstract: This paper explores the work of a unique graduate math methods class that used its difficult start with laptop computers as an opportunity to develop teacher-student relationships that were supportive and collaborative. This teacher dropped the role of all-knowing lecturer to move among the students asking questions that drew multiple ways to express theories from students in a Sketchpad program. Instead of isolated work at computer stations, students carried their computers to each other's table to share this tool for knowledge building and the conceptual understanding of geometry. Observations in this classroom and two others found students sharing their developing skills, discoveries and experience with each other and their professors in an atmosphere that sometimes left the observers wondering who was the teacher and who was the student.

Introduction

This examination of the use of laptop computers in the college classroom began with a class that made clear why faculty members in many universities do not model use of technology (Mousand & Bielefeldt, 1999; Wetzel, 1993). The teacher's discomfort with the wayward touchpad cursor on the laptop, the disappearing projected screen, and a challenging software program seemed to prove through their failure the truth of Groves and Zimmel's (2000) assertion that professors want computers and a software program that are easy to use and instructional technology (IT) support that makes their job in the classroom look easy. The students' distress with the roaming cursor on their laptops' touchpads was equaled by their own unfamiliarity with the new software program. To these observers it seemed to be an example of a disastrous first lesson.

However, this instructor and her students turned their initial turmoil with the laptop computer and a new software program into an equalizing learning experience. They demonstrated the truth of Smaldino and Muffoletto's (1999) claim that students first gain understanding of applications through an in-depth examination of the way the program works in the classroom. This paper explores the work of a unique class that used its difficult start not as an obstacle but as an opportunity to develop teacher-student relationships that were supportive and collaborative. As the students' role in the decision-making process grew in the classroom, the roles of teacher and student became equalized (Holland, 1994).
Laptops as Power Mediators

Learning in schools is marked by a basic, concrete division between powerful teachers and the powerless students (Giroux & Penna, 1981). As students gained opportunities to problem solve and initiate activities, the powerful teacher as lecturer role shifted to one of teacher as mediator in the graduate methods class on geometry. After two class periods, the laptop computer forced the professor to move among the students asking questions that turned student's initial line segments into radii of circles, sides of parallelograms and angles, and edge bisectors. Students were constructing, labeling, and measuring geometric forms with the aid of Sketchpad and discussing how these forms combined isolated theorems into theory. This graduate class of classroom teachers and teaching consultants were using the laptop and a software program, Sketchpad, as another manipulative tool in their conceptual approach to teaching geometry and linking geometric concepts to algebra.
