The professor and her students continued to evaluate ways of exploring geometric concepts with Sketchpad and other reinforcing manipulatives during each class period of the semester. Students were free to complete class tests with the assistance of Sketchpad and the laptops or with other classroom manipulatives. The final six hours of class found students in the class offering collaborative lessons with the laptops and the Sketchpad software. Interviews with teachers and teaching consultants in this class made clear that they were aware of the way they have begun to work as equals in the room co-constructing knowledge. Discoveries came fast as geometric forms could easily be removed and restructured with the Sketchpad software. Instead of being isolated at computer stations students carried their computers to each other's table to show their work and share this tool for knowledge building and the conceptual teaching of geometry.

As members of the Preparing Tomorrow's Teachers for Technology (PT3) team, we followed the work of this class and two other classes this semester to chronicle the relationship of the teacher, students, and laptop computers and to lend assistance when needed. The students shared their developing skills, discoveries and experience with each other and their professors in an atmosphere that sometimes left the observers wondering who was the teacher and who was the student.

References

Abstract: The University of Houston's Preparing Tomorrow's Teachers for Technology (PT3) team has found an unexpected tool for the evaluation of the effectiveness of its restructured instructional technology class. The individual listservs offered with the three new three-semester, one-hour labs that replaced the original three-hour single course provided a cross-sectional study of student progress through the labs. This satellite view of the three semester lab restructuring suggested that despite a disorienting first semester, preservice teachers progressed toward the incorporation of technology in the classroom culminating with authentic lesson integration for their students.

Introduction

As a major part of its Preparing Tomorrow's Teachers for Technology (PT3) grant, the University of Houston PT3 team has restructured the instructional technology class for its pre-service teachers. The original three-hour class was reorganized into three one-hour labs taken over three semesters beginning in the pre-service teacher's junior year. The goal has been to employ a constructivist approach to facilitating the integration of technology into the methods of instruction these students are learning in their education courses, a goal encouraged by Leggett and Persichette (1998). The long-term goal is to encourage the use of appropriate technology in the future K-12 population taught by these graduates. This year a cross-sectional study of the effectiveness of the three labs was facilitated by the postings of students in their individual listservs or hypergroups.

The listservs supplement the labs by expanding social and knowledge networks (Hansim, 1993) with the other sections taking their course and with the team of Technology Fellows that facilitate the lab. The listservs are examples of Baym's (2000) "communities of practice" with both a virtual and real time class life for these students.

A Chronicle of Student Progress

For the PT3 team, the listservs also provide a satellite view of the progress of the students through this series of three labs. The beginning students in the first semester lab were still adjusting to constructivist nature of the class as the following two students explain in their early postings.

Student 1: It has been very difficult for me, considering I have never had a computer class since high school. I am not sure of what the exact expectations are, and what the process is of turning them in. Is there tutoring, or someone who could write out the steps for me to follow? Thank you!

Student 2: I'm very confused about this class as a whole. It seems like most of the learning I have to do on my own.
As these students are asked to hone their technology skills as part of their co-construction of knowledge for integrating technology into teaching methods in the classroom, they are often overwhelmed because they find themselves to be the architects of their own learning.

Students began to think for themselves in the second semester. Note a student’s early response to the new vocabulary that describes the students’ work accountability system as it shifts from the standards set by the International Society for Technology in Education (ISTE) standards to skill proofs and knowledge proofs.

Student 3: I think I am finally grasping the concept of having knowledge proofs and skill proofs instead of ISTE’s. Knowledge proofs are an explanation—like a preservice teacher type manner—of the knowledge gained, and skill proofs are a very short explanation of what I did with that particular skill.

Even though these students in the second semester of lab work were beginning to think like pre-service teachers, they were still missing the application in the classroom as practicing teachers that the students in the final semester were experiencing. Notice the contrast in the responses of students 4 and 5 to Internet sources for teachers.

Student 4: A useful website for the classroom that have reviews of software for the classroom is http://www.superkids.com. This website has education articles and educational tools that every teacher can use in his or her classroom.

Student 5: My 5th graders are studying the founding of Jamestown in Social Studies. EDSITEment has a link that contains maps, labor contracts, court records, public records, newspaper clippings, ... all about the founding of the Jamestown Colony. ... My kids can use this site to help “build a new settlement.” I’ve bookmarked this site for future use when I have my own class.

Although Student 5 was not yet teaching on her own, she was in the classroom every day and had found a way to integrate technology into a lesson now and in her future role as a teacher on her own. Student 4 in the second semester of her technology lab was still referring to her teaching experience in the third person.

The students in the third semester were also learning about the discrepancy between having computers in the elementary school classroom and using or being trained to use the computer in the university classroom as students 6 and 7 explain in their postings.

Student 6: The computers in my class are all brand new Dell computers. They have windows 2000, Accelerated Reader, School House Rock, Grammar Crunch, Internet. They have all kinds of games and software discs that the children can use.

Student 7: I have not seen a tremendous amount of technology in any of my methods classes. My math methods prof has used technology in our classroom in meaningful ways, from videos, to a power’s of 10 exercise that was great. My other methods classes have had discussions about the use and importance of technology integration, but have not had actual technology present. I look forward to visits from the tech fellows in our methods classes in order to enrich our learning and the learning of our future students.

The students in the final semester were surprised and pleased to see computers in their classrooms. They were also surprised that their methods teachers were not actively using technology in their teaching. However, the students did find ways to integrate technology into their practice teaching and appreciated the technology lessons the tech fellows would bring to their methods class.

This satellite view of the three semester lab restructuring suggests that despite the early disorientation for the first semester students, the payoff for the technology lab students develops as they reach the classroom and finally get to practice what they have been learning. Student 8 offered a similar conclusion in her last posting on the listserv.

Student 8: I learned a great deal the last three semesters about integrating technology into the classroom. ... Children need to be stimulated and challenged in the schools and I value the importance of technology in helping me to do that.

EDENStandards: Standards for Digital and Education Equity

Kevin Rocap
J. David Ramirez
KimOanh Nguyen-Lam
Yolanda Ronquillo

Along with Standards for challenging content and discipline-specific teaching methods, we need Standards for equity, inclusion and diversity-responsiveness in K-12 teaching and learning and teacher preparation. If we neglect the imperative to address historic inequities with regard to underserved learners even as we work to integrate emerging technologies into teaching, learning and teacher preparation we can expect to exacerbate Digital, Education and Opportunity Divides. Panelists for this presentation are colleagues from the Center for Language Minority Education and Research (CLMER) at California State University, Long Beach. The Equity through Distributed Education Network (EDEN) a PT3 Catalyst grant for which CLMER serves as lead agency has worked with diverse educators to develop EDENStandards for meaningful, diversity-responsive approaches to technology-enhanced teaching and learning. We will share our EDENStandards, discuss their implications and share a number of teaching and learning, teacher preparation, professional development, community-building and policy approaches that flow from attention to these EDENStandards.

Panel Participants and Presentations

Panelists will focus on key diversity and equity issues addressed in the framework of the EDENStandards. This discussion will include proposing an equity vision for 21st century learners, addressing key elements of education reform from an equity perspective and sharing the use of CLMER "equity lenses" of: Language, Critical Pedagogy, Anti-Racist Education, Community Learning Theory, Standards and Technology Fluency. Panelists will describe how these lenses are operationalized in approaches to professional development, teacher preparation, policy work and work with schools, districts and communities.

Kevin Rocap, Director of the PT3 EDEN Project, will describe the process of developing the EDENStandards and the key practices of the Center that reflect these standards, sharing strategies, resources and lessons learned. These will include sharing information and strategies regarding an innovative professional development approach for developing communities of practice among teachers, administrators, parents, pre-service teachers, teacher education faculty and others to develop equitable, diversity-responsive K-12 learning projects and supportive cross-role community approaches to equitable education reform.

J. David Ramirez, Executive Director of CLMER, will discuss "making the invisible visible," diversity-responsive approaches to assessment and accountability designed to address both Education and Digital Divides. Dr. Ramirez will address specific issues of educational equity with regard to English Language Learners, girls, religious minorities, children of color, low-income children and children with special needs. A framework for assessment and evaluation that draws on critical multicultural and anti-racist theories and practices will be shared, along with examples of the application of the framework to projects and K-12 practices.

KimOanh Nguyen-Lam, Director of an Alternative Bilingual Teacher Preparation project and a policy forum leader, will describe the development and work, over the last several years, of a national network of Southeast Asian and Pacific Islander educators and community leaders (the APA Forum). Dr. Nguyen-Lam will discuss the myth of the model minority and share the priority issues and action agenda of the APA Forum and related organizations committed to addressing the needs of underserved Southeast Asian communities. Further, she will share her work creating distributed learning courses that address the CLMER vision of a multilingual, multicultural 21st century learner. Courses will be discussed for their capacity to support K-12 Two-Way Bilingual Immersion programs and the integration of technology-enhanced, performance-based assessments in the development of high-quality, diversity-responsive teaching and learning practices.

Yolanda Ronquillo will describe the work of CLMER in facilitating the development of Community Learning and Technology Centers that link K-12 learning and community-based learning, and
that level the playing field for diverse, underserved learners. Further, Ms. Ronquillo will share uses of image, metaphor and storytelling in adult learning and as a support to cross-cultural community building and action planning in K-12 education reform. The promotion of digital equity will be discussed as a significant outcome of work across several school communities in the Hawaiian Islands.

All panelists will invite participants to consider ways to apply EDENStandards and related equity frameworks within their own situated practices and communities.
Global Learning Networks in K-12 and Teacher Pre-Service

Kevin Rocap, CLMER/CSULB, US
Kristin Brown, CLMER/CSULB, US
Carla B. de Herrera, CLMER/CSULB, US

Global Learning Network projects provide excellent opportunities for domestic and international K-12 collaborations that are multilingual, multicultural and academically challenging. Further, they can promote cross-cultural understanding, a commitment to social justice and provide challenging content and pedagogy for traditionally underserved learners. This workshop describes K-12 Global Learning Network projects and new learning projects that link pre-service teachers, teacher educators and K-12 classrooms. The Center for Language Minority Education and Research (CLMER) has facilitated and co-sponsored K-12 Global Learning Network projects since 1996 in collaboration with I*EARN and “De Orilla a Orilla.” As part of the Equity through Distributed Education Network (EDEN) PT3 Catalyst grant CLMER has enhanced and extended these projects significantly to include teacher education faculty and pre-service teachers. These projects are performance-based additions to teacher preparation coursework and field experiences, with great potential for providing a meaningful, multilingual and multicultural enhancement to teacher preparation.

Workshop Purpose

This workshop engages participants in understanding the power of Global Learning Network projects not only as K-12 learning projects, but as powerful tools for in-service and pre-service teacher professional development. This workshop will address the following objectives:

1. Provide a model for the design and implementation of academically challenging, social justice-oriented Global Learning Network projects.
2. Engage participants in examination and discussion of successful projects.
3. Share innovative uses of Global Learning Networks for Teacher Professional development and Teacher Education.
4. Engage participants in action-planning around potential participation in Global Learning Network projects.

Workshop Methods

Presentation and discussion of a critical pedagogy framework used in the design of Global Learning Network projects will be facilitated, with discussion among participants and use of a graphic organizer for participants in pairs or threes to brainstorm use of the framework on content of their own choosing. Logistics permitting, three presentation stations will be set-up so that participants can rotate through three presentations of different Global Learning Network projects including two that have been used to link pre-service teacher educators with K-12 classrooms and to other pre-service educators for bilingual study of learning theories. If this format is impractical, presentations will be done from the front of the room with small group processing and discussion between presentations. We will facilitate dialogue on the power of Global Learning Networks, the protocols for participation, cross-cultural issues and how to deepen projects with social action outcomes for addressing issues of diversity, equity and international education. Also, we will facilitate discussion regarding the professional development and pre-service value of Global Learning Network projects for creating motivated, international communities of practice. Small group work will be facilitated for action planning and next steps regarding participation in projects.
Technology Rich Lessons from the Field

Cindy Ross, Bowling Green State University, US
Rachel Vannatta, Bowling Green State University, US
Mike Duplay, Bowling Green State University, US

This poster will present numerous examples and samples from children, teachers, university students, and university faculty demonstrating their growth and current practices of technology use in the classroom. These projects represent a variety of age levels as well as curricular areas. In addition, lesson plans from classroom teachers and university faculty will be presented as examples of the infusion of technology into the classroom. This collection of technology enhanced lessons will be demonstrated from the project website that is available to others as a way to share information. Each of these lesson plans not only demonstrates the infusion of technology into the classroom but each also includes the identification of the ISTE standard(s) facilitated in the lesson. The participants have included elementary, secondary, special education students, teachers, preservice teachers and university faculty. The university faculty represents regular education and special education methods as well as faculty from arts and sciences.

The materials that will be displayed represent a variety of software programs that have been used in the classrooms; they include Kidpix, PowerPoint, Inspiration, Kidspiration, “Work Appleworks, etc. These products also represent a variety of ability levels as well as growth by the teachers and the students. University faculty has been working to develop their skills to begin to or further infusion of technology in instruction and assignments in their classrooms.

A scavenger hunt was developed to have teachers and faculty identifies ISTE Standards within lessons and from poster board presentation to facility the understanding of these standards. This will also be shared. Student products will demonstrate how technology has been infused into a variety of themes and content areas.

Individuals representing the project directorship, university faculty, trainers, and preservice teachers will be apart of the poster/demonstration to explain the materials prepared by the project participants.
Faculty Development Training Time: 96 is Not Enough!

Tweed Ross, Kansas State University, US
Rusty Taylor, Kansas State University, US

As part of a United States Department of Education Preparing Tomorrow's Teachers to Use Technology (PT3) project faculty from College of Education, Arts and Sciences, Community Colleges and local school districts participated in yearlong intensive academies. The guiding philosophy behind these academies is that “Teachers will teach as they were taught.” Unless we change the habits and practices of the professoriate and clinical instructors who work with future teachers, little progress will be made in changing the teaching methods of preservice teachers about to enter the profession. To bring about the needed change in teaching practice on the part of those charged with preparing future teachers, the College of Education set about creating intensive academies for faculty and teachers to integrate technology into the classroom. The intensive academies for faculty identified many factors necessary to successfully modify teaching habits of university faculty and clinical instructors. Some of these factors were anticipated. Others came as a revelation. All came about because of an intensive review and evaluation process developed to assist this effort.

This paper will discuss the review process that was maintained throughout the academies and used to guide in an on-going, nearly real-time manner the activities of the academy. Also, this paper will cover the many interested findings from these evaluation activities and discuss possible reasons and necessary modifications that future technology leaders will need to address in their design of technology and pedagogy development for university faculty and clinical instructors. Among these are:
- Initial partnership creation
- Required infrastructure
- Successes and barriers
- Tailor the program to a diverse audience.
- Making a win-win partnership
- Long-term implications for success
The Right Hand Helping the Left: Tech Savvy Students Assisting Classroom Teachers

Tweed Ross, Kansas State University, US
Sue Maes, Kansas State University, US

This presentation will cover a newly launched initiative as part of a Preparing Tomorrow’s Teacher’s to Use Technology (PT3) grant project. It is based on two premises. First, that some students entering the teaching profession possess advanced technology skills before they are admitted to the College of Education (e.g. good high school preparation or personal motivation). These students are not challenged by the basic technology course in the college. This project will allow these student an opportunity to advance their skills and gain practical experience. Secondly, many College of Education Methods faculty and K-12 teachers find that the development time necessary to accomplish technology enriched instructional activities is limited in their already crowded day. They may need extra help in initiating or finishing a technology-based instructional unit. A hands-on experience developing and using software applications, directed by an educational professional, is a powerful model for a teacher candidate.

Research studies from The Office of Technology Assessment (OTA) and the International Society for Technology in Education (ISTE) both confirm that the majority of education faculty do not model technology use to accomplish teaching objectives nor do they teach students entering the teaching profession to use information technologies for instruction. The public school educator is also critical in providing the real day to day capstone experiences preservice teachers need prior to entering the teaching profession. Students do not learn from technology per se, but from creative teachers who have knowledge of technology options and model technology through the use of curriculum enriched experiences and activities.

In an effort to address these needs, sixty-one (61) faculty and public school educators have participated in a Preparing Tomorrow’s Teacher’s to Use Technology (PT3) grant opportunity designed to integrate and model appropriate technology applications in the classroom environment over the past two years. The PT3 focus was on the guiding philosophy that “teachers teach as they have been taught” and through curricular revision, advice from well known consultants, assistance from peer and technical mentors, plus on-site hands-on technology workshops, participants developed a mediated project using appropriate technologies to enhance student learning.

Extensive evaluation and frequent reality checks revealed that participants in this project felt empowered and were enthused to use technology in their classroom(s), but lacked the necessary development time to build additional mediated learning experiences after completing the scheduled workshops. Therefore, in this third year of the PT3 project, this new initiative allows qualified preservice students an opportunity to take some accelerated coursework/training and be paired with a practicing teacher (one of the sixty-one PT3 Alumni) to help facilitate the development of instructional-based units for the classroom.

A win-win partnership!
You Can't Do it Alone: Requirements for Preservice Teacher

Tweed Ross, Kansas State University, US

Preparing Tomorrow's Teachers to use Technology (PT3) at one College of Education was a unique experience in forming collaborative teams across several educational levels. This PT3 Grant was closely interwoven with another United States Department of Education Improving Instruction grant effort aligned with a College of Education and its associated Professional Development K-12 Schools, College of Arts & Science faculty and Community Colleges. One of the real challenges in Preparing Tomorrow's Teachers to use Technology effectively in class in an effort to improve student learning is building collaborations between the College of Education (COE)---which ultimately provides the methods and pedagogical experiences for pre-service teachers---and the many departments and colleges that are allied with the COE through undergraduate experiences. These other stakeholders provide the formative and capstone experiences for teachers about to enter the profession. A typical learning path found COE teacher candidates engaging in learning experiences with community colleges, college of arts and sciences, and school districts. Each of these institutions has fundamental differences in organizational mission and outlook toward education. All are directed toward developing young people who are involved in the teaching and learning process. Developing effective collaborations, particularly in implementing technology, is one of the key components of getting the These collaborations are not hastily built to meet immediate demands. They take years of compromise, minor collaborations and trust building before the grant is written and the technology components are added. Once technology is added to the mix of skills that future educators must master for the classrooms of tomorrow, these collaborations involve extensive communication at the administrative level, technology support level, technology training level, and supervised teacher level. Another critical highlight of this work was the integration of technology and the vertical integration of instructional improvement. This project resolutely refused to simply teach the technology applications. Instead the project required participants to do three steps: 1) identify a difficult or repetitious teaching/learning concept from their curriculum, 2) identify learning objectives, and 3) select appropriate technology enhancements that would further student learning. This presentation will review the efforts that resulted in this successful collaboration in several parts.

Assessing Program Alignment With Technology Standards

Regina Royer
Department of Education
Salisbury University
United States
rdroyer@salisbury.edu

Abstract: The faculty in the elementary education program at Salisbury University utilized a database to gather data regarding their integration of technology in course objectives, learning activities, and instructor modeling. An examination of their use revealed that faculty used technology with students primarily to access information and to communicate. Fewer faculty modeled the use of technology to support learning activities within the classroom. Greater access to technology in the classroom and continued faculty development are necessary if faculty are to use technology as a tool for teaching.

The Study

The study posed the following question: In what ways is technology being used in the elementary education program at Salisbury University?

Method

Background

Through Salisbury University’s PT3 Capacity and Implementation PT3 grants, faculty were participating in professional development in the area of technology and were beginning to utilize technology in their courses. With the release of Maryland’s Teacher Technology Standards, the faculty needed data to determine if students in the elementary education program were having learning experiences that enabled them to meet these technology standards. Further, the faculty needed to determine if students in all sections of a single course were getting the same experiences with technology. The faculty needed a way to examine current practice and developed a database to provide the necessary data.

Data Collection and Analysis

Based on the Maryland Teacher Technology Standards (MSDE, 2001), the database provided a checklist of technology indicators within three areas: technology objectives, technology rich learning activities, and instructor modeling of technology-based teaching strategies. During the Fall 2001 semester, elementary education program faculty, using course syllabi as guides, entered data into the database, indicating which of the indicators were addressed in their courses.

Findings

The data revealed that the Maryland Teacher Technology Standards were being addressed in the elementary education program. The most frequent reference to technology in course objectives, occurring in 61% of the program syllabi, was in the area of information access. The next section of the survey examined the use of technology in learning activities for each course in the program. Again, the program was strong in using technology to access information. For example, 79% of the faculty indicated that they
required students to research a topic using an electronic source of information. Sixty-one percent of the faculty required students to use email to communicate. Using email (88%) and providing students with Internet resources (82%) dominated instructor modeling of technology-based teaching strategies as well. Additionally, many faculty were using web resources to provide students with online syllabi (45%) and web based discussion areas (36%). Fifty-two of the faculty indicated that they use PowerPoint to convey information to the class.

Conclusions

An examination of the data revealed how and where technology was being used and for what purposes. On the whole, there was minimal reference to technology in program course objectives. Faculty used technology as a tool to meet content area objectives and for the most part did not indicate the use of technology as a primary outcome of their courses.

Examination of the faculty's use of technology in learning activities revealed a pattern of usage. Technology was primarily used as a tool to access and organize information and to communicate. For example, most faculty were requiring students to access information on the Internet (79%) and to use email to communicate (61%). Technology integration was addressed primarily through assignments. Forty-two percent of elementary program faculty indicated that they required students to develop a lesson, unit plan, or learning center that incorporated best practices for technology integration. The second most common integration activity (36%) was to require students to examine educational software. No other indicator for technology integration was addressed by more than 15% of program courses.

Elementary education faculty frequently modeled the use of technology for information access and communication. Many of them provided lists of Internet resources that were pertinent to their content areas and even more used email to maintain contact with their students. Almost half of the faculty had their course syllabi online. Faculty, however, were not yet modeling many of those strategies that utilize technology to facilitate learning. Thus, while faculty were using technology to support their courses and while students were using technology to support their learning, in many cases neither were experiencing those strategies for integrating technology that are more appropriate for the K-12 classroom. Currently, teachers in the K-12 setting rarely communicate with their students through web based syllabi, discussion boards, or email. However this seemed to be one of the most prevalent strategies for integration in the elementary education program at Salisbury University. Computers were not yet commonly used as tools to enable students to develop understandings within content areas. Computer programs that can help shape and construct student understandings such as databases, spreadsheets, concept maps, WebQuests, multimedia production, scientific probes, and simulations were not widely used. In the elementary education program, technology was primarily a tool to access information and communicate.

Implications for Practice

The data analysis revealed that faculty were indeed including technology within their courses. In the area of technology integration, however, faculty were primarily instructing about technology by assigning students to create lessons that used technology instead of teaching with technology. Schools of education need to continue to provide professional development to assist faculty with integration strategies. Additionally, education departments need to continue to provide increased access to technology. When completing the survey, several faculty mentioned access as an impediment to integration. At SU not all classrooms are equipped with technology. While the department does have a computer lab and a mobile laptop cart, reservations must be limited because of the large number of faculty who must share these resources. Under these conditions, it is difficult for faculty to teach with technology on a regular basis. There must be ready access to technology before it will become a seamless part of teacher education.

References

Abstract: As part of second year initiatives under our PT3 grant, significant changes to instructional technology facilities and increased training opportunities are providing faculty, pre-service teachers, and classroom teachers with significant technology support. We have increased our efforts to ensure that educators at all levels receive training on the use, operation, and integration of technology into their respective curriculum areas. Through these initiatives, we have learned many lessons in reference to “what works” and what “doesn’t work”. This paper and presentation will highlight lessons learned as we continue to experiment with methods to help university faculty, practicing and pre-service teachers increase their knowledge about technology and enhance their ability to successfully integrate it into their teaching.

Introduction

A historically white public institution and a small historically black private institution have partnered in their faculty development efforts as part of a PT3 Implementation grant. Through this grant, two diverse universities have jointly implemented a series of initiatives to transform their respective teacher preparation programs. Specific initiatives include: 1) providing release time for faculty to develop and infuse instructional technology into their courses and to serve as leaders in their respective disciplines; 2) increased opportunities for university faculty, practicing and pre-service teachers to receive individualized technology assistance by creating an “Infusio” Laboratory that provides "hands-on" assistance to incorporate technology into classroom instruction, and 3) offer workshops and technology discussions geared for educators at all levels to provide opportunities to share ideas and technological innovations with peers.

This paper highlights lessons learned as we continue to implement our PT3 grant, evaluate our progress, and seek solutions to technology and pedagogical problems as they arise.

Lesson Number One: Time

Typically, faculty at VCU teach a nine-hour course load each semester. Through our PT3 grant, several faculty each semester are provided a course release (three hours) which allows them to partake in technology training sessions. These sessions provide instruction on the use and integration of technology into their respective content areas. Through our observations, we have found that faculty who successfully implement new technology into their courses (i.e. the use of a course management system, such as Blackboard Course Info) must commit a large amount of time to learning how to use these new tools. Faculty report that often they are just starting to gain confidence with a new technology tool just as their course release time is about to end.

To provide faculty members with more time to hone their skills and develop appropriate technology activities that match their course objectives, we are providing each faculty member who obtains a course release during the academic year with a summer stipend to continue their technology exploration. Several technology training sessions are offered during the summer. Faculty comment that they appreciate the opportunity to explore technology on their own during a slower paced time of year. As one faculty member stated: “Having time in the summer allows me to get to know a program in-depth. I can explore technology resources and really think about what I want to use with my class, and more importantly – decide what I don’t want to use with my class. Technology blends into what I am doing!”
Lesson Number Two: Technology Savvy Faculty and Limited Resources

Both VCU and VUU have come a long way in expanding available technology resources for both students and faculty. VCU has a state of the art technology-teaching lab, and is in the process of hard wiring several classrooms in the education building. These classrooms will contain a mounted projector, which easily allows software programs and Internet tools to be shown to students. VUU has enhanced their wireless network, which allows faculty to access the Internet and VUU's network from a variety of classrooms.

As faculty become more technology savvy, we have found that they want to provide hands-on technology experiences to their students during class time. When interviewed, one faculty member reported: "I'm grateful for the opportunity to learn about such wonderful technology, in some ways the more I learn the more I become frustrated about our current state of affairs...my opportunity to use [technology] in my instruction is hampered by the lack of technology in our own classrooms...how am I to model the use of technology for my students?"

The PT3 project coordinators at both universities are attempting to address this problem. At VCU, we are investigating the purchase of wireless notebook networks which can easily be used in classrooms. As new laptops are purchased, we are mandating that they have built in wireless capability. As the demand for "hands-on" learning grows, we are also examining our current physical space and determining if we can create another technology teaching lab in an existing classroom. We have also facilitated discussions with colleagues in other buildings across our campus to determine whether they may have technology rich classrooms that we may use on a limited basis. Additionally, we are informing the technology officers of the university of our needs. Our thinking is that if we require more technology rich teaching environments, our colleagues throughout the university must also have these needs. At VUU, staff there are expanding their wireless network and are in the process of updating their computer lab.

Lesson Number Three: More Learning, More Training

We have been delighted that faculty have taken advantage of the many training opportunities provided to them in the School of Education and throughout the university. While faculty learn much at these training sessions, we have found that often they require some one-on-one assistance or a review of material covered during a training session. We have been able to provide this support through the Infusio lab which is housed at VCU.

The Infusio Lab, which is partially funded by PT3 funds is a staffed facility which contains several computer workstations and a variety of equipment. The lab houses a two-way video-conferencing distance education classroom, interactive whiteboards, Mimeos, and a variety of scanners and digital cameras. Due to increased use, we have hired a lab director who oversees the day-to-day operation of the facility and supervises several graduate students who work with faculty. As faculty and their students learn more about the uses and applications of technology, we have found that there is an increased demand for assistance in the Infusio Lab. Therefore, we have expanded the days of operation to five days a week and have also extended the hours of the lab til 8 P.M. to accommodate the schedules of university faculty and student teachers.

While Infusio staff are available to provide assistance to faculty and students, we have recently started to create "job aids" which provide clear directions on how to use a variety of equipment and software which both universities use. These aids are useful to faculty who need step-by-step guidance when using a new piece of hardware or software. The lab has also purchased CDs which provide instruction on a variety of software programs. These CDs can be checked out, and also allow faculty to learn at their own pace.

Conclusion

As university faculty and pre-service teachers use and learn more about technology, we are finding that we must examine how we best train and provide technology opportunities for members of the university community. We are in our second year of our PT3 grant, and are quite pleased with the progress we have seen in the areas of technology integration. Having to rethink policy and change established practices shows us that we are making significant progress in the use and integration of technology into our respective School's of Education.
Enhancing Student Centered Classrooms with Technology

Abstract: This paper is a report on training provided for in-service teachers through a PT3 grant at a regional university in the south US. Teachers were trained using a new instructional design model that focuses on learning on a continuum and shifts activities from teacher-centered to student-centered. Technology was integrated at all levels of learning and multiple resources were made available to the teachers. Learning Units were created and implemented in local classrooms. Videotapes were obtained of portions of the implementation of the learning units and students response was positive, enthusiastic, and showed strong interest in having more lessons that used the computer.

Introduction

Valdosta State University is the recipient of a three-year, US Department of Education grant entitled, “Preparing Tomorrow's Teachers to Use Technology.” One of the components of the grant project is to work with local teachers to develop interactive learning activities using various technologies. The method chosen to train practicing teachers to develop learning units, utilize technology, and implement the units in their classrooms was workshops. Teachers were offered stipends for products they created and substitute teachers were paid for when teachers needed to miss class to work on their products.

The Project

Participants were required to attend 6 face-to-face sessions at Valdosta State University (VSU), use online discussion boards for collaboration with peers and colleagues, and communicate with instructors via email. Furthermore, participants contracted to design and develop technology integrated learning units, implement the learning units in their schools during the upcoming term, allow observation and evaluation by a PT3 team member during the unit in their school, as well as have the unit used by another teacher and obtain formative evaluation of the unit. Once evaluation occurred the unit was refined and submitted for final approval and publication in the Virtual Learning Resource Bank (VLRB), an online resource created for teachers through VSU's PT3 grant project.
The workshop is designed to introduce teachers to creative ways of integrating technology at every level of learning. An instructional design model was developed to provide the framework for the workshops. The model is based on the principle that learning occurs on a continuum, and with appropriate planning, teachers can accomplish objectives that are directly related to grade-specific (K-12) state standards. The learning units follow a theoretical model that ties objectives, instructional strategies, technology, and assessment together to form activities that promote success for learners in every grade.

Participants are introduced to a vast number of resources during the workshop. WebQuests, Excursions, Virtual Field Trips, and Virtual Reality worlds are among a few of the Internet based resources that teachers are introduced to. For some, these resources become an important part of their teaching. One teacher said, "For me, the most valuable part of the PT3 experience has been learning about WebQuests and the vast number of relevant web sites for teachers. I also came away with a great learning unit that was valuable to my students."

Lessons Learned

Data were collected throughout the workshops and include surveys, interviews, observations, videotapes, and workshop artifacts. Qualitative data indicate that workshops have been quite successful. Participants frequently comment on the use of the model in designing their instruction. One teacher said, "I have thoroughly enjoyed today's session. New techniques were learned and I especially enjoyed seeing the model. The model is one that should be used by all teachers in all grade levels." Another commented "By planning my learning unit according to the workshop model I was able to closely plan my unit to the QCC's [Quality Core Curriculum, Georgia's state standards] and integrate technology in new ways."

The workshop has been administered multiple times throughout the previous two years and will continue to be offered through 2002. Several things were discovered during the first workshop that inspired change in formatting for the workshops that followed. Teachers who participated in the workshop had an average of over 16 years teaching in the field and were essentially unfamiliar with the process of creating instruction that tied to state standards. Not only were we surprised at the inexperience with attending to standards, but also we were quite disturbed by the inability of teachers to write the type of learning objectives that we were boking for in the units that were to be published on the web. Discussions with workshop participants led us to conclude that many of them had been teaching for so long that much of what they did was second nature, in their heads, and rarely transmitted to paper. Therefore, when they were asked to articulate these ideas clearly in a way that others could use them, many teachers were neither comfortable nor confident in their ability. Although later workshops spent more time teaching these skills, teachers still continued to come to the workshop in need of such instruction. However, in those workshops there was a significant increase in comments like the one by a science middle school teacher who said, "By planning my learning unit according to this model it made teaching the unit easier. I was able to see what QCC's were covered for each lesson."

Conclusions

A great deal of data has been gathered as a result of this project and in the future we believe there will be much to offer the academy in the way of lessons learned. However, currently what is important is that the PT3 grant that VSU is administering seems to be making a positive difference in the learning experiences of children in rural South Georgia, as well as spreading enthusiasm among teachers for the potential of integrating technology into their classrooms. Evidence of this is clear in the response of one participate to the survey question, "What happened as a result of having another teacher use your unit?" The response was, "The seventh grade teacher who used the unit for his class wants me to help him come up with a unit in his class using the Internet and computers. He does not like the computer but he said that his students were highly excited about the learning on the computer and that he would like to incorporate the computer lessons in his usual teaching lessons. This was a successful workshop for me and I want to thank you PT3!!!"
Handheld Technology in Field Based Reporting

Abstract: This is an exploratory paper on the uses and applications of handheld technology in field based reporting. It focuses on the adoption of handheld devices by student-teacher supervisors and department chairs in their day-to-day observation and documentation functions. In this paper, handheld devices are defined as portable and personal data assistants carrying among others, word processing capabilities using a Microsoft Word translator. Initial observations indicate a favorable perception of the use of handhelds as a portable word processing computer. However, the Graffiti® writing system and the reliance on paper forms for field-based reporting present a few obstacles in adopting handheld technology in field-based reporting.

Background

Personal data assistants (PDA) are no longer solely used as address and appointment keepers. They have become small-scale computers that offer tremendous portability and connectivity. In the palm of your hand, you can access multiple educational as well as word processing programs. The handheld device can be used as a note-taking medium to document meeting notes and personal memos. To facilitate the note-taking process, a Microsoft Word translator and a portable keyboard are introduced in this paper. Several Microsoft Office translators are available on the market namely “Documents-to-Go®”, “install buddy”, “Quickword” and others. The third-party software programs enable Microsoft Word files to be viewed, edited and created on the Palm OS handheld. The keyboard is integrated in this application since it allows for rapid data input.

Handhelds in Education

In this paper we are surveying the possible uses of handhelds by student-teacher supervisors and department chairs. Many teachers supervise student-teachers in the field and the task requires them to travel to school sites and write reports about their observations. This process could be completed using a handheld device and a portable keyboard. This alternative method of documentation ensures the information is backed up on the handheld and on a personal computer. Likewise, department chairs who commonly attend and preside over numerous meetings, could also benefit from the documentation possibilities of PDAs. For this latter group, meeting notes can be inputted and registered on the handheld.

The observations presented on this paper were based on the experiences of the student-teacher supervisors and department chairs at the College of Education, San Francisco State University. In training the said audience, the
basic Palm operating system features such as Graffiti®\(^1\) writing, beaming\(^2\) and the operating system's main menu which includes the preferences, phone book, appointment book and memo pad were first introduced. Afterwards, the content was customized to each individual's needs. During the follow up meetings, the participants individually described their job and the elements they could use help in. Some expressed the need to facilitate appointment scheduling while others wished to set alarm reminders for their appointments. The majority foresaw using their handheld as a note-taking device.

Results

With the combination of a handheld, a Word translator and keyboard, supervisors and department chairs alike can easily take notes during meetings or field based observation visits. Files created on the handheld can be copied to the personal computer through the ‘HotSync®’ process. This process allows for files created or modified on the handheld to be transferred to the personal computer. Likewise, files created or modified on the personal computer can also be transferred to the handheld.

Moreover, the observations underscore the weakness in using Graffiti® to input data into the handheld. Graffiti® writing is often slow and some find it difficult to learn. The addition of a portable keyboard to the handheld greatly enhances the data input process. In the case of field-based reporting and meeting note taking, where there is intensive writing, it is important to have the help of a keyboard to expedite the process.

The Word translator, which in the study is Documents-to-Go®, greatly enhances the use of handhelds in field-based reporting and meeting documentation. The portability of Microsoft Word documents appeals to the participants who see the advantages of being able to use their handheld as a small-scale computer.

Overall, the use of handheld devices in field-based reporting offers promising possibilities. It boasts a paperless process where files are created and stored in digital format on personal computers. Observation comments can easily be e-mailed to student-teachers. However, the general educational system is still paper based. The student-teacher observation process is reliant on carbon copy based forms. The advantage of using the standard carbon copy form lies in the fact that supervisors can give student-teachers a copy of the observation feedback on the spot. Moreover, supervisors are used to this paper format and it may be difficult for some to adopt this new method to document information.

---

\(^1\) Graffiti® writing is a unique way to write alphanumeric characters so that it could be recognized on the handheld.

\(^2\) Beaming refers to sending information from one handheld to the other using infrared sensors.
Effecting Pedagogical Change through an Action Research Process

Abstract: This paper will describe a PT3 implementation grant that is based on a dual-approach collaborative development model grounded in an action research process. Action research involves constant change and therefore is the appropriate methodology to meet the goals of this project. This model provides a concentrated effort on developing personal and professional technology expertise of both faculty and students in a preservice teacher program in a university setting. Action research provides the foundation for this project, but it is also the process for all interactions that occur throughout the grant implementation involving both the team and stakeholders.

Project Overview

The University of Houston PT3 implementation grant is based on a dual-approach collaborative development model grounded in an action research process. One half of our development model is comprised of our work with our teacher education faculty. Our project Curriculum Specialists meet first with each faculty member, including professors and adjunct instructors, to establish a collaborative relationship and to identify skill levels, instructional needs, and comfort with technology. After this initial relationship building, each curriculum specialist brings in a Technology Fellow to work one-on-one with the faculty member, building on the existing knowledge base and progressing from that point. If personal technology skills need to be established, the technology fellow works weekly with that faculty member to facilitate teaching technology skills acquisition. The more technologically advanced faculty members may need only occasional assistance on specific topics or skills of interest. In addition to mentoring, Technology Fellows are available to assist with set up and operation of necessary technology, equipment checkout, and whole class presentations. This individual attention allows faculty to grow at their own pace and to receive assistance when and where they need it. Our team meets faculty members in their offices, their homes, and even in local coffee shops. Our use of individual technology fellow mentors truly allows for meaningful and consistent relationships to be formed between our team and our faculty. Although our action research is flexible, a well-formed infrastructure is essential for faculty engagement (Groves, & Zemel, 2000).

In addition to being the main contact for faculty, Technology Fellows are also the main contacts for students, accessible in campus-based methods courses, during weekly one-hour lab workshops, and electronically via e-mail. To provide an environment in which our future teachers can visualize the appropriate and exemplary use of technology in education, we have implemented structural changes to our technology course. We have restructured the existing three-credit hour required technology in education course into three one-credit-hour sections that are taken over the three-semesters immediately prior to the student teaching experience. Thus far,
we have taught the first two of those three sections. Campus-based students attend a one-hour weekly lab session with optional open lab times available. Technology Fellows are the most knowledgeable about the progress and commitment of faculty as well as the most aware of student needs for technology-rich environment through which to demonstrate their technology proficiency. This two-sided collaborative effort forms the heart of our program and has already proven successful in bringing together faculty and students in the creation of a strong technology-rich program. Action research involves constant change and therefore is the appropriate methodology to meet the goals of this project.

**Action Research as a Design and Development Process**

Action research derives from the perspective that a problem experienced by any person does not exist in isolation, but is indivisibly linked to and grounded in a set of interactions, relationships and social worlds that are part of the ongoing history of experience of the individual concerned. Research seeks to discover the particular ways in which it might be possible for people to understand the problems and to creatively engage in ways of resolving features of the situation that have become problematic. The first questions in research, therefore, are “What is the issue?” “Who is primarily affected by the issue?” and “Whose research, therefore, is it?” Answers to those questions provide the overarching agendas driving the procedures outlined below.

Further issues arise when these questions have been answered, since the purpose of inquiry is to extend people’s understanding, taking them through and past existing definitions of the situation—towards the new ways of defining or explaining what is happening—to the new ways of envisaging the problem or situation resulting from processes of investigation. Providing people with this frame of reference requires them to position themselves quite differently in relation to people and events, requiring them to take a stance of inquiry and to be able to work productively alongside people they may see as "enemies", "outsiders" or "experts". The processes presented below suggest, first, some fundamental working principles guiding these processes, then provide a set of procedures to work through the first stages of a process of inquiry.

**The Basic Action Research Process**

The need for systematic, structured processes of investigation indicates the need for frameworks of inquiry to guide research activity. A Look, Think, Act process provides a simple way of envisaging the basics steps to the type of inquiry explicated in this project. For this project, we have also added a fourth step—Share—as a means of disseminating the resources and lessons learned. This process is cyclical and not linear, and it enables participants to systematically acquire information, reflect on its significance, and plan the next steps in the process. It is a constructive process, in which emerging understandings gradually refine and clarify elements of the situation, gradually increasing the scope of investigation to encompass all major factors influencing the issue investigated. This process assumes that there is an issue providing the focus for investigation, and a particular context in which the issue will be investigated. Though the issue may change or be re-framed, and the context broadened or narrowed as people provide input, the process remains essentially the same.

LOOK entails gathering relevant information to build a picture of the situation, enabling the researcher to describe what is involved, what is happening, and how, where and when events and activities occur. Information is acquired by observing, interacting and talking informally with people.

THINK requires researchers to explore and analyze the emerging picture. In the preliminary stages of investigation reflection enables a clearer understanding of the stakeholding groups affected by or affecting the issue, and identifying people in each group who should be included in the processes of inquiry.

ACT defines the actions emerging from reflection. It requires people to plan their next steps and implement appropriate activity.

SHARE describes the dissemination of the information to a larger community.

EVALUATION of these steps requires a return to the beginning of the cycle.
Although the look, think, act, share routine is presented in a linear format throughout this paper, it should be read as a continually recycling set of activities. As participants work through each of the major stages, they explore the details of their activities through a constant process of observation, reflection, and action. At the completion of each set of activities, they will review (look again), reflect (reanalyze), and re-act (modify their actions). As experience will show, action research is not a neat, orderly activity that allows participants to proceed step by step to the end of the process. People will find themselves working backward through the routines, repeating processes, revising procedures, rethinking interpretations, leapfrogging steps or stages, and sometimes making radical changes in direction.

Community-Based Action Research

In practice, action research can be a complex process. The procedures are likely to be ineffective, however, unless enacted in ways that take into account the social, cultural, interactional, and emotional factors that affect all human activity. Community-based action research seeks to change the social and personal dynamics of the research situation so that it is noncompetitive and nonexploitative and enhances the lives of all those who participate. This collaborative approach to inquiry seeks to build positive working relationships and productive interactional and communicative styles. Its intent is to provide a climate that enables disparate groups of people to work harmoniously and productively to achieve their various goals. A key feature of community-based action research is that it takes into account the impact of activities on the lives of people engaged in or subject to investigation. Its intent is not only to get the job done, but also to ensure the well-being of everyone involved.

The art and craft of community-based action research includes the careful management of research activities so that stakeholders can formulate jointly constructed definitions of the situation. The aim of inquiry is not to establish the truth or to describe what really is happening, but to reveal the different truths and realities held by different individuals and groups. Even people who have the same facts or information will interpret them differently according to their own experiences, worldviews, and cultural backgrounds.

The task of action researchers, therefore, is to develop a context in which individuals and groups with divergent perceptions and interpretations can formulate a construction of their situation that makes sense to them all—a joint construction. The major purpose of the process is to achieve a higher-level synthesis, to reach a consensus where possible, to otherwise expose and clarify the different perspectives, and to use these consensual/divergent views to build an agenda for negotiating actions to be taken. This process is fundamental to action research, requiring people to work together with purpose and integrity to ensure the effective resolution of their issues and problems.

Working Principles of Action Research

There is no one right way in which to engage action research. The processes will differ from group to group, from issue to issue and from context to context. They do so because people in each new situation will describe and interpret similar events in quite different ways. The major task of any particular project, therefore, is to creatively find ways to enable the diverse groups to negotiate a definition of the situation enabling them to work productively together. There is a strong need to take into account the differences in culture and perspective, and the emotional responses of people who engage in the processes of inquiry.

Action Research with Faculty

Contact with faculty has paralleled on a lesser scale the action research model of the entire project. The most significant process that the grant team uses with the faculty members is an interview process. In action research this takes the shape of questions, feedback, and more clarifying questions. In our grant experience, it was quickly apparent that faculty and curricula were so diverse that only the one-to-one exposure of action research could uncover their individual needs and issues. Bailey (1997) compares the process of technology and staff development with the activities undertaken by early American pioneers. The paths are largely uncharted before the exploration begins.

In spite of the differences among faculty and curricula, a few central themes emerged:

- Physical access to technology
Faculty needed assistance at their level
Time was an essential element
Relevancy piqued interest
Student-professor-tech fellow
Plateaus and "What Next"
Individual technology in curriculum approaches

Access
Initial meetings required strong attention to the professor's needs and interests. Many stated that they would use more technology if more "computers/projectors/internet connections" were available. Campus limitations to physical components of technology emerged as a key problem. Because of the dollars involved in improving access to technology, this is not an issue that can be quickly resolved. The action research process, however, was instrumental in bringing the situation to notice, a necessary first step in progress.

With this awareness, the grant team was able to help many faculty members identify and apply for equipment funding. Policies on "check-out" and use of departmental resources were reexamined. The one-on-one assistance that the team of technology fellows provided gave other professors the encouragement to budget for appropriate technology. With the assurance of assistance, new numbers of instructors were willing to book labs, check out equipment, and investigate new venues for technology integration.

Assistance
Other reticent faculty members were initially concerned that the assistance that would be forthcoming would be inappropriate, and a poor use of their time. The action research model, however, allows the support to be tailored for each instructor's particular need. Both proficient and beginner technology using instructors were concerned with this. Proficient users wanted to be recognized for their skills, and beginners were more afraid of perceived obstacles. The dialog between the tech fellow and professor about real needs fostered the growth of both a collaborative relationship and a safe and productive learning environment.

This supportive relationship was just as important later, when faculty began investigating more technology integration with their own students. Consistently, the professors have been enthusiastic about technology exploration when they trust this support system.

Time
Often the professors were inclined to feel they were too busy to learn more technology until the team member offered a technology that could save the professor time or effort. Interviews with our faculty members also revealed that they are rarely on campus at the same time, and even less likely to be free simultaneously. There were many opportunities for informal learning through lunch-hour "brown-bag" events, but there were always numbers of instructors who reported that their schedules prevented them from attending. The tech fellows were able to bridge this difficulty by scheduling individual support directly into each professor's available time slots. This flexibility made scheduling so convenient for each faculty member, that many of them arranged to have weekly, standing sessions. Multi-session training such this has been reported to enhance faculty understanding and feelings of competency with technology (Smith, 2000).

Relevancy
Above all, our instructors were interested first in technology that would be useful, and not in technology for technology's sake. A number of professors began the collaboration with very direct and limited requests. As stated earlier, the goal of the dialog between the tech fellow and the instructor was to tap into the instructor's needs and interests. Once the faculty member began to see usefulness or a more efficient result, the discussion generally broadened into a more inquisitive, creative, and less directive approach to technology.

Student-Professor-Tech Fellow
A second relevancy for the professors was that the tech fellows also were technology instructors to the preservice teachers. This meant that the tech fellows were in a unique position to be a sort of a bridge between the professors and the students. The undergraduate technology lab courses were structured so that preservice students could focus on their academic requirements, and the tech fellows would provide them with lab support for their classroom projects. This enabled the professors to understand what they could expect from their students, and enabled the tech fellows to better assist their lab students.
Plateaus and “What Next?”

One of the most compelling phases in action research is at the end of a spiral of “Look, Think, and Act.” These spirals can be imagined in all different sizes for all of the various faculty involvements and all the individual goals set at any point in time. At the end of the revolution, sometimes we see a “plateau” with the individual faculty members. It is difficult to seek something that one does not know is there, and it is also difficult for professors to imagine needing or using a component of technology that they are not yet aware of. These plateaus have given the team enormous opportunities to develop strategies for introducing new levels of achievement to the faculty.

The team was initially reticent to provide many discrete curriculum integration suggestions, fearing that the professors would feel overwhelmed. This may, in fact, be true during early stages, but as the team developed and introduced alternate views and suggestions for technology integration, the faculty met them with applause. Though this appeared to be one of the biggest surprises in faculty work, under our action research model we were able to redirect our approaches to satisfy this faculty interest.

Technology in Curriculum Approaches

The “look (listen) and think” part of our action research plan led the team to find concrete ways to help the faculty think through the whole idea of technology integration into the curriculum. For this, the faculty feedback on previous technology integration ideas was organized into a chart corresponding to traditional classroom and educational techniques. Examples of these would include “class discussion, presentations, communication, group work, research,” and the like. Tech fellows would meet with each professor individually over one course syllabus, and explore the syllabus and chart together. Areas where technology might be appropriate would be discussed. Negotiations and modifications were encouraged, and often resulted in an even better idea of technology use in education.

Summary

Our program was redesigned to include several critical factors for success: the use of an action research approach to ensure that progress towards goals is continually assessed and evaluated; the purposeful creation of collaborative learning environments in which future teachers are empowered to develop content, pedagogy, and technology strategies; and a dual approach to address the best ways to develop and use skill with technology for instruction.

Pedagogical change is the outgrowth of both the integration of technology and the development of the collaborative community created by the project. The integration of technology that provides for active participation in the learning process encompasses instructors, team members, and students in the process of change. Through this collaboration, the team members have found that many instructors of future teachers have become eagerly engaged in learning to integrate the appropriate use of technology into their teaching. By modeling technological integration and the concomitant pedagogical change, these professors are helping the future students of these pre-service teachers acquire the technical integration skills critical to success in the 21st century.

As a result of the action research model, the faculty at the College of Education has begun a steady and comfortable migration toward greater and more effective technology integration. Although systemic changes are slow and difficult to distinguish, there is such ample anecdotal feedback, that the PT3 team is certain of the ripple that has already been created through our many spirals with the faculty.

References:

Abstract: This paper describes a multi-directional approach aimed at enhancing preservice technology integration within the University of Houston College of Education. Strategies used by the grant team include reorganizing the structure and content of the undergraduate preservice technology classes, a one-on-one approach between team and faculty for facilitating individual technology growth, an ongoing offering of workshops and lunch seminars, and a consistent team-faculty approach toward increasing appropriate and fitting technology integration within various and differing curricula.

Introduction

The University of Houston PT3 grant, Action Communities for Teaching Excellence, has adopted a multi-faceted approach to address and facilitate preservice technology integration. Following an action research model, the PT3 team has identified three major areas in teacher education where attention to technology may benefit the preservice teachers. These areas are: the preservice "Technology in Education" courses, the undergraduate education classes, and the preservice field-based experiences at area schools.

Processes

A variety of strategies were aimed at enriching technology experiences of the preservice teachers. Facing what many consider a multimedia revolution, Vogel and Savage (1996) predicted displacement of traditional modes of thought and action. The strategies for technological change in the College of Education reflect that view as well. Historically, the preservice "Technology in Education" class for undergraduates consisted of a single traditional three-hour course. The one semester technology course was broken into three one hour courses spread across three semesters, and a constructivist curricular approach facilitated projects with relevance to the students' other current education courses.

As the technology courses were restructured, the PT3 team also initiated meetings with the faculty who taught the undergraduate core courses in education. Since folk wisdom dictates that these professors'
visions of technology integration are unlikely to exceed their own level of experience with technology, the PT3 staff offered individual technology instruction and support to faculty. Faculty technology development can be viewed as a process that is not solely oriented toward faculty mastery of classroom technology, but toward the use of instructional technology to enhance students' achievement of curricular objectives (Cagle & Hornik, 2001). Faculty members were interviewed for subject matter and teaching style, along with technology interests and visions of technology integration. A team member was matched with each interested faculty member to promote a collaborative and consistent relationship with the grant team.

Following faculty involvement in personal technology exploration, the topic of curriculum integration was approached, with an eye for providing preservice students additional opportunities to explore technology in their College of Education assignments. Faculty and PT3 team members joined for a collaborative look at technology possibilities offered within their curricula.

As preservice students moved out into the schools for their field based experiences, the PT3 team made contact with the field based methods teachers to offer continued support and collaboration on site. One-on-one technology support was expanded to include all undergraduate methods teachers.

Responses

As the contiguous technology course semesters unfolded, the preservice students evolved into a remarkable community of technology users. The current students entering field experiences display confidence in their ability to integrate existing technology at any level of real-world availability.

Quick and Davies (1999) reported that faculty development participants requested training opportunities fitting their time constraints. University of Houston College of Education faculty particularly favored a one-on-one team approach toward individual technology skills development. An interviewing and matching process was employed to meet varying skills, interests, and schedules. Brown bag and workshop opportunities were also available to address common interests.

The next tier of faculty support explored particular curricular interests and additional integration opportunities. This again was carried out on a case-by-case basis, resulting in many new and innovative curriculum additions. Instructors responded positively to the collaborative nature of the additional exploration. Particularly well received was a series of charting processes developed by the team to provide consistent scaffolding for these tailored individual approaches. For example, faculty feedback on previous technology integration ideas was organized into a chart corresponding to traditional classroom and educational techniques, including “class discussion, presentations, communication, group work, research,” and the like. Tech fellows would meet with each professor individually over each course syllabus, and explore the syllabus and chart together, discussing areas where technology might be appropriate. These charting processes facilitated a convenient and easy way to explore technology options in almost any curriculum environment.

Conclusions

The variety of strategies employed by the PT3 team at the University of Houston College of Education are gradually impacting the nature of technology use in all areas associated with preservice education. Not only are preservice teachers emerging from the education program with enhanced skills and proficiencies, but the nature of technology use by faculty is also changing around them. An integrated community of technology users is emerging from the classrooms and offices of the College of Education.

Abstract: Through a U.S. Department of Education PT3 grant, the University of Illinois at Chicago (UIC), in partnership with the Technology Resource Network of the Chicago Public Schools (CPS) and other Consortium partners, designed a flexible process for integrating technology-infused instruction into urban pre-service teaching courses for elementary and secondary programs. This poster presentation describes this 5-pronged process, which includes: (1) interdisciplinary team-based curriculum development; (2) faculty development initiatives; (3) infrastructure development to support teaching with technology in all of the teacher education programs; (4) technology-rich pre-service coursework and field placements; and (5) standards-based accountability mechanisms across all teacher education programs at UIC.

Introduction

In an effort to bring about educational reform, many states have changed to a standards based competency model and adopted new accountability procedures that demand results from students, teachers and schools. These standards and procedures follow the lead of current research in education, requiring teachers to have substantial background in both content and pedagogical knowledge (Ball, 1994; Ball & McKeen, 1990; Seixas, 1998; Shulman, 1986). A strong push in the standards movement is toward the use of technology enhanced instruction.

Research has indicated that the traditional model for technology education, a single technology competency course or multiple competency modules, has been found inadequate (Moursund & Bielefeldt, 1999). Rather, effective technology infusion in PreK-12 classrooms requires teacher preparation coursework that fosters the development of content-rich, pedagogically sound strategies for integrating technology throughout the entire teacher preparation curriculum.

The purpose of this poster presentation is to describe the components of a comprehensive PT3 initiative occurring at the University of Illinois at Chicago (UIC) in cooperation with the Chicago Public Schools (CPS).

Design team concept and processes

Interdisciplinary subject-area design teams collaborate to create discipline rich technology materials that can be infused into teacher education methods courses. The activities of the design teams begin with an assessment of curricular needs.
within the College of Education. These needs are then addressed through the development of easily accessible technologies. Each module is based on a set of domain thinking skills and concepts (such as, in a History course, supporting claims with evidence from documents), which are embodied in the use of specific kinds of technology tools (such as hyper-text linking from text to documents). The technologies employed are used to support the learning objectives, rather than just being used as an add on to instruction.

**Professional development strategies**

Professional development strategies were designed to help faculty identify synergistic places in their courses for marrying content and technology and to increase faculty members’ abilities to use appropriate technologies to achieve specific outcomes within their domain. Strategies for professional development included interactive technology tool-based workshops, a technology development center designed to provide faculty with support for creating technology-based course materials, and summer curriculum institutes for developing technology infused curriculum within teacher education courses.

**Infrastructure development**

Through ongoing systematic technology planning and deployment, infrastructure could support all aspects of this initiative. Technology planning activities will be described.

**Developing and sustaining technology rich field experiences**

Fieldwork plays a pivotal role in a teacher candidate’s education, and insuring that a field placement can support technology integration is an essential component. Methods implemented to develop and nurture university-school partnerships included recruitment assessments, technology-based curriculum development workshops for k12 mentor teachers and teacher candidates, and the establishment of an online learning community for consortium partners.

**Evaluation**

Program evaluation is an extremely important part of successful projects in educational technology reform, without which no program can make any claim of success. In this poster session, innovative data collection techniques via the WWW and authentic performance indicators will be demonstrated.

Abstract: LINKS is a three-year technology project designed to integrate technologies into the teacher preparation curriculum at the Texas Woman's University (TWU). The project is supported by a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology implementation grant. As part of the systemic approach to the integration of technology, the project supports changes in university faculty involvement and roles, technology curriculum content and delivery. Two broad research questions were used to guide this study: (1) how were the development of faculty technology proficiencies supported and (2) what was the progress of the participating faculty in infusion of technology in university web-based course delivery? Second year findings regarding the examination of changes in faculty attitudes and behaviors and the effectiveness of the implemented project are provided.

Introduction

Preservice teachers need to experience technology within a meaningful context in both their learning opportunities at the university and their field-based student teaching experiences. A crucial element in supporting the development of "fearless users of technology" is the modeling of advanced and emerging technologies by faculty who instruct preservice teachers (OTA, 1995; Topp, Mortenson, & Gradgenett, 1995; Wetzel, 1993). In order to model this type of framework within their course structures, faculty must change attitudes and behaviors toward the use of technology (Joyce & Showers, 1983; Schrum, 1999). They must model the use of various technologies to increase instructional effectiveness, be cognizant of the high level of skills essential for preservice teacher certification, and focus on the metacognition surrounding the use of technology as a tool. As Strudler and Wetzel (1999) assert, the "goal of technology integration is a moving target" (p.80), and therefore must be studied within the context of continued learning and professional development for both the student and the instructor.

Learning and Integrating New Knowledge and Skills (LINKS) is a three-year technology project designed to integrate technologies into the teacher preparation curriculum at the Texas Woman's University (TWU). The project is supported by a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology implementation grant. As part of the systemic approach to the integration of technology, the project supports both changes in university faculty involvement in addition to changes in technology curriculum content and delivery. This study's purpose is to describe changes in behaviors and attitudes as well as changes in institutional processes. Two broad research questions were used to guide this study: (1) how were the development of faculty technology proficiencies supported and (2) what was the progress of the participating...
faculty in infusion of technology in university web-based course delivery? To address these questions, second year findings regarding the examination of changes in faculty attitudes and behaviors and the effectiveness of the implemented LINKS project are provided.

The Study

In order to increase the quantity of technology-proficient teachers who use technology to support teaching and learning, the University must change, the curriculum must be changed, and active partnerships must be created and maintained between professors from diverse disciplines. The change process itself must be studied to monitor changes in attitudes and behaviors of participants. This study is grounded in the Concerns-Based Adoption Model (Hord, Rutherford, Huling-Austin, & Hall, 1987) that monitors changes as an innovation is implemented. Changes in participants' technological proficiency over time, implementation concerns, and in some cases their levels of technology use were monitored.

A needs assessment from a purposive sample of current faculty addressed faculty needs relating to the integration of advanced technology tools into course delivery. Their perceived critical needs were in three areas of: (1) productivity; (2) connectivity; and (3) the integration of technology. Faculty members see productivity as a priority including support in development of their skills relating to multi-media presentations and the creation of a professional web page for use in classroom instruction and communication with pre-service teachers. The survey data indicated the need for training to extend their multimedia presentations with more advanced media tools and the use of connectivity tools such as the World Wide Web and asynchronous and synchronous forms of communication. Building from these perceived needs, the LINKS program for faculty was created and implemented.

A volunteer sample of university instructors (N=20) agreed to participate in professional development sessions. Sessions primarily focused on an orientation to LINKS resources and the preparation of web-based course delivery via Blackboard, the university’s web-based course delivery template. Data were collected on instructors’ stages of concern, levels of use, and perceptions of the utility and quality of training. Faculty participants included individuals from the following disciplines: Biology, Chemistry and Physics, Family Sciences, Health Studies, Kinesiology, Performing Arts, Philosophy and Psychology, Reading, Teacher Education, and Visual Arts.

Training Goals. Two primary training goals existed: (a) Introduction of the LINKS standards and resources, and (b) support for instructor delivery of web-based courses as models for the future teachers in their classes. The goals were implemented through a series of technology-training sessions divided into two categories a whole-group professional development sessions geared to broad topics, and hands-on professional development sessions specializing in specific areas for remediation or advanced work.

Training Sessions Overview. In order to provide a model for preservice teachers, faculty were encouraged to integrate technology into the design and delivery of their instruction. These sessions also served as a training vehicle for the preparation of web-based course delivery via Blackboard, the University’s delivery template. Sessions were administered throughout the year, seven per semester. These two-hour sessions (28 hours total) were delivered in a University computer lab, using Blackboard as the method of delivery. All materials were available on the class Blackboard site for later reference. By using Blackboard to communicate with the faculty participants, meaningful learning was integrated into their own Blackboard course development.

Personnel from Information Technology Services (ITS), the Distance Education Support Team, and specialists from the library services collaborated with LINKS personnel in organization and implementation of the training. Professional development sessions included an introductory LINKS project overview, sessions on Internet resources, Internet searches, creating a virtual office, uploading course material and online tests, and seven sessions addressing the use of Blackboard, the university’s web-based course delivery template. Blackboard sessions covered the following topics: preparing documents, adding information, uploading material, using shortcuts, changing the appearance of courses, adding security measures, student management, and online assessment. One-on-one assistance was available from LINKS staff on request.

Data sources. The Concerns Based Adoption Model (CBAM) was used to assess university instructors’ progress toward the use of Blackboard. Pre- and posttest data were collected for the Stages of Concern Questionnaire (SoCQ) and Levels of Use. Parametric paired-sample t-tests assessed differences across time. To assess quality and utility of the training sessions, qualitative analyses were conducted for open-ended items on session evaluation forms.
Concerns about Technology. The SoCQ monitors changes in attitudes and behaviors as an innovation is implemented. The SoCQ consists of 35 items that are rated on a 7-point Likert scale with three anchors: 1 (not true of me now), 4 (somewhat true of me now), and 7 (very true of me now). The instrument measures the intensity of concerns around three main clusters (self, task, and impact concerns). The technical qualities of the instrument are acceptable. Cronbach alpha coefficients of internal consistency range from .64 to .83, and the test-retest Pearson r correlations range from .65 to .86.

Level of Use (LoU) Questionnaire. For the first project year (1999-2000), data on instructors' Level of Use was collected through individual interviews. Due to excessive time requirements for individual interviews, project staff developed an objective LoU questionnaire to be administered online intermittently during year 2. Drawing on year-one interview responses, project staff developed items related to Blackboard use. Eight distinct levels of use of an innovation have been identified (Nonuse, Orientation, Preparation, Mechanical Use, Routine Use, Refinement, Integration, Renewal). According to Hord et al. (1987), each stage encompasses a range of behaviors with distinctive actions that move the individual to the next level. CBAM's LoU interview was adapted to describe the behaviors of university instructors relative to the adoption of Blackboard. The LoU Questionnaire included 56 items rated dichotomously as 0 (disagree) or 1 (agree), with 7 items for each of the eight dimensions. The purpose of the LoU was to establish participants' level of use at various stages of the innovation adoption process.

Quality and Utility of Training. Instructors completed session evaluation forms including both objective and open-ended items. Their evaluations first asked for ratings on a 6-point scale from strongly disagree (1) to strongly agree (6) for the training sessions' possible effects on motivation to use technology in the classroom and ability to use technology more effectively. On a final item, respondents rated sessions overall on a 6-point scale ranging from not at all helpful (1) to extremely helpful (6). All participants completed three open-ended items: (a) What have you learned or gained from the training sessions? (b) What is your main concern about using the information? and (c) Do you have any suggestions for making the training sessions more effective?

Findings

Stages of Concern Questionnaire (SoCQ). Mean instructor ratings on the seven stages of concern (awareness, informational needs, personal implications, time management, consequence for students, collaboration with others, and refocusing or refinement) are presented in Table 1. Significant pre- and posttest differences were evident for faculty on two domains, with both related to self-concerns. Outcomes suggested that instructors' initial awareness and informational concerns (M = 2.36 and M = 4.64, respectively) had decreased significantly by spring ((M = 1.70 and M = 3.57, respectively). Management, consequence, collaboration, and refocusing concerns intensified, although not significantly.

Levels of Use (LoU) Questionnaire. Results for the LoU Questionnaires are summarized in Figure 1. Individual LoU profiles were created for university instructors (labeled U1 to U13). To construct the profiles, mean item ratings were first calculated for the eight stages of the LoU, with mean ratings ranging from zero (disagree) to one (agree). Next, individual pretest (initial LoU) and posttest (final LoU) outcomes were determined for each university instructor. Mean ratings at least one standard deviation above the instructor
group average (mean of 0.7 or higher) were regarded as strongly exemplifying a “stage of use.” Instructors are organized in three categories as “beginners who progressed,” “mechanical users who made strong progress,” and “mechanical users who failed to progress.”

**Key.** U = University Instructor (n = 13). P = Pretest (Initial LoU). P = Posttest (Current LoU). Shaded area indicates a mean rating of 0.7 or higher on a scale of 0.0 (disagree) to 1.0 (agree).

**Nonusers/novice users with moderate growth.** Four instructors (labeled U8, U12, U7, and U13) began as nonusers or were at the orientation/preparation stage, but over time they progressed to a higher level of use. As an example, university instructor eight (U8) considered himself a nonuser at pretest and progressed to orientation by posttest. Although progress was made, this individual is currently exploring the value of Blackboard, but has not made a decision to start using the innovation. Another instructor (U12) began as a nonuser, but she progressed to mechanical use of Blackboard. SoCQ mean ratings for these instructors showed they had lower informational (3.4), collaboration (4.0), and refocusing (3.7) concerns, while their personal (4.6), management (4.7), and consequence (4.9) concerns were moderate.

**Mechanical users with strong growth.** Another four instructors (labeled U1, U2, U3, and U5) began as mechanical users, but they progressed over the year to become routine, stabilized Blackboard users wanting to refine Blackboard to increase student impact, collaborate with colleagues to achieve a collective impact, and to alter Blackboard to increase impact. Interestingly, the mean SoCQ ratings for these instructors were comparable to the beginners who showed moderate growth. They had lower informational (4.0) and refocusing (3.8) concerns, and moderate personal (4.5), management (4.8), consequence (4.6) and collaboration (4.4) concerns.

**Mechanical users with no growth.** Five of the university instructors (labeled U4, U6, U9, U10, and U11) showed no growth from pretest to posttest on the LoU Questionnaire. Four of five began as mechanical Blackboard users, while one was preparing for first use. Notably, these university instructors had very high personal (5.7), consequence (6.2), collaboration (6.4), and refocusing (5.8) concerns, whereas they had very low informational (3.8) and management (3.2) concerns.

**Quality and Utility of Training**

**Most important learning.** The most important learning usually coincided with the session topic. For example, instructors mentioned learning about “changes in Blackboard,” “logistics of Blackboard,” “direct access to multiple search engines,” and “basic HTML.” Instructors also noted heightened awareness and knowledge of technology resources, most commonly the various Internet search engines and online library and database resources. Several instructors reported gains in their knowledge of the LINKS project and its benefits.

**Main concerns regarding application of the information.** Common concerns centered on the time needed for technology and instructors’ personal technology skill proficiency. Instructors mentioned a need for time to “learn,” “assimilate new information,” “practice these new skills,” “play with it all,” and “the amount of time to do it for every course!” Typical concerns about limited technology proficiency included “lack of familiarity,” “my own inadequacy to learn fast enough,”” putting all the pieces together,” “learning all of the acronyms,” “becoming more comfortable with [the] Internet,” and “taking advantage of the information.” Instructors also expressed concern with their ability to retain their technology skills, the availability and quality
Suggestions for making sessions more effective. Suggestions for improvement included instructional pace, training content, and a desire for more hands-on opportunities. Several instructors advised slowing the pace of the sessions or creating separate sessions for novices and more advanced technology users. They stressed the "different levels of expertise" among session participants and a need for "more hand-holding." In addition to pace, instructors also offered suggestions for changes in training content, including "opportunities to see concrete examples," "more practical information," and a greater concentration on Blackboard. Fewer suggestions related to the provision of hands-on activities and training timing, and several instructors noted that no improvements were needed.

Conclusions

This project introduced university faculty members to the LINKS project and resources, and supported instructor delivery of web-based courses as models for future teachers. Descriptive statistics and profiles for the SoCQ suggest that instructors' self-concerns declined while task and impact concerns heightened. The majority moved toward higher levels of technology use. Qualitative analyses of open-ended evaluation items revealed concerns with their own ability, the time needed, and the applicability of their new learning.

Findings regarding the implementation and effectiveness of the LINKS project within the teacher education program has implications for increasing the technology proficiencies of entry-level teachers as well as providing a model for other universities undertaking similar changes in teacher preparation programs. Further, the resources created by LINKS, such as the Technology Passport, are available to other institutions on the project web site. Findings have particular relevance to explain how university professors can be supported as effective models of technology use in web-based course delivery and electronic communication with students. The documentation of learner-centered standards for preservice teachers through the Technology Passport provides a much-needed model to monitor and assess changes in preservice teachers' technological proficiencies related to the Texas Education Agency’s Learner-Centered Proficiencies for Texas Schools.

Introduction

Through a unique technology infusion approach, The Learning and Integrating New Knowledge and Skills (LINKS) project addresses national, institutional, and teacher education goals as preservice teachers are prepared to use a variety of technologies. Funded through a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology implementation grant, the LINKS program encompasses the integration of technology use as intrinsic to all courses leading to professional certification as well as within the professional education field-based courses. In the professional education field-based coursework, preservice teachers complete their documentation of technology skills mastered and demonstrate the use of these tools in a variety of school settings. Specifically, this study addresses these questions: (1) how did LINKS support technology infusion in teacher preparation, (2) to what extent did preservice teachers build technological skills and understanding, (3) how did mentor and supervising teachers build technological skills and serve as guides of technology integration?

The Study

Overview. As participants in the LINKS project, students progressed through university coursework, technology seminars, documentation of proficiencies in a Technology Passport, and field-based placements as they moved through Intern I, II, and Residency over three semesters. Responsibility for preparing students was divided among technology seminar leaders, university liaisons, and supervising teachers. This study focused on the second and third cohorts of three separate cohorts established for this project. Cohort 2 included 62 Intern IIs in fall 2000, 41 of which continued as Residents in spring 2001. For Cohort 3, 66 preservice teachers participated as Intern Is in fall 2000, and 62 progressed to Intern IIs in spring 2001. As Intern Is and Intern IIs, preservice teachers participated in three technology seminars, bi-weekly conferencing groups, and completed the Technology Passport. During Residency, preservice teachers began their student teaching and attended two technology seminars. Pre- and posttests were administered to all preservice teachers to assess changes in technological proficiency and use, as well as attitudes and concerns. Parametric paired-sample t-tests were utilized for analyses of quantitative data for preservice students with complete data sets. In addition, preservice teachers completed evaluations at the end of each semester to assess the utility and quality of their TechTrek experience.

Training. Each semester, Interns interacted weekly with mentor teachers during classroom observations. Mentors (N=30) participated in on-campus training sessions and received assistance designed to encourage their receptivity toward technology use. During Residency, preservice teachers were paired with supervising teachers for their student teaching experience. A select group of supervising teachers (N=15) participated in specialized training dedicated to creating classroom appropriate technology products.
for use and evaluation in the classroom setting. Both supervising and mentor teachers completed training evaluations to assess quality and utility of training. In addition, supervising teachers also completed instruments to assess technological proficiencies, attitudes, and use.

**Data Sources.** Implementation data came from reviews of project documents, attendance records, evaluation forms, information on LINKS-related web sites, and interviews with project staff. Data sources for the student, supervising and mentor teacher populations are listed below.

**Preservice teachers.** Quantitative measures were administered at the beginning and end of the fall and spring semesters. Measures included: Self-Evaluation Rubrics for Basic Computer Use, Advanced Computer Use, and Internet Use, and the Stages of Concern Questionnaire (SoCQ). Parametric paired-sample t-tests assessed differences across semesters. Qualitative data were derived from course evaluations to assess changes in attitudes about technology.

**Supervising and mentor teachers.** Supervising teachers completed the Self-Evaluation Rubrics for Basic Computer Use, Advanced Computer Use, and Internet Use at the end of their semester as supervising teachers. Quantitative results were compared with those for preservice Residents. Qualitative analyses were conducted for open-ended items on questionnaires completed by email and on session evaluation forms by both supervising and mentor teachers.

**Findings**

This study presents findings for the second-year of the three-year grant. Results for preservice educators revealed that participants considered themselves more technologically proficient after experiencing the technology integration, with statistically significant pre- and posttest differences for all domains of the Basic Computer Use, 10 out of 11 domains on the Advanced Computer Use, and all domains on Internet Use. Preservice teachers moved toward higher impact concerns and relatively low self-concerns as measured by the SoCQ. Qualitative analyses revealed generally positive acceptance of and comfort with technology, as well as confidence in curricular integration of technology. Interestingly, supervising teachers expressed less technology proficiency overall, and scored lower than Residents on all domains on the self-evaluation rubrics for Basic Computer Use, Advanced Computer Use, and Internet Use. Qualitative analyses of open-ended items indicated that supervising teachers were generally positive about technology integration, and being paired with a Resident appeared to be a supportive factor. Concerns related to time, resource quality and availability, and personal skill proficiency.

**Conclusions**

Findings regarding the implementation and effectiveness of the new LINKS curriculum within the teacher education program has implications for increasing the technology proficiencies of entry-level teachers as well as providing a model for other universities undertaking similar changes in teacher preparation programs. Further, the resources created by LINKS, such as the Technology Passport, are available to other institutions on the project web site. The documentation of learner-centered standards for preservice teachers through the Technology Passport provides a much-needed model to monitor and assess changes in preservice teachers' technological proficiencies related to the Texas Education Agency’s Learner-Centered Proficiencies for Texas Schools.

For contributions to the implementation of this project, Drs. Sharla Snider and Vera Gershner and would like to express appreciation to the project’s external evaluator, Kelly Shapley, Texas Center for Educational Research, Director. Funding was provided at the implementation level through the Preparing Tomorrow Teachers to Use Technology (PT3) initiative sponsored by the United States Department of Education.
Abstract

This paper presents the first year findings of a mixed-method study of the High Touch Mentoring for High Tech Integration project at a suburban state-supported university. This three-year project was funded in part by the Preparing Tomorrow's Teachers to Use Technology (PT3) Federal grant program. Participants were teacher education faculty (faculty partners), K-12 technology proficient teachers (teacher partners) and preservice teacher education candidates. The purpose of the study was to: gather baseline data about faculty members', teacher mentors', and preservice teachers' backgrounds and usage of technology; examine how well the faculty-teacher partnerships were working; determine how the faculty-teacher partnerships affected the integration and use of technology in faculty partner teacher education courses; and provide feedback for formative and summative improvement of the project.

Theoretical Framework

The ideal way to prepare preservice teachers for incorporating technology into classrooms is by integrating technology-based learning environments into the college curriculum, with university faculty modeling usage (Sprague, Kopfman, Dorsey, 1998). However, a recent survey by the Milken Exchange (1999) revealed that most faculty, whether in colleges of education or in the disciplines, do not model the use of technology in their courses. Faculty, like teachers, need time to develop technology skills and to learn how to teach with technology. They need to reflect on their own teaching practice and beliefs. They need to explore software appropriate to their content area and need support as they begin to implement new teaching approaches. One faculty development model that is receiving much attention is one-to-one mentoring in which faculty can focus on their own individual needs (Thompson, Hansen, and Reinhart, 1996, Sprague, et. al., 1998, O' Bannon, Matthew, and Thomas, 1998). Little research has been done on this model to determine its effectiveness on a wide scale.

In June 2000, George Mason University (GMU), a state-supported institution located in a highly diverse urban/suburban region near Washington, DC, was awarded a PT3 grant by the U.S. Department of Education. This PT3 project involves pairing K-12 teachers with faculty from the Graduate School of Education (GSE) in one-to-one mentoring relationships. These teachers are providing models for the effective use of technology, are demonstrating various software and web-based programs that can be used in education, and are assisting GSE faculty in redesigning their teacher preparation courses. Sixteen GSE faculty members participated in the first year of the project.

Methods and Results
Quantitative and qualitative methods were employed in this study. Quantitative methods included the use of pre- and post- web-based surveys that faculty partners, teacher partners, and preservice candidates completed. Qualitative methods included classroom observations of GMU professors and teacher partners, informal interviews of several faculty and teacher team members, and document review. A paired-samples t-test on pre-post faculty data for comfort levels and for frequency of use was performed. Significance was set at .05. A Cronbach's Alpha Reliability (.9571) was conducted on the post-survey. Qualitative data from the interviews and classroom observations were reviewed for common themes among the participants. Data reported reflects pre- and post-surveys from twelve first year teams of GMU faculty and K-12 teachers. Data also include classroom observations of 9 professors, and 9 teacher partners, and informal interviews with 7 professors and 3 teachers.

Based on a 4-point Likert scale, three of the items on the pre-post questionnaires were significant. Under frequency of use faculty rated their use of technology imbedded in pedagogy at a higher level on the post-test (Pre-test Mean=2.0, Post-test Mean=2.8, p=.012). Under comfort level faculty rated an increase of comfort in modeling the use of technology in the K-12 curriculum (Pre-test Mean=2.75, Post-test Mean=3.3, p=.027) and in participating in online professional development and collaboration with other education professionals (Pre-test Mean=2.6, Post-test Mean=3.6, p=.004).

Findings of all other data collected indicate that:
1. Overall, as a result of the mentoring relationships, professors integrated technology in ways they would not have without the grant opportunity.
2. Over 80% of the teams formed a close relationship that resulted in an increased use of, understanding of, and infusion of technology by the faculty.
3. Overall, faculty partners increased their technology skills and level of comfort whether they were novice or advanced technology users prior to joining a team.
4. Several factors promoted positive professor-teacher-mentor relationships:
   - The pairing of professors with teachers who had several years of experience at a variety of grade levels (especially at the elementary school level)
   - The pairing of professors with teachers who had the resources to model a variety of uses of technology (e.g., whole group in a lab, small groups in a classroom, a variety of software programs)
   - Provision of release time for teacher-mentors to meet with professors
   - Description of clear goals, objectives, and expectations of all parties involved at the onset of the project

Discussion

The results of this study provide evidence for further efforts for one-to-one mentoring between university faculty and K-12 teachers in order to ensure faculty members develop the necessary skills and knowledge needed to integrate technology into their teacher preparation courses. Pairing the faculty members with K-12 teachers allowed them to see the challenges of integrating technology in K-12 education. It also gave the faculty the opportunity to explore a variety of software programs and websites. Such opportunities have resulted in an increase of technology integration in the faculty partners' courses.

Perceptions Held by Participants in a Preservice Teacher Preparation Program Regarding the Role of Technology in Education

Charlotte Stromfors, Krista Glazewski, Thomas Brush
Educational Technology
Arizona State University
United States
charlotte.stromfors@asu.edu

Abstract: The PT3 funded program at Arizona State University investigates the effects of integrating technology skills in the preservice teachers' methods courses. How preservice teachers will integrate computers in their teaching practices tends to be framed by their perceptions about the role of technology in education, their experiences in their undergraduate teacher-training program, and the role models they encounter along the way. Through a series of focus groups this study attempts to capture the perceptions the held by preservice students and their instructors towards the role that technology plays in teaching practices (K-8).

Introduction

In the face of rapid advancements in technology, possibilities for enhancing instruction have equally expanded. Those who will be primarily responsible for the implementation of technology in education will be classroom teachers (Piña & Harris, 1993). Therefore, it is important to examine the perceived role of technology in both the university and the K-12 arenas, where preservice teachers transition from students to practicing teachers. Researchers have identified key obstacles to infusing technology into preservice teacher training. For methods instructors, a lack of university faculty training, lack of administrative expectations, an inadequate amount of time for skill development, plus lack of technical support have contributed to faculty inefficacy regarding technology use (Ertmer, 1999). The resultant lack of appropriate modeling by classroom teachers and teacher-educators presents a considerable obstacle (Beyerbach, Walsh, and Vannatta, 2001). In conjunction with the PT3-funded initiative, one large university envisions technology as an integrated component in a field-based teaching experience for preparing teachers. Students' experiences in this field-based model include the following: a) modeled activities; b) opportunities to develop and implement technology-rich instructional activities in authentic teaching situations; and c) technical support (Brush, Igoe, Brinkerhoff, Glazewski, Ku, & Smith, 2001). The research discussed in this paper focuses on collecting comparison data from participants in this initiative. The data collection is aimed at addressing the following questions: 1) What perceptions do methods faculty and preservice teachers hold regarding the role of technology in K-8 environments? 2) What beliefs and attitudes do methods faculty and preservice teachers have related to teacher preparation for technology integration?

The Study

Participants included four methods course instructors who conduct field-base courses, and eight preservice teachers who participated in the field-based experiences. In order to ascertain the perceptions held by participants, four focus groups were formed: Language arts / social studies methods faculty (n=2); math and science methods faculty (n=2); Preservice teachers participating in language arts / social studies methods courses (n=2); and Preservice teachers participating in math / science methods courses (n=2). Data were collected in October 2001. A researcher led each focus group separately using a semi-structured interview protocol. The protocol questions related to current uses of technology, beliefs regarding the role of technology in education, perceptions of the effectiveness of preservice teacher preparation for technology integration, and ideas for effective technology integration preparation. Each one-hour session was taped and transcribed. The results were analyzed for overlapping and contrasting themes.

Findings

The overall findings indicate that technology as a learning tool is seldom modeled in an educational setting, either in methods courses or in the K-8 classroom. The preservice teachers in this study tended to minimize the role of technology in this formative stage in their careers. Dedicating the extra time towards learning new skills and developing instruction using technology skills were viewed as impediments to change from the traditional method of instruction.
Focus group data indicated five trends. 1. *Perceptions held regarding the importance of technology in education:* Pre-service teachers viewed technology with a mixed importance. Member of this group felt that technology made students “lazy” and perceived important skills were being lost as the consequence of computers. Pre-service teachers generally felt the Internet provided a positive, but limited, resource for information. Although the methods instructors regarded computer literacy as important, they cited online investigations, graphing data, and communicating with peers as more appropriate uses technology in education. All groups thought it would be easier to introduce technology in grades above the primary level (K – 3). The language arts / social studies faculty indicated technology use was important when it “fit neatly into the flow of real classroom life,” but they could not articulate a means for accomplishing this. 2. *Classroom experiences and observations:* In response to inquiries in this area, the pre-service teachers were generally more negative than positive. Each classroom had at least one computer, but its apparent role was non-educational. A typical comment was: “I assume it is used by teachers for grades and worksheet.” Methods instructors had few personal experiences with technology integration. Computer use was limited to personal productivity, such as email and a student database. 3. *The quality of preservice teacher preparation:* Preservice teachers felt ill prepared for technology integration in. One stated, “I’m computer illiterate...I don’t see myself using the computer to instruct students.” Methods instructors felt students possessed basic skills, but they were not prepared to use these skills as instructional tools. 4. *Perceived impediments to integration of technology in education:* The most frequently mentioned impediments to integration of technology were time to learn skills, time to develop integration strategies, insufficient resources, and insufficient support. Preservice teachers had not been encouraged to try a technology-based lesson, nor did they consider it as part of the school culture where they served as interns. The methods instructors identified a lack of training opportunities, on-site technical and instructional support, and reliable hardware as impediments. They were motivated to integrate technology more in their courses, but felt uncomfortable with their current skill level. 5. *Perceived solutions for the future:* More time, access, and resources were identified as keys to successful technology integration in the teaching/learning environment. Pre-service teachers agreed that the modeling of lessons using exemplary technology integration was important. Methods instructors felt a minimum of a 5 computer workstations in each classroom; a projection system to display computer output; and support (instructional and technical) would be a good start.

**Conclusion**

The focus group results suggest that he greatest impediments to integration are time, information, and equipment. The implication is that this is true from the university to the elementary classroom. The use of technology in teaching concepts is only minimally observed or practiced (if at all) by any of the groups, instructors or preservice teachers. Therefore, it seems unlikely that the use of technology for the enhancement of learning is perceived as a significant educational strategy. Methods faculty expressed a willingness to integrate more technology into their teaching, but they felt a need for training and support. Unless preservice teachers observe exemplary use in the classroom and by the university faculty, it will not be deemed important. Unless they are encouraged to integrate technology into practice lessons, they cannot expect to experience its benefits. Unless the equipment is there and functioning, they cannot expect to do either one.

Abstract: The practice of using mini-grants to encourage faculty members to explore using technology with their students has been documented as an effective model of professional development (Strudler & Wetzel, 1999; Strudler & Weiss, 2001). With the 2001 mini-grants, Project THREAD took the concept a step further and implemented the Summer Technology Institute. This series of workshops provided faculty with hands-on technical training as well as various methods of integrating technology throughout their courses. By providing both technical and pedagogical skills associated with technology, the 2001 mini-grants proved to be even more successful. This paper will discuss the Summer Technology Institute and findings related to its implementation. For more information and examples of faculty projects please see: http://www.unlv.edu/projects/THREAD/.

Project THREAD (Technology Helping Restructure Educational Access and Delivery), is a U.S. Department of Education PT3 grant awarded to the University of Nevada, Las Vegas. As part of the grant’s overreaching goal, Project THREAD has implemented programs that weave together a mixture of new and existing learning opportunities in order to prepare pre-service teachers for tomorrow’s technology-rich classrooms. One such initiative was the Summer Technology Institute, held during the 2001 summer session at UNLV.

The Summer Technology Institute consisted of a series of workshops and one-on-one training to support faculty taking part in Project THREAD’s mini-grant program. Under the mini-grant program, UNLV professors brainstormed ways that they could effectively integrate technology into student learning activities. They then submitted proposals that included the specific kind of technology that they would use as well as how they planned on integrating this technology into their teaching. In exchange, the mini-grant program offered a professional stipend to cover the time and expense required to learn new technical skills, redesign the courses, and implement the new course modules. In order to assist faculty with this challenge, Project THREAD implemented the Summer Technology Institute to provide ongoing support throughout the course of the program. As a final part of the mini-grant program, faculty were required to update their course syllabi to reflect the integration of technology.

Specific objectives of the mini-grant program and the Summer Technology Institute included:

- enhancing the ability of university faculty and field supervisors to effectively model technology use and support pre-service teachers in their use of technology;
- making technology resources readily available to faculty so that they will have access to varied and necessary models and resources for their use in teaching and
- helping university faculty modify their courses to meet ISTE standards for integrating technology.

The goal of the program was to provide a means for faculty to make time in their schedules for professional development and to provide training and support based on their needs. During 2000, thirteen College of Education faculty members took advantage of this opportunity. While the program was successful, (Strudler & Weiss, 2001) it was a challenge to meet all of the training and support needs on an individual basis. In the following year, the Summer Technology Institute was implemented, as the mini-grant program expanded throughout the UNLV campus, to include seven departments and four colleges. In 2001, twenty-one mini-grants were awarded to 25 faculty members working on 15 professional development projects. Projects included instructional use of digitized video, teaching with educational software, and using web-based resources.
The workshops of the Summer Technology Institute were carefully designed to meet the technical and instructional needs of faculty. Various workshops, such as "Introduction to Imaging with Digital Cameras, Video Cameras, and Scanners," "Creating I-Movies," and "Creating Web Sites Using Dreamweaver" focused on specific technical skills. Other sessions concentrated on integrating technology in the classroom with sessions like "Technology in the Elementary and Secondary Math Classroom," "Technology in the Science and Social Studies Classroom," and "Teaching with a Mobile Lab." Workshops focused on technical skills as well as integrating technology were offered because the current research shows that professional development involving technology must include instructional support in order to be successful (Ronnkvist, Dexter, & Anderson, 2000).

In light of this research, faculty members were advised as to which workshops they should take in order to best help them achieve their integration goals. In addition, project staff offered ongoing support, including help with hardware/software product selection and installation, as well as individualized instruction and access to useful Internet resources. By providing opportunities to learn about integrating technology that were site-based, ongoing, content-focused, and involved faculty as active learners, Project THREAD was able to create a series of workshops that were based on an effective model of professional development (Birman, Desimone, Porter & Garet, 2000).

Outcomes

Reaction to the 2001 Summer Technology Institute was overwhelmingly positive. Thirty-seven faculty members participated in at least one session. Over the course of three weeks, there were a total of 197 registrations for the 21 sessions. Faculty used the opportunity to participate in the mini-grant program to learn ways that they could incorporate technology in their teaching practices. All of those faculty members attending workshops and receiving mini-grants indicated in workshop evaluations that they had gained skills and/or knowledge and would use this knowledge with their students (Anderson, 2001). The next step will be to begin a comprehensive planning process based on the ISTE-NETS Standards for Teachers. This will include visiting College of Education faculty to examine how they have integrated the technology learned during the Summer Technology Institute and throughout the mini-grant program.

Future Directions

For the 2002 mini-grant program, we are considering creating specific strands which determine the type of technology that will be used by faculty. These might include digital video technology, productivity tools, and online teaching and learning. By concentrating the areas of mini-grants, we would be able to better tailor professional development workshops to meet the specific needs of instructors. Also, with the Summer 2002 Technology Institute, Project THREAD plans on offering a clear sequence of workshops that would provide an ideal balance between technical and integration skills. These sessions would be required of mini-grant participants so that they could develop the necessary skills in order to effectively integrate technology in their courses. Through implementing specific technology strands and expanding summer institute sessions, Project THREAD will continue to visit the mini-grant concept to improve upon this professional development model.

Abstract: This paper reports on initiatives to restructure pre-service teachers' field experiences to support the integration of technology. The field experience component is multifaceted and involves close coordination with the local school district. Implementing changes in this placement process poses challenges to planners and coordinators. Several ongoing projects are described that address systemic changes in the process. Included is information on creating request options for students, revising student handbooks, addressing the development of field supervisors, and providing alternative models for students' field experiences.

Introduction

Project THREAD (Technology Helping Restructure Educational Access and Delivery), is a U.S. Department of Education PT3 grant awarded to the University of Nevada, Las Vegas (UNLV) in collaboration with the Clark County School District (CCSD), the nation's fastest growing urban school district. The project's overarching goal is to weave together a mixture of learning opportunities to prepare pre-service teachers for tomorrow's technology-rich classrooms (Strudler & Heflich, 2000). A critical component of meeting this goal has involved revising expectations and procedures for students' field experiences. This paper documents our efforts in this area. It begins with some brief background information, followed by a description of specific initiatives, and concludes with a discussion of our outcomes thus far and future directions that we envision for our program.

Background

A study of first year teachers in CCSD confirmed gaps in their preparation to use technology. In a recent survey, only 25% of beginning teachers reported that they were required to teach a minimum of one lesson using computers in their field experiences (Strudler, McKinney, Jones & Quinn, 1999). This finding is consistent with the survey reported by Willis & Mehlinger (1996), which concluded that technology was barely considered in student teaching placements and only a minority of student teachers were required to teach with computers in student teaching. As the literature attests, this component of technology integration in teacher preparation is clearly the most lacking, and arguably, the most important. Since technology has been implemented unevenly across K-12 schools and classrooms, it is difficult to place education students with teachers who are both accomplished in technology integration and have adequate access to appropriate computer resources. Researchers have concluded that this would likely remain a problem for some time (Mergendoller, Johnston, Rockman & Willis; 1994). But as the Office of Technology Assessment's report
noted (U. S. Congress, 1995), if information technologies are to become an integral part of teacher education programs, "K-12 and university educators must work together to integrate technology into curriculum and classroom practice" (p. 165). Project THREAD is addressing this need through various collaborative initiatives designed to support the integration of technology into students' field experiences.

Field Experience Initiatives

The field experience component of the grant involves a collaborative effort between UNLV and CCSD, and is clearly entrenched within each of the organization's policies, procedures, and cultures. Major changes, therefore, are not easily implemented, especially due to the large number of student teachers that need to be placed each semester. In view of this, rather than attempting to revamp the entire placement system, we decided to initiate an opportunity for students to request a placement with a technology-using teacher. While our goal, of course, is for all student teachers to be placed in technology-rich environments, we adopted the strategy of placing those who made special requests as we transition toward providing such experiences for all students. We also sought to impact the entire program by revising current expectations for technology use in field experiences. In addition, we addressed the need for professional development for field supervisors as well as experimented with alternative models for students' field experiences. Each of these initiatives is discussed below.

Creating Request Options

Based on effective practices identified in exemplary colleges of education (Strudler & Wetzel, 1999), students now have the option to request student teaching placements with a technology-using teacher. UNLV's field experience office collaboratively planned with CCSD to make this option available. The field experience applications were revised to include this preference, and the office adjusted its database to include this information with the student names forwarded to the school district for placement. The school district placement office then began the process of trying to match interested students with mentor teachers who commit to infusing technology in students' field experiences. While we initially attempted to do this for practica and student teaching, it was decided by CCSD to forego inclusion of practica students due to the difficulty of accommodating such placements for all who requested them.

To appreciate the level of collaboration needed to modify this process, it is helpful to review details of the process of placing a student teacher. On the university side, once the prospective student teachers have completed all requirements and forms, their names are entered into a database which includes their requests for grade levels, location, and a column indicating whether they request placement with a technology-using teacher. The database is then forwarded to the school district office and principals from around the district are contacted to see if they are interested in hosting student teachers. The principals consult with their teachers and decide what placements should be made based on the student teacher requests. Once the teacher has accepted the student teaching placement, the information is forwarded back to the university so that supervising teacher assignments can be compiled.

The selection process for the cooperating teachers has posed clear challenges to the goals of the project. Initially, criteria for technology-using cooperating teachers were not clearly defined in the grant. Though we had hoped that principals would select teachers who were accomplished in their use of technology tools in the curriculum, in some cases principals viewed this as an opportunity to provide technology training for teachers and thus selected those most in need. Furthermore, cooperating teachers voiced concern about their roles and whether or not their technology skills were adequate for the task.

Eventually, we fine-tuned our expectations to meet this challenge and communicated more clearly with school leaders. To address these issues, more site visits were initiated, an online communication folder was established, and information booklets with frequently asked questions were developed to address the concerns of the teachers and support them in their role of mentoring student teachers. A sample booklet is available at the Project THREAD website: http://www.unlv.edu/projects/THREAD. Similarly, expectations for the project were more clearly articulated for students, thus minimizing confusion and resulting in greater satisfaction with the program.
What is emerging from this process is a clearer picture of what we need for a good student teaching experience that integrates technology. Communication with the schools through the principal has proven to be quite beneficial in developing a positive presence for the grant. Communication with each school's technology coordinator (known as educational computing strategists within CCSD) has resulted in increased support for student teachers as they plan and implement technology-integrated lessons.

Revising Handbooks

While the option for technology-based placements helps pre-service teachers who are motivated to use technology, we are committed to making technology a required part of all students' field experiences. To accomplish this, key faculty and field supervisors were selected to participate in a planning retreat in the summer of 2001, led by our Associate Dean and Director of Teacher Education. The purpose of this session was to revisit and revise expectations for field experiences. This effort, funded by Project THREAD, was designed to address current professional standards, including the integration of technology in various subject areas.

At this point, the committee developed a revised draft of the handbook under the direction of the Associate Dean. The draft is currently under review by other education faculty members and an educational technology specialist. After all of their recommendations are received, the committee will reconvene and finish revising the document. Once the practica revision is completed, a similar process is envisioned to revise our student teaching handbook.

Including Supervisors

Orientation meetings for university supervisors included a component about the goals of Project THREAD and technology use in field experiences. At those meetings, responses from the field supervisors indicated a need to provide them with information on technology uses in the classroom. To accomplish this task, we conducted a needs assessment with field supervisors. Results of that survey were used to design a series of workshops to introduce the supervisors to a range of technology uses in the classroom. A majority of the responding supervisors (75%) indicated that technology was very important in teacher education. We found, however, that many of the supervisors had minimal comfort with computer applications that enhance classroom instruction. The workshops, designed to address these needs, focused on presentation software, generic productivity applications, and an introduction to digital still and video cameras.

Altogether, 27 field supervisors participated in our first series of workshops. The hands-on practice time and one-on-one support helped develop their personal skills with technology. In addition, field-based videos were used to provide a framework for understanding and "seeing" what technology use looks like in K-12 classrooms. This combined approach of enhancing personal skills and providing a framework for understanding is a key piece in developing their capacity for assessing technology use during practicum and student teaching placements as well as supporting the efforts of their students. The impact of these workshops was best summed in a comment from one of the participants: "Technology will have a major impact on education...I feel fortunate to be able to participate in this worthwhile project. As a supervisor of student teachers, I need to have as much knowledge as possible to be able to help them out in the field."

Providing Alternative Student Placement Models

One model involved the creation of a cluster of five professional practice schools in conjunction with CCSD. Two elementary schools, two middle schools, and a high school all located within close proximity of each other, were identified to focus on creating positive field placement opportunities for pre-service teachers. The cluster schools all serve large populations of low-income, minority, and special needs students. A second model, involving the Paradise Professional Development School (PPDS), advanced technology integration through a field-based cohort program.
The Cluster School Model

In planning for the implementation of our project with our school district partners, we did not explicitly address the levels of technology at the schools or the levels of use by the teachers. Selection of the schools was based on meeting demographic criteria and the recommendations of CCSD's administrators. We were not in a position to dictate partner schools that were chosen and believed that it was important to work with the schools that were selected. As was previously discussed, principals at the school sites selected the cooperating teachers for the project.

Typically, cooperating teachers from the school district attend four half-day sessions designed to address their role as mentors. For this project, an additional half-day was added to each of the four sessions. The focus of the additional half-day was to support cooperating teachers in developing their skills with technology as well as learning how to integrate technology in teaching activities. Project THREAD funded the additional time. CCSD and UNLV personnel delivered the workshops jointly. Over the past few semesters, an average of 26 cooperating teachers participated in these workshops.

During the fall, 2001 semester, Project THREAD expanded its professional development workshops for cluster teachers to include an online graduate course, Internet for Educators. The professional development activities in this course were designed so that participants could learn how to create web-based curriculum materials and effectively model using technology in the classroom. The classes were ongoing, content-focused, and involved teachers as active learners, traits that make professional development more effective (Birman, Desimone, Porter & Garet, 2000).

Paradise Professional Development School (PPDS) Model

A second alternative program that seeks to expand technology use in field experiences is the Paradise Professional Development School. This initiative offers expanded opportunities over the traditional field placement system to articulate expectations between the university and its K-12 partner school. The PDS cohort model, planned collaboratively by UNLV and CCSD, was designed to prepare pre-service teachers to be effective in urban settings with diverse student populations. Technology integration was identified as a major priority for the program.

It should be noted that similar to the cluster schools, we consider the cooperating teachers and administrators to be our “clients” in the project. While our ultimate goal is to better prepare pre-service teachers, we seek to do this by restructuring the system and increasing the capacity of UNLV and CCSD personnel who work within it. To help accomplish this goal, a comprehensive series of monthly workshop (four per semester) were presented for PPDS mentor teachers and university supervisors in the school. Workshop topics included: Mentoring and Communication, Meeting the Standards: Technology and Others, Students and Teachers as Researchers, and a Constructivist Approach to Teaching and Assessment. Project THREAD personnel and the Educational Computing Strategist taught the workshops.

Conclusions/Future Directions

Our experience with reforming pre-service field experiences provides further evidence for the importance of this work and the challenges that are involved. In retrospect, we believe our “two-pronged” approach for reform is a good one. That is, we have chosen to focus on selected alternative programs—a cluster of professional practice schools and a technology-rich professional development school—while also addressing the larger program and the need for implementing systemic change at that level. We have accelerated the change process by working with a subset of “volunteer” pre-service teachers, schools, and cooperating teachers, while fully recognizing that our longer term goal is to reform the entire program to ensure that technology integration is a required and supported component of all students’ field experiences.

For the alternative programs, we have learned about the need to clarify our expectations, and communicate them more clearly to pre-service teachers and school district partners. Via brochures, handbooks, and online information, we are finding that participants better understand our goals and expectations, and satisfaction with the program has increased. We have also found that by being more proactive in selecting
partners at the “front end” who support the goals of the program, we can minimize problems that will likely arise. With our grant, we have been able to “buy” time for technology development through our workshops. However, issues of support and access within the schools are also critical factors in the success of the placements and are items that cannot be bought. As the literature clearly attests, we have learned that schools with strong administrative support for the program from the principal and the on-site technology coordinator offer the greatest access and support for our student teachers.

We are currently in the second year of our PT3 Implementation grant—which was preceded by one year as a capacity-building project. During that time participating schools have changed (e.g., two partner school became Edison schools and needed to withdraw from our program), and we have benefited from our experience in selecting new partners. For the final year of our grant (2002-03), we plan to ask all partner schools to assess their participation in the project and reapply if they would like to continue. We will assess how well we believe the schools supports the goals of the project and possibly make a change or two to ensure that our collaboration with partner schools provides a “win-win” for all concerned. We see this as a good “next step” to build upon the momentum that we have established thus far in accomplishing the goals of the project.

We will also seek to create more formal procedures for the placement of student teachers with technology-using mentor teachers. Our goal is to institutionalize all changes so that program initiatives will continue beyond the life of the grant and the particular individuals currently involved. As with our current effort to revise the field experience handbook, we will continue to formalize expectations and procedures in writing and seek “buy in” from key UNLV and CCSD personnel.

As we continue this work, ongoing project evaluation efforts will address the effectiveness of students’ field experiences. Surveys will be administered to pre-service teachers at the end of their student teaching experience, along with exit interviews, lesson plan analyses, and classroom observations. Overall, we hope to gather all-important evidence to document if our efforts to integrate technology into students’ field experiences are indeed impacting the quality of their preparation for tomorrow’s classrooms. For now, though, we view our initial efforts regarding field experiences as becoming “unstuck” and are very pleased with the collaboration we have had with our K-12 partners. Through these initiatives, we believe Project THREAD is making significant progress toward achieving its goals of supporting pre-service teachers in their preparation for teaching in 21st century classrooms.

Teachers as Leaders Using Technology:
Evidence from Innovative Changes to Teacher Education

Erika L. F. Sueker
PT3 Grant Evaluator, Independent Educational Consultant,
Golden, CO, USA esueker@rmi.net

Sherri A. Buss
Instructional Technology Specialist, College of St. Catherine,
Minneapolis, MN, USA sabuss@stkate.edu

Abstract: The Teachers as Leaders Using Technology group is a consortium of one institution of higher education and three elementary schools, located in a large metropolitan area. Faculty (P-12 and college) and prospective teachers are engaging in technology-rich learning experiences, both on campus and in fieldwork settings. An Instructional Technology Specialist provides in- and out-of-class support to both groups. This innovative teacher education project aims to increase the likelihood that new teachers will integrate technology into their classroom practices, and that faculty and teachers will use technology to create improved curriculum for all students, helping to close the digital divide.

Problem

Despite many advances in educational technology for P-12 students, pre-service teachers who learn about technology tools and applications during their preparation often do not effectively integrate technology into their classroom teaching once they become certified. Prior to that point, they need enough practice with new technology skills to feel confident enough to use them with students (U.S. Office of Technology Assessment, 1995). They need specific goals and expectations, reassurance, and the availability of in-class assistance during their first classroom methods and teaching experiences (Brand, 1998). Some studies have shown that the most crucial determining factor in whether teachers will integrate technology into their classrooms is the level of support they receive from school administrators (Sandholtz, Ringstaff & Dwyer, 1997). Thus this problem is multi-faceted and systemic, going beyond the often-stated needs for thorough instruction in educational technology tools and applications, understanding of cognitive psychological principals of learning from different media, and constructivist teaching methods (e.g., Grabe & Grabe, 1996). In addition, the problem raises the issues of faculty modeling of technology use, technology access during fieldwork and student teaching, and training and support during education coursework and beyond. The difficult problem of digital equity for diverse populations is also inherent in any discussion of technology integration (Bennetts, 1999).

To respond to these needs, the Education Department at the College of St. Catherine’s, a private women’s college in the Twin Cities area, is engaged in a project called Teachers as Leaders Using Technology, funded by a federal PT3 grant. The department is implementing far-reaching changes affecting faculty and students, policies and practices, to ensure that graduates will be better prepared to integrate technology into their future teaching. The Department has created partnerships with a diverse set of local schools that are serving as fieldwork and student-teaching locations for the prospective teachers. The varying amounts of technology at use in these partner schools, as well as the differing school sizes, structures, and diverse student populations, will allow comparison of the effects of St. Catherine’s changes in various teaching environments.
Proposed Solution

The purpose of the Teachers as Leaders Using Technology program is to prepare teachers who are proficient in using technology to increase P-12 student learning, and who can use technology to improve their own productivity. Three major changes are being implemented over three years, with the goal of becoming self-sustaining. (1) Faculty (P-12 and college) and prospective teachers are engaging in technology-rich learning experiences both on campus and in fieldwork settings. A major factor in this change is a laptop lease program required for all prospective teachers. The belief is that using computers and associated devices should become as natural as using books, pens and paper. Students will use their laptops for classwork, assignments, and assessments. During fieldwork and student teaching, prospective teachers will prepare lessons, give presentations to students, use a digital camera, and create grade-keeping spreadsheets. Faculty will revise their syllabi, hold monthly discussions regarding standards for technology use, model the use of technology in the classroom, and communicate with students via email and the Department website. (2) An Instructional Technology Specialist (ITS) is providing in- and out-of-class support to both faculty and prospective teachers. The ITS will provide workshops, training, and support for all aspects of the technological changes. She travels to the fieldwork and student-teaching sites and provides assistance to prospective teachers and faculty there. She participates in interdisciplinary faculty study groups to discuss cross-discipline applications, technology-related classroom experiences, and many other aspects of integrating technology. (3) An Instructional Technology Network to be implemented in Year Three will sustain support after students complete the teacher preparation program. Graduates will access technology and pedagogy support that will be monitored by a web-manager. Users will ask questions, share information and pedagogical ideas, interact with others striving to integrate technology, and learn about new resources.

Goals

The goals associated with these three changes are: (1) for faculty and prospective teachers to develop greater potential for infusing technology into teaching and learning experiences by experimenting with a variety of applications both in the college classroom and in the P-12 settings; (2) for faculty in the partner schools and the college of education, as well as the prospective teachers, to use technology to design curriculum that responds to all students' learning needs and styles, and that demands the use of higher-order thinking skills, resulting in more effective problem solving and decision-making; and (3) for graduates of the teacher education program and P-12 teachers in the partner schools to stay connected and receive on-going support via an Instructional Technology Network. To accomplish the three major goals of the project, the Department will provide technology support for prospective teachers and faculty (college and P-12) throughout the process of closely aligning on-campus classroom experiences, fieldwork experiences, student-teaching experiences, and first-year teaching experiences with the National Educational Technology Standards (NETS).

Examples of the technology-rich learning experiences that faculty and prospective students are engaging in include learning new technological tools such as spreadsheets, digital cameras, video editing, and presentation software techniques. They are also studying content-based software, how the use of technology and related teaching practices can affect student learning, and issues involved in teaching students about technology. Students are keeping ongoing electronic portfolios of their experiences, assignments, curriculum designs, lesson plans, and other products involving the use of technology. The portfolios will serve as assessment tools as well as records of student work and references for their future teaching. Faculty and prospective teachers are currently attending workshops on computer maintenance, Access database creation and use, Lotus Notes, Excel, PowerPoint, and Publisher. Future workshops will be created based on the needs of the program as it evolves. Through their fieldwork and student teaching in the consortium schools, prospective teachers are learning about the wide variety of technology applications already available for school children. At one partner school, students will experience the limitations of a hodgepodge system of donated computers in need of upgrading as well as the creative ways teachers can capitalize upon even basic resources. At another they will encounter, some standard applications for libraries and media centers, the use of email for communication within a school and district, and software resources in all content areas. At the third they will have the opportunity to use technology fully infused throughout a large school, including specialized equipment and
software for the hearing-impaired, flight simulators and other high-level applications, and sophisticated technology use for all aspects of education.

Research and Evaluation

To assess the success of the project, longitudinal research is being conducted by an external evaluator. During the first year, students beginning the program with the newly implemented departmental changes will be compared to second-year students who were not the targets of the changes. These beginning students will then be followed for three years to look for evidence of continued improvement as the departmental changes become more solidified. In the second year of the program, research will focus on student teachers who have experienced the Department changes, as compared to student teachers from the previous year who did not. In the third year, the Instructional Technology Network will be created to support the first-year teacher graduates who were the beginning students in Year One. These teachers will be compared to previous first-year teachers who did not have access to the Network or other departmental changes.

Prospective teachers' comfort and ability with using educational technology tools and applications will be measured through performance-based assessments, including but not limited to electronic portfolios and observation of their teaching, as well as through self-report surveys. Variables that are expected to modify their success in integrating technology into their teaching include the location and circumstances of their student teaching and fieldwork experiences (e.g., higher- vs. lower-tech schools, focus on immigrant populations, relationship with partner school administrators and mentor teachers), the amount of support and training they receive (e.g., contact with the ITS, workshops, modeling of technology use by faculty), and their attitudes toward technology in education.

The University of Florida Teaching and Technology and Technology Initiative is a PT3 funded initiative designed to facilitate and accelerate systemic change related to technology integration in our teacher education program. The initiative involves the collaboration of several organizations within the University of Florida, the School Board of Alachua County, Apple Computer, and the Center for Technology in Learning and Teaching at Iowa State University. In this poster session we will outline the goals of the project, overview the ongoing activities we are supporting to meet these goals, share the implementation strategies we are using to meet the needs of our teacher education program, and discuss our evaluation strategies which are designed to ascertain the effectiveness and impact of the project.

Introduction

In the PT3 trailer movie, Tom Carroll remarked that the PT3 program is about creating teaching and learning environments that promote and facilitate learning with a capital ‘L’ and technology with a lowercase ‘t’. This statement captures the essence of the University of Florida Teaching and Technology Initiative (UFTTI). This initiative is a PT3 funded project designed to facilitate and accelerate systemic change related to technology integration in our teacher education program. The UFTTI involves the collaboration of several organizations within the University of Florida, the School Board of Alachua County, Apple Computer, and the Center for Technology in Learning and Teaching at Iowa State University. The goals of the initiative are to:

1. Develop a comprehensive institutional vision for technology integration that will consider new state and national standards involving a variety of stakeholders and enable effective technology integration in our traditional and nontraditional teacher education programs.
2. Design and implement innovative faculty development efforts that will enable professors working with preservice and potential preservice teachers to effectively implement content-specific, technology-based instructional strategies in their courses and model uses of instructional technology in their teaching.
3. Create opportunities for technology-based field experiences that will enable students in the Unified Elementary Proteach and "Project SITE" programs to observe and implement curriculum-focused, technology-based instructional strategies.
4. Facilitate and support college-wide implementation of electronic portfolios designed to promote student-centered assessment.
5. Disseminate project results and resources to our faculty and other teacher education institutions.

Steps Toward the Goals

Upon notification of PT3 funding beginning in July 2001, we began to implement our action plans for each of the goals previously listed. With streamline budgetary and personnel resources at the University of Florida as a part of our teacher education environment, our action plans are designed to not only be grounded in theoretical frameworks but to also take advantage of existing programs, resources, and
personnel. We will briefly share some of our action plans in this paper and will expound in more detail events occurring in the UFTTI at our poster session.

**Establishing an Institutional Vision**

Although the College of Education has made progress in equipping the college with technology, there has not been consistent leadership in the area of instructional technology. We believe it is critical that the foundations for establishing a vision for the use of technology in the College of Education begin. We recognized that building consensus and developing a vision for the College of Education will take considerable time and effort. Therefore, to guide us in this process we relied upon the various educational change models found in the book *Surviving Change: A Survey of Educational Change Models* by James B. Ellsworth as well as the guidance from others including our advisory board and external evaluators.

**Provisioning Faculty Development**

The faculty development initiatives in the UFTTI are categorized into general faculty development and content-specific faculty development. This action plan has been based upon research that suggests innovative faculty development models which focus on individuals are most effective in producing educational change, that exemplary faculty development prepares teachers to use technology in their discipline, and that effective faculty development efforts enable teacher educators to enhance their instruction so that future teachers are prepared to advance student learning with technology. The UFTTI developed a cohort of Teaching and Technology fellows to provide specialized, content-specific assistance to faculty members in the Colleges of Education and Liberal Arts and Sciences. Also created was the Teaching and Technology Incentive Program for faculty members to conceptualize and implement innovative strategies for integrating technology into their teacher education courses. In addition, we provide an extensive array of technology workshops along with consulting-on demand and a College of Education online support center.

**Technology-based Field Experiences**

In the UFTTI selected preservice teacher education students are paired with an inservice teacher(s). These teams will focus on implementing an in-depth instructional project and/or series of min-lessons in the classroom. The goals of these field experiences are to create more positive relationships with teachers and schools in our district, provide authentic technology-related experiences for students, and to have a mutually beneficial technology-related experience for the preservice and inservice teacher.

**Electronic Portfolios**

All teacher education students at the University of Florida are required to develop an electronic portfolio to demonstrate mastery of the Florida Accomplished Practices. These portfolios also provide students with a vehicle to reflect upon their learning as well as communicate information about themselves. Each student’s portfolio is a dynamic, iterative document that evolves and expands throughout the student’s collegiate experience. Although there has been considerable success in the Electronic Portfolio Project, the PT3 grant has allowed this project to develop a stronger infrastructure that prepares faculty and students to evaluate electronic portfolios for mastery of the Florida Accomplished Practices. In addition, we are striving to develop a culture of faculty buy-in that promotes similar beliefs about and compatible strategies for implementation of electronic portfolios.

**Future Steps**

As we approach the end of our first year in the University of Florida Teaching and Technology Initiative, we know there is much work still to be done. We will continue to work to establish a vision for the use of technology in the College of Education, strengthen our faculty development opportunities and technology-based field experiences, and expand the Electronic Portfolio Project.
Empowering 21st Century Teachers MPS PT3

Kathy Swope, Milwaukee Public Schools, US

The MPS PT3 catalyst initiative formed a consortium to enrich the teaching/learning process by maximizing the integration of technology across the curriculum. New learning resources that assist higher education faculty and future educators will be identified through innovative learning communities developed through the membership of the consortium. Project activities include: establishing a communication loop of effective practices between National Advisory Board and teacher preparation faculty; increasing effective resources for teacher training faculty; training schools of education faculties on tools which effectively bridge the gap between classroom practices, state and local standards, and assessment; and providing interactive video distance learning which allows for live collaboration among master classroom teachers integrating the use of technology into the curriculum, teacher preparation faculty and pre-service teachers. Anticipated outcomes from these efforts are that future teachers will integrate technology across the curriculum.

The interactive demonstration/discussion will highlight the activities implemented to meet the goals of the project. The Empowering 21st Century Teachers Consortium includes the Milwaukee Public Schools, Marquette University, the University of Wisconsin-Milwaukee, the University of Wisconsin System, and the Council of the Great City Schools.

The Goals of the project:
• Increase national and state collaboration around the integration of technology in teacher preparation
• Improve the technology integration skills of colleges' and universities' teacher training faculty
• Increase the number of graduates of teacher training colleges/universities who have technology integration skills
• Decrease the existing educational gaps between standards, assessments, and the day-to-day classroom lessons using effective practices and technology-based mechanisms.

Activities include:
• Creation of a National Advisory Board to increase access to national expertise and broaden the knowledge base for integrative technology practices in education.
• Train schools/departments of education faculties on tools which effectively bridge the gap between classroom practices, state and local standards, and assessments
• Provide interactive video distance learning which allows for the collaboration among master classroom teachers integrating the use of technology into the curriculum, teacher preparation faculty and pre-service teachers
• Develop and distribute video tapes of classroom activities which demonstrate effective technology use in K-12 classrooms.

National Advisory Board
This Board guides the paradigm shift to technology-rich learning environments impacting all educational levels. This National Advisory Board works with the consortium to disseminate and publish project results to Institutions of Higher Education across Wisconsin, the region and nation. This initiative assists colleges and universities in tapping the technological resources both human and tangible, already in place in school systems in order to build capacity at the college level and in K-12 systems. In the scheme of Empowering 21st Century Teachers both college and K-12 school staffs are acknowledged. Under the guidance of the National Advisory Board, each learns from the other.
• Provide in-service training opportunities for teacher preparation faculty on engaged learning using K-12 Master Teachers, who integrate the use of technology into the curriculum.
• Establish a communication loop of effective practices between National Advisory board and teacher preparation faculty
• Increase effective resources for teacher training faculty
Curriculum Design Assistant (CDA)
The CDA is a web-based central knowledge database of instructional plans. The MPS Curriculum Design Assistant (CDA) was developed by teachers for teachers. This successful internet curriculum tool is in its third revision and is now oracle based with a whole new look and feel. The CDA has been proven to be an effective tool for all K-12 educators and pre service teachers. Educators can share successful standards based instructional plans, units, projects or staff development with peers and pre service teachers by entering them into the central knowledge database. The CDA allows for easy access to state and local standards as well as the ISTE technology standards. Many of the instructional plans integrate technology for instruction and assessment. Modifications and accommodations can also be included in instructional plans so that ALL students can be included and successful! Video streaming is a new enhancement to the CDA.

Video
We have a Milwaukee Distance Learning Group. There are over 50 sites within MPS that now have two way video capabilities. This vehicle is used in a number of ways including enrichment of curriculum; providing rich coursework opportunities, staff development, community programming, administrative meetings, virtual fieldtrips, expanding partnerships, maintaining face-to-face relationships, and connecting with university partners. Preservice teachers are able to be involved in instructional experiences never before possible. Several teachers state: "Educating tomorrow's leaders requires today's children to be exposed to the global community, a reality that interactive technology makes possible." And "Interactive video enhances our curriculum in a powerful way. Our students can connect and share experiences with kids throughout the state and beyond."

Technology Thursdays
Our Technology Thursdays are offered twice a month to provide practical and useful professional development opportunities that merge the latest in learning technologies and the best in pedagogical techniques. Most of these sessions represent a pairing of technology savvy and curriculum expertise, and are led by a team of facilitators. Topics focus on the instructional practice, supported by technology. For example; "Writing Instruction Supported By Technology", Participants in this session learn about using technology to facilitate the writing process using word processing, graphic organizers, publishing software, and some research engines. The emphases includes ascertaining when the use of technology is most effective within the context of the writing process for various grade levels K - 5. Other topics include a focus on mathematics, reading, multicultural education, the research paper, and special sessions for educational leaders. These sessions are open to any teacher, preservice teacher or university faculty. There is no cost to participants, or their school and are brief Two-hour overviews. This provides the opportunity to sample a number of topics without committing to an entire semester of workshops.

We will share the results of this work with an in-depth demonstration of the Curriculum Design Assistant, CDA; a web based tool that gives teachers point and click access to detailed standards based lessons and resources, a discussion of the work of both the local and national advisory board, a show and tell of the various video projects and a glimpse of an innovative staff development model known as Technology Thursdays.
If It's Not Online and It's Not Live, What is It?

Sharon Tettegah, University of Illinois, Urbana Champaign, US
John Sfondilias, University of Illinois, US
Cathy Thurston, University of Illinois, US

There has been a good amount of discussion in the literature (online and otherwise) regarding the pros and cons of live ("bricks and mortar") versus online (distance) education (Dominguez and Ridley 1999; Knox, 2000; Miller, Smith & Tilstone, 1998). These discussions sometime imply a dichotomy between several modes (face to face, mixed media and distance education) or an all or none approach to teaching and learning that infrequently represents most educational environments. Whatever the long-term future, in the current and near-term, teacher education consists of predominantly live instruction with numerous opportunities for the infusion of technology in the curriculum.

In our PT3 project, we take a pragmatic approach and look at what technologies are available, how technology will be used, what makes instructional sense, and what makes political sense (i.e., what will faculty and teachers accept and adopt?). Technology is integrated into the curriculum, as any instructional method would be through curriculum development (Crotty, 1995). Our evaluation plan assesses the impact technology infusion has on achieving learning objectives of a course. We believe that teaching involves a continuum of technology (and always has), and results in a product that can simply be regarded as "instruction and learning," with its associated goals and objectives. We evaluate how well those goals and objectives are attained. Of course, we attempt to break down, as much as it is feasible, the contribution of the various teaching and learning strategies to learning outcomes. A preliminary evaluation is included in this presentation.

Specific courses in Curriculum & Instruction are targeted for the initial phase of the project. We consider technologies based upon a number of factors including ease of integration, cost (both people and $$), existing campus and departmental support, and potential for maximum positive impact upon teaching and learning using a variety of electronic technologies. These technologies include email, discussion boards, comprehensive course management systems, word processors, Powerpoint, streaming audio and video, electronic portfolio development and java applets. Selected examples of such technology integration are included in this presentation.

Ultimately, regardless of whatever else we accomplish in this PT3 project, our project must show promise for improving the teaching and learning process, which (facilitation, instructional design and curriculum) happens in classrooms. We have designed our technology interventions to be consistent with what we know about how people learn and what constitute good teaching practices. Our integrated model for infusing technology selects and incorporates, peer coaching, collaboration, mentoring, problem-based learning and modeling using new technologies based upon their instructional appropriateness. The overall model is presented with particular emphasis upon how project management and evaluation, and specific technology interventions fit within the teaching and learning communities of practice, while realizing that internet and other forms of technology are useful tools that can provide resources just as a chalkboard, overhead projector or video cassette recorder (Rosen, 1999).

Revised Standards for ISTE/NCATE Accreditation and National Recognition

Lajeane Thomas, Louisiana Tech University, US
Dianne Porter, Louisiana Tech University, US
Harriet Taylor, Louisiana State University, US
Peggy Kelly, California State University, San Marcos, US

DESCRIPTION: Examine revised ISTE/NCATE accreditation program standards for Educational Technology Facilitation (preparing campus technology leaders) and Educational Technology Leadership (preparing district, regional, or state technology leader).

SUMMARY: The International Society for Technology in Education (ISTE) recognizes that educational computing and technology foundations (NETS for Teachers) are essential for all teachers. ISTE also acknowledges educational computing and technology specialty areas beyond these foundations and has established program standards for initial and advanced programs. These program standards assist teacher education units, and professional organizations and agencies in understanding and evaluating the educational preparation needed for specialization within the field.

Lajeane Thomas, Chair of the ISTE Accreditation and Standards Committee and additional members of that committee will present the newly revised NCATE/ISTE Accreditation Standards for Educational Computing and Technology programs. These two sets of standards are designed to identify standards, performance indicators, and performance tasks identifying what candidates prepared for Educational Computing and Technology Facilitation (ECT-F) and Educational Computing and Technology Leadership (ECT-L) should know about and be able to do with technology.

The standards presented address the initial and advanced educational computing and technology programs including: (1) the educational computing and technology facilitation initial endorsement; and (2) the advanced educational computing and technology leadership program. Institutions that offer one or more of these programs should respond to the corresponding program standards. Included in the resources provided in the session are rubrics for use in identifying the level performance for candidates.

Educational Computing and Technology Facilitation -- Initial Endorsement Guidelines

Educational Computing and Technology Facilitation (ECTF) endorsement programs meeting ISTE standards will prepare candidates to serve as building/campus-level Technology Facilitators. Candidates completing this program will exhibit knowledge, skills, and dispositions equipping them to teach technology applications; demonstrate effective use of technology to support student learning of content; and provide professional development, mentoring, and basic technical assistance for other teachers who require support in their efforts to apply technology to support student learning.

Educational Computing and Technology Leadership -- Advanced Program Guidelines

Educational Computing and Technology Leadership (ECTL) advanced programs meeting ISTE standards will prepare candidates to serve as Educational Computing and Technology Directors, Coordinators, or Specialists. Special preparation in computing systems, facilities planning and management, instructional program development, staff development, and other advanced applications of technology to support student learning and assessment will prepare candidates to serve in technology-related leadership positions at district, regional, and/or state levels.

These programs prepare candidates to keep abreast of changes in educational computing and technology and their impact on education. In addition, candidates are equipped to utilize and integrate a broad range of educational computing and technology applications to enhance student learning. Finally, candidates will be prepared to work effectively as professional leaders to advance their specific fields within a culturally diverse society. Resources including the standards, rubrics, and guidelines for seeking national recognition through ISTE and NCATE for these university programs can be found at the following Internet locations: http://cnets.iste.org and http://www.ncate.org
Radical Change in a Traditional Setting: Lessons Learned

In an age when change is a norm, lifelong learning a critical mandate for prosperity, and technology a revolutionizing force, transforming traditional education practice is a central theme at Valley City State University (VCSU). Beginning with the distribution of IBM notebook computers to all faculty in January of 1996 and to all students at the start of the 1996-97 academic year, VCSU became the first notebook university in North Dakota and of a small number across the country.

With the universal access to notebook computers, the teacher education faculty at VCSU altered teaching and learning significantly. Teacher education faculty can walk into nearly any classroom knowing that they will be able to display presentations developed with PowerPoint, ask the entire class to find resources on the worldwide web, work with on-line courses at any time, and receive e-mail documents which they can display as a basis for class discussion.

Technology has provided VCSU faculty in the teacher education unit with tremendous capacity to revolutionize education both on campus and in the public schools. Integration of technology into the elementary education classroom has been a very important goal of the unit the past three years. To help achieve this goal, the VCSU elementary education department has formed partnerships with six other educational entities to strengthen and improve learning with technology. The department is also in the second year of their PT3 Grant that seeks to provide opportunities for VCSU elementary education faculty, preservice teachers and classroom teachers from the Valley City area to work together to integrate technology into their courses and to create a learning community among themselves for the purpose of using technology to improve learning.

The grant goals include creating a learning community and developing complex reasoning and problem solving skills. VCSU faculty, K-6 teachers, and candidates participate in collaborative projects designed to develop complex reasoning and problem solving skills. Cooperating teachers representing the various consortium schools collaborate with VCSU faculty and candidates to restructure learning experiences in their classrooms that reflect current best practices for using instructional technology strategies and tools. Another goal prepares elementary education graduates to use technology to help their future students improve learning by developing complex reasoning and problem solving skills.

The success of the PT3 grant is a reflection of the direction VCSU has been moving the past eight years. VCSU has been a national leader in instructional technologies and the resources available at VCSU ensure that successful efforts continue and the university will be an example for others to follow.
As VCSU has moved in this direction, we have learned many lessons. The collaborative projects have brought a new level of authenticity to the technology training of VCSU students. But this authenticity has required VCSU faculty to be willing to give up control of the learning setting and be willing to share it with the student and the classroom teacher. We have also learned that our students need to know how to be consultants when they work with classroom teachers. The teachers are at varying stages of readiness to integrate technology into their classrooms. Some are already deeply involved while others still feel unprepared. We have sponsored workshops to help the teachers gain skills and brainstorm ideas. We are preparing consultant guides for our students to help them better meet the needs of the teachers, especially those who are in the beginning stages of technology use.

Besides the above, this session will include in-depth results of the evaluations of the workshop and collaborative projects and the strengths and challenges the data reveals.
Developing Interactive Computer Tutorials for Current and Future Teachers
Sudheer Vaka, Bhargav R Marpuri, Taha Mzoughi, and Jessie Burnette Hamil
Mississippi State University
Bosede Aworuwa
Alcorn State University

Increasingly, proficiency in the use of computers is becoming a necessary skill for all teachers. They need to use computers for teaching, class and lecture preparation, class assignments, class management, research, and professional development. However, many current teachers lack even the basic skills for operating a computer, let alone integrating the use of computers into their teaching. As a result, many local and national programs have emerged to offer teacher training on the use of computers and the use of computers in teaching. Alcorn State University and Mississippi State University have received grants from the US Department of Education, Preparing Tomorrows Teachers to Use Technology program, to provide this type of training.

In both programs, the training includes hands on activities and interactive collaborative sessions that allow for exchanges between the teachers and between teachers and trainers. The training targets basic skills as well as more advanced skills and strategies for classroom integration. Teachers attending our workshops have felt that they have learned a lot and their confidence about the use of computers have increased significantly. To help insure that they can carry that newly acquired knowledge beyond the workshop, we found it necessary to provide them with resources that they can use on their own at their own pace. The resources should help them reinforce the skills that they have learned during the workshops and work on more advanced activities than the ones they were able to complete during the workshop.

Our strategy was to insure that the resources are easy to use and that they provide a gradual approach to the learning process. Additionally we wanted them to be interactive and to meet the needs of people of different learning styles and skill levels. Skill Level 1 tutorials are intended to meet the needs of teachers who have little or no computer skills. Level 2 tutorials are for teachers with more advanced computer skills. Another important component was to have some teachers participate in authoring some of these tutorials and to sometimes provide the actual training. A study by the “The Computer Learning Foundation” suggests that training of teachers by teachers is more effective than training by administrators [Alden.] By providing and authoring the training teachers experience the benefits of technology for themselves and get a first hand experience on using technology in teaching.

We currently have developed twenty interactive tutorials. They are compiled into a manual that we started using during training sessions. The interactive version is provided on CD-ROM and on the Web for easy download.
Assessment of Online Technology Modules in Pre-Service Teacher Education Courses

Jeanne Vilberg
Learning and Technology Center
Clarion University of Pennsylvania
United States
jvilberg@clarion.edu

Darla Ausel
Learning and Technology Center
Clarion University of Pennsylvania
United States
dausel@clarion.edu

Abstract: Teams of faculty, administrators and staff at three State System of Higher Education (SSHE) universities in Western Pennsylvania developed online technology modules incorporating the International Society for Technology in Education (ISTE) standards to enhance pre-service teachers’ use of technology and provide opportunities for faculty to model effective technology in the classroom. This paper will report the findings of a study on the use of online modules in teacher education courses at Clarion University where 244 pre-service teachers were surveyed on their experiences. Results indicated that the students found the online modules to be a valuable component in their courses, providing new and innovative ways to engage students using technology.

Introduction

In its third year of a $1.7 million Preparing Tomorrow’s Teachers to Use Technology (PT3) implementation grant, a consortium of three universities in rural Pennsylvania (Clarion, Edinboro and Indiana) is continuing its success in infusing technology into the teacher preparation curriculum by helping faculty develop appropriate assignments requiring technology use for students and incorporate them into their courses. Building on the National Council for Accreditation of Teacher Education (NCATE) and the International Society for Technology in Education (ISTE) pre-service teacher competencies for technology education, the universities are developing technology integration plans that prepare the faculty as well as the students to infuse technology (NCATE 2001). Findings in a 1998 report for the Milken Exchange on Education Technology indicate that "the biggest challenge facing institutions today is preparing faculty to model the effective use of technology as a teaching and learning tool" (Willis & Raines 2001). In the first two years of the PT3 grant the members designed and implemented a strategy for professional development opportunities for faculty, technology support, and enhancing the pre-service teacher education experiences through technology. In year three, implementation and integration of online course modules in the teacher education curriculum is providing a wide range of educational technology experiences for pre-service teacher education students.

It is no longer enough to have computers in the schools or required courses that teach students how to use computer applications. Faculty need to model appropriate use of technology and effectively integrate technology across the curriculum (Abdal-Haq 1995, ISTE 2001). At Clarion University the Learning and Technology Center staff and education faculty collaborated to create a professional development experience for faculty on how technology can be used effectively in the classroom. Presented as a hands-on, weeklong immersion in technology applications in the summer, the “Technology Chalkboard” series laid a foundation for the development of the online technology model. Based on a modular approach, each technology application (electronic communication, spreadsheets, multimedia, mindtools, videoconferencing, technology classrooms, digital imaging, online courses, webquests) was presented in a three-hour session incorporating foundation, application, and integration skills that lowered the entry level for faculty and teachers to begin their...
investigation of effective uses of technology in teaching and learning. McKenzie (2001) defines the challenge of professional development to “inspire and prepare classroom teachers to launch curriculum rich activities with the tools that make sense.” The “Technology Chalkboard” model reinforces this idea by providing a foundation for faculty to model technology integration.

In the fall Clarion, Edinboro and Indiana university faculty, administrators and staff collaborated to develop the model into nine online course components (Electronic Communication and Collaboration, Integrating Electronic Spreadsheets, Mindtools, Digital Imaging to Enhance Instruction, Developing Multimedia Presentations, Videoconferencing for K-12 Education, WebQuests, Developing Instruction Online, Reshaping Classrooms Using Technology) for use in the teacher education curriculum, enabling faculty to more easily integrate technology in their courses and meet the need for future technology proficient teachers.

Methods

Nine faculty teaching education core or methods courses were recruited to develop the online technology modules in collaboration with project directors and support staff. Three faculty developers at each consortium institution selected five faculty and four K-12 teachers in their intermediate unit to implement and assess the modules. The module implementation design included in-service as well as pre-service teachers to provide a common connection for the students’ field experiences.

Overall, approximately 1,200 students at the three campuses will use the modules through the spring semester of 2002 to investigate classroom technology applications. Similar to the “Technology Chalkboard” model used by faculty, the modules incorporated three main components. In the first (framework) the students were introduced to the technology, in the second (exploration) the students explored examples of how the technology can be used in the classroom at either the elementary or secondary level, and in the third (integration), the students integrated the technology into a lesson plan incorporating ISTE standards designed for their field experience. The modules focused on how the technology could be used to support the curriculum and designed so that they could be replicated for use at each of the institutions and across courses. Students completed specific assignments for each of the three areas and used electronic communication and discussion boards to share their experiences. To meet the needs of both pre-service and in-service teachers and for future professional development needs, the modules were designed so that they could be integrated into the classroom or used as standalone learning tools, enabling anytime, anywhere learning.

In Fall 2001 faculty at each institution began to integrate the online technology modules into web-enhanced teacher education courses using WebCT and Blackboard courseware. Not all modules were fully implemented in the fall semester, however. Obstacles to completing the modules were the lack of instructional design support in developing the modules and faculty expertise in redesigning content to fit the Web environment. This study will focus on three of nine modules that were implemented and assessed at Clarion University.

The three online modules (WebQuests, Mindtools, and Reshaping Classrooms) were incorporated into six teacher education courses, impacting approximately 400 students. The WebQuest module was used with ELED-324 Teaching Elementary Mathematics (3 sections) and SCED-539 Resource Materials for Science Education (1 section); the Mindtools module was used in ELED-325 Teaching Elementary School Social Studies (2 sections) and ED-327 Instructional Strategies and Management (1 section); and the Reshaping Classrooms module was used in ED-217 Micro Applications in the Classroom (4 sections) and ELED-331 Children’s Literature (1 section).

Two measures were taken to evaluate the online modules; the first was incorporated into the module as an assignment consisting of a student reflection of the online module experience (Was it a valuable learning experience? Did it expand your knowledge about the technology or about a concept? How will you use the experience in your classroom? How can it be used to meet standards?) and the second was a 10-item survey on how effectively the technology module was integrated into the course, its ease of use, and whether the module was a valuable part of the course. Out of the 400 education students enrolled in the targeted courses, 117 completed the student reflection and 244 (7 sophomores, 96 juniors, 134 seniors and 7 graduate students) participated in the voluntary survey. The students rated their technology level as: beginner (18), intermediate
user (64), advanced (131), and expert (31). The survey used a five-point Likert scale ranging from 1=Strongly Disagree, 2=Disagree, 3=Neutral/No Opinion, 4=Agree, 5=Strongly Agree. Seven faculty developers, cooperating faculty and K-12 teachers also submitted an online assessment survey following completion of the course module.

Results

Student survey responses are reported in Table 1. Items 2 and 5 dealt with the module's ease of use in the course. The students found that they needed little help in using the online module (3.62) and learning the computer applications (3.81). Each module was designed with clear navigation properties that were consistent among modules and a good foundation for understanding the technology application. For example, the Mindtools module incorporated a tutorial on Inspiration software as well as a free download of the software. Table 2 reports responses based on students' perceived technology level. In general user level was positively related with ease of use and learning the computer application. The more advanced the user the more positively they rated ease of use (beginner, 2.89; intermediate user, 3.55; advanced user, 3.63 and expert user, 4.19) and learning the application (beginner, 3.56; intermediate user, 3.64; advanced user, 3.85 and expert user, 4.13).

Items 1, 3 and 6 focused on the appropriateness of the module and how well it was integrated into the course. These items were positively rated by the students: learning how to use the technology module was adequately discussed in class (3.91), the technology module assignments were appropriate for this course (3.98) and the technology module was well integrated with the rest of the course (3.67). Student reflections indicated that they were enthusiastic about integrating technology into the classroom. Students suggested using WebQuests to enhance content knowledge and enable higher-level student thinking, using the Web for research, creating scavenger hunts as a way to make students discover information for themselves, and using virtual field trips to help students become more actively involved in their learning.

Item 4 rated the amount of time needed to complete the module assignments. Overall, the students did not feel the module assignments required too much time; however, there was variability between user level and how the instructor implemented the online module. Some instructors integrated the technology module more fully into their courses while others used it as a supplement. Further, individual technology modules required different learning skills depending on the learner and the technology application.

Items 7 and 8 reflected the student's understanding and interest in the material. Students' responses indicated that the modules had a positive effect on their understanding (3.47) and enhanced their interest in the course material (3.42). Student reflections confirmed the survey results. Ninety-eight percent (115 out of 117) reported that the module expanded either their knowledge about the technology or classroom content. Recurring comments were that 1) they learned when and how it is appropriate to use technology, 2) it expanded knowledge of standards and made them much easier to understand, 3) they learned how technology can be used for student-centered and discovery approaches, and 4) the module showed the steps to implementing technology as well as strategies and paths for various subjects and various types of teachers. Comments like, “The module opened my eyes to new and innovative ways to help my students learn by using technology,” “Before looking at the module, I didn't know much at all about the different [technology] options available” and “[I was] amazed at the information this module has to offer” were numerous.

Items 9 and 10 evaluated the value of the online module for the student. Students positively rated the module as a valuable part of the course (3.67). Student reflections supported this data; 97% (113 out of 117) of students reported that the module was a valuable learning experience. They reported 1) gaining a deeper understanding of what technology can do to enhance children's learning experiences, 2) feeling more secure about using technology in student teaching, 3) learning new ways to make lessons more student centered, 4) realizing the importance of integration of technology in the classroom, 5) acquiring an expanded view of the one computer classroom, and 6) finding the module a great learning experience to discover a new way of teaching. Students commented positively on the importance of technology in the classroom: “[The module] expanded my view on the use of technology.” “[I] Now know the important impact technology can have on both learner and teacher.” “This online module opened my eyes to the importance of computers in the classroom.”
Conclusion

The findings from this study indicate that online modules incorporating technology into the pre-service teacher education curriculum can be valuable tools. Students in pre-service teacher education courses reported that the modules promote the use of technology in their field experiences and expand their knowledge of ways to effectively integrate technology into the curriculum. Through the experience the students were challenged to think about how technology can help their students learn in the classroom. A student described it this way, "One crucial aspect I learned...was that it is so important not to use technology separate from the curriculum, but rather find any way possible to infuse it within the curriculum to enhance learning. I realized that students would be able to understand concepts on a higher level when technology is used in the classroom." Several students in speech and language pathology were especially positive about the online module experience: "I never realized how blind I was when it came to integrating technology into a speech and language therapy session or clinic." "At first I was unable to make a connection between technology and speech therapy, but with more information later on, a light bulb went on and I finally pieced together what I was missing."

On the use of standards one student commented: "Technology can be incorporated in the existing curriculum in almost any subject. Spreadsheets could be incorporated into a math lesson or the students could use an Internet scavenger hunt to learn more about something they are studying in social studies. By incorporating technology into the existing curriculum we can meet both the content standards and the technology standards at once. The key is to begin with the standard and learning objective you want students to achieve and then incorporate technology effectively."

While the use of the online technology modules has been positive overall for the students, faculty will need to further evaluate and improve content in the Spring 2002 semester. As part of the collaborative project, all nine modules will be shared among the institutions to be evaluated and revised for use in the teacher education curriculum at each campus. The students' responses to the online modules indicate it will be well worth the effort.

A 2001 Fund for the Improvement of Education (FIE) Cooperative Faculty Project grant from the Community of Agile Partners in Education (CAPE) funded the development and implementation of the modules.
PT3 (Past, Present, and Potential): Sustaining Existing Technology Integration Efforts While Anticipating the Future

Rick Voithofer, Ohio State University, US
Suzanne Damarin, Ohio State University, US
Donna Weatherholtz, Ohio State University, US
Jennifer Strickland, Ohio State University, US

This proposed panel will offer a cross section of experiences and lessons from the implementation of a Preparing Tomorrow's Teachers to Use Technology (PT3) award in an urban setting at a large Midwestern university. Following a one year capacity building grant, this PT3 grant is currently in the second year of its three year duration. The participants in the panel will include one of the grant's principal investigators, the grant project manager, a faculty member involved in both teaching pre-service teachers technology skills and training teacher education faculty in technology integration, and a graduate assistant who is helping elementary and middle school teacher education faculty and students with technology infusion. The panel participants will address the following topic(s):

1. Project Manager - Overview of the grant including a history of its implementation
2. Faculty member - Pre-service teacher technology course and faculty technology integration training
3. Graduate Assistant - Elementary and middle school teacher education
4. Grant PI - Sustaining Change in Changing Times

A more in-depth description of each panelist's presentation follows:

Presenter 1 - Project Manager (Grant Overview)

This presentation will offer an overview of the current grant structure and its history. The Technology Enhanced Teaching and Learning (TETL) Implementation Grant, awarded by the U.S. Department of Education's Preparing Tomorrow's Teachers to Use Technology (PT3) Program, focuses on increasing the technological knowledge and skills of students in teacher education programs to ensure that every graduate will be able to use technology effectively in the classroom. The emphasis on systemic change and improvement in the College of Education's teacher education programs' curriculum makes use of technology to improve teaching practices and student learning opportunities.

The goal of the Technology Enhanced Teaching and Learning Implementation Grant is:

1. to integrate technology thoroughly and effectively into pre-service teacher education programs
2. to decrease the "digital differences" in an urban school district
3. to build upon the best features of existing teacher education programs
4. to involve K-12 teachers in all phases of the project
5. to assure sustainability of the resulting revised programs and practices
6. to prepare faculty and students to meet the national accreditation technology standards.

The project includes professional development in the uses of technology in the classroom. The professional development and support component targets mentor teachers, clinical educators, pre-service teachers and faculty to increase their knowledge and abilities to effectively incorporate technology into field experiences, school classrooms and pre-service courses. Professional development efforts focus on 1. providing a variety of learning activities including hands-on engagement with classroom technologies; 2. on-going support to promote participants' application of what they learn to their own courses and classrooms; and 3. reflecting on the professional development activities.

The local urban school district and the district education association join the College of Education in this grant as partners in pre-service courses, field experiences and technologically-rich school classrooms. In this partnership, technology issues, such as equity, diversity, and the digital divide in urban schools are addressed.
**Presenter 2 – Faculty member (Pre-service teacher technology education / Faculty technology integration training)**

This presentation will discuss PT3 supported work in a required technology education class for pre-service teachers and faculty technology integration training.

"Media and Technology in Education" is the only required technology course for pre-service teachers in the teacher education program at this university. The course provides students with basic technology skills in web development, Microsoft PowerPoint, and Microsoft Excel while teaching them how to evaluate technology resources (i.e. web sites and educational software), use electronic communication including discussion boards and create lesson plans that incorporate media and technology in teaching high order thinking skills. By the end of the course students leave with a complete web-based teaching portfolio. The course teaches students a constructivist approach in which technology is treated as only one aspect of the classroom ecology. Changes in the course over the past two years and plans for course evolution will be central to this discussion.

In addition to describing this course, the presenter will explain teacher education faculty technology training that is being supported by the grant. This training includes workshops on web development, PowerPoint, Excel, video production, computer graphics, WebCT, and computer troubleshooting. In addition to these workshops, faculty receive individualized training from educational technology faculty and graduate assistants on their office computer. Both workshops and individualized training include technical instruction and suggestions for technology integration that moves beyond using technology as merely an add-on to their courses.

**Presenter 3 – Graduate Assistant (Elementary and Secondary Education)**

The presentation will describe PT3 supported work in technology integration in elementary and middle school teacher education. The elementary and middle childhood cohorts consist of ten faculty members, sixty Master of Education students, five graduate assistants, and fifty public school teachers (i.e., cooperating educators). Their community of learners (COL) holds as its mission the preparation of professionals who are broadly concerned with multidisciplinary approaches to education, and bringing to bear such approaches on problems of teaching and learning for diverse populations of students. This program area is centrally defined by a continuing examination of issues related to integration. Watchwords for the program include "learner-centered" and developmental approaches, holistic teaching, and social construction of classroom culture, inquiry, and informal and experience-based approaches to curriculum.

With the onset of the College’s PT3 grant the elementary and middle school cohorts have continually examined and engaged in discovering how technology can become integrated into their pedagogies thereby infusing their program with significant technology experiences. This area has engaged in group and individual workshops, offered student computer labs along with a weekly discussion group surrounding technology in the classroom for the students. Additionally, they’ve offered workshops and conferences for the cooperating educators in the public schools as well as weekly discussion groups surrounding technology and education.

This presentation will describe a variety of projects underway that explore various technologies and how these technologies can improve and enhance current pedagogies. Currently a number of the elementary and middle school cohort, cooperating educators, and all of their graduate students have and maintain websites for electronic portfolios, course support, classroom display, and school information. A group of cooperating educators and a faculty member are exploring ways to use their websites as a means to engage in deeper thinking about their practice. Another group of cooperating educators with a faculty member are exploring the use of wireless technology using HandSpring Visors to find ways in which ubiquitous computing can facilitate thinking and learning. Another group is exploring video and how this can improve individual practice.

**Presenter 4 – Grant PI (Sustaining Change in Changing Times)**

With a year of capacity building and nearly two years of PT3 implementation, the TETL projects have effected considerable change, heightening faculty knowledge and use of technology, increasing pre-service teacher experience using technology instructionally, and generally making technology an integral part of the meaning of teacher education at this University. Are the changes strong enough to flourish in times of fiscal restraint? Or, will these changes wither and die in the institutional storms of budget restructuring, economic recession, new forms of faculty and program accountability, and other factors impacting teacher education?

This presentation summarizes, first, the ways in which the we sought to assure sustainability of change in the design of the TETL projects, and secondly, the nature of the institutional and state-mandated threats to
sustainability on the immediate horizon. The dangers to sustainability and potential means of assuring continuity are examined in detail and various ways we are addressing them are described. The paper then argues that due to the way the TETL project is structured, any external funding for technology will have greater change value in times of fiscal crisis than in "good times." As we continue in a deepening recession, any new monies ear-marked for integration of technology into pre-service teacher education programs will constitute a larger percentage of the total funds available for state or institutionally mandated curriculum revision. The result will be a more thorough integration of technology into all other changes, thus increasing the probability of sustaining PT3 induced changes.
Teaming with Technology: Faculty Design Teams for Technology Integration in Teacher Education

Greg Waddoups
Rodney Earle

Brigham Young University

Background/Introduction

Connecting curriculum and technology is a goal of the McKay School of Education teacher preparation program. As part of the federal Preparing Tomorrow’s Teachers to Use Technology (PT3), the McKay School of Education is supporting graduate and undergraduate students, technology specialists, public school teachers, and university faculty in a collaborative effort to create technology-enhanced curricula. The key feature of these efforts is the development of faculty design teams which are organized and supported to create technology-enhanced and problem-based curriculum. Successful support of these faculty design teams requires providing training for individuals concerning theories of integration, instruction on how to use a particular technology, as well as support for the team to develop a common purpose.

From our analysis of the initial activities of the PT3 support staff and the faculty design teams, we have discovered basic principles that have led to successful personal and institutional change. First, early efforts must be made to understand the needs of key stakeholders involved in the teacher preparation program. Meeting the needs of key stakeholders and building buy in from them is crucial for the early success of the implementation of the BYU PT3 grant activities. Second, a core team, led by faculty must be organized and function to initiate the institutional change activities. It is crucial
that these change efforts be seen as organic and originating from the faculty. Indeed, faculty members occupy a unique place as mediators between administrators, students, and district support staff and as such are important change agents. Third, faculty design teams should be organized according to naturally occurring alliances in the Teacher Education program. This requires understanding these alliances and using them to bolster reform initiative. Fourth, flexible support structures including access to instructional technologies and training must be constructed to support the various needs and interests of teacher education faculty and design team members. A “one size fits all” approach to reform will not be successful in the context of Teacher Education programs. Fifth, for faculty design teams to be successfully they must be committed to the idea of technology and system reform. Sixth, it is important to foster collaboration between and among faculty design teams. It is only through this collaboration that systemic reform can take hold and lead to institutional change (Fullan and Stielgelbauer, 1991).

In this presentation, we provide detailed case studies highlighting the ways in which these principles are realized in the formation, development, and support of faculty design teams. In addition, these case studies demonstrate the ways in which the “faculty design team model” facilitates systemic reform within the BYU College of Education and how these reforms reach affiliated schools and districts. In this way, change is seen as multiply embedded in a system of relationships, rather than the possession of an individual or an institution. Case study research has a long history as a qualitative research method for capturing the complexity of systemic reform and institutional change (Fullan, 1996; Merriam, 1987; Stake, 1988; Yin, 1979). We also hope these two case studies will serve as a model for other Teacher Education programs interested in adopting
the use of faculty design teams for accomplishing technology integration and systemic reform.

Case study one will focus on the efforts of a faculty design team to develop electronic portfolios for pre-service students. This design team consists of tenure track faculty, clinical faculty associates, and technology support staff. This case describes the ways in which support from the PT3 initiative raised awareness among individual design team participants concerning the need for technology integration and facilitated alignment among team members on the utility of electronic portfolios. Case study two focuses on a design team in the area of history and social science curriculum who prior to the PT3 initiative did not have the technical or conceptual understanding to integrate technology into their teacher education courses. This case describes the ways in which support for individual team members and facilitation of team alignment has led to systemic reform within this content area. Through this case study we demonstrate the ways in which changes in faculty uses of technology have led to changes in the technology use of pre-service teachers.

We conclude this presentation by discussing the extent to which the six principles of successful technology integration and systemic reform are realized within the context of these two case studies.
Knowledge Innovation for Technology in Education (KITE)

Feng-Kwei Wang, Chi-Ren Shyu, David Jonassen
School of Information Science & Learning Technologies
University of Missouri – Columbia
wangfeng@missouri.edu, shyuc@missouri.edu, jonassen@missouri.edu

Abstract. The Knowledge Innovation for Technology in Education (KITE) project is funded by US Department of Education to build a knowledge repository with case-based reasoning capabilities to capture and disseminate the best practices and lessons learned of technology integration experiences by teachers and teacher educators. The project's overarching mission is to build a K-16 community of practice through this knowledge repository that enables learning through sharing, communal understanding through storytelling, continuous exchange and creation of new knowledge, and collective problem solving.

“Today’s students live in a global, knowledge-based age, and they deserve teachers whose practice embraces the best that technology can bring to learning” (Lemke, 1999, p.i of ISTE study).

As the face of American classrooms continues to change with rapidly increasing technological changes, greater diversity, and a projected need for 2.2 million new teachers in the next decade, teacher training institutions are faced with the challenge of graduating new teachers who will be adept at keeping pace with the technology explosion in the classroom. A 1999 study entitled Will New Teachers be Prepared to Teach in a Digital Age? —commissioned by the Milken Exchange on Education Technology and conducted by the International Society for Technology in Education (ISTE)—documented that while teacher preparation programs are well-intentioned, they are not providing the kind of training and exposure teachers need to be proficient in integrating technology in their teaching.

Issues

To increase the level of technology integration, the ISTE study strongly recommends that “in order to provide models for change, researchers, professionals societies, and education agencies should — on an ongoing basis — identify, study, and disseminate examples of effective technology integration ...” The advocacy for sharing examples illuminates four common issues that have hindered teacher education from overcoming problems in technology integration. First, it is important to realize that many problems in technology integration are universal for teacher educators and inservice teachers. However, because of lack of collaboration, many educators and teachers are powerless or inadequate to tackle these problems individually. Second, it is very likely that some educators and teachers have successful experiences in integrating technology. However, their successes often occur in isolation and are not documented and thus are not disseminated to others in any systematic manner. As a result, these hidden experiences cannot be shared across the entire teacher enterprise. Third, for some novice teachers, they need to learn. Probably, the best way to learn is through observing other experienced teachers. This experience transfer helps a novice teacher learn better, faster, and more effectively from successes and mistakes of other teachers. Fourth, experienced teachers are often entrenched with their practices and are not receptive to newer and better strategy, technology, process, and practice. In today’s environment of rapid changes and technological discontinuity, even sharable knowledge and expertise often become obsolete quickly. Without constant reflection, successful experiences can easily become “stale” or even the root of failure.

Project Design
The lack of collaboration and sharing experiences between educators and teachers result in tremendous waste of resources on duplicate efforts and loss of valuable knowledge and expertise. In response to these issues, the Knowledge Innovation for Technology in Education (KITE) project funded by the Preparing Tomorrow’s Teachers to Use Technology (PT3) program builds upon the foundation set in place by the Technology Integration Process Knowledge Repository Project (TIP-KR) and the TechConnect Project, both of which captured a collection of stories describing teacher education faculty's and inservice teachers' experiences in integrating technology.

The project involves a consortium of 8 teacher education programs collaborating to create and diffuse technology integration knowledge. As the lead institution of this project, The University of Missouri-Columbia (MU) will enhance and continue to support the ongoing development of the knowledge repository, with improvements in depth of analysis, breadth of content, and functionality to strengthen its effectiveness. The knowledge repository applies case-based reasoning, a contemporary theory of human memory and intellect, to describe and index stories and cases as they are added to the repository. It documents and organizes experiences in technology integration as cases. These cases will be categorized and indexed so they can be retrieved easily by all community members. In this way, technology integration problems are solved by finding similar previous experiences captured in the knowledge repository and applying the lessons to the new experience.

MU will provide global access to the repository through the Web, provide training to partner institutions, introduce partners to effective technology integration tools, provide follow-up support throughout the project period, and engage in ongoing project evaluation. Each partner institution will identify 1) a Knowledge Scout who will be responsible for collecting, reporting, and updating technology integration cases from his/her institution in the knowledge repository; and 2) a Technology Integration Specialist who will serve as the local change agent and project coordinator.

Project Goals

Adopting a knowledge repository approach and case-based reasoning, the Knowledge Development Consortium seeks to expand and enhance its initial efforts in the TIP-KR and TechConnect through a collaborative partnership for innovation and change involving selected teacher education programs and K-12 schools. The project's overarching mission is to build a K-16 community of practice through a knowledge repository of technology integration that enables learning through sharing, communal understanding through storytelling, continuous exchange and creation of new knowledge, and collective problem solving. In the context of the technology integration community, its significance is manifested by the following project goals:

- Create a community memory to preserve the intellectual asset of the community of practice;
- Engender a process for continuous knowledge creation;
- Build professional excellence through knowledge sharing;
- Form a virtual learning community beyond time and space boundaries;
- Establish a conducive environment to effective knowledge creation and diffusion; and
- Assess effectiveness of new knowledge produced from this project.

Abstract: Six learning circles were formed to pilot study the technology integration and collaborative learning initiative of Southwest Mississippi Center for Educational Technology (SMCET), a PT3 Implementation Grant project. The learning circles consist of pre-service teachers, university faculty at Alcorn State University; and in-service teachers and K-12 students from four school districts. University professors and their partner teachers jointly develop activities based on K-12 curriculum. University students (pre-service teachers) assist K-12 students to complete the activities using variety of technologies. The goal was to find out what kinds of human-technology interaction promote learning among different level of learners in the learning circles, and how that might contribute to an understanding of how best to use technology in the classroom. As a result of this project, faculty and teachers are rethinking their teaching strategies and exploring a model of teacher education that involve stronger university-K-12 collaboration and technology use in the classroom.

Introduction

Many of today’s educational technology initiatives are focusing on integration, as it is becoming evident that training in basic technology skills alone has not been enough to get teachers to automatically plan for the use of technology in the classroom. According to Robert Tinker, President of the Concord Consortium, “In spite of the decades that computers have been in schools, we have yet to see the revolution they could cause in learning.” Teachers need training on implementation and integration that is based on tested models. Several models of technology integration are being developed to help educators make the transition from the traditional lecture method to creating technology-rich learning environments for their students. The Tri-Rivers Educational Computer Association (TRECA)’s Summer Academy (TSA) was developed to help teachers learn how to integrate technology by experiencing integration both as ‘students’ and teachers. Through a two-week professional development, teachers experienced learning and teaching with technology tools such as online discussion forum, taking fieldtrips and recording events with digital cameras, and producing multimedia projects in several subject areas (Crohen, 2001). Another model of technology integration is the Virtual High School, which delivers online instructions to 8,000 students in 150 high schools across the United States and in 10 foreign countries (Allen, 2001).

Learning Circles is a model of learning with technology developed by Margaret Riel and colleagues, and sponsored by AT&T for several years. It has been used successfully in several settings to explore learning issues, and evidence abounds that it promotes student achievement. According to Riel (1990), students in a Learning Circle use better grammar and syntax when they collaboratively author newspapers and booklets with peers from around the world. Learning Circles are usually organized around specific projects, which may involve online activities. "The best Learning Circles have clear work activities specified that require planning, execution, and reporting, followed by comparison and collaboration across sites" (Jonassen, Peck, & Wilson, 1999). Jonassen (2000) contends that collaboration in Learning Circles is easier among known rather than imaginary audience.

The learning circle concept is based on the constructivist approach, where technology is seen as a tool with which learners think and learn. The constructivist views learners as constructing their own reality by interpreting life experiences. These interpretations assume meaning through social negotiation that takes place through active collaboration (Jonassen, Peck, & Wilson, 1999). The role of the teacher in this collaboration is to create environments in which learners can actively construct their own knowledge rather than recapitulating the teacher’s interpretations of the world. This environment also assume that the teacher becomes a learner in some instances, especially since technology is a relatively new tool to the teacher while it is a tool that the student is growing up with. The Learning Circles in the current study were adapted to fit local conditions, but assumes many of the elements of the ones created and tested by Riel and colleagues.
The Learning Circles

Six Learning Circles were formed in Fall of 2001 to pilot study the technology integration model of the Southwest Mississippi Center for Educational Technology (SMCET), a project of the “Preparing Tomorrow’s Teachers to Use Technology”, sponsored by the U.S. Department of Education. Each Learning Circle was awarded a mini-grant of $2000, which was matched by the four partner school districts in equipment and other resources, such as teachers' time and lab hours. Establishing the learning circles served a two-fold purpose of enabling us to explore how technology can enhance learning in the classroom at both university and K-12 levels, and to provide environments in which pre-service teachers learn to become technology-using teachers. The goal of the Learning Circles is to promote effective learning and students' achievement through technology integration into the classrooms of the participants. Among the expected outcomes of the Circles' activities are that all levels of learners in the circles develop: a) technology literacy skills, b) reading skills, c) higher-order thinking skills, c) collaboration skills, and d) research skills. We believe that these skills are the key to school achievement. Each Learning Circle designed curriculum-based activities to be completed by student participants within the context of the regular classroom, supplemented by out-of-class experiences. The following table contains the composition and activities of the Learning Circles:
<table>
<thead>
<tr>
<th>Learning Circle #1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project Name: Mainstream Integrated Technology (MIT).</td>
</tr>
<tr>
<td>Participants Description: One 4th grade class and teacher at Wilkinson County Elementary School, Woodville, MS; One Professor of History and a pre-service teacher majoring in History Education at Alcorn State University</td>
</tr>
<tr>
<td>Project Description: Immerse students in technology-rich, project-based learning environment. As students rotate through work centers to complete project tasks, they also acquire skills required in the curriculum framework. The university student serves as a facilitator for the 4th graders, developing project ideas on Social Studies topics.</td>
</tr>
<tr>
<td>Role of Technology: Word processing to type reports of class activities; Taking virtual field trips; Researching various topics on the Internet; Creating class website and electronic portfolios of students' works; Creating digital images with scanners and digital cameras.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Learning Circle #2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project Name: Enhancing Mathematics and Language Arts Learning with Technology in a Special Education Classroom.</td>
</tr>
<tr>
<td>Participants Description: One High School Science teacher and a class of 10th-12th grade students in Human Anatomy, Physiology, and Botany courses at Natchez High School, Natchez, MS; One Biology professor and two pre-service teachers majoring in Biology Education at Alcorn State University.</td>
</tr>
<tr>
<td>Project Description: Main focus is technology integration into the instruction of three science courses as a way to motivate students to learn the subjects. The university professor and the science teacher jointly explored and selected materials including software, equipment, and Internet sources. This is supplemented with weekly presentations and experiments led by the University professor. The high school students are assigned projects and reports in which pre-service teachers serve as facilitators and peer-collaborators.</td>
</tr>
<tr>
<td>Role of Technology: Researching science topics on the Internet; Developing presentations in PowerPoint; Using standalone software, such as A.D.A.M. to explore science topics; Laboratory equipment for experiments; Large screen TV with AverKey attached to a computer for whole class instruction and presentations.</td>

Learning Circle #6

Project Name: Integrating Technology in a Science Classroom.

Participants Description: One Science teacher and a class of high school students in Botany and Environmental Science courses at Natchez High School, Natchez, MS; One Biology professor, and Pre-service teachers majoring in Biology Education at Alcorn State University.

Project Description: This program focuses on using technology to facilitate learning of Botany and Environmental Science to meet the Mississippi Science Framework. The teacher selects course-related web sites for students to explore, supplemented by presentations and experiments led by the University professor, assisted by the pre-service teachers. Strong collaboration with Learning Circle 3 in several activities.

Role of Technology: Researching course materials from the Internet; Reading Daily Science news from the Internet; Preparing class presentations in PowerPoint; Using large screen TV with AverKey hooked up to a computer for whole class instruction and presentations.

Table 1: Learning Circles Description. See http://smcet.alcorn.edu/LearningCircles for more descriptions.

Monthly Meetings

Collaboration across sites takes the form of exchange of ideas during monthly meetings and participation in weekly online chats in the Circles’ online community. Faculty and teachers share information about the progress in their Learning Circles, teaching issues, problems, and solutions. As illustrated in the extract below, Circle members learn classroom tips from one another:

trena : I think all of this is great! I just have questions about the management of your class in using the technology. How do you arrange for all of your students to have access to the technology?
Bosede : I guess Belinda can answer that better than I
Belinda : Trena my students are grouped in three's and we rotate every twenty minutes. I have three computers, so when they get to the computer, they have a task to do as a group or an individual. It depends on what I want them to do.
Belinda : One time, they had to do Sequential Events. "How to Make a Ham and Cheese Sandwich." We had practiced earlier in the week on paper and through discussion the words they should use and what I will be looking for. Well of course they loved it.

Reflection is emphasized during the meetings and in online chats. Faculty and teachers are encouraged to ask questions such as what does this new teaching approach mean to my students and me? How am I coping with the intellectual disequilibria that the approach represents? What does my role as a facilitator of learning entail? What am I learning from this experience? The afternoon session of the monthly meeting is devoted to training on specific technologies being used in the Learning Circle classrooms.

Conclusions

It is too early in the pilot year to begin to look for specific impacts of the Learning Circles. However, some interesting patterns are emerging that may be of interest to educators and technology advocates. One such pattern is that university and K-12 educators in the Circles are beginning to realize the advantage of pre-service teachers making early connection between their teacher education curricula and real life classroom events. The Learning Circle provides opportunity for more intensive, integrated and longer practicum experiences for students that have not been possible before.

"... I had no idea that it was going to have such an impact on the students as it did, both groups of students really – the college students and the public school students. Once they got into the classroom, once we've finally decided on how many hours they would do and what days they would go, they bonded with the students there. As they bonded, they really got more work done than anticipated. So they did work with the students by e-mailing them, not only that, they developed PowerPoint presentations, and they presented their PowerPoint [presentations]. And students, both the university and A.W. Watson students were very excited. It was really a learning situation for the students. It was really a learning situation for me because I found that students were very enthusiastic about going back to the public school and working with students there..." (Doris, University faculty, Learning Circle 5, Interview Fall 2001)
Rethinking teaching. Teachers and faculty in the learning circles are rethinking their teaching strategies. The learning circle approach, with the integration of technology, forced participants to begin to look critically at what they do in the classroom, to face issues of own and students' learning. They are realizing that traditional teaching strategies seem to underestimate the intellectual abilities of children, and their natural capacity for motivation through exploration. Even though developing a book report in PowerPoint may be regarded as low-end use of technology, it represents a major shift in the way these students used to learn. Having to organize information in presentation format, selecting appropriate slides and illustrative graphics enable deep processing of information that may not have occurred in the traditional book report. Also, by becoming learners themselves, teachers and faculty members are more sensitive to learning concerns of their students. In addition, the faculty and teachers are learning to balance the need to hold on to what is familiar and trying something new, something that is not safe, perhaps, but may be more rewarding. Some of the educators are able to make this shift easily while some are making it gradually. Student participants seem to take the changes in stride. University students (pre-service teachers) found that they enjoyed the time they spent in the school with the children (K-12 students). It further confirmed the reasons they wanted to be teachers.

Action Research
Action research was built into this project to enable us answer the question of what makes educational technology effective in the six situations under study. We wanted to find out the skills and knowledge that students gain by using technology as a tool of learning; how using technology changes organization of learning environment, and the outcomes that can reasonably be expected at different stages and forms of technology implementation. Some of the baseline data we have collected include, 1) students scores on the Terra Nova tests for current and previous years, students scores on teacher made pre-test based on the Terra Nova format, and scores on first 9-week examination. These will be analyzed to establish baseline information about students' achievement level at the beginning of the project. During the year, other data will be collected for formative and summative evaluation purposes. Quantitative data will be supplemented with qualitative information from students, teachers, and faculty. These include journal and reflection notes, sample products, sample e-mail conversations, online chat and discussion transcripts, interviews, and analysis of videotaped classroom events.

Abstract: This paper discusses issues learned while evaluating 12 PT3 projects in various stages of the grant's funding period. Although many issues can be discussed we have chosen to focus on issues related to gathering data from faculty and the efficacy of self-reported technology skills. As external evaluators, we bring a unique perspective on PT3 and will share our thoughts on how the evaluative data assist project directors with program development.

Overview

Rockman Et Al is an independent research and consulting firm, specializing in the study of technology's role and impact on education. We are currently serving as external evaluators of 12 Preparing Tomorrow's Teachers to Use Technology (PT3) projects, funded by the U.S. Department of Education to support the efforts of schools and colleges of education (SCOE) to integrate the use of technology into pre-service teacher education. The projects we are evaluating include Implementation and Catalyst grantees in various stages of the funding cycle; they represent large and mid-size public and private SCOEs in the West, Northeast, Mid Atlantic, and Southern regions of the country. While each project brings its own perspective to preparing its pre-service teachers and transforming teacher education, we have found that there are also common themes related to the implementation and evaluation of the PT3 projects. It is with this lens that we share our unique perspective as external evaluators and discuss our lessons learned.

In reviewing the data we found a number of common themes related to evaluating PT3 projects, however, in this paper we focus on some of the challenges we faced as external evaluators, including: developing instruments that measure technology skill, using self-reported data to inform project development, identifying barriers to project implementation, and helping project directors revisit their project timelines.

Issues and Challenges

Many of the PT3 projects we evaluate are seeking to transform teacher education programs by educating faculty about how to model the meaningful integration of technology into pre-service teacher education. Typically this transformation begins by supporting faculty in the use of technology in their own courses. To provide project directors with meaningful data we developed a series of pre- and post-survey questions that require faculty to rate their technology skills on a 5-point scale, (ranging from 1 = “cannot perform” to 5 = “I can teach others”). These skills questions focus on basic computer operations, use of telecommunications, use of productivity tools (word processing, spreadsheets, data bases), use of the Internet, and developing Web pages and multimedia presentations. The challenge in developing this instrument was using terminology that was understandable for all faculty whether they were technology users or not. Our assessment of these skills was focused on basic operations and not the integration of these skills. The purpose was to set the stage for project directors about what skills faculty participants were bringing to the project and to help guide the development of faculty training workshops.

We have found that faculty participants are comfortable with basic computer operations and using the computer for basic productivity such as word processing, sending and receiving email and searching the Internet.
Faculty, on average, did not consider themselves to be skilled in desktop publishing, creating Web pages and multimedia presentations, and troubleshooting.

While we rely heavily on faculty members’ self-reported data in our reporting, we acknowledge that there are limitations to doing so. We have found that faculty tend to overrate their ability to use various technology applications. They tend to rate themselves higher when they are not proficient users of technology because they are not aware of what they do not know. We have found that faculty self-ratings on the post-survey remain the same or even decrease. This we feel is attributed to faculty, through participation in the program, gaining a true understanding of the various technologies. Whereas, on the pre-survey they may have overrated their skills due to lack of knowledge, the post-survey appears to be a truer measure of their technology skills. This poses a challenge for evaluators because in reporting the data it appears that the project is not having a meaningful impact on project participants.

In addition to the aforementioned difficulties in using data gathered from the faculty members, we learned that certain unanticipated issues developed for the project directors. Project directors are required to establish project goals and objectives and set timelines for meeting them. Given that many of the project directors are the technology innovators on their campuses, they believed at the outset that they could have an impact on the teacher education faculty at a rate that would meet the timelines.

In looking at how our PT3 clients began implementing their projects, we found that the majority of directors did not anticipate the time that would be needed to train the faculty in basic technology skills. This is consistent with Wisniewski’s (2000) finding that three years is often insufficient to truly impact the acquisition of skills and knowledge that lead to a change on the part of individual faculty members. Project directors were surprised that while faculty support was embedded into the project (e.g. technology training, tutorials, and technical support) that they still faced faculty resistance to full cooperation and participation. Our evaluation activities identified that a number of the tenured faculty members lacked sufficient skills to become early adopters of technology, thus limiting their ability to understand how to integrate it into their courses. This finding led directors to refocus their initial efforts from integration of technology into pre-service course work to technology skill development.

The most difficult barrier to overcome was that of time. A challenge for evaluators was to help the directors redesign their original timeline and goals in order to accommodate the difficulties they faced. As evaluators we helped the directors review what they first hoped to accomplish and how they could refocus their efforts to accomplish many of their original goals. Our data included feedback on perceived barriers to integrating technology. Using a 4-point scale, with 1 = never a barrier and 4 = often a barrier, responding faculty, on average, rated lack of time (M=3.2) as the greatest barrier to technology integration, with 74% of the faculty indicating that it was sometimes or often a barrier. This was followed by inadequate equipment (M=3.0), the uncertainty of how to infuse technology into teacher education courses (M=2.8), and the lack of personal technology skill and knowledge (M=2.7). With these data we helped the project directors face some of the issues they may have overlooked in writing the grant proposal. For some of the grant projects this required a narrowing of activities, for others it required expanding their original target group to include additional faculty (i.e. adjunct, Arts and Sciences).

Our evaluation goals this year are to show that while technology integration occurred at a slower rate than intended, that realized change and shifts in attitude have begun and will continue. We are in the process of helping to design and support the ways in which these PT3 grants will continue to affect participating faculty in the goal of supporting teacher candidates.

Abstract: PT3 implementation grant funds have been used to restructure a teacher education program to meet the National Educational Technology Standards (NETS). Technology-enhanced unit plans written by preservice teachers were coded to see which NETS were met. Technology as Productivity tool was met most often followed by Technology as Research Tool. The results of this study seem to indicate that our preservice teachers are using these higher level thinking skills in the unit plans they write. It also indicates that enhancing units planning with technology encourages these types of activities in the units developed by our students.

Introduction

Preparing Tomorrows Teachers to Use Technology (PT3) implementation grant funds have been used to restructure a teacher education program to meet the National Educational Technology Standards (NETS) defined by the International Society for Technology in Education (ISTE). Grant related activities include (1) the creation of curriculum design teams to develop technology-enriched curriculum for both the teacher education program and K-12 schools and the mentoring of BYU faculty and BYU students in the use of the technology-enriched curriculum; (2) collaboration with arts and science departments, five public school districts and the State Office of Education in the development of K-12 technology-enhanced curriculum, and with the two other PT3 grant recipients in Utah to share resources and efforts; and (3) evaluation of the process and products supported by the PT3 funds. This paper will discuss the products developed by preservice teachers in redefined courses by reviewing which NETS standards they have met.

Theoretical Framework

Researchers, parents, and politicians have called for reform in K-12 education to include the integration of learning technologies (Fullan and Stielgelbauer 1991; Means, 1994). One approach of reform in teacher education programs includes providing in-service training to practicing teachers designed to help them change their teaching practice (Fullan and Stielgelbauer, 1991). A second approach includes reforming
preservice education to include the use of learning technologies in the context of problem based teaching and learning. The PT3 project in this study focused on both approaches. Teacher education programs often perpetuate the isolation of technology from curriculum and instruction. In many instances, prospective teachers take a computer literacy class separate from content methods classes and rarely engage in real collaboration on how school teachers could integrate technology into authentic learning experiences. Likewise, many public school classrooms do not link instruction to real-life situations or technology integration so the practica experiences of preservice teachers are limited (Pappillion & Cellitti, 1996)

The PT3 funded re-structuring efforts outlined here are designed to alleviate these weaknesses in traditional teacher preparation through simultaneous re-design of teacher preparation and K-12 curricula enriching both with technology integration. Preparing tomorrow’s teachers to integrate technology into their instruction requires university faculty to provide preservice teachers with examples and experiences of learning enhanced with technology. These goals are being achieved through creating curriculum design teams composed of School of Education faculty, content specific methods teachers, cooperating teachers, and instructional design and technology specialists who together will re-design our current teacher preparation curricula with the purpose of integrating technology.

Data Collection

The large research agenda for this PT3 grant is to study the systemic change of a preservice program. This paper will address a smaller agenda that of evaluating technology-enhanced unit plans developed by preservice teachers in three teacher education classes. Which NETS standards do the unit plans meet? Do they meet more than one standard? If so, which standard is the most commonly uses with other standards? How does this evaluation of products help teacher education faculty mentor preservice teachers in the development of technology-enhanced curriculum and instruction?

The three instructors of the courses introduced unit design and discussed enhancing the purpose of the unit plans with technology. They selected direct instruction, inquiry learning, and problem-based learning examples and discussed the different uses of technology in each type of unit. They assigned the preservice teachers to write a technology-enhanced unit plan. Each unit was coded by other students and by faculty members on the evaluation team of the PT3 grant as to the type of instruction used and which NETS standard for students it supports. The NETS standards are: (1) Basic Operations and Concepts, (2) Social, Ethical, and Human Issues, (3) Technology Productivity Tools, (4) Technology Communication Tools, (5) Technology Research Tools, and (6) Technology Problem-Solving and Decision-Making Tools. Results were tabulated for total number of standards met, for which standards correlated to other standards, and for a relationship between standards met and the type of instruction used.

Results

Currently 47 unit plans have been written and coded by 3 students each for a total of 141 evaluations. Students only circled the Standard that they felt was addressed in the unit plan. They did not evaluate whether or not the Standard was essential to the unit plan. Of the 141 evaluation 1% coded a lesson with only one standard being met, 4% marked two standards, 7% marked three standards, 51% marked four standards, 35% marked five, and 2% marked all six standards. “Basic operations and concepts” (marked 124 times) and “productivity” (122) were the most common standards met followed by “research” (112), “problem solving and decision making” (88), “communication” (78) and “social, ethical and human issues” (66).

The researchers were surprised to see so many evaluations marked with 4 and 5 standards being met. They wondered if the students understood what it meant to mark a standard so they asked them why they had marked so many. The students said that if the students were using technology in any way they marked basic operations, even if the instruction was not in computer operations. They also commented that they marked technology productivity tool when the students used any software package to produce something, a
report, statistically results, a PowerPoint presentation, etc. Again the instruction in the lesson was not about using the tools, but the assignments in the unit plan were.

Three faculty members have coded 52 unit plans using the following rubric:

<table>
<thead>
<tr>
<th>Basic Operations and Concepts</th>
<th>Not present in the unit plan</th>
<th>Present but not essential to the unit plan</th>
<th>Present and improves the unit plan</th>

solving problems and making informed decisions.
- Students employ technology in the development of strategies for solving problems in the real world.

Table 1: Rubric for Coding Unit Plans for NETS Met

Standard 1 (Basic Operations and Concepts) and Standard 2 (Social, Ethical and Human Issues) were coded as a zero for every unit plan by every evaluator. The unit plans were not about learning to use technology or the ethical issues of technology. Figure 1 summarizes the coded scores of the other 4 standards.

![Figure 1: NETS Coding Frequencies](image)

The "Technology as Productivity Tool" standard had the fewest "0" ratings and the highest "2" ratings. "Technology as Research Tool" standard had the highest "3" ratings. "Technology as Problem-solving and Decision-making tool" was very close in "3" ratings. "Technology as Communication Tool" had the most "0" ratings and was low in the other three ratings as well. Productivity and research coded together 38 times followed in frequency by productivity and problem-solving (25), and research and problem-solving (25). Productivity and communication were coded together 22 times. Communication and research matched 17 times. Communication and problem-solving matched 16 times. One more interesting finding was that when research and problem-solving were coded "3" then productivity and communication were almost always coded as a "2" or more.

**Summary**

The researchers were not surprised to see "Technology Productivity Tools" as the most common standard met. Most preservice teachers had assignments in their unit plans for students to create reports using presentation software. The researchers were surprised and pleased to see "Technology as Research Tool" as the next most frequent standard met. Many of the unit plans required students to gather data on a website and then analyze it in some way. The teacher was doing less lecturing and was acting more as a guide to the students as they researched topics in groups. This seems to indicate that technology-enhanced unit plans include inquiry learning that requires problem solving and communication. Research, problem-solving and decision-making require higher-level thinking skills of students. Our teacher education program encourages this type of lesson and unit planning. The results of this study seem to indicate that
our preservice teachers are using these higher level thinking skills in the unit plans they write. It also indicates that enhancing units planning with technology encourages these types of activities in the units developed by our students.

The researchers will continue to review the units that were coded to meet research, problem solving and communication to see if they are based in inquiry instruction and problems-based learning. They will also review those units that had the fewest standards met to see if they are based in direct instruction. Finally the researchers will review those units that met the "social, ethical, and human issues" standard to see how this standard can be brought to other units.

Preservice Teachers, Technology, and Information Literacy in the English Literature Classroom

Karin E. Westman

Kansas State University
United States
westmank@ksu.edu
naomiw@ksu.edu

Abstract: This paper reports the results of a survey we conducted to assess our preservice teachers' use of technology in the English classroom. These survey results, in conjunction with our experience teaching preservice teachers, suggest that preservice teachers are frequently uncritical readers of the web pages that a search engine or directory provides, and that they need assistance in linking their current technological skills to the study of literature and language -- two skills necessary for meeting the new performance standards for technology in the K-12 language arts classroom. We then report the results of our pilot program designed to foster information literacy in our preservice teachers. By incorporating a writing-based technology curriculum composed of online discussion, online research, and web projects, we found that the literature classroom offers an excellent opportunity for preservice teachers to develop information literacy and to see instructors model the teaching of literature through technology.

As many scholars and teachers have noted in journals such as Contemporary Issues in Teacher Education, faculty who teach preservice teachers have an obligation to incorporate technology into course curriculum (Pope & Golub, 2000; Willis, 2001; Willis & Raines, 2001). This obligation, however, must extend beyond the borders of the Education classroom. As two professors of English literature who regularly incorporate technology into our English courses, we see a rich opportunity to foster the critical reading and writing skills that preservice teachers need in order to meet the new national emphasis on technology in the K-12 classroom. We also see the opportunity to fulfill many educators' calls to model strategies for incorporating technology into the study and teaching of literature (Pope & Golub, 2000; Willis & Raines, 2001; Carroll & Bowman, 2000; Jonassen, 2000). Our paper argues for the advantages of a writing-based technology curriculum for preservice teachers, especially for those in Language Arts. We seek to establish what David Jonassen (2000) has called "intellectual partnerships" between students and their computers (p. 4); while Jonassen posits this theory for students in the K-12 classroom, we see a need for such pedagogy in the college preservice classroom as well. Today, we will first provide the results of a survey assessing our Education majors' use of technology. Second, we will introduce and summarize the results of a technology-intensive pilot course designed to help preservice teachers meet the performance standards for the K-12 classroom. Only by using "computers as mindtools" (Jonassen, 2000, p. 1) can we help preservice teachers attain the higher level thinking skills they must, in turn, impart to their students.

If, as Cynthia Bowman (2000) points out, "information literacy requires students to conduct searches, evaluate, and create new ideas" (para. 14), we must prepare our preservice teachers to assist their future students with these tasks. Indeed, information literacy is not only recommended for preservice teachers, but increasingly required of them. In the year 2000, National Council of Teachers of English and the International Reading Association mandated that K-12 teachers should be prepared to foster students' technological abilities. Standard 8 of the twelve "Standards for the English Language Arts" reads, "Students use a variety of technological and information resources to gather and synthesize information and to create and communicate knowledge"; other standards implicitly refer to technology as a component ("List of Standards for the English Language Arts," 2000). In our own state of Kansas, the teacher licensure standards now include a new emphasis upon instructional technology, particularly in preparation for language arts. We must be sure, then, that our preservice teachers attain a high level of information literacy as well as a facility with technological resources. A recent survey of 255 Education majors in our English classrooms at Kansas State University reveals, however, that we are falling short of our goal: our preservice teachers show some facility with technology, but they lack information literacy.

The results of our survey indicate that a high percentage of preservice teachers recognize the importance of current technologies both to their success in their college courses (72%) and for their chosen profession (86%). Many also show a high level of competence with current technologies such as word processing, even if knowledge...
of other technologies remains low (only 49% have designed a web page or PowerPoint presentation, for instance). In our survey, 84% of Education majors reported using the internet primarily to access their e-mail; only 7% cited research as the primary reason for using the web -- the same percentage who reported using the web for sports, entertainment, or business information. These use patterns suggest that preservice teachers may not have much experience critically evaluating the materials they find. This conclusion is supported by the fact that 74% of the Education majors surveyed reported using an internet search engine such as Yahoo, Excite, Google, or Infoseek to research information for their English classes before any other online resource, such as electronic full-text or abstract databases available through the library or a catalog of library print materials. Most preservice teachers are using the internet for research, but are they familiar with its wide range of resources, if they primarily use the web for email?

This high number -- 74% -- therefore attests to our students' ability to access the Internet, but we wonder about our students' ability to evaluate the sources they encounter and to apply their skills for a larger audience. There's no question that the internet is perceived by Education majors to be an important resource for the study of English at the college level: 47% of students surveyed found online resources "helpful" and another 23% found them "very helpful." When queried about the kinds of internet resources they found most useful for their study of English, 32% reported accessing primary texts, 24% retrieving critical essays, 19% researching historical and cultural backgrounds of texts, and 13% using writing style handbooks. While we do not know what students "count" as critical essays -- for example, do our students perceive teacher-resource guides from a publisher to be "critical essays"? -- these figures suggest that we need to make sure our students know how to evaluate a primary text, a critical essay, and other web-based documents, since they are seeking them out. If preservice teachers are not able to evaluate resources now, how will they be able to assist their own students? In addition, the ability to research and evaluate historical and cultural background would be an extremely helpful use of the internet for their future profession; however, as our survey results show, it is by no means our students' primary motive for consulting web resources, garnering only 19% of the responses. Finally, when asked which online resources they would like to know more about, students evenly spread themselves over the four categories: 23% selected primary texts, 25% critical essays, 24% historical and cultural background materials, and 26% writing style manuals. This remarkably balanced breakdown suggests that students are aware of the importance of all four categories but may not feel confident that they know enough about how to find, evaluate, and use these sources.

These survey results, in conjunction with our experience in the English classroom, suggest that our Education majors are frequently uncritical readers and interpreters of the web pages that a search engine or directory provides, and that they need assistance in linking their current technological skills to the study of literature and language -- two skills necessary for meeting the new performance standards for technology in the K-12 language arts classroom. As English teachers, we know that not all editions of primary texts are equal; therefore, we need to alert students to the elements of a primary text that will be most accurate and helpful to their study. We know that critical essays published online are not necessarily as authoritative or as reputable as print essays, while at the same time recognizing that an increasing number of critical essays are indeed being published in this format. In addition to alerting our students to the differences of quality and implied audience among journals, we need to be offering them the same guidance for documents which appear on the World Wide Web. We may know, as David Jonassen, in Jonassen, 2000, p. 188). The Internet and the Web offer a tremendously rich variety of historical and cultural background materials -- a course in Indian and Pakistani literature, for example, can link directly to English-language Indian and Pakistani newspapers for information about contemporary issues in those countries. However, students also need to be able to distinguish the reliable material from the less reliable, the obviously biased from the implicitly biased. In one children's literature class, for example, students offered as background to a study of Pippi Longstocking David Nagel's web page "The Evil of Pippi Longstocking: the Red-haired Harbinger of the Apocalypse" without any awareness of its parodic critical stance. Other students have quoted as scholarship the teacher guides from publishers' websites, showing little awareness of the potential conflicts of interest between the site's commercial and educational goals. Even style manuals may differ in authority and scope.

We are hardly the first to identify these problems: Cynthia Bowman (2000) and Carol Pope and Jeffrey Golub (2000) have raised similar concerns about information literacy in the preservice classroom. However, we believe that the problems we have described are more systemic than those scholars suggest. Even to create a WebQuest for Cynthia Bowman's class, as she describes for us in her essay "Infusing Technology-Based Instructional Frameworks: A Response to Pope and Golub" (2000), requires a degree of higher order thinking and critical evaluation skill than many of our students have demonstrated in our English classrooms. Clearly, there is much to be done in helping our students to use such resources efficiently and reliably, so they can in turn teach
In the time remaining today, we will outline several writing-based strategies designed to foster information literacy in preservice teachers. Our claim for the advantages of a writing-based technology curriculum develops from the results of our survey and the results of a pilot course here at Kansas State University that integrates technology into the teaching of a required literature course for Elementary Education majors, English 355 “Literature for Children.” We initiated this pilot program with one section in June, 2001 and added two sections in Fall 2001; the pilot program continues with one section in Spring 2002 and 2 sections in Fall 2002. Each section caps at 23 students; the class meets in a computer lab classroom designed so that students sit at the computers or at a large seminar table. A ceiling-mounted projector allows the instructor to project images and text on a screen from a computer at the instructor’s podium or from a visual presenter.

The course design emphasizes three components which are easily transferred to the K-12 classroom: computer-mediated writing practices, online research, and web page construction. In designing the course, we wanted to test our hypothesis that these three components foster the critical writing and reading skills necessary for information literacy. We also wanted to see if these interactive skills would demonstrate how to transfer essential technological skills to the teaching of literature. Preliminary results from student evaluations indicate the success of the pilot program. Through observation and hands-on projects, many of our preservice teachers have indeed increased their information literacy and acquire both “academic” knowledge and “tacit” knowledge (Willis, 2000) about integrating technology into the teaching of literature.

First, synchronous and asynchronous online discussions encourage our preservice teachers to be self-reflexive about the act of written communication and the audiences for whom they write. Our instructors asked their students to use real-time collaborative small group discussions during class and to post to a threaded bulletin board discussion outside of class. These two forms of online discussion emphasize features of group exchange which students often take for granted as they use words. Unable to rely on facial expressions, tone of voice, and gestures as they would in face-to-face conversations, students must exercise their linguistic resources and use written cues in order to communicate successfully with their peers and instructor, their intended audience. Our results indicate that synchronous and asynchronous discussion is even more of a “mindtool” than David Jonassen suggests (2000, p. 239). Since both the real-time chats and the threaded bulletin board postings are archived, students can return to these documents for review and further development of their ideas. The written conversations students have about the course material can then become stepping stones to more formal writing projects.

Though some students greeted these two technologies with skepticism, by the end of the course many students rated these components as “highly valuable” for analyzing class reading assignments, particularly because they were able to hear each classmate’s analysis of the material. Recursive use of postings by instructors during class time not only connect online discussions to face-to-face discussions, illustrating a symbiotic relationship between traditional and technological pedagogies; it also offers various models for students to use in their own classrooms. In sum, these online discussions highlight the crucial role written communication plays in a technological society, where email, listservs, and text-based documents are the dominant forms for the exchange of ideas. To be literate in the information age, one must be able to communicate effectively through text-based technologies.

The second component, online research for a group web project, most directly addressed our concerns about information literacy in the preservice classroom: students work collaboratively to research and compose a biography and bibliography for one of the children’s authors on the syllabus, drawing upon online and print resources. The resulting documents become part of their web site for their author. As instructors, we quickly learned that many students did not know the criteria they should use to evaluate resources available through the internet. Our preservice teachers were unfamiliar with strategies for directed searches in online subscription databases and on the web, and many were unable to identify the qualitative differences between a source located through a library database and one a search engine had retrieved. Our students’ confusion was most evident when they were asked to create the bibliographic citations for the information on their computer screens: they did not know where to look on the web page for the requisite information, or why they might need to include an author or sponsoring organization, or why they should note if the resource was first published in print and then made available through a database or on a web page.

By instructing and modeling the evaluation process for students during class time, instructors could demonstrate the critical tools that the students would need for their own research. Knowing that their biography and bibliography would not only be read and graded by their instructor but also available to a general audience on a web site provided a strong warrant for their efforts. Held responsible for their research methods and the resulting information, our students wished to present themselves as credible and informed authors. After completing this part of the pilot course, our preservice teachers say that they are ready to apply those criteria to the many web pages they others.

In designing the course, we emphasized three components which are easily transferred to the K-12 classroom: computer-mediated writing practices, online research, and web page construction. In designing the course, we wanted to test our hypothesis that these three components foster the critical writing and reading skills necessary for information literacy. We also wanted to see if these interactive skills would demonstrate how to transfer essential technological skills to the teaching of literature. Preliminary results from student evaluations indicate the success of the pilot program. Through observation and hands-on projects, many of our preservice teachers have indeed increased their information literacy and acquire both “academic” knowledge and “tacit” knowledge (Willis, 2000) about integrating technology into the teaching of literature.

First, synchronous and asynchronous online discussions encourage our preservice teachers to be self-reflexive about the act of written communication and the audiences for whom they write. Our instructors asked their students to use real-time collaborative small group discussions during class and to post to a threaded bulletin board discussion outside of class. These two forms of online discussion emphasize features of group exchange which students often take for granted as they use words. Unable to rely on facial expressions, tone of voice, and gestures as they would in face-to-face conversations, students must exercise their linguistic resources and use written cues in order to communicate successfully with their peers and instructor, their intended audience. Our results indicate that synchronous and asynchronous discussion is even more of a “mindtool” than David Jonassen suggests (2000, p. 239). The second component, online research for a group web project, most directly addressed our concerns about information literacy in the preservice classroom: students work collaboratively to research and compose a biography and bibliography for one of the children’s authors on the syllabus, drawing upon online and print resources. The resulting documents become part of their web site for their author. As instructors, we quickly learned that many students did not know the criteria they should use to evaluate resources available through the internet. Our preservice teachers were unfamiliar with strategies for directed searches in online subscription databases and on the web, and many were unable to identify the qualitative differences between a source located through a library database and one a search engine had retrieved. Our students’ confusion was most evident when they were asked to create the bibliographic citations for the information on their computer screens: they did not know where to look on the web page for the requisite information, or why they might need to include an author or sponsoring organization, or why they should note if the resource was first published in print and then made available through a database or on a web page.

By instructing and modeling the evaluation process for students during class time, instructors could demonstrate the critical tools that the students would need for their own research. Knowing that their biography and bibliography would not only be read and graded by their instructor but also available to a general audience on a web site provided a strong warrant for their efforts. Held responsible for their research methods and the resulting information, our students wished to present themselves as credible and informed authors. After completing this part of the pilot course, our preservice teachers say that they are ready to apply those criteria to the many web pages they
encounter now as students and to the pages they will help their own students evaluate. Even though we might hope or expect our preservice teachers to learn such critical reading skills in another course -- and some do -- it seems crucial to integrate these skills into a literature course, so that students connect a skill to its application in their work as teachers of language arts. Not only do they develop their own information literacy, but they also see the instructor modeling the process for a class of students.

The third component of our technology intensive pilot program is a group web project for which five to six students design and upload a series of linked web pages devoted to an author on the syllabus, such as Shel Silverstein or L. M. Montgomery. Web projects which receive high marks become part of the department's online resource site for children's literature. As David Jonassen notes, citing D. N. Perkins, K. E. Hayes and others, hypermedia offers yet another process-based learning strategy, one which facilitates learning by constructing knowledge (2000, p. 206; p. 211). Just as putting together a traditional research paper brings awareness of the processes of selection, inclusion, and elision that determine the resulting document, so, too, does constructing a web page and a web site. For the web project assignment, students create a site for an author, providing a researched biographical narrative (500-700 words), a two-part bibliography which includes works by the author and an annotated list of 8-10 sources about the author's work, and a series of "Critical Context" essays (400-500 words) on such topics as "History of Literary Production," "Style of Illustration/Art," and "Theme." Our preservice teachers are therefore asked to pay attention to the audience, the visual composition, the selection of content, and the location of the pages they create, as they enter an existing conversation about children's literature.

As earlier research studies would suggest (Lehrer, 1993; Carver et. al., 1992; Jonassen, 2000), student response to this component of the pilot class was overwhelmingly favorable; the web project was most frequently cited as the "most valuable skill" learned in the technology intensive course. In their evaluations, two students noted how the web project helped them research an author, and three stated it helped them learn more about an author. While a more traditional research project may have achieved similar results, the imperative to write for and persuade an audience beyond the classroom walls played a significant role in the project's success, motivating student performance. The project also boosted our students' confidence in and comfort with using technology -- important hurdles to overcome for many Education majors. "I am no longer afraid of web-building," announced one preservice teacher in her written evaluation. Web page design was also cited as one of the technologies which preservice teachers could already imagine adapting for their own classrooms, either as a tool to teach their students about selecting and presenting resources or as a way to communicate information to students and parents.

The study of literature, with its emphasis upon interpretation and implied readers, is the ideal setting for modeling applications of information technology. Our preservice teachers are able to experience, from their dual role as student and future teacher, how technology can enhance appreciation of literature and language. The instructional methods employed in this pilot course provide a model for Education majors' own use of technology in their future classrooms. Students' increasing comfort with and control over technology allows them to experience technology as a vital learning and teaching resource, a link between the written and spoken word.

Abstract: The West Virginia University PT3 grant (U.S. Department of Education’s Preparing Tomorrow’s Teachers to Use Technology) entitled “Trek 21-Educating Teachers As Agents of Technological Change” is a three-year grant designed to build, within the educators participating in West Virginia’s Teacher Education program, the capacity to use and integrate instructional technologies for teaching and learning. Trek 21 professional development constituents include PK-12 teachers in five West Virginia counties. The Trek 21 model of professional development includes a sequence of annual events including a summer institute, continuity meetings, site visits, and mini-conferences. Details from Trek 21 events have evolved to formulate a durable and sustainable professional development model. Trek 21 aims to refine the design, implementation, and evaluation for the professional development delivered during the 2002 three-week summer institute. This paper examines how lessons learned from first and second year institutes impacted the professional development process and guided essential design revisions for year three.

Introduction

As educational technology continues to evolve from a supplemental skill to a fundamental requirement, educators are being challenged to integrate instructional technology into lessons. In order to make the best use of technology in the classroom, teachers are required to exceed simple proficiency in existing and emerging computer technologies. They must be capable of determining how to integrate this technology appropriately for classroom use.

Professional development with instructional technology as a focus is complex. Design and delivery must be flexible enough to accommodate the wide range of computer expertise and the variety of environments in which teachers work. In addition, this specialized training must be geared toward creating self-sufficiency and sustainability of skills for practicing teachers. The three-year design of the Trek 21 project provides a unique opportunity to gather both short-term and long-term feedback from project participants, resulting in a continuously evolving design of professional development.

Trek 21 PT3 Project

Grants from the PT3 Initiative provide funding for innovative programs to develop technologically proficient educators who are well prepared to meet the needs of 21st century learners. “Trek 21: Educating Teachers as Agents of Technological Change” is a 3-year PT3 implementation grant from the U. S. Department of Education designed to prepare educators involved in West Virginia University’s five-year teacher preparation
program to integrate instructional technologies into their teaching. The grant was awarded to the College of Human Resources and Education at West Virginia University (WVU) in 1999.

Trek 21 looks to impart lasting change in the culture of teacher practice. The Trek 21 professional development model is sequenced in such a manner so as to ensure long-term adoption of new practice, continuous support and feedback, and sustainability beyond the project. To help accomplish this change, the Trek 21 project includes an annual cycle of professional development events for PK-12 teachers. The cycle of events includes professional development institutes during the summer, continuity meetings in the fall and spring, school site visits, and mini conferences.

Summer Institutes

PDS Institutes address genres of instructional technology applications (Harris, 1998), target technical training, and prepare instructional technology materials and resources necessary for immediate integration into classroom instruction. The final outcome of this three-week institute is a teacher-developed, web-based instructional unit, which is implemented in the fall by the teacher in collaboration with a pre-service student intern.

Continuity Meetings/Site Visits

Following the summer institutes, Trek 21 holds continuity meetings with PDS faculty once each semester (fall and spring) to address issues related to the successful integration of instructional technologies at their location. School site visits occur throughout the year to provide continued support and gather data on unit implementation and local concerns.

Mini Conferences

Scheduled to occur twice each academic year, a mini-conference is held in partnership with West Virginia’s “Technology, Teacher Education, Tomorrow” (T3) non-profit organization whose mission is to share best practices, receive technology enhancement training, and deliver presentations of activities related to the integration of instructional technologies. These conferences serve as our opportunity for state-wide dissemination of Trek 21 research results and presentation by participants of best practice where the integration of instructional technologies is central.

Year One

The institutes were designed to take place over a three-week period, to allow adequate time for technical training and unit development. A total of 47 participants were divided into three groups attending three separate institutes. The instructional technologies targeted were primarily web page development, electronic presentations, and conversion of paper-based to digital materials.

Prior to the summer institutes, participants received a packet containing surveys relating to computer use. Participants were asked to answer a series of questions about their current use and knowledge of computers. The data were analyzed, classifying participants as novice, intermediate, or advanced computer users. During year one, the majority of participants self-reported as novice computer users. As a result, the institutes were designed to provide clear expectations, concise instructions, and only the basics of each instructional technology targeted during the training sessions.

Week one of each institute emphasized pedagogical instruction, including topics such as reviews of teaching, lesson development, storyboarding, and examples of instructional technologies. Mid-week, participants were given a laptop computer and were trained on the fundamentals of computer use. By the end of week one, participants were introduced to basic web page creation. Week two included one or two training sessions per day on instructional technologies followed by development time, allowing participants ample opportunity to practice new skills and to develop their web-based units. Week three was devoted entirely to development time, with participants receiving individual help with the completion of their web pages and
integration of instructional technologies into their units. At the end of week three, participants presented their units to the group.

Three reviewers (two from inside the project and one from outside the project) evaluated participant units using an externally-developed rubric. Initially a low percentage of teacher units passed the evaluation and were posted. The teachers whose units were not posted were notified of essential modifications. After revisions made during the fall continuity meeting, all 47 teacher units met the requirements of the rubric and were posted to the Trek 21 web site.

Year One Findings

A review of the year one institute showed that preparing for and implementing three separate summer institutes strained both staff and facility resources. Additionally, feedback from participants revealed a need for both consistently available technical assistance and sufficient pedagogical expertise as it relates to instructional technologies during unit development. Participants particularly stressed the need for more time for unit development. However, analysis of lessons brought to the institute by participants revealed that only 30% had come prepared with complete lessons plans, 32% had partially complete lesson plans, and 38% arrived with no lesson plans, requiring the allocation of critical development time to be put toward planning of content and lessons.

These findings emphasized the need in year two to design for optimal allocation and organization of time and resources, particularly in the areas of facility planning, staffing, organization, and communication.

Year Two

To better utilize available resources, the three institutes were combined so that 27 participants attended one three-week institute. Graduate assistant roles were restructured with emphasis on providing instructional design guidance, training on use of various instructional technologies, and technical support. In year two Instructional Leaders (ILs), made up of university faculty and PK-12 expert teachers, were added to perform the following functions: (1) provide participants with pedagogical expertise throughout the institute and establish comfort levels needed for progress, (2) bridge the knowledge gap between potential and actual implementation of a given instructional technology in participants' lessons, (3) serve as quality control by discussing with participants the connections between goal/objective statements as a classroom teacher, their chosen method of assessment, and their selected instructional technologies, and (4) serve as reviewers for completed units.

Efforts were taken to ensure that participants were adequately prepared before arriving at the institute. Packets of information completed by participants pre-institute were reviewed to make certain that each teacher arrived at the institute having fully documented lesson plans, thus allowing for the maximum allocation of institute time to be used for instructional technology training and integration. Templates were designed to assist participants in detailing units and lessons. A Leadership and Planning Committee, consisting of several first year participants and Trek 21 staff members, was established to provide suggestions for year two of the institute. The emphasis of the committee was the finalization of the unit/lesson templates. Institute participants were asked to complete the templates and submit copies prior to arriving at the institute. This pre-organization of units and lessons allowed the institute focus to be on the instructional technologies rather than on organization of content, as originally intended.

In addition, web page templates were designed to assist participants with the proper design and navigation of their web pages. Teachers could focus more on developing the content of their web pages and spend less time on the web-based instructional design issues.

During week one of the institute, participants were introduced to the project, as well as to topics such as reviews of teaching, lesson development, storyboarding, and examples of instructional technologies. Later in the week, participants were introduced to their notebook computer and the basics of web page development. Monday and Tuesday of week two included morning group instruction and afternoon development time. The same instructional technologies as year one were targeted, with the addition of concept mapping software. Participants were also instructed in the use of a File Transfer Protocol (FTP) application to enable them to independently post their information to the server. The rest of the week was devoted to development, with optional breakout sessions on various topics. Week three was devoted entirely to the development of units. This
flexible design provided special-interest training and offered returning participants the opportunity to learn advanced topics while allowing other participants to concentrate on basic skills and unit development.

Units were evaluated based on an internally-developed rubric. Seven unit reviewers were tasked with evaluating all units independently. Based on averaged scores from the seven reviewers, units were either posted to the Trek 21 web site or revisions were suggested. Of the 27 participant units, only four required minor revisions before posting. A Trek 21 representative met with the teacher, explained the necessary changes, and provided support in revising the unit.

Year Two Findings

Year two participants arrived with a greater range of skills due to the experienced status of year one participant returnees, as well as advances in computer use by many of the participants, as reported on computer use surveys. The greater number of units passing the initial review demonstrated the importance of pre-institute preparation of lessons and units by participants and the value of the Instructional Leaders' assistance and support. Participant feedback was largely positive. However, some participants pointed out inconsistencies between the terminology used in the templates and rubric and that used by PK-12 teachers. Planning for year three would emphasize refining pre-institute preparation, additional Instructional Leaders, standardizing the language used in the templates and rubric, and the scheduling of basic skills training with more advanced topic breakout sessions.

Year Three

Year three will accommodate a maximum of 60 participants attending one institute. In order to accommodate the expected range of technology skills, participants will be divided into three separate groups based on skill level.

The template packet has been revised to include simplified and clearer instructions for the participants. Revisions include a revision of the terminology on the unit/lesson templates to better represent the language used by PK-12 educators. The evaluation rubric has also been slightly modified to align the rubric with the changes made to the unit/lesson templates.

Year two strategies will be employed again, although clearer daily and weekly goals will be communicated by the Instructional Leaders, ensuring that participants can reach benchmark accomplishments throughout each week of the institute. The same technology skills as year two will be presented.

During week one, examples of successful integration of various instructional technologies will be demonstrated by Instructional Leaders. This will assist participants in gathering ideas on the instructional technologies that will be appropriate for their particular units. In addition, a greater amount and variety of topics will be offered in both group and optional breakout sessions. These sessions will allow participants to focus on the technologies that they choose to learn and accommodate returnees who want to expand their existing skills. Early in the institute, teachers will be provided with a rubric checklist and encouraged to frequently review their web lessons during development. Instructional leaders will be instrumental in facilitating this process. This will provide additional guidance regarding expectations of the teacher units and help participants create units that will pass initial evaluation.

Conclusion

Because technology is an integral part of everyday life, educators have an added responsibility of utilizing instructional technology in their classrooms. Through durable and sustainable professional development, instructional technology can be successfully and appropriately integrated into teaching.

Professional development in the area of instructional technology requires effective communication and flexibility to meet individual teacher needs. As Trek 21 moves into its third and final project year the design and instruction of professional development has continually evolved to best facilitate the integration of instructional technology into lessons. The integration of experienced Instructional Leaders, the development of a Leadership and Planning Committee, the utilization of unit/lesson templates, the scheduling of breakout session
on various topics, and the use of an evaluation rubric by both participants and external reviewers have all led to the specification of clear and distinct roles and appropriate support mechanisms for project participants. These refinements in design and implementation have resulted in a steady growth in the number units that can pass initial review, an increase in participant satisfaction, and as we enter the project's final year, a significant increase in the number of PK-12 teachers wishing to participate in this professional development.

“Building Partnerships: Creating the History Teaching Institute at Ohio State”

Gregory Wilson
Department of History
University of Akron
USA
Gwilson@uakron.edu

Brad Austin
Department of History
The Ohio State University
USA
Austin.102@osu.edu

Abstract: This paper will examine the process involved in creating the History Teaching Institute at Ohio State (http://ohioteach.history.ohio-state.edu), an outreach project between the Department of History at Ohio State and Advanced Placement U.S. and European history teachers in Ohio. It serves as a positive, yet cautionary tale for those interested in creating outreach and engagement efforts between universities and K-12 schools, as well as those who want to encourage greater use of new technologies and media in the history classroom.

Introduction

The History Teaching Institute (HTI) is a program designed by faculty, staff, and graduate students in the history department at Ohio State University to foster partnerships between historians in the academy and in-service Advanced Placement high school history teachers in Ohio. It focuses upon content development and use of new media in the classroom. Gregory Wilson, now at the University of Akron, directed the first year of the program and Brad Austin, the current director, took over in 2001. HTI has been funded through two $50,000 grants from the Battelle Endowment for Technology and Human Affairs. This paper addresses the process of conceiving, creating, and directing a program that seeks to leverage the resources of a large, nationally ranked history department to build a partnership with the K-12 community. It elaborates on the process of creating a user-friendly web site, complete with web reviews, lesson plans, and helpful links to other useful sites. It will focus particularly on the limitations and benefits of creating a community of practice between university staff and teachers through the mechanism of an on-line platform. Finally, by showing the pleasures and pitfalls of cooperative ventures between history faculty and teachers, the presentation will add to our understanding of both outreach and engagement between universities and K-12 teachers as well as teaching history with technology.

Context

Before discussing the details of the History Teaching Institute, it is necessary to place its creation in the larger public discourse regarding higher education and the K-12 system. From several directions, there is a growing concern with fostering partnerships between college faculty in specific disciplines and K-12 teachers. Many cite a crisis in K-12 education as a reason for such interest. For example, in the 17 August 2001 edition of the Chronicle of Higher Education, Vartan Gregorian, president of the Carnegie Corporation noted that higher education institutions “must accept much of the responsibility for the dismal state of public-school teaching today” (Gregorian, 2001, p. B7). He also pointed out that high numbers of teachers majored in
education, not in a subject area, compromising the education of students in the K-12 system and leaving them unprepared for college (Gregorian, 2001, p. B7). The degree to which there is a crisis in education is perhaps debatable, but there is no doubting the benefits of closer cooperation between faculty and K-12 teachers to faculty, teachers, students, and our communities.

Within the profession of history, as well as from organizations closely related to it, there has been a growing interest in creating partnerships and outreach programs between faculty and K-12 teachers. For example, both the American Historical Association and the Organization of American Historians have teaching divisions and in their journals and newsletters publish regular items on K-12 collaboration. More recently, the National Council on Education and Disciplines (NCED) created the National History Project (NHP) to strengthen education in the later years of high school and early years of college by fostering partnerships between college faculty and high school teachers (Bennett, 2002, p. 11).

**Beginnings**

While part of this larger context, the immediate impetus for the Ohio State project came from faculty, staff, and graduate students involved with the Goldberg Program for Excellence in Teaching in the history department. The Goldberg Program has an emphasis on fostering the best practices of using new technology in the classroom and those involved wanted to expand into professional development for teachers. However, neither Ohio State nor the history department had the resources to fund such a project, and so it began with a one year grant from the Battelle Endowment for Technology and Human Affairs (BETHA) and focused on advanced placement (AP) high school history teachers from around Ohio.

We chose AP because we felt that the content and scope of the classes most closely matched those found in a typical survey level class taught at Ohio State. For example, the AP U.S. history exam is given each May along with the other AP exams administered by the College Board and covers material from roughly 1450 to the present. It contains various sections including multiple choice, short answer, and essay questions, and a section called the Documents Based Question (DBQ). The DBQ is centered on a distinct 50-year period, which teachers know ahead of time, and asks students to answer a question based on their analysis of a set of primary sources that could include images, texts, graphs, charts, and diagrams. For those teaching the college survey class in U.S. history, the time period and types of questions follow closely the experience for most college teachers. The textbooks and the level of student also resembled those found in college. For these reasons, we believed focusing on AP would enable faculty and teachers to communicate more effectively and design a program based on shared experiences and goals.

**Teachers**

The 15 teachers we recruited in the first year came from across the state and showed a range of experience teaching and using new technology in the classroom. We used an on-line survey to gather information from teachers applying to the program. Those representing schools serving higher socioeconomic levels formed the majority, including private and suburban public schools. There were some from urban districts that served middle to lower socioeconomic communities; we had no teachers apply from rural districts. In terms of technology, roughly one-third were well acquainted with using software such as PowerPoint, using the web for resources, and creating class web sites. A few had little if any experience using technology beyond the overhead, and most occasionally used computers in the class and had some experience using the web for classroom teaching. Their teaching experience ranged from one who was just beginning to one who had been teaching for 30 years. On average, the group had taught for about 5 years and most had taught AP U.S. history before.

**Structure**

The nature of the grant and the expertise of those involved shaped the structure of program. The administration of the HTI consisted of a director, a faculty consultant, and three advanced graduate students who worked closely with groups of teachers. Originally we had planned to focus on both European and United
States history. However, after recruiting a staff whose expertise lay in the latter, we decided to open admissions to the program to only AP U.S. history teachers. Using a mailing list supplied by the Admissions office at Ohio State, we advertised our new program by sending each high school in Ohio a flyer that described the program and provided information on how to apply. Unfortunately, the timing of the flyer was such that it did not go out until June, when many teachers had already begun their summer break. Still, we received 15 applications and decided to accept all of them.

To provide a more intimate and, we hoped, a more rewarding experience, we created three workgroups with each one having five teachers and a graduate student who would assist teachers with content and technology applications. The director oversaw the program and with the faculty consultant began the process of searching for new grants. We also wanted to create a richer experience by moving beyond the traditional week-long summer institute and create a year-long program that would make a larger impact in the way teachers integrated technology into their classes and also in the content knowledge they had of United States history.

We used a web-based system of communication to foster discussion, send information, and answer questions from teachers across Ohio. We designed a web site and forged a partnership with Metacollege that gave HTI free use of their new web-based learning platform similar to the ones offered by Blackboard and WebCT. (Metacollege has since gone out of business). To fuse content with technology, we then began writing web-based lesson plans on various topics in United States history that made use of resources found on the web and created PowerPoint lectures that we shared with teachers. In turn, we hoped teachers would share their ideas on content and on how they integrated technology into the classroom.

Implementation and Monitoring

Starting in June 2000, it took three months to establish the structure and we then brought the teachers to Ohio State for a one-day workshop in October on the AP grading process and using the web-based platform. At the conclusion of the workshop, teachers and HTI staff made the verbal commitment to exchange information via the web and to plan classroom visits during the school year so HTI staff could monitor the program. The HTI staff also provided documents readers to the teachers to assist them further in promoting textual and image analysis.

There is a difference between creating web-based communication platforms and using them, and we learned this almost immediately. The HTI web site contained lesson plans, links, and announcements and the Metacollege platform provided a discussion board, an area to transfer files, and e-mail. From the start, the e-mail function worked intermittently and teachers found it difficult to upload and download PowerPoint and Word files to share and analyze. Given the varied range of experience of the teachers with new media, such difficulties led to dissatisfaction and disillusionment for many participants. In addition, we found that such frustrations combined with a busy schedule meant that most teachers abandoned active participation in the program after three months. Of the 15 who began, only 4 stayed in regular contact. We also found that most teachers had their lessons and curriculum already set for the year, which limited implementation of ideas presented on the HTI web page or in discussions.

Of those remaining, we visited three classrooms to assess the project and observe how they used technology in the classroom. In two of our classrooms, we found a constructivist approach to learning where students used new media to create classroom projects. At Indian Hill, in an affluent area just outside Cincinnati, our AP teacher had six computers in her classroom, a large lab facility, as well as a technical support person. During our one-day visit, she focused on Gilded-Age politics and assigned a project where groups of students searched the web for information on key political figures and reported back to the class what they found. We also viewed projects done earlier in the semester that consisted of PowerPoint presentations on presidents that utilized images, text, and in some cases audio files of songs pertinent to the time period. At Village Academy, a small private school in Powell, the teacher did not have computers in the class and on the day we visited, his students were presenting their PowerPoint projects on the Spanish American War in the school computer lab. As with the first school, these presentations incorporated text, images, and sound.

The third teacher we visited taught at Bay Village High, a large public school located outside of Cleveland. Here, the instructor had a large television in the class with a keyboard and internet access. As with the others, Bay Village also had a separate computer lab. On this day, the teacher had requested that we demonstrate some of our PowerPoint lessons on the Great Depression and New Deal art. In these presentations, we used images, text, graphs, an audio clip of a speech by Franklin Delano Roosevelt, and songs from the Great
Depression. The problem in his venue was that the television screen was not large enough to display effectively many of the images and artwork, thus students had to stand around the screen while we discussed.

Following these visits and after the AP exam in May, we held a concluding workshop to provide closure and assess the past year's experiences. Only two of the original 15 attended, which told us a great deal about the issue of sustaining interest in a yearlong program. Here, we invited Gary Kornblith of Oberlin College to discuss his experiences with using new media in the classroom and, since we received a one-year renewal grant from BETHA, followed this with a discussion of ways to improve the programs of HTI in the future.

Second Year Adjustments and Conclusions

The first issue in assessing this experience relates to grant funding. Grants are critical to fostering projects, but their limited nature can make it difficult to sustain a program. This was true for the HTI, which had $50,000 for one year to hire a staff, create a web-based communication system, recruit teachers, hold workshops, visit classes, and assess progress. In the meantime, the staff constantly scanned the horizon for additional funding; fortunately, the Board for BETHA granted a one-year extension. This provided some reprieve, but to truly make a difference, projects need the security of longer-term funding. Grants can also constrain the project in certain ways that may make it difficult to alter the methods or details. In this case, BETHA required a series of lesson plans based on the role of technology in U.S. and European history. By itself this is a worthwhile effort, but not all teachers were able to make use of these lessons, especially when they did not fit into the plan for the upcoming AP exam.

The second area related to technology and new media, and here the evidence from our project is mixed. Given that many teachers have little or no experience with using new media, or simply do not have much time, any web platform designed to foster a virtual community of practice must be seamless. There exists potential for learning communities of faculty, teachers, and students that can foster the exchange of ideas and information. However, all the teachers involved expressed their strong desire that regular, face-to-face contact be an integral part of any project. In so far as expectations of use, we found that teachers rely more on having students use software and Internet resources than they themselves do. Teachers did not regularly integrate new media into their lectures or discussions, but rather relied on students to create projects that required searching for images, texts, and sounds.

In the second year of our project, we have tried to address many of the problems that we identified during our first year. First, we altered the History Teaching Institute's structure, eliminating the group leader positions and hiring a full-time director to coordinate all aspects of the Institute's operations. We also added European history. Second, in response to what our first-year participants had recommended, we lengthened the summer workshop to four days. Simply put, we had placed too much faith in the ability of our one-day summer session and our website to create a community of practice. Teachers and staff wanted more time to get to know each other, and the absence of a sense of camaraderie hurt the program for the rest of the year. During our second summer session, we scheduled 7 meals together and built into our agenda plenty of discussion time. This fostered group spirit, but more importantly it allowed teachers the time to share their experience and insights from the high school classroom — something college faculty could not provide. Even so, in their evaluations of the workshop, the teachers recommended even more time to share ideas face-to-face.

Finally, we recognized that no matter how well conceived a virtual community might be one-on-one contact is critical to maintain teacher interest in a professional development program. Consequently, the director visited most of the teachers' classrooms, some more than once, during the first half of the second year.

Did all this help students with the AP test? We don't know. Given the difficulty of sustaining interest in the program over one year, it was impossible to measure in any statistically significant way the impact of technology on AP scores. Presumably, there exists potential for a research project that does this; but such a project would require a larger amount of money and a longer time frame than was possible under the BETHA grants that funded HTI.

Did teachers gain from this project? In interviews and surveys at the end of the first year of the project, those that stayed with it said yes; and two expressed a desire to be part of the second year project underway now. The evaluations at the end of our second summer session were even more positive. For example, one teacher thought that it was "fantastic that OSU is reaching out to the high school teachers in Ohio" and was "truly impressed by the enthusiasm and dedication to teaching of all involved instructors (1
could name them all as being outstanding)." Another participant captured the open and collegial atmosphere of the most recent seminar with his comments: "I was at first skeptical that I would learn a great deal, yet I was surprised by how much I actually gained from the institute. First of all, the instructors were excellent. All previous academic experience with history professors had left me with the impression that condescension and pretentious attitudes were prerequisites for the job. However, the professors at the institute were intelligent, enthusiastic, and truly concerned with advancing the technological teaching methods. The instructors were sincerely a breath of fresh air as they showed their dedication to teaching (as opposed to dedication to research)." This teacher concluded, "In sum, the HTI emphasized practical and realistic technological teaching methods that I can and will utilize in the classroom as opposed to theoretical/philosophical issues that do not advance teaching and learning. The HTI gets an A+ and should be expanded in order to reach more of Ohio’s history teachers."

Our experience shows that teachers enjoy being part of a community of practice, sharing ideas, and being seen as professionals. This point is crucial for any cooperative venture between faculty and K-12 teachers. Teachers in the HTI also gained ideas about using new media in the classroom, even if they did not completely overhaul their teaching methods or lesson plans. Most often they used images located on the web site as well as those exchanged through e-mail to supplement their lectures and discussions. Teachers also made use of the readers given out at the beginning of the program. Finally, as faculty educated themselves about the AP process and what was and was not useful for teachers, they were able to discuss their ideas with teachers, enriching the dialogue for all involved.

The structure of the HTI reflect some of the best practices of professional development for teachers (Corcoran, 1995). Giving teachers time to debate and discuss both during workshops and on-line models constructivist teaching. Providing a four-day workshop, as well as classroom visits and virtual discussions, offers teachers the opportunity for deep, intellectual engagement. Finally, throughout the program, we demonstrated a respect for teachers as professionals and offered opportunities for teachers of various degrees of experience to share their expertise and understanding.

Clearly there are still areas we need to improve. Certainly the attrition rate was too high in the first year, and although it is much better in the second it is quite clear that we underestimated the difficulty of sustaining interest and commitment to the program. We also need to recruit and maintain contact with more teachers from under-served districts, including inner cities and rural communities. Rather than a statewide effort, with such a small staff and budget, having all teachers be in a local district may have helped sustain interest. Not only would doing so reduce travel costs and time, this more concentrated and focused project would have the added benefit of creating a more natural cadre of interested teachers who would be more likely to stay in contact and continue sharing resources and ideas after their participation in the program.

In the end, programs like the History Teaching Institute have as their goals to improve teaching, enrich student interest and knowledge about a subject, and to improve student performance in class and on various tests like the AP exams. The HTI has accomplished some of the first two goals and could not assess the third. While it has been successful, it has not been a complete success. However, it does provide an example of both the promises and pitfalls of cooperative ventures between faculty and K-12 teachers and provides the groundwork for future, more sustainable projects that should receive support and funding from universities and K-12 personnel.

Abstract: This paper will examine the process involved in creating the History Teaching Institute at Ohio State (http://ohioteach.history.ohio-state.edu), an outreach project between the Department of History at Ohio State and Advanced Placement U.S. and European history teachers in Ohio. It serves as a positive, yet cautionary tale for those interested in creating outreach and engagement efforts between universities and K-12 schools, as well as those who want to encourage greater use of new technologies and media in the history classroom.

Introduction

The History Teaching Institute (HTI) is a program designed by faculty, staff, and graduate students in the history department at Ohio State University to foster partnerships between historians in the academy and in-service Advanced Placement high school history teachers in Ohio. It focuses upon content development and use of new media in the classroom. Gregory Wilson, now at the University of Akron, directed the first year of the program and Brad Austin, the current director, took over in 2001. HTI has been funded through two $50,000 grants from the Battelle Endowment for Technology and Human Affairs. This paper addresses the process of conceiving, creating, and directing a program that seeks to leverage the resources of a large, nationally ranked history department to build a partnership with the K-12 community. It elaborates on the process of creating a user-friendly web site, complete with web reviews, lesson plans, and helpful links to other useful sites. It will focus particularly on the limitations and benefits of creating a community of practice between university staff and teachers through the mechanism of an on-line platform. Finally, by showing the pleasures and pitfalls of cooperative ventures between history faculty and teachers, the presentation will add to our understanding of both outreach and engagement between universities and K-12 teachers as well as teaching history with technology.

Context

Before discussing the details of the History Teaching Institute, it is necessary to place its creation in the larger public discourse regarding higher education and the K-12 system. From several directions, there is a growing concern with fostering partnerships between college faculty in specific disciplines and K-12 teachers. Many cite a crisis in K-12 education as a reason for such interest. For example, in the 17 August 2001 edition of the Chronicle of Higher Education, Vartan Gregorian, president of the Carnegie Corporation noted that higher education institutions “must accept much of the responsibility for the dismal state of public-school teaching today” (Gregorian, 2001, p. B7). He also pointed out that high numbers of teachers majored in
education, not in a subject area, compromising the education of students in the K-12 system and leaving them unprepared for college (Gregorian, 2001, p. B7). The degree to which there is a crisis in education is perhaps debatable, but there is no doubting the benefits of closer cooperation between faculty and K-12 teachers to faculty, teachers, students, and our communities.

Within the profession of history, as well as from organizations closely related to it, there has been a growing interest in creating partnerships and outreach programs between faculty and K-12 teachers. For example, both the American Historical Association and the Organization of American Historians have teaching divisions and in their journals and newsletters publish regular items on K-12 collaboration. More recently, the National Council on Education and Disciplines (NCED) created the National History Project (NHP) to strengthen education in the later years of high school and early years of college by fostering partnerships between college faculty and high school teachers (Bennett, 2002, p. 11).

Beginnings

While part of this larger context, the immediate impetus for the Ohio State project came from faculty, staff, and graduate students involved with the Goldberg Program for Excellence in Teaching in the history department. The Goldberg Program has an emphasis on fostering the best practices of using new technology in the classroom and those involved wanted to expand into professional development for teachers. However, neither Ohio State nor the history department had the resources to fund such a project, and so it began with a one year grant from the Battelle Endowment for Technology and Human Affairs (BETHA) and focused on advanced placement (AP) high school history teachers from around Ohio.

We chose AP because we felt that the content and scope of the classes most closely matched those found in a typical survey level class taught at Ohio State. For example, the AP U.S. history exam is given each May along with the other AP exams administered by the College Board and covers material from roughly 1450 to the present. It contains various sections including multiple choice, short answer, and essay questions, and a section called the Documents Based Question (DBQ). The DBQ is centered on a distinct 50-year period, which teachers know ahead of time, and asks students to answer a question based on their analysis of a set of primary sources that could include images, texts, graphs, charts, and diagrams. For those teaching the college survey class in U.S. history, the time period and types of questions follow closely the experience for most college teachers. The textbooks and the level of student also resembled those found in college. For these reasons, we believed focusing on AP would enable faculty and teachers to communicate more effectively and design a program based on shared experiences and goals.

Teachers

The 15 teachers we recruited in the first year came from across the state and showed a range of experience teaching and using new technology in the classroom. We used an on-line survey to gather information from teachers applying to the program. Those representing schools serving higher socioeconomic levels formed the majority, including private and suburban public schools. There were some from urban districts that served middle to lower socioeconomic communities; we had no teachers apply from rural districts. In terms of technology, roughly one-third were well acquainted with using software such as PowerPoint, using the web for resources, and creating class web sites. A few had little if any experience using technology beyond the overhead, and most occasionally used computers in the class and had some experience using the web for classroom teaching. Their teaching experience ranged from one who was just beginning to one who had been teaching for 30 years. On average, the group had taught for about 5 years and most had taught AP U.S. history before.

Structure

The nature of the grant and the expertise of those involved shaped the structure of program. The administration of the HTI consisted of a director, a faculty consultant, and three advanced graduate students who worked closely with groups of teachers. Originally we had planned to focus on both European and United...
States history. However, after recruiting a staff whose expertise lay in the latter, we decided to open admissions to the program to only AP U.S. history teachers. Using a mailing list supplied by the Admissions office at Ohio State, we advertised our new program by sending each high school in Ohio a flyer that described the program and provided information on how to apply. Unfortunately, the timing of the flyer was such that it did not go out until June, when many teachers had already begun their summer break. Still, we received 15 applications and decided to accept all of them.

To provide a more intimate and, we hoped, a more rewarding experience, we created three workgroups with each one having five teachers and a graduate student who would assist teachers with content and technology applications. The director oversaw the program and with the faculty consultant began the process of searching for new grants. We also wanted to create a richer experience by moving beyond the traditional week long summer institute and create a year long program that would make a larger impact in the way teachers integrated technology into their classes and also in the content knowledge they had of United States history.

We used a web-based system of communication to foster discussion, send information, and answer questions from teachers across Ohio. We designed a web site and forged a partnership with Metacollege that gave HTI free use of their new web based learning platform similar to the ones offered by Blackboard and WebCT. (Metacollege has since gone out of business). To fuse content with technology, we then began writing web-based lesson plans on various topics in United States history that made use of resources found on the web and created PowerPoint lectures that we shared with teachers. In turn, we hoped teachers would share their ideas on content and on how they integrated technology into the classroom.

Implementation and Monitoring

Starting in June 2000, it took three months to establish the structure and we then brought the teachers to Ohio State for a one-day workshop in October on the AP grading process and using the web based platform. At the conclusion of the workshop, teachers and HTI staff made the verbal commitment to exchange information via the web and to plan classroom visits during the school year so HTI staff could monitor the program. The HTI staff also provided documents readers to the teachers to assist them further in promoting textual and image analysis.

There is a difference between creating web-based communication platforms and using them, and we learned this almost immediately. The HTI web site contained lesson plans, links, and announcements and the Metacollege platform provided a discussion board, an area to transfer files, and e-mail. From the start, the e-mail function worked intermittently and teachers found it difficult to upload and download PowerPoint and Word files to share and analyze. Given the varied range of experience of the teachers with new media, such difficulties led to dissatisfaction and disillusionment for many participants. In addition, we found that such frustrations combined with a busy schedule meant that most teachers abandoned active participation in the program after three months. Of the 15 who began, only 4 stayed in regular contact. We also found that most teachers had their lessons and curriculum already set for the year, which limited implementation of ideas presented on the HTI web page or in discussions.

Of those remaining, we visited three classrooms to assess the project and observe how they used technology in the classroom. In two of our classrooms, we found a constructivist approach to learning where students used new media to create classroom projects. At Indian Hill, in an affluent area just outside Cincinnati, our AP teacher had six computers in her classroom, a large lab facility, as well as a technical support person. During our one-day visit, she focused on Gilded-Age politics and assigned a project where groups of students searched the web for information on key political figures and reported back to the class what they found. We also viewed projects done earlier in the semester that consisted of PowerPoint presentations on presidents that utilized images, text, and in some cases audio files of songs pertinent to the time period. At Village Academy, a small private school in Powell, the teacher did not have computers in the class and on the day we visited, his students were presenting their PowerPoint projects on the Spanish American War in the school computer lab. As with the first school, these presentations incorporated text, images, and sound.

The third teacher we visited taught at Bay Village High, a large public school located outside of Cleveland. Here, the instructor had a large television in the class with a keyboard and internet access. As with the others, Bay Village also had a separate computer lab. On this day, the teacher had requested that we demonstrate some of our PowerPoint lessons on the Great Depression and New Deal art. In these presentations, we used images, text, graphs, an audio clip of a speech by Franklin Delano Roosevelt, and songs from the Great
Depression. The problem in his venue was that the television screen was not large enough to display effectively many of the images and artwork, thus students had to stand around the screen while we discussed.

Following these visits and after the AP exam in May, we held a concluding workshop to provide closure and assess the past year’s experiences. Only two of the original 15 attended, which told us a great deal about the issue of sustaining interest in a yearlong program. Here, we invited Gary Kornblith of Oberlin College to discuss his experiences with using new media in the classroom and, since we received a one-year renewal grant from BETHA, followed this with a discussion of ways to improve the programs of HTI in the future.

Second Year Adjustments and Conclusions

The first issue in assessing this experience relates to grant funding. Grants are critical to fostering projects, but their limited nature can make it difficult to sustain a program. This was true for the HTI, which had $50,000 for one year to hire a staff, create a web-based communication system, recruit teachers, hold workshops, visit classes, and assess progress. In the meantime, the staff constantly scanned the horizon for additional funding; fortunately, the Board for BETHA granted a one-year extension. This provided some reprieve, but to truly make a difference, projects need the security of longer-term funding. Grants can also constrain the project in certain ways that may make it difficult to alter the methods or details. In this case, BETHA required a series of lesson plans based on the role of technology in U.S. and European history. By itself this is a worthwhile effort, but not all teachers were able to make use of these lessons, especially when they did not fit into the plan for the upcoming AP exam.

The second area related to technology and new media, and here the evidence from our project is mixed. Given that many teachers have little or no experience with using new media, or simply do not have much time, any web platform designed to foster a virtual community of practice must be seamless. There exists potential for learning communities of faculty, teachers, and students that can foster the exchange of ideas and information. However, all the teachers involved expressed their strong desire that regular, face-to-face contact be an integral part of any project. In so far as expectations of use, we found that teachers rely more on having students use software and Internet resources than they themselves do. Teachers did not regularly integrate new media into their lectures or discussions, but rather relied on students to create projects that required searching for images, texts, and sounds.

In the second year of our project, we have tried to address many of the problems that we identified during our first year. First, we altered the History Teaching Institute’s structure, eliminating the group leader positions and hiring a full-time director to coordinate all aspects of the Institute’s operations. We also added European history. Second, in response to what our first-year participants had recommended, we lengthened the summer workshop to four days. Simply put, we had placed too much faith in the ability of our one-day summer session and our website to create a community of practice. Teachers and staff wanted more time to get to know each other, and the absence of a sense of camaraderie hurt the program for the rest of the year. During our second summer session, we scheduled 7 meals together and built into our agenda plenty of discussion time. This fostered group spirit, but more importantly it allowed teachers the time to share their experience and insights from the high school classroom – something college faculty could not provide. Even so, in their evaluations of the workshop, the teachers recommended even more time to share ideas face-to-face.

Finally, we recognized that no matter how well conceived a virtual community might be one-on-one contact is critical to maintain teacher interest in a professional development program. Consequently, the director visited most of the teachers’ classrooms, some more than once, during the first half of the second year.

Did all this help students with the AP test? We don’t know. Given the difficulty of sustaining interest in the program over one year, it was impossible to measure in any statistically significant way the impact of technology on AP scores. Presumably, there exists potential for a research project that does this; but such a project would require a larger amount of money and a longer time frame than was possible under the BETHA grants that funded HTI.

Did teachers gain from this project? In interviews and surveys at the end of the first year of the project, those that stayed with it said yes; and two expressed a desire to be part of the second year project underway now. The evaluations at the end of our second summer session were even more positive. For example, one teacher thought that it was “fantastic that OSU is reaching out to the high school teachers in Ohio” and was “truly impressed by the enthusiasm and dedication to teaching of all involved instructors (I
could name them all as being outstanding)." Another participant captured the open and collegial atmosphere of the most recent seminar with his comments: "I was at first skeptical that I would learn a great deal, yet I was surprised by how much I actually gained from the institute. First of all, the instructors were excellent. All previous academic experience with history professors had left me with the impression that condescension and pretentious attitudes were prerequisites for the job. However, the professors at the institute were intelligent, enthusiastic, and truly concerned with advancing the technological teaching methods. The instructors were sincerely a breath of fresh air as they showed their dedication to teaching (as opposed to dedication to research)." This teacher concluded, "In sum, the HTI emphasized practical and realistic technological teaching methods that I can and will utilize in the classroom as opposed to theoretical/philosophical issues that do not advance teaching and learning. The HTI gets an A+ and should be expanded in order to reach more of Ohio's history teachers."

Our experience shows that teachers enjoy being part of a community of practice, sharing ideas, and being seen as professionals. This point is crucial for any cooperative venture between faculty and K-12 teachers. Teachers in the HTI also gained ideas about using new media in the classroom, even if they did not completely overhaul their teaching methods or lesson plans. Most often they used images located on the web site as well as those exchanged through e-mail to supplement their lectures and discussions. Teachers also made use of the readers given out at the beginning of the program. Finally, as faculty educated themselves about the AP process and what was and was not useful for teachers, they were able to discuss their ideas with teachers, enriching the dialogue for all involved.

The structure of the HTI reflect some of the best practices of professional development for teachers (Corcoran, 1995). Giving teachers time to debate and discuss both during workshops and on-line models constructivist teaching. Providing a four-day workshop, as well as classroom visits and virtual discussions, offers teachers the opportunity for deep, intellectual engagement. Finally, throughout the program, we demonstrated a respect for teachers as professionals and offered opportunities for teachers of various degrees of experience to share their expertise and understanding.

Clearly there are still areas we need to improve. Certainly the attrition rate was too high in the first year, and although it is much better in the second it is quite clear that we underestimated the difficulty of sustaining interest and commitment to the program. We also need to recruit and maintain contact with more teachers from under-served districts, including inner cities and rural communities. Rather than a statewide effort, with such a small staff and budget, having all teachers be in a local district may have helped sustain interest. Not only would doing so reduce travel costs and time, this more concentrated and focused project would have the added benefit of creating a more natural cadre of interested teachers who would be more likely to stay in contact and continue sharing resources and ideas after their participation in the program.

In the end, programs like the History Teaching Institute have as their goals to improve teaching, enrich student interest and knowledge about a subject, and to improve student performance in class and on various tests like the AP exams. The HTI has accomplished some of the first two goals and could not assess the third. While it has been successful, it has not been a complete success. However, it does provide an example of both the promises and pitfalls of cooperative ventures between faculty and K-12 teachers and provides the groundwork for future, more sustainable projects that should receive support and funding from universities and K-12 personnel.

Introduction

The History Teaching Institute (HTI) is a program designed by faculty, staff, and graduate students in the history department at Ohio State University to foster partnerships between historians in the academy and in-service Advanced Placement high school history teachers in Ohio. It focuses upon content development and use of new media in the classroom. Gregory Wilson, now at the University of Akron, directed the first year of the program and Brad Austin, the current director, took over in 2001. HTI has been funded through two $50,000 grants from the Battelle Endowment for Technology and Human Affairs. This paper addresses the process of conceiving, creating, and directing a program that seeks to leverage the resources of a large, nationally ranked history department to build a partnership with the K-12 community. It elaborates on the process of creating a user-friendly web site, complete with web reviews, lesson plans, and helpful links to other useful sites. It will focus particularly on the limitations and benefits of creating a community of practice between university staff and teachers through the mechanism of an on-line platform. Finally, by showing the pleasures and pitfalls of cooperative ventures between history faculty and teachers, the presentation will add to our understanding of both outreach and engagement between universities and K-12 teachers as well as teaching history with technology.

Context

Before discussing the details of the History Teaching Institute, it is necessary to place its creation in the larger public discourse regarding higher education and the K-12 system. From several directions, there is a growing concern with fostering partnerships between college faculty in specific disciplines and K-12 teachers. Many cite a crisis in K-12 education as a reason for such interest. For example, in the 17 August 2001 edition of the Chronicle of Higher Education, Vartan Gregorian, president of the Carnegie Corporation noted that higher education institutions “must accept much of the responsibility for the dismal state of public-school teaching today” (Gregorian, 2001, p. B7). He also pointed out that high numbers of teachers majored in
education, not in a subject area, compromising the education of students in the K-12 system and leaving them unprepared for college (Gregorian, 2001, p. B7). The degree to which there is a crisis in education is perhaps debatable, but there is no doubting the benefits of closer cooperation between faculty and K-12 teachers to faculty, teachers, students, and our communities.

Within the profession of history, as well as from organizations closely related to it, there has been a growing interest in creating partnerships and outreach programs between faculty and K-12 teachers. For example, both the American Historical Association and the Organization of American Historians have teaching divisions and in their journals and newsletters publish regular items on K-12 collaboration. More recently, the National Council on Education and Disciplines (NCED) created the National History Project (NHP) to strengthen education in the later years of high school and early years of college by fostering partnerships between college faculty and high school teachers (Bennett, 2002, p. 11).

Beginnings

While part of this larger context, the immediate impetus for the Ohio State project came from faculty, staff, and graduate students involved with the Goldberg Program for Excellence in Teaching in the history department. The Goldberg Program has an emphasis on fostering the best practices of using new technology in the classroom and those involved wanted to expand into professional development for teachers. However, neither Ohio State nor the history department had the resources to fund such a project, and so it began with a one year grant from the Battelle Endowment for Technology and Human Affairs (BETHA) and focused on advanced placement (AP) high school history teachers from around Ohio.

We chose AP because we felt that the content and scope of the classes most closely matched those found in a typical survey level class taught at Ohio State. For example, the AP U.S. history exam is given each May along with the other AP exams administered by the College Board and covers material from roughly 1450 to the present. It contains various sections including multiple choice, short answer, and essay questions, and a section called the Documents Based Question (DBQ). The DBQ is centered on a distinct 50-year period, which teachers know ahead of time, and asks students to answer a question based on their analysis of a set of primary sources that could include images, texts, graphs, charts, and diagrams. For those teaching the college survey class in U.S. history, the time period and types of questions follow closely the experience for most college teachers. The textbooks and the level of student also resembled those found in college. For these reasons, we believed focusing on AP would enable faculty and teachers to communicate more effectively and design a program based on shared experiences and goals.

Teachers

The 15 teachers we recruited in the first year came from across the state and showed a range of experience teaching and using new technology in the classroom. We used an on-line survey to gather information from teachers applying to the program. Those representing schools serving higher socioeconomic levels formed the majority, including private and suburban public schools. There were some from urban districts that served middle to lower socioeconomic communities; we had no teachers apply from rural districts. In terms of technology, roughly one-third were well acquainted with using software such as PowerPoint, using the web for resources, and creating class web sites. A few had little if any experience using technology beyond the overhead, and most occasionally used computers in the class and had some experience using the web for classroom teaching. Their teaching experience ranged from one who was just beginning to one who had been teaching for 30 years. On average, the group had taught for about 5 years and most had taught AP U.S. history before.

Structure

The nature of the grant and the expertise of those involved shaped the structure of program. The administration of the HTI consisted of a director, a faculty consultant, and three advanced graduate students who worked closely with groups of teachers. Originally we had planned to focus on both European and United
States history. However, after recruiting a staff whose expertise lay in the latter, we decided to open admissions to the program to only AP U.S. history teachers. Using a mailing list supplied by the Admissions office at Ohio State, we advertised our new program by sending each high school in Ohio a flyer that described the program and provided information on how to apply. Unfortunately, the timing of the flyer was such that it did not go out until June, when many teachers had already begun their summer break. Still, we received 15 applications and decided to accept all of them.

To provide a more intimate and, we hoped, a more rewarding experience, we created three workgroups with each one having five teachers and a graduate student who would assist teachers with content and technology applications. The director oversaw the program and with the faculty consultant began the process of searching for new grants. We also wanted to create a richer experience by moving beyond the traditional week long summer institute and create a year long program that would make a larger impact in the way teachers integrated technology into their classes and also in the content knowledge they had of United States history.

We used a web-based system of communication to foster discussion, send information, and answer questions from teachers across Ohio. We designed a web site and forged a partnership with Metacollege that gave HTI free use of their new web based learning platform similar to the ones offered by Blackboard and WebCT. (Metacollege has since gone out of business). To fuse content with technology, we then began writing web-based lesson plans on various topics in United States history that made use of resources found on the web and created PowerPoint lectures that we shared with teachers. In turn, we hoped teachers would share their ideas on content and on how they integrated technology into the classroom.

Implementation and Monitoring

Starting in June 2000, it took three months to establish the structure and we then brought the teachers to Ohio State for a one-day workshop in October on the AP grading process and using the web based platform. At the conclusion of the workshop, teachers and HTI staff made the verbal commitment to exchange information via the web and to plan classroom visits during the school year so HTI staff could monitor the program. The HTI staff also provided documents readers to the teachers to assist them further in promoting textual and image analysis.

There is a difference between creating web-based communication platforms and using them, and we learned this almost immediately. The HTI web site contained lesson plans, links, and announcements and the Metacollege platform provided a discussion board, an area to transfer files, and e-mail. From the start, the e-mail function worked intermittently and teachers found it difficult to upload and download PowerPoint and Word files to share and analyze. Given the varied range of experience of the teachers with new media, such difficulties led to dissatisfaction and disillusionment for many participants. In addition, we found that such frustrations combined with a busy schedule meant that most teachers abandoned active participation in the program after three months. Of the 15 who began, only 4 stayed in regular contact. We also found that most teachers had their lessons and curriculum already set for the year, which limited implementation of ideas presented on the HTI web page or in discussions.

Of those remaining, we visited three classrooms to assess the project and observe how they used technology in the classroom. In two of our classrooms, we found a constructivist approach to learning where students used new media to create classroom projects. At Indian Hill, in an affluent area just outside Cincinnati, our AP teacher had six computers in her classroom, a large lab facility, as well as a technical support person. During our one-day visit, she focused on Gilded-Age politics and assigned a project where groups of students searched the web for information on key political figures and reported back to the class what they found. We also viewed projects done earlier in the semester that consisted of PowerPoint presentations on presidents that utilized images, text, and in some cases audio files of songs pertinent to the time period. At Village Academy, a small private school in Powell, the teacher did not have computers in the class and on the day we visited, his students were presenting their PowerPoint projects on the Spanish American War in the school computer lab. As with the first school, these presentations incorporated text, images, and sound.

The third teacher we visited taught at Bay Village High, a large public school located outside of Cleveland. Here, the instructor had a large television in the class with a keyboard and internet access. As with the others, Bay Village also had a separate computer lab. On this day, the teacher had requested that we demonstrate some of our PowerPoint lessons on the Great Depression and New Deal art. In these presentations, we used images, text, graphs, an audio clip of a speech by Franklin Delano Roosevelt, and songs from the Great
Depression. The problem in his venue was that the television screen was not large enough to display effectively many of the images and artwork, thus students had to stand around the screen while we discussed.

Following these visits and after the AP exam in May, we held a concluding workshop to provide closure and assess the past year's experiences. Only two of the original 15 attended, which told us a great deal about the issue of sustaining interest in a yearlong program. Here, we invited Gary Kornblith of Oberlin College to discuss his experiences with using new media in the classroom and, since we received a one-year renewal grant from BETHA, followed this with a discussion of ways to improve the programs of HTI in the future.

Second Year Adjustments and Conclusions

The first issue in assessing this experience relates to grant funding. Grants are critical to fostering projects, but their limited nature can make it difficult to sustain a program. This was true for the HTI, which had $50,000 for one year to hire a staff, create a web-based communication system, recruit teachers, hold workshops, visit classes, and assess progress. In the meantime, the staff constantly scanned the horizon for additional funding; fortunately, the Board for BETHA granted a one-year extension. This provided some reprieve, but to truly make a difference, projects need the security of longer-term funding. Grants can also constrain the project in certain ways that may make it difficult to alter the methods or details. In this case, BETHA required a series of lesson plans based on the role of technology in U.S. and European history. By itself this is a worthwhile effort, but not all teachers were able to make use of these lessons, especially when they did not fit into the plan for the upcoming AP exam.

The second area related to technology and new media, and here the evidence from our project is mixed. Given that many teachers have little or no experience with using new media, or simply do not have much time, any web platform designed to foster a virtual community of practice must be seamless. There exists potential for learning communities of faculty, teachers, and students that can foster the exchange of ideas and information. However, all the teachers involved expressed their strong desire that regular, face-to-face contact be an integral part of any project. In so far as expectations of use, we found that teachers rely more on having students use software and Internet resources than they themselves do. Teachers did not regularly integrate new media into their lectures or discussions, but rather relied on students to create projects that required searching for images, texts, and sounds.

In the second year of our project, we have tried to address many of the problems that we identified during our first year. First, we altered the History Teaching Institute's structure, eliminating the group leader positions and hiring a full-time director to coordinate all aspects of the Institute's operations. We also added European history. Second, in response to what our first-year participants had recommended, we lengthened the summer workshop to four days. Simply put, we had placed too much faith in the ability of our one-day summer session and our web site to create a community of practice. Teachers and staff wanted more time to get to know each other, and the absence of a sense of camaraderie hurt the program for the rest of the year. During our second summer session, we scheduled 7 meals together and built into our agenda plenty of discussion time. This fostered group spirit, but more importantly it allowed teachers the time to share their experience and insights from the high school classroom—something college faculty could not provide. Even so, in their evaluations of the workshop, the teachers recommended even more time to share ideas face-to-face.

Finally, we recognized that no matter how well conceived a virtual community might be one-on-one contact is critical to maintain teacher interest in a professional development program. Consequently, the director visited most of the teachers' classrooms, some more than once, during the first half of the second year.

Did all this help students with the AP test? We don't know. Given the difficulty of sustaining interest in the program over one year, it was impossible to measure in any statistically significant way the impact of technology on AP scores. Presumably, there exists potential for a research project that does this; but such a project would require a larger amount of money and a longer time frame then was possible under the BETHA grants that funded HTI.

Did teachers gain from this project? In interviews and surveys at the end of the first year of the project, those that stayed with it said yes; and two expressed a desire to be part of the second year project underway now. The evaluations at the end of our second summer session were even more positive. For example, one teacher thought that it was "fantastic that OSU is reaching out to the high school teachers in Ohio" and was "truly impressed by the enthusiasm and dedication to teaching of all involved instructors (I
could name them all as being outstanding).” Another participant captured the open and collegial atmosphere of the most recent seminar with his comments: “I was at first skeptical that I would learn a great deal, yet I was surprised by how much I actually gained from the institute. First of all, the instructors were excellent. All previous academic experience with history professors had left me with the impression that condescension and pretentious attitudes were prerequisites for the job. However, the professors at the institute were intelligent, enthusiastic, and truly concerned with advancing the technological teaching methods. The instructors were sincerely a breath of fresh air as they showed their dedication to teaching (as opposed to dedication to research).” This teacher concluded, “In sum, the HTI emphasized practical and realistic technological teaching methods that I can and will utilize in the classroom as opposed to theoretical/philosophical issues that do not advance teaching and learning. The HTI gets an A+ and should be expanded in order to reach more of Ohio’s history teachers.”

Our experience shows that teachers enjoy being part of a community of practice, sharing ideas, and being seen as professionals. This point is crucial for any cooperative venture between faculty and K-12 teachers. Teachers in the HTI also gained ideas about using new media in the classroom, even if they did not completely overhaul their teaching methods or lesson plans. Most often they used images located on the web site as well as those exchanged through e-mail to supplement their lectures and discussions. Teachers also made use of the readers given out at the beginning of the program. Finally, as faculty educated themselves about the AP process and what was and was not useful for teachers, they were able to discuss their ideas with teachers, enriching the dialogue for all involved.

The structure of the HTI reflect some of the best practices of professional development for teachers (Corcoran, 1995). Giving teachers time to debate and discuss both during workshops and on-line models constructivist teaching. Providing a four-day workshop, as well as classroom visits and virtual discussions, offers teachers the opportunity for deep, intellectual engagement. Finally, throughout the program, we demonstrated a respect for teachers as professionals and offered opportunities for teachers of various degrees of experience to share their expertise and understanding.

Clearly there are still areas we need to improve. Certainly the attrition rate was too high in the first year, and although it is much better in the second it is quite clear that we underestimated the difficulty of sustaining interest and commitment to the program. We also need to recruit and maintain contact with more teachers from under-served districts, including inner cities and rural communities. Rather than a statewide effort, with such a small staff and budget, having all teachers be in a local district may have helped sustain interest. Not only would doing so reduce travel costs and time, this more concentrated and focused project would have the added benefit of creating a more natural cadre of interested teachers who would be more likely to stay in contact and continue sharing resources and ideas after their participation in the program.

In the end, programs like the History Teaching Institute have as their goals to improve teaching, enrich student interest and knowledge about a subject, and to improve student performance in class and on various tests like the AP exams. The HTI has accomplished some of the first two goals and could not assess the third. While it has been successful, it has not been a complete success. However, it does provide an example of both the promises and pitfalls of cooperative ventures between faculty and K-12 teachers and provides the groundwork for future, more sustainable projects that should receive support and funding from universities and K-12 personnel.

Abstract: This paper will examine the process involved in creating the History Teaching Institute at Ohio State (http://ohioteach.history.ohio-state.edu), an outreach project between the Department of History at Ohio State and Advanced Placement U.S. and European history teachers in Ohio. It serves as a positive, yet cautionary tale for those interested in creating outreach and engagement efforts between universities and K-12 schools, as well as those who want to encourage greater use of new technologies and media in the history classroom.

Introduction

The History Teaching Institute (HTI) is a program designed by faculty, staff, and graduate students in the history department at Ohio State University to foster partnerships between historians in the academy and in-service Advanced Placement high school history teachers in Ohio. It focuses upon content development and use of new media in the classroom. Gregory Wilson, now at the University of Akron, directed the first year of the program and Brad Austin, the current director, took over in 2001. HTI has been funded through two $50,000 grants from the Battelle Endowment for Technology and Human Affairs. This paper addresses the process of conceiving, creating, and directing a program that seeks to leverage the resources of a large, nationally ranked history department to build a partnership with the K-12 community. It elaborates on the process of creating a user-friendly web site, complete with web reviews, lesson plans, and helpful links to other useful sites. It will focus particularly on the limitations and benefits of creating a community of practice between university staff and teachers through the mechanism of an on-line platform. Finally, by showing the pleasures and pitfalls of cooperative ventures between history faculty and teachers, the presentation will add to our understanding of both outreach and engagement between universities and K-12 teachers as well as teaching history with technology.

Context

Before discussing the details of the History Teaching Institute, it is necessary to place its creation in the larger public discourse regarding higher education and the K-12 system. From several directions, there is a growing concern with fostering partnerships between college faculty in specific disciplines and K-12 teachers. Many cite a crisis in K-12 education as a reason for such interest. For example, in the 17 August 2001 edition of the Chronicle of Higher Education, Vartan Gregorian, president of the Carnegie Corporation noted that higher education institutions “must accept much of the responsibility for the dismal state of public-school teaching today” (Gregorian, 2001, p. B7). He also pointed out that high numbers of teachers majored in...
education, not in a subject area, compromising the education of students in the K-12 system and leaving them unprepared for college (Gregorian, 2001, p. B7). The degree to which there is a crisis in education is perhaps debatable, but there is no doubting the benefits of closer cooperation between faculty and K-12 teachers to faculty, teachers, students, and our communities.

Within the profession of history, as well as from organizations closely related to it, there has been a growing interest in creating partnerships and outreach programs between faculty and K-12 teachers. For example, both the American Historical Association and the Organization of American Historians have teaching divisions and in their journals and newsletters publish regular items on K-12 collaboration. More recently, the National Council on Education and Disciplines (NCED) created the National History Project (NHP) to strengthen education in the later years of high school and early years of college by fostering partnerships between college faculty and high school teachers (Bennett, 2002, p. 11).

Beginnings

While part of this larger context, the immediate impetus for the Ohio State project came from faculty, staff, and graduate students involved with the Goldberg Program for Excellence in Teaching in the history department. The Goldberg Program has an emphasis on fostering the best practices of using new technology in the classroom and those involved wanted to expand into professional development for teachers. However, neither Ohio State nor the history department had the resources to fund such a project, and so it began with a one year grant from the Battelle Endowment for Technology and Human Affairs (BETHA) and focused on advanced placement (AP) high school history teachers from around Ohio.

We chose AP because we felt that the content and scope of the classes most closely matched those found in a typical survey level class taught at Ohio State. For example, the AP U.S. history exam is given each May along with the other AP exams administered by the College Board and covers material from roughly 1450 to the present. It contains various sections including multiple choice, short answer, and essay questions, and a section called the Documents Based Question (DBQ). The DBQ is centered on a distinct 50-year period, which teachers know ahead of time, and asks students to answer a question based on their analysis of a set of primary sources that could include images, texts, graphs, charts, and diagrams. For those teaching the college survey class in U.S. history, the time period and types of questions follow closely the experience for most college teachers. The textbooks and the level of student also resembled those found in college. For these reasons, we believed focusing on AP would enable faculty and teachers to communicate more effectively and design a program based on shared experiences and goals.

Teachers

The 15 teachers we recruited in the first year came from across the state and showed a range of experience teaching and using new technology in the classroom. We used an on-line survey to gather information from teachers applying to the program. Those representing schools serving higher socioeconomic levels formed the majority, including private and suburban public schools. There were some from urban districts that served middle to lower socioeconomic communities; we had no teachers apply from rural districts. In terms of technology, roughly one-third were well acquainted with using software such as PowerPoint, using the web for resources, and creating class web sites. A few had little if any experience using technology beyond the overhead, and most occasionally used computers in the class and had some experience using the web for classroom teaching. Their teaching experience ranged from one who was just beginning to one who had been teaching for 30 years. On average, the group had taught for about 5 years and most had taught AP U.S. history before.

Structure

The nature of the grant and the expertise of those involved shaped the structure of program. The administration of the HTI consisted of a director, a faculty consultant, and three advanced graduate students who worked closely with groups of teachers. Originally we had planned to focus on both European and United
States history. However, after recruiting a staff whose expertise lay in the latter, we decided to open admissions to the program to only AP U.S. history teachers. Using a mailing list supplied by the Admissions office at Ohio State, we advertised our new program by sending each high school in Ohio a flyer that described the program and provided information on how to apply. Unfortunately, the timing of the flyer was such that it did not go out until June, when many teachers had already begun their summer break. Still, we received 15 applications and decided to accept all of them.

To provide a more intimate and, we hoped, a more rewarding experience, we created three workgroups with each one having five teachers and a graduate student who would assist teachers with content and technology applications. The director oversaw the program and with the faculty consultant began the process of searching for new grants. We also wanted to create a richer experience by moving beyond the traditional week long summer institute and create a year long program that would make a larger impact in the way teachers integrated technology into their classes and also in the content knowledge they had of United States history.

We used a web-based system of communication to foster discussion, send information, and answer questions from teachers across Ohio. We designed a web site and forged a partnership with Metacollege that gave HTI free use of their new web based learning platform similar to the ones offered by Blackboard and WebCT. (Metacollege has since gone out of business). To fuse content with technology, we then began writing web-based lesson plans on various topics in United States history that made use of resources found on the web and created PowerPoint lectures that we shared with teachers. In turn, we hoped teachers would share their ideas on content and on how they integrated technology into the classroom.

Implementation and Monitoring

Starting in June 2000, it took three months to establish the structure and we then brought the teachers to Ohio State for a one-day workshop in October on the AP grading process and using the web based platform. At the conclusion of the workshop, teachers and HTI staff made the verbal commitment to exchange information via the web and to plan classroom visits during the school year so HTI staff could monitor the program. The HTI staff also provided documents readers to the teachers to assist them further in promoting textual and image analysis.

There is a difference between creating web-based communication platforms and using them, and we learned this almost immediately. The HTI web site contained lesson plans, links, and announcements and the Metacollege platform provided a discussion board, an area to transfer files, and e-mail. From the start, the e-mail function worked intermittently and teachers found it difficult to upload and download PowerPoint and Word files to share and analyze. Given the varied range of experience of the teachers with new media, such difficulties led to dissatisfaction and disillusionment for many participants. In addition, we found that such frustrations combined with a busy schedule meant that most teachers abandoned active participation in the program after three months. Of the 15 who began, only 4 stayed in regular contact. We also found that most teachers had their lessons and curriculum already set for the year, which limited implementation of ideas presented on the HTI web page or in discussions.

Of those remaining, we visited three classrooms to assess the project and observe how they used technology in the classroom. In two of our classrooms, we found a constructivist approach to learning where students used new media to create classroom projects. At Indian Hill, in an affluent area just outside Cincinnati, our AP teacher had six computers in her classroom, a large lab facility, as well as a technical support person. During our one-day visit, she focused on Gilded-Age politics and assigned a project where groups of students searched the web for information on key political figures and reported back to the class what they found. We also viewed projects done earlier in the semester that consisted of PowerPoint presentations on presidents that utilized images, text, and in some cases audio files of songs pertinent to the time period. At Village Academy, a small private school in Powell, the teacher did not have computers in the class and on the day we visited, his students were presenting their PowerPoint projects on the Spanish American War in the school computer lab. As with the first school, these presentations incorporated text, images, and sound.

The third teacher we visited taught at Bay Village High, a large public school located outside of Cleveland. Here, the instructor had a large television in the class with a keyboard and internet access. As with the others, Bay Village also had a separate computer lab. On this day, the teacher had requested that we demonstrate some of our PowerPoint lessons on the Great Depression and New Deal art. In these presentations, we used images, text, graphs, an audio clip of a speech by Franklin Delano Roosevelt, and songs from the Great
Depression. The problem in his venue was that the television screen was not large enough to display effectively many of the images and artwork, thus students had to stand around the screen while we discussed.

Following these visits and after the AP exam in May, we held a concluding workshop to provide closure and assess the past year’s experiences. Only two of the original 15 attended, which told us a great deal about the issue of sustaining interest in a yearlong program. Here, we invited Gary Kornblith of Oberlin College to discuss his experiences with using new media in the classroom and, since we received a one-year renewal grant from BETHA, followed this with a discussion of ways to improve the programs of HTI in the future.

Second Year Adjustments and Conclusions

The first issue in assessing this experience relates to grant funding. Grants are critical to fostering projects, but their limited nature can make it difficult to sustain a program. This was true for the HTI, which had $50,000 for one year to hire a staff, create a web-based communication system, recruit teachers, hold workshops, visit classes, and assess progress. In the meantime, the staff constantly scanned the horizon for additional funding; fortunately, the Board for BETHA granted a one-year extension. This provided some reprieve, but to truly make a difference, projects need the security of longer-term funding. Grants can also constrain the project in certain ways that may make it difficult to alter the methods or details. In this case, BETHA required a series of lesson plans based on the role of technology in U.S. and European history. By itself this is a worthwhile effort, but not all teachers were able to make use of these lessons, especially when they did not fit into the plan for the upcoming AP exam.

The second area related to technology and new media, and here the evidence from our project is mixed. Given that many teachers have little or no experience with using new media, or simply do not have much time, any web platform designed to foster a virtual community of practice must be seamless. There exists potential for learning communities of faculty, teachers, and students that can foster the exchange of ideas and information. However, all the teachers involved expressed their strong desire that regular, face-to-face contact be an integral part of any project. In so far as expectations of use, we found that teachers rely more on having students use software and Internet resources than they themselves do. Teachers did not regularly integrate new media into their lectures or discussions, but rather relied on students to create projects that required searching for images, texts, and sounds.

In the second year of our project, we have tried to address many of the problems that we identified during our first year. First, we altered the History Teaching Institute’s structure, eliminating the group leader positions and hiring a full-time director to coordinate all aspects of the Institute’s operations. We also added European history. Second, in response to what our first-year participants had recommended, we lengthened the summer workshop to four days. Simply put, we had placed too much faith in the ability of our one-day summer session and our web site to create a community of practice. Teachers and staff wanted more time to get to know each other, and the absence of a sense of camaraderie hurt the program for the rest of the year. During our second summer session, we scheduled 7 meals together and built into our agenda plenty of discussion time. This fostered group spirit, but more importantly it allowed teachers the time to share their experience and insights from the high school classroom—something college faculty could not provide. Even so, in their evaluations of the workshop, the teachers recommended even more time to share ideas face-to-face.

Finally, we recognized that no matter how well conceived a virtual community might be one-on-one contact is critical to maintain teacher interest in a professional development program. Consequently, the director visited most of the teachers’ classrooms, some more than once, during the first half of the second year.

Did all this help students with the AP test? We don’t know. Given the difficulty of sustaining interest in the program over one year, it was impossible to measure in any statistically significant way the impact of technology on AP scores. Presumably, there exists potential for a research project that does this; but such a project would require a larger amount of money and a longer time frame than was possible under the BETHA grants that funded HTI.

Did teachers gain from this project? In interviews and surveys at the end of the first year of the project, those that stayed with it said yes; and two expressed a desire to be part of the second year project underway now. The evaluations at the end of our second summer session were even more positive. For example, one teacher thought that it was “fantastic that OSU is reaching out to the high school teachers in Ohio” and was “truly impressed by the enthusiasm and dedication to teaching of all involved instructors.”
Another participant captured the open and collegial atmosphere of the most recent seminar with his comments: "I was at first skeptical that I would learn a great deal, yet I was surprised by how much I actually gained from the institute. First of all, the instructors were excellent. All previous academic experience with history professors had left me with the impression that condescension and pretentious attitudes were prerequisites for the job. However, the professors at the institute were intelligent, enthusiastic, and truly concerned with advancing the technological teaching methods. The instructors were sincerely a breath of fresh air as they showed their dedication to teaching (as opposed to dedication to research)." This teacher concluded, "In sum, the HTI emphasized practical and realistic technological teaching methods that I can and will utilize in the classroom as opposed to theoretical/philosophical issues that do not advance teaching and learning. The HTI gets an A+ and should be expanded in order to reach more of Ohio's history teachers."

Our experience shows that teachers enjoy being part of a community of practice, sharing ideas, and being seen as professionals. This point is crucial for any cooperative venture between faculty and K-12 teachers. Teachers in the HTI also gained ideas about using new media in the classroom, even if they did not completely overhaul their teaching methods or lesson plans. Most often they used images located on the web site as well as those exchanged through e-mail to supplement their lectures and discussions. Teachers also made use of the readers given out at the beginning of the program. Finally, as faculty educated themselves about the AP process and what was and was not useful for teachers, they were able to discuss their ideas with teachers, enriching the dialogue for all involved.

The structure of the HTI reflect some of the best practices of professional development for teachers (Corcoran, 1995). Giving teachers time to debate and discuss both during workshops and on-line models constructivist teaching. Providing a four-day workshop, as well as classroom visits and virtual discussions, offers teachers the opportunity for deep, intellectual engagement. Finally, throughout the program, we demonstrated a respect for teachers as professionals and offered opportunities for teachers of various degrees of experience to share their expertise and understanding.

Clearly there are still areas we need to improve. Certainly the attrition rate was too high in the first year, and although it is much better in the second it is quite clear that we underestimated the difficulty of sustaining interest and commitment to the program. We also need to recruit and maintain contact with more teachers from under-served districts, including inner cities and rural communities. Rather than a statewide effort, with such a small staff and budget, having all teachers be in a local district may have helped sustain interest. Not only would doing so reduce travel costs and time, this more concentrated and focused project would have the added benefit of creating a more natural cadre of interested teachers who would be more likely to stay in contact and continue sharing resources and ideas after their participation in the program.

In the end, programs like the History Teaching Institute have as their goals to improve teaching, enrich student interest and knowledge about a subject, and to improve student performance in class and on various tests like the AP exams. The HTI has accomplished some of the first two goals and could not assess the third. While it has been successful, it has not been a complete success. However, it does provide an example of both the promises and pitfalls of cooperative ventures between faculty and K-12 teachers and provides the groundwork for future, more sustainable projects that should receive support and funding from universities and K-12 personnel.

Appeals to citizens about global warming, alternative medicine, and water quality indicate the need for citizens to understand the models presented to them, to sensibly evaluate predictions, to consider validity of models, and to understand the power and limits of modeling. The sheer complexity of policy questions settled by models from this or that agency in the body politics calls for citizens to understand scientific models. For the sciences and the humanities alike the underlying goals of education form a democratic liberal tradition that promotes freedom of the individual and requires an awakening and deep application of critical thinking (Nussbaum, 1997). The revolution in computational modeling and computer intensive informatics such as data mining have become essential new 21st Century methodologies of deep critical inquiry. Teachers in training need to know how to use these new tools in the classroom and to make them available to our next generation of students. Through computer simulations, 3D models and extensive web-based resources designed for the learner we can make concepts available to students that twenty years ago were only understood by those upper 5% of students skilled in the formal mathematics.

A major recommendation of the report Setting a Research and Planning Agenda for Computer Modeling in the Pre-College Curriculum (Final Report: NSF RED-9255877) is that "[c]omputational modeling ideas and activities should have a key and central role throughout the science curriculum - not peripherally, and not only as part of a special or optional course." Models help "abstract from reality key features that enable us to gain insight into the fundamental processes underlying external complexity." Relationships between variables must be made explicit in both a qualitative and a quantitative sense. Observation, measurement, graphing, curve fitting, modeling, and visualization are all part of a continuum of doing science. Curriculum issues are also addressed in this report. "There is a need for a set of guidelines and models for use in integrating models and simulations into locally-relevant curriculum in a way that allows students to achieve the new goals."

The AAAS Benchmark science standards also indicate the need for computer-based modeling. The benchmark common themes emphasize connections between seemingly disparate science content. In using and creating computer models, student attention can be focused on similar structures and behavior. For example, a predator prey interaction model and a physical spring model share the oscillation structure. Disruption and resumption of equilibrium can be found in both biological and earth systems. Assimilating an understanding of such structure and behavior leads to acquisition of the "schemas" of science content which have been shown to distinguish experts from novices. (Chandler, & Sweller, 1991)

The PT3 funded EdGrid program sponsors seven teams to explore various models of integrating modeling and visualization as methods of discovery and scientific analysis into teacher preparation. This panel will present what we have learned and focus on some the most promising strategies. The teams include:

University of Alabama in Birmingham

The School of Education at the University of Alabama at Birmingham (UAB) and the ASPIRE program at the University of Alabama at Huntsville are collaborating in the formation of an EdGrid team to accomplish three objectives in the pre-service teacher education program at UAB. First, concepts of modeling and visualization are being infused in existing teaching methodology courses for the K-12 curriculum that will provide training for all students in the secondary mathematics and science pre-service program. Second, a course in mathematics modeling is being developed by the mathematics department faculty that will replace an existing course. The new course will be required for all secondary education majors. Finally, a new advanced technology course emphasizing advanced topics in the use of Excel and Web-based tools is being developed. Planning is underway for a senior research
project using modeling and/or visualization for those who wish to complete a project.

**Biology Student Workbench**

Biology is increasingly becoming an “information-driven” science. Biological research involves constructing meaning using the vast amounts of information compiled from experiments in the laboratory and observations in the field. The application of information technology to molecular biology research is evolving into a new discipline, bioinformatics. Biology Workbench, a bioinformatics tool, provides access to biological databases and analysis tools through a web browser. Biology Student Workbench is a growing collection of education enhancements to the Biology Workbench including, tutorials, inquiry-based laboratories and resource materials, all of which help high school students and teachers to conduct open-ended investigations in molecular biology. The project specifically addresses a pre-service teacher audience, and it supports the use of the inquiry-based learning and teaching approach to science education. The project objectives are to:

- Develop inquiry-based bioinformatics curricula in collaboration and cooperation with the faculty and students in the teacher certification programs.
- Integrate the curricula into science and math methods courses.
- Disseminate the curricula nationwide.

**Lesley University**

Currently, the Technology-in-Education Program at Lesley University is the only pre-service education program at the University that requires its students to take a course in computer modeling. The goal is to have computational science formally included in all pre-service education programs at Lesley University. The intended audience is students enrolled in non-science, non-technology teacher training programs. One product of this project is the development of a module, "Introduction to Computational Science," that will be used in Lesley University undergraduate and graduate teacher education programs. The module is being adopted for use in all teacher education programs as part of the on-going curriculum revisions. As with K-12 classroom teachers, university instructors need opportunities for professional development to support their learning how to teach science. A module training and mentoring program for the education faculty has been created and is being implemented.

**Maryland Virtual High School**

The MVHS EdGrid Collaborative Team intends to influence the secondary mathematics and science teacher preparation programs in the state of Maryland and beyond by demonstrating that computational modeling and scientific visualization can be incorporated successfully into existing mathematics, science, and teacher preparation courses at community colleges, independent colleges and state universities. Team members, which include college faculty, science and math teachers, and pre-service teachers, are developing and field-testing instructional materials which use modeling and visualization. In-service teachers provide real-world feedback for the materials being developed for pre-service teachers. These modules take advantage of existing computational tools and materials and will incorporate constructivist instructional strategies.

The project has four main objectives. They are to:

- create two-week modules that include modeling and visualization tools as essential components of the module, complete with teacher support materials, student activity materials, and performance assessments, and that encourage higher thinking skill development.
- hold design institutes whose product will be at least one, two-week module each year that will be used in appropriate college courses and K-12 classrooms.
- participate in regional and national workshops to share expertise, ideas and materials.
- foster broad scale dissemination of materials into teacher preparation programs in the state of Maryland and nationally.

**Shodor Education Foundation**

Building on the award-winning courseware, Project Interactivate (http://www.shodor.org/interactivate/), this project has developed additional lesson materials that incorporate computational technology integrated with the content of the middle school mathematics curriculum. These materials are currently indexed to the leading NSF standards-based curricula. Links to each state's specific curricular guidelines will be made. Each campus has identified one or more courses for specific modification to incorporate modeling and visualization to both content and methods courses. Finally, inter-institutional exchanges are supported; faculty from each campus travel to other campuses to
share their experiences and to lend assistance with modeling and technology. The project has three main objectives. They are to:

- create summer institutes for faculty that focus on modeling and visualization in undergraduate curriculum.
- develop curriculum for middle school mathematics education that includes lesson materials, incorporates computational technology with middle school mathematics content, is indexed to standards-based curricula, and provides links to each state’s specific curricular guidelines.
- facilitate and design inter-institutional exchanges for faculty on each campus to lend support and assistance to other faculty and institutions who will spread the reforms across both states.

**SRI International**
Advances in 3D visualization have led to the development of scientific tools that allow complex data sets to be rendered in ways that facilitate the discovery of patterns. Research in education has shown that these tools can be adapted for use by middle and high school students. In the Earth Sciences curriculum at the high school level, California state standards specify that students gain an understanding of Energy in the Earth System: solar radiation, movement of heat, and climate. Each of these areas of Earth Science involve working with data and models. Measured and derived data such as incoming solar energy, carbon release, ocean currents, plant green up, and temperature differences can be displayed and analyzed by students to ask questions for inquiry and understand patterns and models. SRI International has developed TerraAnalysis, a terrain visualization tool that can allow a viewer to discern patterns that are terrain dependent. The visualization being mapped usually represents a variable related to the terrain such as a remotely sensed image, temperature, or vegetation growth.

The project has three main objectives. They are to:

- Develop at least two, online learning modules that show how visualization and modeling can be used for learning.
- Write a “lessons learned” document that describes the barriers and affordances to adoption by preservice teachers.
- Infuse the concepts of modeling and visualization into the existing CalStateTEACH Technology Enhancement Project (CSTEP) in the development of indices to relevant visualization and modeling resources.

**University of Illinois at Urbana-Champaign**
The goal of this project is to develop materials to assist pre-service and in-service secondary mathematics and science teachers to learn to incorporate visualization technology into their teaching, and to integrate mathematics and science. Several faculty members of the College of Education in collaboration with the National Center for Supercomputing Applications are focusing their efforts on developing activities that will prepare teachers to use visualization technology to enhance and extend students’ learning of integrated mathematics and sciences. Teachers can use technology effectively to present information, search for information, keep records and communicate, and such uses of technology by teachers can result in improved student learning. However, the most direct and effective way to bring about enhanced student learning of mathematics/sciences through visualization technology is to prepare teachers to incorporate it into their teaching.

*Setting a Research and Planning Agenda for Computer Modeling in the Pre-College Curriculum* (Final Report: NSF RED-9255877, PIs: Bolt, Beranek, & Newman and Lesley College)
There is little doubt about the ubiquitous nature of technology use in our culture. What has followed is a call to infuse technology within schools as an essential tool to enhance instruction and provide vivid, useful and creative learning experiences. A range of educational organizations such as the CEO Forum, SITE, ISTE, NCATE, and most content specialty associations recommend the use and infusion of technology within teacher preparation programs. Technology offers possibilities for solving "emerging" educational problems, but only if teachers are prepared to use the technology in support of student learning, thinking and problem solving. The Towson University teacher preparation program requires pre-service teacher candidates to become active participants in meeting this challenge. The purpose of this FY2002 PT3 Implementation project entitled, Mentoring to Master Technology Integration Project (MM-TIP), is to enhance teaching and learning through the increased use of technology within the University teacher education program and regional consortium. The University views the appropriate integration of technology as a vehicle to enhance learning and to change the nature of the learning community associated with the University. This mentoring project is centered around three major goals: first, to assist faculty in developing their own skills in using technology; second, to encourage faculty to utilize and integrate those technology skills into their teaching in effective and meaningful ways; and, finally, to model best practices in teaching with technology and to guide pre-service teacher candidates in incorporating technology into their own lesson planning and teaching.

The teacher education program extends across multiple colleges within the university framework, including faculty from the College of Education (COE) at Towson University, the Colleges of Liberal Arts (CLA), and Mathematics and Science (CMS) who teach pre-service teacher candidates in their classes. The members of the regional consortium are from several of the Professional Development Schools (PDS) Network associated with Towson University within two public school systems in the Baltimore area (Baltimore and Howard Counties), and faculty members at Harford Community College, a two-year institution which transfers a large number of teacher education candidates to Towson University each year. In addition, the Towson University Center for Instructional Advancement through Technology (CIAT) and the Center for Technology in Education (at Johns Hopkins University) serve as partners for this project.

The vehicle for infusing technology into teaching and learning in this project is a mentor-protégé staff development model with additional targeted staff development and on-going electronic communications. The keys to success in the FY2000 PT3 Capacity Building grant project were (a) the ongoing work and assistance of a mentor to help each faculty integrate technology into their teaching, (b) a supportive environment for collaboration and learning for each protégé, (c) all faculty involved as protégés were required to use technology in their teaching with a focus of student learning, and, (d) clear and specific rewards for integrating technology into teaching. As a result of that successful project, there is an improved system that supports faculty initiative and innovation with technology. Enthusiastic educators at Towson University and in the Professional Development Schools (PDS) K-12 classrooms are using technology on a regular basis for a variety of activities.

The results of the mentor-protégé model implemented in the FY2000 Capacity Building PT3 project serve as the motivation in extending the focus of that project beyond the original 20 University faculty and 8 PDS K-12 faculty to include the current eight consortium partners. In addition, we have expanded our faculty support efforts by providing an electronic learning community (ELC) for on-going discussion, sharing of best practices, and technical support for the consortium partners.

Our conference presentation will include an overview of the MM-TIP project including its goals and objectives, procedures for developing and monitoring the mentor/protégée partnerships, the framework for moving protégées from learning skills to modeling best practices, and the data collection and evaluation processes. In addition, we will share some of the projects that have been developed by faculty who participated as protégés in the project.
Toward Improving Reflective Practice: An Online Model for Student Teaching

Dr. Martha Jeanne Yanes and Dr. James B. Curts
Department of Curriculum and Instruction
University of Texas-Pan American
United States

yanesm@panam.edu

Abstract: This paper discusses how the University of Texas-Pan American's PT3 Grant program extends the field-based teacher preparation program to include new modes of online communication to improve reflective practice. The formation of action research teams and their online activities are explained. Initial results are discussed and plans for quantitative and qualitative analysis of the interaction process and project effectiveness are presented.

The University of Texas – Pan American (UTPA) is the largest producer of teachers in the State of Texas and graduates more than 1000 teachers annually. The undergraduate teacher preparation program includes a field-based component that comprises 50% of student activity. The program is based in the concept of a Professional Development School as defined by the Sid W. Richardson Foundation. "The Professional Development School borrows heavily from the tested medical model of teaching hospitals, where practitioners, researchers and clinical professors work together to expand the knowledge base of medicine, improve medical services to patients and prepare future practitioners." The ideal outcome of the Professional Development School model is that university faculty, pre-service teachers, teacher intern, and mentor teacher practitioners collaborate in the investigation of learning and instruction, the implementation of effective teaching practices, and the dissemination of their findings. But unlike the teaching hospital, the separation resulting from dispersing interns into area schools isolates the constituents. The task of supervising the growing population of UTPA’s pre-service teachers at multiple sites tended to reduce substantive interactions between university researchers and field practitioners.

A desire to correspond as closely as possible to the Professional School Model led to an analysis of the standing program. During pre-service teacher internships a field supervisor from the field observation office has the primary responsibility to maintain contact with university faculty. Field supervision is an especially time-consuming task given the number of interns and the size of the service area. It was found that little time existed for the field supervisor to consult with university teaching and research faculty and that there was no formalized mechanism to maintain personal contact between interns and professors. The program followed the typical linear model of preparation in which the student moves forward through three distinct phases, from general studies to major and minor studies, and then on to pedagogical preparation. The departmentalization innate to university structure limits opportunity for close collaboration among faculty units to actually follow students through the preparation cycle. The effect is that the three preparation phases appear as "ends" unto themselves. It is assumed that intern teachers engender the theoretical connection from phase-to-phase, into the internship classroom, and finally into professional practice. The communication breaks at the end of each phase do not project a holistic model of successful teaching perceived as a continuum of interaction between content, theoretical and pedagogical knowledge. These thoughts turned attention to the process of reflective practice as an activity that focuses on skills necessary to this desired ongoing interaction.

State teaching standards follow the trend to identify reflective practice (Schon, 1981, 1987) as an essential skill for teachers. Some feel that only a strong foundation in reflective practice supported by a theoretical foundation will adequately equip teachers with the skills that promote the adaptability needed to meet the challenges of changing contemporary classrooms (Norton, 1994). However, there appears to be no agreed-upon definition of the skills that contribute to reflective practice. Students voiced a need to know precisely "what to observe, how to observe, and how to reflect on the information from observations and how do something about the information." It is commonly accepted that the skills for reflective practice are developed through dynamic activities that involve ongoing observation, modification and evaluation of learning. The writers feel that professional interpretation and evaluation of observation data is dependent
not only upon personal creative insight but also upon a connection to theory. Methods associated with action research seem to provide a practical mechanism to connect data from classroom observation to theory as well as provide formats for follow-up activity. Parsons & Brown (2002) state that an "action researcher engages in a process of observing-doing-observing-adjusting and doing again." The writers felt that clear identification of the steps in action research and practice with that process could potentially strengthen teachers' mental models to support reflective practice and sustain professional activity toward ongoing solution of learning problems. "Action research offers teachers and teacher educators an opportunity for individual professional growth through ongoing dialogues with people and texts and an equally important opportunity to create a learning community within a school" (Squire, 1999). Obvious societal factors like rapid globalization, technological, social and economic changes have a dynamic impact on education that demand ongoing professional development among practitioners and researchers. The stated considerations intensified interest to insert an explicit model for reflective practice based in action research that would include experienced faculty researchers in the internship phase of the teacher preparation program. It was determined that to support such a model a means to bridge the physical distance between field interns and university research faculty was needed.

The PT3 Grant provided resources to develop technological skill among pre-service teachers and faculty. Grant activity and also presented the opportunity to explore Web-based communication as a tool to bridge the physical distance between university faculty and field placement sites in the standing teacher preparation model. These investigations stimulated the initiation of the infrastructure for an online learning community to provide a virtual place for collaboration and training. This infrastructure supported the initiation of the online student-teaching component that enables frequent communication between university faculty and mentor-intern teams at remote sites. It is important to state that the new online student teaching activity is an enhancement to the standing successful internship model and not a substitute. The goal of the online component is to strengthen intern teachers' skill in reflective practice through action research activities that extend university researchers' expertise to situate practical theoretical applications in the remote classrooms during the internship phase of preparation. The use of an online environment provided means:

1. To ease communication and consultation among university faculty, mentor teachers and interns separated by distance;
2. To collaborate to conduct action research activities that models skills innate to reflective practice;
3. To affirm the essential relationship between content, theoretical and pedagogical knowledge as the basis for reflective practice;
4. To support development of technological skill and an understanding of technology-supported learning;
5. To encourage technology-supported instructional activity in order to expand possibilities for innovative instructional solutions; and,
6. To demonstrate a broader process for professional consultation that provides example of collaboration empowered by web-based communication.

To implement the online student-teaching component action research teams are formed in the following manner. Questionnaires are distributed to identify mentors, interns and faculty who have expressed interest in technology-supported learning. Once identified, a faculty content specialist from a teaching discipline is teamed with a COE faculty. They are then matched with five mentor-intern teams that have expressed specific interest in learning issues related to faculties' research agenda. The criteria for participation are that team members must have a genuine interest in collaborative research and demonstrate willingness to develop necessary technology skills. Targeted technological skills include use of Web browsers, email, uploading and downloading documents, file transfer protocols, online library resources, Internet search engines, discussion boards, chat, video conferencing, and instructional design procedures. Support systems provided by the PT3 project include the Web-based infrastructure, individualized just-in-time technical assistance from PT3 staff, consultation with an instructional designer, and online tutorials. Additionally, each intern-mentor team is issued a laptop equipped with a wireless modem to assure capability and ease of Web access. To maintain consistency with the approach of the UTPA PT3 Grant, that technology is best learned when it becomes a tool for learning, explicit instruction in the use of technology is embedded as team activities indicate need. The PT3 Instructional Developer
handles the daily activities necessary to mediate the online environment. The PT3 co-directors and Instructional Developer survey team activities to insure that team needs are met in a timely manner.

Once activated, the comprised team follows an agreed-upon routine common to action research: observe, identify a learning issue for treatment, research, analyze, design instructional treatment, apply, evaluate student performance, assess effectiveness, and report findings. All team communication takes place in a private space provided within a Web-based environment called the Electronic Learning Community (ELC). By substituting online communication for physical meetings at remote sites, time spent for team collaboration ranges from one to three hours per week for an eight-week period during the internship. An eight-week period is specified to contain the activities within a practical time period that allows the teacher intern the opportunity to realize all the steps of the research project and to participate in authoring the final report. Varied online technologies support communication, email, file transfer protocols, video conferencing, etc., so that faculty members can virtually join the mentor and intern in an analysis of the content covered at the placement site during the internship.

The team begins collaboration through online discussions about the content to be covered at the placement site in order to identify a learning issue relevant to the instructional setting and of interest to faculty. When an issue is identified, they develop a research agenda that includes a timeline for observations and investigations. The analysis of observation data and research findings assists the team to develop a hypothesis and a plan for instructional treatment. In the case of this project, at least one technology-based instructional activity must be included in the plan. The PT3 instructional developer is available to assist the team with instructional design processes and the creation of the technology-based lesson. Teaching strategies and lesson activities derived from the analysis and design are applied in the classroom. Data regarding student response and performance during the instructional treatment is recorded according to agreed upon protocols. Video of actual student activity is recorded and field supervisors also provide valuable on-site observations. The team analyzes the recorded results to evaluate the effectiveness of the instructional treatment. Finally, a report of team activity and findings is collaboratively authored, and posted to the public area of the ELC. The video is included with the analysis so that other teachers can view the authentic examples as well as access the theoretical and instructional design information.

The end products of the online student-teaching component are; a demonstration of action research skills to support reflective practice, a higher technology skill level among participants and a growing archive of best teaching practices. The project report and video become part of faculty’s research information and are also included in the teacher intern’s electronic portfolio.

Important to implementation of any change is the stakeholders’ motivation to participate. That motivation is dependent upon perceived benefits. By using Web-based communication to eliminate the time-consuming travel to field sites the online student-teaching component appears to comprise significant benefit to all stakeholders in the following ways:

1. It establishes and strengthens the professional relationships among collaborating members.
2. Content and pedagogical experts acquire a closer connection to the real classroom.
3. The action research model provides the interns and mentors with a clearly defined format for reflective practice that reinforces the relationship between theory and practice.
4. The results provide faculty with ongoing access to practitioners and field data not readily accessible through traditional means.
5. The mentor teacher, intern and field supervisor have access to content and research expertise when developing instructional activities.
6. All participants improve technological skills while using technology to learn about learning and to enhance instructional treatment.
7. A growing online archive of best-teaching practices is available to other researchers and practitioners.

Another implicit goal of the online student-teaching component is that participation in the online learning community will be extended beyond the internship period. Reports from beginning teachers that relate a feeling of isolation compel interest in providing formats for broader communication models. With this in mind, the online student-teaching component presents Web-based communication as an activity that can easily be extended into professional life. Though at this writing the online student-teaching component is in the first semester of implementation, it does demonstrate potential to benefit team members and the larger teaching community by providing a precise model for reflective practice that demonstrates a process for continued collaboration and professional growth. Formal assessment of the project includes both quantitative and qualitative evaluations. The following records are maintained; team logs to measure time
input, records of training, frequency and type of technical assistance; and questionnaires to measure participants satisfaction. A count and evaluation of final reports and archived examples will be conducted at the end of the semester. Surveys to measure continued use by participating intern teachers of the online community are planned during their first year of professional practice. These studies and resulting best practice archives will provide data to assess the overall effectiveness of the project.

Student Teachers Supported by Technology

Elizabeth Years
School of Education
St. Bonaventure University
United States
yearscsl@sbu.edu

Student Teaching Technology Sites (STTS) are student teaching placements that are equipped with a media cart. On the media cart is a laptop, projector, scanner, digital microscope, printer, and digital camera. Each laptop is ready to run HyperStudio, Inspiration, Timeliner, PowerPoint, and more. It is very simple to install other software. The Friedsam Library on campus at St. Bonaventure University has an extensive software collection, and STTS sites are located within a reasonable distance from campus—so borrowing software is not difficult.

The STTS student teachers are required to incorporate technology into their lessons as much as possible, but there is not a required number of times to use technology per placement. The student teacher's goal should be to have the students use as much technology as possible in the classroom.

The STTS program offers a great deal to everyone involved. First, teachers in the student teaching placements must have an interest in taking a student teacher who will be working and incorporating technology. It is beneficial to the cooperating teacher because he or she will learn from the student teacher how to incorporate technology into lessons.

The students benefit from this experience because they are presented with more technology, and they have the opportunity to become actively involved with technology. In my student teaching experience, the students used Microsoft Word, Inspiration, PowerPoint, National Inspirer, Short Vowel software, Story Maker Deluxe, and a digital camera. The students are excited about having a media cart in the classroom, and they are eager to get involved in the lessons when technology is being used.

The student teacher benefits from STTS because she has more access to technology as a result of the equipment provided with the university's PT3 grant. The student teacher learns right along with the students. The student teacher also has the opportunity to see her students become engaged in an interesting lesson. Another benefit is being closer to campus, which means a shorter drive (a real advantage in rural NY where some student teachers must drive up to an hour each way)!

In my personal experience as a student teacher, I have learned that it is harder than it looks to fit everything planned into one day. Using technology requires more time in terms of planning and class time. It takes dedication to teaching and technology to be a part of STTS. For example, in my third grade placement I presented a slide show, on Monarch butterflies, using PowerPoint to the students. After doing their own research on different aspects of the Monarch the students, in pairs, created their own slide. We compiled the slides together and the students presented their work. This took a fair amount of planning on my part, as well as class time. However, it was well worth it, as the students gained something from this lesson. The students were so proud of their own work, but they were also eager to discover what their peers had to present. The day following the students' presentation, the daily journal prompt was “I learned Monarch butterflies...” It was incredible to see how much the students got out of a PowerPoint slide show. Students who had never become engaged did this time. This was a very rewarding experience for a student teacher.

In some cases it does take a lot of preparation to use technology in the classroom. However, some times it takes little preparation at all. For example, in a third grade class I was reviewing short vowel sounds. I used Short Vowel software as an anticipatory set. The students were eager to use the laptop and projector in the classroom. Each student had the opportunity to come up to the laptop, call on a peer, and use the mouse to categorize objects according to the short vowel sounds in the objects’ name. In this
situation, the prep time for this activity was very short. To prepare for this anticipatory set I had to obtain the software from the library and download it onto the laptop.

Another wonderful way to incorporate technology into the classroom is by using the Internet. I use the Internet frequently when writing lesson plans; there are wonderful ideas for teachers on the Internet. Even more importantly I encourage my students to use the Internet as a resource. When completing a reading unit on discovery I took my fifth grade class to the computer lab to research a place they would like to “discover”. The places ranged from Colorado to the Bahamas. The students were given a short time to learn something about their place using the Internet. They were allowed to print one page of information. Next, the students had to practice their public speaking skills and present one interesting fact that they “discovered” about the place to the class. This lesson was very easy to plan and it encouraged students to use technology as a resource.

One of the most incredible pieces of technology we are provided with at STTS is a digital camera. When teaching a lesson on Descriptive writing in fifth grade, the student had to work in groups to create a list describing the Oreo and how to take it apart. Each student was given an Oreo to manipulate. I took pictures of the students completing the activity. The following day the students were required to take their list and put it into paragraph form. Before giving the second half of this assignment I felt it was important to review Descriptive writing. I created a PowerPoint presentation that included the steps to writing a descriptive piece and the pictures of the students working with the Oreos the previous day. The students were so excited to see their peers working together. I had their full attention during the presentation. The pictures of the students working in cooperative groups are beneficial to me because I am able to import the pictures into my electronic portfolio.

The pictures taken while the students are learning may also be used in a classroom newsletter that may be sent home to the parents. My cooperating teacher was eager to learn how to import pictures taken with the digital camera into Word documents. We used several pictures from a variety of lessons that I taught to be in the newsletter sent home. It really helps parents to see that their children are constructing their knowledge and interacting with one another.

Students are also able to use the digital camera. The camera conveniently comes with a strap to hang the camera around the neck. In both third and fifth grade the students in my classes were able to use the digital camera confidently. In third grade the students took pictures of one another to display on a bulletin board for open house. In fifth grade the students wrote and typed their goals. On the final copy of their goals they took pictures of one another to import into a Word document. These were also put on display. In both situations the students were able to learn from one another and demonstrate their ability to use the digital camera.

I realized that it is a little easier to do more with older students with technology. They are able to use a word processor fairly quickly. When using Inspiration with fifth graders, I was able to pick a “student helper” to guide students at the laptop. In my third grade experience using Inspiration, I had to be there to guide the students at the computer.

Overall, being a student teacher in an STTS has been a wonderful experience. I feel more prepared to use technology in the classroom. However, it has been a realistic experience for me as well. Even though it has been a good experience for me, I am confident that it has been a learning experience for the children too, and that is what is most important.
Using technology to teach reading and writing is exciting, challenging, and rewarding. Discovering and learning to use new pieces of technology and new software programs is an ongoing endeavor. Even more challenging is creating software to meet students' needs. Exploring ways to use technology to effectively enhance literacy instruction is also time consuming. Undaunted by these challenges the authors of these papers share the ways they use technology in their teaching. Papers include discussions of methods courses developed for preservice teachers, ways to use the Internet in methods courses, how to integrate technology in English as a second language instruction and English as a foreign language instruction, and ideas for using technology to teach writing.

Liu's paper describes the development and implementation of a course designed to prepare students to teach reading using technology. Students learn to use a variety of technologies, to evaluate software packages, to examine web resources, and to design reading instruction that incorporate appropriate technologies and software. Baker writes about her experiences using case-based instruction and field experiences in a block of literacy courses. Students perceive that these activities help them grow as literacy teachers.

Language arts teacher candidates working with Marquez-Zenkov and Hamon participated in a unique methods course centered on the proposed renovations of public schools in their area. Students combined technology and language arts as they interviewed constituents, researched the topic, and wrote reports using a course web site for online peer editing. An introduction to WebQuests was included in the course. Teacher candidates in Kimbell-Lopez's reading methods class developed WebQuests. Her students discovered that imbedded within their WebQuests were a number of reading/language arts processes. Students in these methods classes learned how to incorporate authentic learning opportunities into their classroom teaching.

Several papers in this section provide descriptions of ways to combine technology and writing. O'Donoghue writes about critical issues involved in the integration of technology in writing programs and offers ideas for addressing these issues. Skillen's article describes Journal Zone an online environment that includes journal writing, collaboration, and cognitive scaffolding. Costa and Maraschin describe how students in an English as a foreign language class are using EquaText, a web-based collaborative writing tool.

Marquez-Chisholm combines Multiple Intelligences Theory, the language objectives from the ESL Standards for PreK-12 Students, and technology. This interactive session will allow participants to experience a multi-disciplinary lesson. Illera's interactive session will demonstrate how to use Lektor for creating and reading electronic books. Nexos, a language portal for cultural learning and collaboration for teachers and learners of Spanish, will be presented by Hellebrandt during an interactive session.

This is a brief introduction to the many interesting papers included in this section. They describe challenging projects and discuss intriguing topics related to reading, language arts, literacy, and foreign language learning. These papers challenge readers to critically examine them, to discover new ideas to use in their own classrooms, and to contact the authors for additional information.
PT3 Facilitates Technology Use in Preservice Teacher Reading Courses

Abstract: Two doctoral candidates majoring in reading education at the University of North Texas developed technology related literacy activities for their preservice reading education courses. These activities were designed to show the place technology has in the language arts curriculum by facilitating the acquisition of literacy skills related to reading and writing. The response of the preservice teachers to the activities featuring technology integration was overwhelmingly positive. Through funding from PT3 grants, new activities are being developed to complement coursework and preservice teachers are being introduced to new technologies as they become available.

Many new and exciting opportunities for teaching reading and writing skills exist for teachers who integrate technology into their language arts curriculum. Preservice teachers at the University of North Texas were able to experience technology integration into language arts methods courses through the efforts of two teaching fellows.

Teaching Reading K-12 is an introductory reading course that is required of all students in the college of education at the University of North Texas. It covers a variety of topics that include knowledge of the reading process, stages of reading and writing development, techniques for teaching reading skills, and an overview of reading assessment. It is a prerequisite of the second course, Assessment in Reading. Assessment of Reading is required for all preservice teachers specializing in elementary education. This course is designed to teach students how to perform reading assessments and provide remedial recommendations for elementary grade students. These preservice teachers assess and tutor children each week.

During the first week of courses, instructions were given to the preservice teachers enrolled in both courses describing how to obtain a free email account provided for all students by the university. Email addresses were collected; a list was created, and then given to the members of each class.

The preservice teachers enrolled in Teaching Reading K-12 met in a computer classroom on February 2. Small groups of students who were not yet comfortable searching the World Wide Web were lead by a peer who was experienced in web searches. After a brief demonstration, the preservice teachers were asked to find resources related to Ground Hog Day and Valentine's Day that could be used in teaching language arts. The class later met in the computer education classroom to learn how to make word puzzles (see http://puzzlemaker.school.discovery.com/). The students were assigned vocabulary words from their textbook and asked to bring short definitions to class in order to be ready to create puzzles. After they finished constructing the puzzles, the instructor made copies for all the students to help them learn the required vocabulary for the course.

PowerPoint presentations were used in both courses to highlight important points in textbook chapters and lectures. The preservice teachers were first attracted by its bright colors and with the ease of which they could see the presentations projected onto the screen by the LCD panel. The students soon began to appreciate other features of PowerPoint, most notably the handouts that could be easily produced for their use. Their comments included, "It saves time in class in not having to write everything" and that it facilitated class discussion because they did not have to concentrate on taking notes. After being viewed in class, the presentations were posted on the course website in HTML and downloadable format for future reference.
Teaching Reading K-12 again met in the computer classroom. They were divided into small groups and taught how to create their own PowerPoint presentations. Each group was given a section of a chapter in their textbook, and in a collaborative effort, the group members designed their own slide show presentations and presented them to their classmates. The students found this activity "helpful" and some felt that they became "more familiar with the chapter."

The preservice teachers were asked at the end of the semester how they might use PowerPoint in their future classrooms. Their ideas covered a broader scope of uses than those they had seen modeled in the reading courses. The ideas given could be divided into two types, those for teacher use and those for children's use. Among the suggestions for teacher use were presentations covering dental care, fire safety, stranger-danger, and other topics that are routinely taught in elementary school classrooms. One student felt that PowerPoint presentations would be useful when used in conjunction with content area textbooks that often prove difficult for beginning readers. Another strength mentioned was its ability to "stimulate visual learners."

The majority of the preservice teachers could foresee uses for PowerPoint as a tool in the hands of their future students. Several believed that PowerPoint should be made available in the writing center in the classroom. Book reports and other types of information gathered by students could be presented to their peers via slide show presentations. Since PowerPoint is user friendly, they felt that even young children could create presentations and would enjoy illustrating their work with graphics. One preservice teacher elaborated on this activity by stating, "Filling up a PowerPoint (and adding pictures) would be less intimidating than having to fill an 8 1/2 x 11 page" for a young child.

An email exchange between the preservice teachers in Teaching Reading K-12 and those in Assessment in Reading was planned by the instructors as a way to demonstrate to their students the value of classroom communication with those who have knowledge that is beneficial in some way and how having e-pals could be a way to motivate children to refine their reading and writing skills. Reading assessment was the last major topic covered in Teaching Reading K-12 and the timing of the email exchange was planned to correspond with that topic.

The majority of the preservice teachers in Teaching Reading K-12 were curious to learn how the content they were learning was applied in a real teaching situation. Since most of the preservice teachers in Teaching Reading K-12 would be required to take Assessment in Reading, they considered the email exchange an opportunity to learn more about the course and its requirements. The instructors monitored the exchange by requiring each email to be carbon copied to them in order for the students to receive participation points.

Comments by the preservice teachers provided positive feedback on the e-pal exchange. The students in Teaching Reading K-12 gave the following responses: "It was neat to be able to talk with people who are further along than I am in their degree plan. It made me look forward to Assessment in Reading", "It was good because it helped tie in what we are learning now to real life as the Assessment in Reading students are experiencing it," and "It was great! It should have been done throughout the whole year."

Preservice teachers in the Assessment of Reading course found themselves in the role of teacher as is illustrated by the following comments, "This was a good experience for me. We tend to learn better when we have to explain to someone else answers to questions. It provided a way to reflect on our own learning about assessment this semester," "I really liked the email discussions. I found it useful to review the information discussed in class. I think it would be good to have the email discussions throughout the entire semester," and "I thought that the E-mail exchange was fun - because I got to play 'the teacher'. It forced me to think broadly about concepts in child development and literacy."

After the email exchange between the two courses was completed, the students were asked to comment on how they might use an email exchange in their future classes. The comments included "I would use this to have young students talk about a certain book", "I think children of all ages would like to email kids from other schools, states, or countries and learn about each other and where they are from."

The university received a PT3 grant and the instructor received a laptop for use in integrating technology into her reading course. A listserv is used each semester to keep the preservice teachers in close contact as they assess and tutor children. It promotes the exchange ideas and allows the preservice teachers to provide support for each other between class meetings. Funding from PT3 was used to purchase digital cameras for preservice teacher use and this new technology resulted in an assignment change. Previously, students had used PowerPoint for presenting chapters in textbook or article summaries. Now they are able to give presentations that feature the highlights of their tutoring sessions and are able to include pictures of projects their students have completed as well as pictures of themselves working with their students. This has become a favorite show and tell activity at end of each semester.
Abstract: The concept of virtual teams is relatively new. However, a virtual team, like any other team, progress through various stages of development and is dependent upon the clarity with which performance outcomes and goals are communicated for achieving success. This presentation focuses on the analysis of the transcripts of on-line meetings of a PT3 virtual team composed of subject area team leaders and project administrators. The lessons learned from this experience helped develop an understanding of the role that clear communication and trust play in building bridges across the digital divide. Lessons from practice will include Internet Field Trips.

The St. Thomas University Plan to Bridge the Digital Divide in South Florida

A consortium of schools with St. Thomas University in Miami, Florida as the lead partner was awarded a PT3 Capacity Building grant during the first year of the PT3 program. The teacher education program at St. Thomas University serves students of many ethnic groups. It is located in an urban area with a large African American population along with immigrants from many Hispanic countries and the Caribbean.

The purpose of the initial grant was to work with area elementary schools, such as Welleby Elementary, to train the pre-service teachers at St. Thomas University and Trinity International University to use computers effectively in classroom instruction and
thereby impact the diverse students in Miami-Dade County. The grant sought to train teachers who will not only teach in the inner city schools but stay in the inner city schools. By serving pre-service teachers who represent these underserved populations, the program sought to impact inner city classroom instruction.

What Has This Program Accomplished?
All of the program objectives were met in the first year and a three-year PT3 Implementation Grant was awarded the following year with more partners, including Florida Gulf Coast University and Golden Glades Elementary. The purpose of the Implementation grant changed the focus from the pre-service teachers to a team of professors, pre-service teachers, and K-6 teachers. It became apparent that, in order to effect systemic change, it was essential to train the professors. It was also essential that practicing K-6 teachers become an integral part of the process. Golden Glades Elementary, located several blocks from St. Thomas University, is a school with a student population that is completely either African American or Black American from the Caribbean. Florida Gulf Coast University is the newest Florida State University located on the West Coast of Florida and equipped with the latest technology in each college classroom.

How Did the Virtual Teams Work Together?
Subject area teams of professors, pre-service teachers, and K-6 teachers were formed. The teams focused on Math, Science, Reading/Language Arts, Social Studies, Exceptional Student Education, Curriculum, General Methods, and English as a Second Language. The focus on ESOL is important in Miami-Dade County because all teachers who are hired must also be certified to teach ESOL because of the large number of immigrant children attending school in Miami-Dade County.

During the first year, each team communicated on-line weekly. They met to discuss both successes and failures in their attempts to integrate technology into their classes. They also completed 50 hours of professional development in technology. In the second year, they worked together as a team to write and field test technology integrated lessons. It was determined that the convergence of learning that takes place in the classroom can be written in detail through lesson planning. The professors and pre-service teachers would begin their attempts to integrate technology into the curriculum with written lesson plans. With assistance from a new partner, BEACON, which hosts an on-line database of lessons, from Bay County, Florida, the professors and pre-service teachers worked together to write lessons that are field tested in the K-6 teacher’s classrooms. In this process of working together, the professors and pre-service teachers learned about the technology available in the partner schools and the classroom conditions such as class size, high stakes testing pressures, and behavior management concerns that they need to consider as they write their lessons.

How Important is Technology Support?
The participants in this program have benefited from expert technology support. The support they have received seeks to decrease reliance on outside sources by empowering the participants to do things for themselves. The effort will be sustained when the federal funding ends as the participants learn enough about technology to be
self-sufficient. Instead of the technology support specialist holding the mouse while others stand amazed, the learner maintains control of the mouse. The process is similar to learning how to drive. The technology support specialist is there to assist and direct, but encourages the learner to take charge.

Why is it Important to form a Collaborative?

The fact that this grant is applied for and awarded as a collaborative can serve to strengthen the work effort and bridge the digital divide. In the first year of Implementation, a cost share crisis developed for the collaborative at St. Thomas University. Two of the original partners, Trinity International University and The 21st Century Teacher’s Network, dropped out of the program; their cost share commitment was lost. St. Thomas University also had a problem with resources whereby they were not able to meet the cost share they had committed. Because the PT3 program requires a matching commitment of funds, officials at St. Thomas University temporarily suspended the grant program until documentation of cost share could be established. This was where the title of the grant, “Bridging the Digital Divide in South Florida,” became the reality of what happened. Representatives from Florida Gulf Coast University were able to supply the missing cost share. Other partners responded in the same way and contributed more then they had committed in the grant application. In this way, the digital divide was bridged because those on one side of the digital divide were able to rely on their partners to help them in a time of need.

On-Line Presence

Information about our project may be viewed at: http://garnet.fgcu.edu. To view these discussions, one may register for the PT3 Fall and/or spring courses and create an identity. Once this is done, posting will be enabled for the viewer. Our website also contains information that documents our workshop activities with our partners. Our website is located at: http://coe.fgcu.edu/PT3/home.htm.

Case Study: Internet Field Trips with Dr. Joseph Furner

Internet Field Trips in Mathematics are exciting. There is a need for technology use in mathematics teaching. This is emphasized in the National Council of Teachers of Mathematics Standards. There is a wealth of websites available for teaching math concepts using the Internet. Dr. Joseph Furner from Florida Atlantic University has participated on the Math team. His role as professor and lesson author has enabled him to produce lessons that can be used by his future teachers. He will present some sample lessons he has written with websites that are available on BEACON at www.beaconlc.org.

National Educational Technology Standard-Based Lesson Plans Are Written

The technology enhanced lesson plans for the Fall 2001 Semester are written and can be viewed on the BEACON database. The website for BEACON is www.beaconlc.org. Selected lessons will be shown at this session.
Teaching Teachers How to Reach the Reluctant Reader Through Multimedia
(When Theory-to-Practice Hits the Wall)

Lawrence Baines, College of Education, Texas Tech University, USA, lawrence.baines@ttu.edu
Peggie Price, College of Education, Texas Tech University, USA, peggie.price@ttu.edu

Abstract: During fall 2001, a cohort of prospective teachers worked with reluctant readers (students who are at least two grade levels behind in reading proficiency) in local schools. These prospective teachers experimented with traditional reading strategies as well as some promising, new multimedia approaches with the goal of enhancing the reading and writing skills of reluctant readers. Although these graduate students were knowledgeable and enthusiastic about multimedia approaches, they found classroom environments in local schools hostile to technology. In general, classrooms lacked any sort of technological infrastructure, teachers exhibited openly negative attitudes towards technology, and there was no support for innovative approaches to teaching reluctant readers. Surprisingly, half of the cooperating teachers were philosophically opposed to individualization, and forbade students from working with reluctant readers at all.

Traditional approaches to enhancing the writing, reading, and thinking skills of adolescent reluctant readers have been drawn from research with young children. Elements from programs such as Reading Recovery (Sensenbaugh, 1994) and Success for All (Slavin & Moore 2000) have been adapted to serve the burgeoning population of illiterate and illiterate American teenagers. According to recent results from the National Assessment of Educational Progress (Greenwald, Persky, Campbell, & Mazzeo 1999), less than 20% of American teens are able to write proficiently or better. Millions of children cannot understand or correctly interpret written materials at an elementary level and may be classified as functionally illiterate (Kaestle, Campbell, Finn, Johnson, & Mickulecky 2001).

Stanovich (2000) and Alverman & Moore (1991) have noted the deleterious presence of Mathew Effects in adolescents. In many ways, reading is an intellectual multiplier. The more students read, the larger their vocabularies become, and the more proficient they become as readers. Likewise, when students rarely read, their skills deteriorate, especially as the level of difficulty with texts escalates as they matriculate through secondary school. So, an ineffective reader in second grade may likely become a non-reader by tenth grade.

Popular, traditional techniques for reluctant adolescent readers include K-W-L (in which the student writes all that he/she knows about a subject, what he/she might want to know, and what they eventually learned), Think-Pair-Share, reading aloud, repetitive reading, vocabulary enhancement strategies such as semantic feature analysis, guided reading, and structured free reading.

Among the most successful adapters of such strategies are the teachers at the Benchmark School in Pennsylvania, a school expressly designed for students who read two or more grade levels behind their peers. Benchmark uses a rigorous, structured learning environment that emphasizes goal-setting, repetition, phonics, choral reading, extensive reading at and below grade level in a variety of genres, and much intensive, one-on-one instruction. If all goes well, after several years of work, students eventually begin to read at or above grade level (Gaskins 1997).

Some researchers (Babbitt & Byrne 2000, Crowley 1995, and McBride 1999) have suggested that problems of self-esteem and self-efficacy, not reading comprehension, are as likely to contribute to poor reading performance as more intellectual causes. Such researchers usually advocate discovering student strengths and interests and using them as springboards to spur interest and achievement in reading.

Elementary schools have been at the forefront in adopting programs which allow students to choose reading materials in their areas of interest. Programs such as DEAR (drop everything and read) and Accelerated Reader require that students be allowed to self-select books and mandate time for free reading during the school day. However, with these programs, teachers usually organize, manage, and chart the books that have been read rather
than help provide remedial instruction for students who have difficulties with the act of reading. Still, Davies and Beaucamps (1999) found evidence that when programs such as AR and DEAR are adapted for use in secondary school, overall reading achievement among participants has improved.

Recently, Baines (1997, 1999, 2000, 2001) has reported impressive results from utilizing multimedia to enhance students’ reading comprehension and writing skills. According to Baines, electronic media help concretize thoughts and feelings so reading and writing become less daunting to reluctant readers. When a teacher uses images, music, and other non-linguistic stimuli as integral components in reading and writing, the quality of student engagement and achievement have been shown to take dramatic leaps. In a recent study of 12 reluctant readers who had previously failed a state competency test for writing, using multimedia techniques resulted in a 100% pass rate on the second administration of the state exam (Baines 1999).

One example of the multimedia approach is the Powerpoint poem, in which students begin by responding to a series of prompts. Student responses are revised into a poem. Then, students draw images or find and cut out images in magazines to correspond with every line in the poem. Next, students scan the images onto disk. Once images for each line of the poem have been scanned, students create a presentation, downloading the images into Powerpoint, typing out the appropriate text so that each Powerpoint slide represents one line of the poem, and adding sound effects and music. As a final step, students revise their original poems to include descriptions of the images and music.

Classroom Instruction and Field Experience

Most preservice and practicing secondary teachers never have had a course in reading nor do they perceive the teaching of reading to be within the domain of their job responsibilities. When confronted with a non-reader in the classroom, most secondary teachers would respond, “I’m a science teacher (or whatever their field of expertise), not a reading teacher!” (Lortie 1975; Price, Schultz, & Verdi 2001). To ameliorate the lack of training for secondary teachers in reading, a new graduate course was developed.

The new graduate course, required of graduate students also seeking teacher certification, covers a variety of approaches to helping the adolescent reluctant reader, including technologically-intensive approaches. Of the ten graduate students enrolled in the initial offering of the course, only one had any previous experience with using computers. (The student with some experience had a spouse who worked for the Public Broadcasting System and she had helped with editing a film once). Prior to the course, no student had used Powerpoint or created a webpage. Only half had ever used email. Of the ten, four were seeking certification in social studies, three in English, two in mathematics, and one in Spanish.

In addition to time spent on campus, the ten graduate students were required to work with a struggling reader in a local school for at least 40 hours during the course of the semester. As part of their coursework, students created films (many used I-movie), Powerpoint presentations, and webpages explicitly for use in their interactions with reluctant readers in the field experience. In their one-on-one interactions with reluctant readers, students were instructed to use both traditional and multimedia approaches, to document the effectiveness of all approaches that they tried, and to write up a case study depicting their successes, failures, and frustrations.

Cooperating teachers were alerted to the duties of the student and the contours of their assignment via a letter of introduction. The cooperating teachers were responsible for matching the student with a reluctant reader. At the end of the term, cooperating teachers were asked to complete an assessment of the student’s attendance, progress, and professionalism.

Results of the Hypothetical Case Study

As part of their final exams, students were given a hypothetical case study depicting the plight of two tenth grade football players named Augie and Javier who tended to misbehave and whose achievement tests indicated that they read on the third grade level. As in the field experience, students were asked to devise a set of lessons and activities
that would help improve the reading and writing skills of Augie and Javier, who were failing badly in most of their classes.

In the hypothetical case study, 8 of 10 students chose both traditional and multimedia approaches. The most popular traditional approaches included K-W-L, allowing students to self-select books (through programs such as Accelerated Reader or DEAR), learning logs, goal-setting, and utilizing reading recovery. K-W-L and other traditional approaches were seen as "innovative" by students, who had little familiarity with such pedagogical techniques. The most popular multimedia approaches included using Powerpoint, the Internet, film, and the creation of a webpage describing favorite books and magazines.

Table 1: Student use of traditional and multimedia approaches in the hypothetical case study

Although the final exam did not ask students to expressly address it, most students also paid great heed to affective issues:

"Knowing that Javier has a violent temper, I would first make sure that the class as a whole is constantly kept busy so that all students would have less time to engage in unwanted behavior."

"To improve their knowledge of English, I would try to draw on their strengths as much as possible in order to increase their sense of self-efficacy, which appears to be very low."

"A probable cause for their continued classroom disruptions is their inability to read and to comprehend text."

Obviously, most students in the graduate course viewed teaching from an affective perspective, a view Schwartz (1987) has called the "missionary mythology" of teaching. In their position as inexperienced teachers, especially the area of reading diagnostics, their prescriptive solutions indicated affective rather than cognitive concerns. In explaining how multimedia might be used to enhance reading, students wrote:

"If Augie liked baseball, I might ask him to do a Powerpoint presentation over the beginnings of baseball. Who were the important people and what were the names of the teams? Are any of the teams still around? One book that would help Augie is A History of America's Game."

"I would have Javier and Augie collect pictures and find music to accompany a Powerpoint poem written about football."

"To teach Augie and Javier Spanish, I would use a bouncy audio tape which combines the capitals of South America with lots of percussion, clips from Walt Disney videos in Spanish...perhaps involve them in designing a website if there's any interest in computers."

Two students chose not to even try multimedia approaches, even in the case study.

**Hitting the Wall**

Students were required to complete 40 hours of work with a reluctant reader in a local school. In general, the response from cooperating teachers to having a graduate student in the classroom was not overly enthusiastic. In Texas, where an obsession with student performance on the state assessment (TAAS—Texas Assessment of Academic Skills) is de rigueur, half of the cooperating teachers (five of ten) forbade graduate students from working one-on-one with an individual student. Representative of the attitude of "not singling out students" was a cooperating teacher who wrote, "When you ask your class to work with only one student, that student's self-esteem is damaged. Everyone in class will know who needs the help. That humiliates the student."
On the other hand, in the case studies of the five students who were allowed to work individually with reluctant readers, most registered surprise by the willingness of reluctant readers to participate. Representative responses from graduate students about how well they were received are as follows:

“Sam and Terry were relegated to a permanent seat in the hall so they wouldn’t disrupt class. Although I figured that I would meet with great resistance, they seemed anxious to participate. Even giddy sometimes.”

“Delanie told me, ‘I think it is fun when you come hang out in my classroom!’ That made me feel pretty good.”

“Bill plays sports and hasn’t been doing well at all in most of his courses. So, in addition to helping him in class, I have shown up at a couple of his games. As a result, he has started pulling up his grades and his attitude seems to have changed.

Despite the apparent successes of the five graduate students who were allowed to work individually with reluctant readers, no graduate student used any multimedia approaches. Although the school district had recently received millions of dollars in funding for technology, graduate students noted the dearth of equipment in the classroom designated for student use. Not only did none of the ten cooperating teachers use technology in instruction (a computer, a camcorder, or anything electronic beyond a transparency machine) at any point during the semester, seven advocated against the use of technology in teaching. Student responses included the following:

“Mrs. Paulito says that teaching is too complicated already, that throwing technology in won’t improve student learning. She seems too busy with the TAAS and discipline problems to think about much else.”

“When I asked Mr. Suarez why he doesn’t use technology, he laughed. He said that the district tried to force them to use computers once, but that they backed off because he knew they couldn’t enforce it.”

Although students learned the multimedia approaches and even applied them in the hypothetical case studies, they viewed the classroom environment as antithetical to innovation. No students used multimedia in their field experience. One student adapted the Powerpoint poem so that it could be done by using construction paper (with each line of the poem and corresponding images pasted on separate pieces of paper) and a cassette player.

Providing Help Where Help is Needed

Although multimedia approaches to teaching reading to reluctant readers are new, exciting, and powerful, several factors militated against their successful implementation in our study. In general, cooperating teachers perceived that any technologically-intensive form of instruction added unnecessary complications to their lessons, thus making them feel more “stressed out.” Also, cooperating teachers acknowledged that they lacked the appropriate technological infrastructure and training to use multimedia approaches effectively, though they didn’t really want equipment or training. One teacher commented, “I have enough to do already without worrying about computers, too!”

On the bright side, despite their initial lack of technological expertise, the graduate students in the new course seemed willing and able to implement multimedia approaches had they had access to the appropriate technologies and a modicum of support from their cooperating teachers. However, with the strong bias against technology openly displayed by cooperating teachers, many of the graduate students came away from the experience questioning the feasibility of implementing multimedia approaches at all.

The most surprising finding from our study was the reticence of cooperating teachers to allow any individualization for reluctant readers. Although each teacher acknowledged that they had several poor readers and that poor readers
were the most likely to fail the course, they forbade 1-on-1 contact, usually on the grounds that such individual attention would likely endanger a student's self esteem. Yet, graduate students reported reluctant readers as open, even anxious to receive personal attention. In the five cases in which cooperating teachers allowed graduate students to help individual students, all five reported some degree of success using traditional approaches. One can only wonder how reluctant readers, who have always struggled with text, can be expected to suddenly transform themselves into accomplished readers without some guidance and direction. Paradoxically, it is the reluctant readers who are the farthest behind who could most benefit from the kinds of jumps in reading and writing competence possible through new multimedia approaches. In our study, these most reluctant of readers were the ones least likely to receive such instruction.

Can Preservice Teacher Education Really Help Me Grow As A Literacy Teacher?: Examining Preservice Teachers’ Perceptions Of Multimedia Case-Based Instruction

Elizabeth A. (Betsy) Baker, University of Missouri - Columbia, US

PURPOSE
In 1985, Feiman-Nemser and Buchmann reported evidence that teachers overwhelmingly perceived that their preservice education did not adequately prepare them to be teachers. Since that time, teacher education programs have made purposeful strides toward improving preservice teacher education. For example, instead of providing student teaching as the only clinical experience, most programs now provide field experiences throughout teacher preparation.

Case-based instruction (CBI) is being used successfully in several professional schools (see Christensen, Garvin, & Sweet, 1991; Merseth, 1997; Shulman, 1992; Silverman & Welty, 1992). Risko and Kinzer (1994) argue that CBI can address weaknesses commonly found in teacher education (see also Lundeberg, Levin, & Harrington, 1999). A variety of cases have been used in teacher education. However, they commonly focus on the teacher, not the students. We wanted to help preservice teachers develop their kidwatching abilities so they can make instructional plans with the needs of children foremost in their minds.

With the support of two grants from USED/FIPSE, we videotaped and collected work samples from 10 elementary children throughout a school year. We digitized the video and work samples to create multimedia materials that are being used for CBI. We refer to these multimedia materials as the Digital Literacy Portfolio Series (DLPS). While we have conducted other studies that examined the effectiveness of using DLPS (Author, 2000a; Author, 2000b), in this study we examined whether the preservice teachers perceived that a seven-semester-hour block of literacy courses that incorporated DLPS and a related field experience helped them grow as literacy teachers.

During our presentation, we will demonstrate DLPS which allow users to track elementary children’s literacy development during seven-eight months of school. DLPS includes video of children reading and writing during math, science, social studies, and literature. DLPS also has scenarios that users can read to understand the video context. Finally, DLPS includes writing samples and portions of children’s books that correspond with the video. This series consists of 18 CD-ROMs that each contain approximately an hour of video.

Our guiding questions were: Do preservice teachers, involved in multimedia case-based instruction, perceive that a block of literacy courses coupled with a field experience helped them grow as literacy teachers? If so, to what do they attribute their growth? These findings contribute to the growing body of knowledge regarding different types of case-based instruction and various effects on preparing teachers to enter the profession.

THEORETICAL FRAMEWORK
Theories of anchored instruction (Cognition and Technology Group at Vanderbilt, 1990) suggest that learners benefit from discussions when they share common experiences. For example, literacy teachers who work in the same classroom benefit from the ability to discuss what happens in their classroom. These shared experiences become the anchor of their discussions. However, providing a similar anchor during teacher education courses is a challenge. It is difficult to place 20-35 preservice teachers in the same elementary classroom so they will have a common classroom experience to discuss. With CBI, the learners’ common experience is a case. Because the learners are familiar with the same cases, they can discuss how their different field experiences are similar and dissimilar to the case. Herein, the learners can gain an understanding of one another’s divergent field experiences and potentially help one another understand each other’s field situations.

Research indicates that effective teachers reflect on their practice (Schon, 1983; Zeichner & Tabachnik, 1984). In other words, they ask themselves questions such as: Are my teaching methods and materials effective? How can I improve my instruction to meet the needs of my students? What can I do differently? What teaching methods and materials work for which students? What information am I lacking and where will I find it? Because reflection is critical for effective instruction, preservice teachers must develop appropriate reflection practices. Such reflection can be addressed in field placements. However, comparing reflections is difficult because of differences in field placements. Thus, peers and instructors can offer only limited feedback, which leaves preservice teachers to develop their own reflection skills. CBI provides an anchor that preservice teachers and instructors can use to discuss and hone their reflective skills.

Theories of situated cognition argue that “knowledge is situated, being in part a product of the activity, context, and
culture in which it is developed and used” (Brown, Collins, & Duguid, 1989, p. 32). In terms of teacher education, just because preservice teachers demonstrate the knowledge to pass tests and write papers about teaching children to read, does not mean they will be able to teach children to read. Theories of situated cognition imply that field experiences are vital for preservice teachers. However, without anchored situations, preservice teachers are limited to their own insights and making their own connections between course work and practice. Due to the common experiences provided by CBI, peers can generate and discuss these connections with the potential of implementing them in the field.

Theories of generative knowledge argue that learners do not commonly make connections between knowledge that is dispensed to them (i.e., via lectures) and situations where that knowledge can be used (i.e., elementary classrooms) (Bransford, Franks, Vye, & Sherwood, 1989; Bereiter, & Scardamalia, 1985; Whitehead, 1929). Instead, learners make better connections when they generate knowledge (Risko, McAllister, Peter, & Bigenho, 1994). CBI purposely requires learners to generate their analyses of the cases (Christensen, 1987; Christensen, Garvin, & Sweet, 1991; Merseth, 1997; Shulman, 1992; Silverman & Welty, 1992).

Teaching is an ill-structured task (Clark, 1988; Greeno, & Leinhardt, 1986). This means that teachers need to be able to make decisions based on constantly changing sources of information; they need to be problem-solvers. Field experiences give preservice teachers opportunities to try methods discussed in courses, but little experience in dealing with the ill-structured, complex nature of teaching. Furthermore, the ill-structured nature of teaching requires preservice teachers to understand the viability of different perspectives. We purposely developed DLPS to capture a variety of classroom complexities that can be discussed from a variety of theoretical and pragmatic perspectives.

**METHOD**

**Participants and Setting**

This study occurred in a midwestern state university in a section of a course entitled, “Emergent Literacy for Elementary Teachers.” The section was selected because Author 1 was the instructor and one of the DLPS developers. The students were first semester Juniors who had taken 8 semester hours of introductory education courses during their Freshman and Sophomore years. They had also done over 20 hours of classroom observations during their Freshman and Sophomore years. This was however, their first semester of taking methods courses. There were 26 students in the class, 24 females and 2 males. All the students were Elementary Education majors.

The course was part of a block of literacy courses that included 2 semester hours of Children’s Literature, 2 semester hours of Emergent Language, and 3 semester hours of Emergent Literacy for Elementary Teachers. These preservice teachers also participated in 2 semester hours of field experience in which they worked with a partner to teach 8-10 literacy lessons to a small group of elementary children. They collaborated with the elementary children’s teacher to design, implement, and reflect on their lessons and the progress of the children’s literacy abilities. The participants took this block of literacy courses as a cohort. In other words, the same group of preservice teachers attended Children’s Literature, Emergent Language, Emergent Literacy, and Literacy Field Experience (9 hours per week) together.

Author 1 is a professor of literacy education. At the time of this study, Author 1 had taught literacy courses to preservice elementary teachers for 9 years. She had used Multimedia Cases in Teacher Education (Kinzer & Risko, 1998) as well as book-based cases (i.e., Avery, 1993; Harp, 1993; Routman, 1994) for 5 years. This was the second semester she used DLPS.

The course met once a week, for three hours, during a 16 week semester. The course was divided into three modules: children’s literacy processes, teacher decision-making, and professional development. Case-based instruction was used throughout the semester. Case-based instruction was used during 11 of the 15 classes (3 other classes were used to complete pre and post tests and provide a general introduction to the course). Specifically, six classes were dedicated to analyzing a multimedia case of a child named Zane, four to Helen, and one to Kenneth. These three cases were collected in the same first-grade classroom. At the beginning of the school year, Zane (European American, male) was considered an emergent reader, Helen (Asian immigrant, bilingual, female) was a developing reader, and Kenneth (Asian American, English First Language, male) was a proficient reader.

**Data Sources and Analysis**

At the end of the semester each preservice teacher voluntarily participated in an individual interview. A trained research assistant conducted and audiotaped the interviews which lasted approximately 30 minutes. These interviews were designed to address the question: How do the preservice literacy teachers, involved in multimedia case-based instruction, perceive the efficacy of their teacher education course work? The preservice teachers were given a folder that contained their case analyses and field reflections throughout the semester. They were asked to examine their own work and answer among other questions: a) have you grown as a literacy teacher this semester, b) if so, list experiences
that contributed to your growth, c) rank order the experiences you listed.

The interview data were transcribed and analyzed by sorting each participant's list of experiences into common categories (i.e., field experiences, case assignments, class readings, etc.). Finally, the categories weighed according to the rankings given by the preservice teachers.

FINDINGS AND DISCUSSION
Analysis of the students' answers revealed three categories of responses: (a) DLPS (class discussions, comparing the digital portfolios to one another, homework, examining DLPS), (b) field experiences (teaching, reflecting about teaching, discussions of field with instructors and supervisor, substitute teaching), and (c) other course assignments (readings, activity demonstrations, analyzing basal). This interview question was open-ended. The students could list anything. Yet, DLPS emerged as one of the three factors that influenced their growth.

In order to understand further how important DLPS was to the students' kidwatching growth, we assigned points to the students' rankings (5 points for first ranking, 4 for second ranking, and so on). Analysis revealed that 51.6% of the weighted statements identified DLPS, 24.2% identified field experiences, 21.4% identified other course assignments, and 1.6% were miscellaneous. In other words, the preservice teachers overwhelmingly attributed their growth to using DLPS.

These findings are significant because one might expect the students to overwhelmingly identify field experiences. After all, during field experiences they discuss topics, model strategies, ask questions, and conduct observations with real children. This data does not indicate that field experiences are insignificant—on the contrary, they outweighed all of the other course assignments combined (except using DLPS).

Training the Trainers: Technology for District ESOL Specialists

Cathy Cavanaugh, Ph.D., Curriculum & Instruction, University of North Florida, USA. ccavanau@unf.edu
Terry Cavanaugh, Ph.D., Curriculum & Instruction, University of North Florida, USA. tcavanau@unf.edu

Abstract: Based on knowledge of ESOL learners, adult education, and teacher integration of technology, two faculty members from a regional state university partnered with the local school district to develop a training program that would ultimately improve the learning of ESOL students. The faculty members, instructional technology professors, worked closely with the school district ESOL director to develop and deliver training that would meet the needs of school ESOL coordinators who work directly with teachers. During the course of one academic year, this organizing team conducted a needs analysis, created training opportunities, and carried out training for all district ESOL coordinators.

The goal of the project described here was to improve the skills of teachers to effectively integrate technology into standards-based lessons for improved achievement of students in programs such as ESOL (English as a Second Language, also known as EFL, ESL, EFL). This training project, using the train the trainers model, provided knowledge, skills and resources to school district ESOL coordinators who would provide training to the ESOL teacher. The research grounding comes from studies of how children learn best using technology, and how teachers best learn to integrate technology into teaching. The standards include National Staff Development Standards, national student and teacher ESOL standards, International Technology Education Association Standards for Technology Literacy, state technology standards, and International Society for Technology in Education (ISTE) student and teacher standards. Because a major barrier to teaching with technology is lack of resources to enhance integration of technology with classroom learning, this project worked to ensure that ESOL teachers received guidance in effective practice for teaching ESOL students with technology with the technology currently deployed in their classrooms.

Nationally, the number of students enrolling in school ESOL programs has increased steadily in recent years. According to the US Census Bureau, the number of Americans in 1990 between the ages of 5 and 17 who did not speak English well was 907,563. In the 2000 Census, the number had grown to 1,161,055 (US Census 2001). ESOL students are often children who come from economically disadvantaged households, and they are far less likely than their native English-speaking classmates to arrive in school with technology skills. In fact, the National Telecommunications and Information Administration reports on the digital divide in “Falling through the Net” that about half as many minority households have computers as white households (NTIA 2000). The same report states that “schools, libraries and other public access points continue to serve those groups who do not have access at home”. Further, groups such as Blacks, Asian Americans and Pacific Islanders are far more likely to use public libraries to access the Internet. Internet access and the skills to use the Internet and the resources found there are important in improving the lives of ESOL students and their families. If ESOL teachers do not use technology in their classes and teach their students to use the technology, students in ESOL classes may not otherwise acquire computer access and skills. The state guide for ESOL teachers and administrators (Florida Department of Education 2000) states, “technology holds an important place in the implementation of the curriculum, linking schools, community, and the world”.

The national teacher shortage includes a shortage in teachers trained and experienced in meeting the unique educational challenges of the ESOL student. ESOL students face challenges of assimilating into a new culture, learning a new language, and learning subject matter in a new language. For these children technology is a tool that has the potential to help them meet content standards, and it is a pathway to employment and further education. Not only can educational technology provide tools especially designed for the language development and content area learning of ESOL students, but technology in ESOL classrooms can also begin to close the digital divide for these students. Through training school district ESOL specialists, area ESOL students are more likely to have teachers with the skills and knowledge to use technology in ways that increase ESOL student achievement. The aim of this training was ensuring academic benefits for students that can be attributed to improvements in teacher practice using technology.
Educational technology is a powerful teaching and learning tool and it requires specific abilities and knowledge to reach maximum effectiveness. Teachers have expressed a need for assistance in integrating technology into their standards-based classroom lessons. The components of the training provided in this program were intended to meet the need expressed by teachers and ESOL coordinators. Adult education principles state that professionals must have time, support and access to technology as well as scaffolds to assist them in using technology in meaningful ways in their jobs (MacKenzie 1999). Because The ESOL coordinators belonged to each of the skill stages of technology use by teachers, the project’s professional development activities addressed teachers at each level with the goal of guiding teachers from their current stage to at least the next stage, and to guide teachers at the Invention stage to higher competence within that stage. The resources and experiences included in the training gave ESOL coordinators the capabilities that will increase their competence in using the technology to move from the Entry stage toward the Invention stage, and therefore to lead classroom teachers through the continuum.

Surveys of employers and higher education institutions show that students should leave school with strong skills in communication, cooperation, problem solving, and self-direction. ESOL students begin their education in Florida’s schools with a significant deficit in English communication. The training of ESOL specialists was intended to give ESOL students in the area schools the pedagogy, tools and expert teachers they need to improve their communications abilities from beginning to fluent levels. Technology is one of the tools that students and teachers can use to achieve language fluency.

In order for the learning, language and technology gaps to be closed, teachers of ESOL children need expanded access to technology equipment, resources, and effective integration methods for the specific needs of their students. The training resulted from a vision of technology-rich classrooms where ESOL students effectively use modern computers and peripherals, with software, online resources and network resources in learning to engage in authentic communications experiences with peers, their families and subject matter experts.

According to ISTE (2000), the most effective learning environments meld traditional approaches and new approaches to facilitate learning of relevant content while addressing individual needs.

The resulting learning environments should prepare students to
- Communicate using a variety of media and formats
- Access and exchange information in a variety of ways
- Compile, organize and synthesize information
- Know content and be able to locate additional information as needed
- Become self-directed learners
- Collaborate and cooperate in team efforts
- Interact with others in ethical and appropriate ways

The national Teachers of English as a Second Language (TESOL) organization suggests that teachers use the following strategies in implementing standards-based instruction (Irujo, ed. 2000):
- Organize learning around what students need to know and be able to do
- Enrich their teaching by cultivating students’ higher order thinking skills
- Guide student inquiry by posing real-world tasks
- Emphasize holistic concepts
- Provide a variety of opportunities for students to explore and confront concepts and situations
- Use multiple sources of information
- Work in interdisciplinary teams
- Use multiple forms of assessment to gather concrete evidence of student abilities

Research on students using technology within the context of specific subject areas shows many benefits. For example, students using word processing feel more positive about their writing skills, improve the quality and fluency of their writing, are more self-motivated in writing, are motivated to achieve literacy, improved in literacy, and want to write more. Word processing lead to more time spent on revising writing drafts, higher quality revisions, and increased the length of writing. When using word processors students more readily developed conceptual abilities, composed more fluently, and produced enhanced science-related documents. Word processing caused students to overlook fewer errors and make fewer errors (Poole 1997). Students had higher comprehension scores after reading electronic text than after reading printed text (Bitter & Pierson 1999).

Students using computers for learning math and problem-solving showed greater achievement gains, learned concepts more effectively, and scored higher on measures of ability to transfer skills to other areas of mathematics. Students who used computers in the science classroom achieved more from computer-based labs than from
conventional activities, more effectively learned to generate graphs and analyze data, more easily transferred understanding from one type of physical activity to another, and gained data-handling skills likely to be valuable throughout life. Students accessing information electronically were able to get information faster and develop research skills (Poole 1997).

Studies of teachers who effectively integrated technology into teaching will serve as a guide in the development of model professional development activities in this project. Properly trained teachers make the difference between success and failure of an integration effort. Teacher training programs are most effective with:

- a hands-on, integration emphasis and a focus on how to use the technology tools on the classroom
- training over time
- modeling, mentoring and coaching, learning through colleague interaction and information sharing
- post-training access to the technology for practice and implementation (Roblyer & Edwards 2000).

The local public school district involved in this project currently serves 2128 active ESOL students in grades preK through 12. Over 39% of the district's teachers work with ESOL students in two-thirds of the district's schools. The first is to hold all students in the district to the same high expectations for learning and academic performance. Another goal of the Commission is to provide all students with access to competent and expert teaching. Based on knowledge of ESOL learners, adult education, and teacher integration of technology, two faculty members from a regional state university partnered with the school district to develop a training program that would ultimately improve the learning of ESOL students. The university faculty members, instructional technology professors with ESOL experience, worked closely with the school district ESOL director in the process of developing and delivering training that would best meet the needs of school ESOL coordinators who work directly with teachers. During the course of one academic year, this organizing team conducted a needs analysis, created training opportunities, and carried out training for all district ESOL coordinators.

The needs analysis for the ESOL technology training program took into account the district's technology assets and infrastructure, the technology ability level of the ESOL teachers, and constraints on scheduling training. The district's A+ Goals (Academic Excellence and Achievement for All Students) emphasize increased use of technology, high-tech learning tools, and the use of computer technology to pinpoint, monitor, and report every student's strengths and weaknesses to help each student reach academic goals in every subject. To meet these goals, the district has implemented a technology model that specifies network connectivity and computer equipment for each classroom. When the model is fully realized, each classroom will have network connectivity, eight data drops, four student workstations, and a teacher laptop plus peripherals. The model is currently being implemented at the high school level, and middle schools will be the focus next.

A main goal of the ESOL technology training was to complement and facilitate implementation of the district model in the target schools. All of the technology skills and resources provided by this project to ESOL coordinators was fully compatible with district standards and integrated seamlessly with current and future network infrastructure. Because each ESOL coordinator involved in this program served schools and teachers with unique needs, the project had a different role in each case. Based on the results of the needs analysis, the structure of the training evolved to include skills, standards and strategies. The training would focus on a set of technology skills that could be broadly applied by the teachers in helping K-12 students to meet essential academic and technology standards using technology that commonly available in ESOL classrooms. The training would be aimed at teachers working at the entry level in educational technology, and it would be offered during district staff development times to reduce the burden on busy schedules.

The training took a four-pronged approach. As an introduction to the integration of technology for improving ESOL learning, the district ESOL coordinators attended sessions given by the university faculty members at the state ESOL conference. The benefits of this method were that the coordinators did not need to make time in their schedules for beginning to learn about technology, and the coordinators received the information along with their colleagues from across the state, enabling them to hear how others were successfully using the technology. The conference sessions, developed at the request of area ESOL specialists, focused on digital cameras, the web, concept maps, writing tools, web resources and word processing. The coordinators received printed handouts and web links to review before participating in the next phase of the training project. They also had time to observe the teachers and the technology in the schools before participating in more immersive experiences.

For their second collective educational technology experience, the ESOL coordinators attended a half-day session during which the university faculty members demonstrated and discussed a range of technology options within the specific context of the area schools. The coordinators then prioritized the technology skills they felt were
most beneficial for their teachers and most practical for their schools and students. The university professors designed a full-day hands-on workshop centering on six core technologies presented in centers in a technology lab. Because a goal of this project was improving ESOL student achievement in communication, equipment, software and Internet resources were chosen to support student reading, writing and speaking abilities. The workshop provided the coordinators with printed guides to using the technology in ESOL classrooms, a CD-ROM with related guides and software, and time to become comfortable using the technology. The components of the training were an overview of national ESOL standards pertaining to technology, uses of the computer as an audio tool, concept mapping software, digital cameras, uses of DVD for language development, improvement of word processing, and the web. Computers connected to the Internet can bring the world of the English language and American culture into the ESOL classroom, and allow student products to leave the classroom through email, enhanced by photos taken by students using digital cameras. Work produced during these enriched communication experiences can be printed using networked printers, so students can carry their new language home to share with their families.

Quality software and digital content resources give teachers the power to address individual learning needs and styles. By providing the coordinators with software recognized for strengthening communications and thinking skills, the training gave coordinators tools to share with teachers that facilitate improved student achievement. Software recommended in the state software catalog and other sources were featured in the training. Software for thinking and communicating had priority, including developmentally appropriate writing, speaking and reading software, and cognitive mapping software. This component met state and federal goals by increasing access to effective software and online resources, thereby assisting teachers in development of technology-supported curriculum integrating district and state standards for content learning, ESOL education, and learning with technology.

In the final stage of training, the ESOL coordinators and the university professors met to plan the redesign of district ESOL teacher training materials. Currently, all teachers of self-contained or mainstreamed ESOL students must obtain state ESOL endorsement. The endorsement requires between 30 and 360 hours of training depending upon the teacher’s certification area. The district ESOL coordinators are responsible for the teacher training. The existing technology component of the training used audiotapes and laserdiscs. Together, the district and university partners constructed a teacher training module that could be taught face-to-face, on a CD-ROM, or online. The revised activities incorporated concept mapping software, web resources, CD and online audio, word processing, digital photography, multimedia presentations, electronic books, and CD-ROM creation.

The components of the training helped the district to meet two of the state and federal goals for teaching and technology: (1) All teachers will have the training and support they need to help all students learn through computers and through the information superhighway, and (2) All schools will have the assistance needed to develop technology-supported curriculum integration strategies which are thoroughly described and aligned with specific state standards. The training and materials helped meet goal 1 by supporting teachers with examples of approaches for teaching with computers and the Internet. They addressed goal 2 by assisting teachers to develop technology-supported lessons aligned with state standards, and by assisting them in meeting state performance standards for ESOL teachers.

The participants did process evaluation of the ESOL teaching with technology professional development activities. Participant feedback was obtained regarding:

- The quality and quantity of the content
- The pace and organization of the activity
- The quality and quantity of the instructional materials provided
- The amount and appropriateness of the tasks for ESOL education

As a result of the range of technology training experiences they received, the district ESOL coordinators are now beginning to diffuse their knowledge, skills and resources to the teachers in ESOL classrooms. However, like many school districts across the country, the local school district is strongly committed to school reform efforts. These efforts require much in the way of teacher professional development, adapting instruction, and change in the operation of schools. As a consequence of these efforts, not all of which include technology as a priority, teachers are left with little time and energy for changing their methods further to integrate technology. While the district ESOL leadership and the majority of the ESOL teachers agree with the importance of technology for their students, other demands have so far prevented significant progress in implementing the new technology approaches with students. Even computer-literate ESOL teachers have been overwhelmed with National Board certification, graduate courses, America’s Choice rollout, and new school-based programs. An additional obstacle for some teachers has been theft of classroom computers.
In order to share the technology approaches developed in this project beyond the local district, the university faculty are beginning a regular technology integration feature in the state TESOL journal. In conclusion, the training program has prepared and will continue to prepare ESOL specialists to guide teachers in integrating technology into instruction, but priorities or conditions faced by teachers will have to change before conditions are optimal for the integration to occur on a large scale.

Electronic narratives are becoming prevalent in education as one way to teach students about narrative structure, content, and even technology (Lehrer, Erickson & Connel, 1994; Downes & Fatouros, 1995; Eagleton, 1999; Leu & Kinzer, 2000; Eagleton & Hamilton, 2001). The reason they are become popular is because they enable the invention of new media and forms for stories, reaching beyond oral speech, handwriting, and movable type (John S. & Anna Lorien, 2001). Electronic narratives provoke amazing plays on the ways that oral or written stories tell events for characters who move among their settings. They allow students to use a variety of technological and information resources to gather and synthesize information and to create and communicate knowledge (NCTE/IRA 2001) around local, state, and national standards.

Many examples of electronic narratives have been developed in response to this new educational technological possibility. Universities and educational institutions in specific are following an interest in narrative by incorporating narrative, interaction, and virtual reality structures in the development of educational technologies for teaching and learning (Karraker, 1996). For example, MIT’s Papert’s Epistemology and Learning (Papert, 2001) highlights some of these concepts in the form of constructionism; HITL (Human Interface Technology Laboratory) researchers at the University of Washington address educational issues in virtual reality (HITL 2001); the Virtual Theater at Stanford University explores the areas of narrative, characters, agents and coherent scenario structure related to children’s learning development (Education index , 2001); finally, the text -based virtual communities of MUDs (Multi-User Dungeon) and MOOs (MUD Object-Oriented) find users collaborating to create virtual stories about their lives and their worlds (MUDS, MOO, etc., for Education, 2001)

Within the genre of electronic narratives, there are various applications of both theory and practice (Roussos, 1996). At one end of this scale are simple levels of interaction such as cartoon video with animation, sound effects, and varying levels of user control (Folk legends of Japan 2001). The more advanced products infuse human experience in developing the electronic story. An example of these more elaborate models is Laurel’s Interactive Fantasy (Laurel, 1991), where users deal with narrative, characters, and plot structure. The software requires the user’s control and manipulation to form the plot, content, and outcome of the story (Steiner & Moher, 1992; Steiner & Moher, 1994; Steiner, 1995).

At either end of the spectrum, one major benefit of the electronic narrative is its ability to integrate concepts of learning theories and curriculum objectives into a computer-based setting, and the opportunity to extend the above efforts into a complete environment that shares common characteristics and experiences between teacher and learners (John S. Nelson & Anna Lorien Nelson). Then therefore, the model of an electronic narrative is indeed a desired educational approach to provide a natural, simple, and familiar mode of access, operation and interaction (Labbo, 1996).

However, while numerous designs of multiple interfaces and hand-on computer software are being developed—and developed for different audiences like teachers, children and parents—there is an increasing need for rubrics to help differentiate between the good and bad products. The field of educational technology would benefit from a further exploration of the term 'electronic narrative', as well as a categorization of the different types of available products and how they might be used in education. Rather than focusing on specific products, there is a call to describe the characteristics behind the development of various types of electronic narratives, assessing them on the quality of presentation and design, the educational value, ease of use, play life, and factors of importance to educators and parents. This approach allows us to continue discussions of important rubrics rather than judging specific software (Review of Children’s Educational Software April 1998 http://www.siLorg/ched/edsoft.html).

Therefore, the main goal of this paper is to further investigate and define the electronic narrative, and to address the strength of electronic narratives as fundamental units of knowledge, memory, and ways we make sense of our lives. Through the existing models and examples of electronic narratives, this paper presents the power of this uniquely engaging, flexible environment for accessing, analyzing, and producing modern forms of communication (Hamilton, 1998). It explores how the application of an electronic environment can simulate a storyteller, which provides the essentials of communication for teaching and learning that are based on the human stories experience (Melanie, 1998). Further, it provides evidence that stories are represented and integrated within technology with less constraints of form. Finally, we describe how an electronic narrative can be developed and integrated in more engaging and meaningful ways in education.

A Distance Education ESL Endorsement Program: Failures and Successes

Nedra A. Crow, National University, San Diego, CA, USA, ncrow@nu.edu
Joan P. Sebastian, National University, San Diego, CA, USA, jsebastian@nu.edu
Peter Serdyukov, National University, San Diego, CA, USA, pserdyukov@nu.edu

Abstract: This paper describes a distance education model for an ESL endorsement program designed for K12 educators. The program evolved through several critical changes based upon technological challenges. Finally, the paper highlights the successes, failures, and lessons learned.

With the increasing population and urbanization of city centers within Utah, the complexion of Utah's children has rapidly changed, mirroring the challenges that have taken place throughout the United States. These population changes created a growing demand for professional development programs to prepare educators to meet the specific linguistic and cultural needs of their students. However, the ESL preparation programs at institutions like the University of Utah were very small endeavors incapable of producing more than a few ESL teachers. Out of such a dilemma came a unique and innovative partnership among six school districts as well as two colleges within the University of Utah dedicated to the development and implementation of a distance education ESL endorsement program for a projected 1800 experienced teachers. The program required that educators take the courses over a three-year period. Three groups of educators would complete the three-year sequence of 26 credits. Each group was called a Round. Each Round was scheduled to begin during Autumn Semester.

This program became known as DEEEP (Distance Education ESL Endorsement Program), and evolved throughout its five-year history because of changing program needs and technological challenges. Given the limited space of this paper, we will: 1) describe the evolution of the program and the distance education delivery approaches and 2) discuss lessons learned.

Evolution of Program and Distance Education Delivery Approaches

In the fall of 1998, Round I began and consisted of eight graduate level courses. These courses were delivered to 18 teaching sites in one rural and five urban school districts. The districts comprised about 75% of Utah's public school population. There were three courses in Year One that used satellite technology delivered and supported at each site by content facilitators. Satellite transmission was contracted through a private provider called Educational Management Group (EMG). Because of the heavy theoretical base of the courses in Year Two, the program developers decided that these courses should be delivered using onsite instruction provided by University clinical faculty members. Year Three consisted of three courses delivered to the participants through video-based instruction, web-enhanced curriculum strategies, and onsite facilitators. Again, EMG was contracted to develop and provide these video modules created by University faculty.

In January of 1999, EMG representatives informed program directors that the company was purchased by Pearson Publishing Company who then determined that EMG was not a viable entity. During contract renegotiations with EMG and Pearson representatives, EchoStar Company was selected to provide the satellite delivery for the Year One courses to Round II and Round III participants. Contract changes also meant that the Year Three video and web-based courses would be developed and implemented by a University of Utah applied technology group called Media Solutions.

The transition to EchoStar was difficult, complex, and complicated for several reasons. Firstly, all satellite equipment that was located on 20 K12 school buildings as well as the uplink facilities at the University of Utah needed to be changed by mid-August of 1999. However, discussions between EchoStar and Pearson representatives were not completed until July. Once satellite and needed computers were installed at the K12 sites, local school educators immediately began to cannibalize the computers and associated hardware, including TVs and cable connectors. Therefore, when EchoStar system testing began a few days before the start of Autumn Semester, communication was non-existent at most sites. This situation strained relationships with K12 educators as well as EchoStar managers and technical staff. Furthermore, technical training for the onsite facilitators was delayed and compromised because of a lack of functioning equipment.
With the start of the Round II, Year One courses, full compromised, satellite transmission became the next challenge. The quality of the transmission was always a point of concern for all parties. From the Echostar standpoint, they were frustrated with the “low tech” equipment at the University of Utah’s uplink studio site. They noted that the non-commercial studio cameras resulted in poor picture quality that was unacceptable to them. Furthermore, the uplink transmission station in Wyoming was not communicating with Echostar facilities in Denver nor K12 downlink sites in Salt Lake City, let alone the University studio facilities. As a result, chaos prevailed and instructional sessions did not. Ultimately, by October of 1999, the satellite transmissions were abandoned in favor of video taped lectures, quickly dubbed, and sent to 10 teaching sites by Federal Express.

Also, during Fall of 1999, video production for Year Three courses began. Because Media Solutions was a University based agency, the DEEEP Directors worked closely to link video production personnel with the instructor for Year Three courses. However, challenges also became evident by November of 1999 when the faculty member did not meet any script or filming deadlines. Therefore, videos crews, studio schedules, and print material were delayed and rescheduled multiple times. These delays compromised the implementation of Year Three.

With development of the Year Three courses behind schedule, and the advent of a new DEEEP Director, new challenges were effecting the program. Then, in May 2000, due to changes in the state’s ESL endorsement requirements and lack of educators’ participation in DEEEP, the program was modified into a two-year, six courses sequence and offered at six teaching sites. The new Director guided development of the website and completion of the program through Round I and II. Under his leadership and that of the previous directors, over 400 K12 educators received a high quality ESL endorsement program influencing countless children. While this number was greatly reduced from the originally projected 1800 educators, the impact is still believed to be significant to these school districts and children.

Lessons Learned

The lessons learned were numerous, painful and revealing. These lessons will be briefly outlined in four themes. Firstly, the closer you can maintain control over the technology, the greater the likelihood of program success and stress reduction. Working with commercial and non-educational providers created a myriad of challenges, the greatest of which was communication and expectation.

Secondly, being on the technical cutting edge with so many stakeholders and for such a large and complex endeavour is a good formula for failure. Sometimes, being on the technical cutting edge means bleeding.

Thirdly, it is important to start small when dealing with highly complex, collaborative, and technologically sophisticated programs. Attempting to deliver an academically rigorous, eight course endorsement program using high level technology to K12 teachers, many of whom, expected workshop, “how to” techniques is a recipe for disaster.

Finally, working with diverse professional stakeholders, including higher education faculty and administrators, K12 administrators, commercial providers, and classroom teachers’ results in cultural conflicts and stressed communication. While the concept of multi-professional collaboration is intriguing and has merit, in reality it is fraught with inherent barriers, competing needs, and often, insurmountable conflicts. This is not to suggest that such collaborative endeavours should not be attempted, it is to stress the need to always put the K12 students in the middle of the table and never lose sight of them. For this is the only reason, that such competing interests and people would and should come together.
Literature, Differentiated Instruction, and the Internet

Abstract: The purpose of this project was to develop a differentiated learning activity that accommodated a variety of reading abilities, interests, learning profiles, and experiences in using technology. Project objectives were (a) exposing participants to a variety of stories written by Beatrix Potter, (b) using the appeal of technology to overcome participants' impression of Potter's works as "babyish" or for "little kids", (c) using the Internet to provide reading texts when multiple copies were unavailable, and (d) developing or enhancing skills in the use of Internet resources.

Introduction

Among popular children's literature, few selections rival the timeless quality of Beatrix Potter's classic works (Lipson, 2000). Many youngsters in today's primary grades fail to read works by Potter because of the discrepancy between the higher readability levels of the books and the young age at which the stories are presented. The majority of these works are suggested for preschool or first graders (Hirsch, 1997).

To assist students who must cope with reading texts that are long or difficult, Mackey & McClay (2000) reported the effectiveness of electronic rather than print books and noted "the introduction of new media and technologies make new demands on readers as they organize and interpret complex forms of text" (par. 1). Studies (Seng, 1998) supported the integration of technology in the early childhood classroom as tools to enhance social, language and cognitive skills.

Students in elementary classrooms vary greatly in important ways, yet a "one-size-fits-all" approach to teaching and learning largely ignores these individual differences. With convincing evidence that success in school is enhanced when teachers attend to differences in readiness levels (Vygotsky, 1986), interests (Csikszentmihalyi, 1997), and learning profiles, (Sternberg, Torff, & Grigorenko, 1998), all too often little meaningful differentiation takes place in most third grade classrooms (Westberg, Archambault, Dobyns, & Salvin, 1993). Tomlinson (1999) described differentiation as "an organized yet flexible way of proactively adjusting teaching and learning to meet kids where they are and help them to achieve maximum growth as learners" (p. 14). She suggested that teachers differentiate content, process, and product according to students' readiness, interests, and learning profile.

Egan (1999) recommended the use of graphic organizers in classroom instruction to make learning more meaningful. She noted the interactive nature of learning activities that employ such organizers and encouraged educators to incorporate them as tools for positive social interaction. McLoughlin and Oliver (1998) reported that since students must share resources, technology-using environments are usually collaborative.
Purpose and Procedures

Participants included 11 boys and 9 girls in grade 3. Students displayed a variety of reading levels, interests, and skills. On entry-level reading measures, six students scored above grade level, nine scored on grade level, and five scored below grade level. Two had repeated a grade; another was slated to repeat third grade the following academic year. Four students participated in a special reading remediation program. Four students attended enrichment classes, although none was identified as gifted. The ethnicity of the student participants was as follows: 15 Caucasian, 2 African-American, and 3 Hispanic-American, 2 of whom had received ESL instruction. The school was in a low income neighborhood; more than 50% of its population were eligible for free or reduced lunch. However, fewer than half of this class qualified for that program.

A reading unit was designed to feature books by Beatrix Potter when it was discovered that only three of the twenty students had read Peter Rabbit and that none of the children was familiar with other works by Potter. The teacher introduced the unit by featuring Peter Rabbit as a read-aloud. A two-session Internet activity was planned for the required weekly visit to the school’s computer lab, using a literature-based website (www.tcom.ohio.edu/books/kids.htm) which included nine of Potter’s works. The lab instructor introduced the website to the class. Additional computer time was available on three classroom computers. Students served as peer coaches. Participants read two of Potter’s e-books and selected two graphic organizers from among five choices of varying complexity for a four-page booklet.

Results and Conclusions

Students completed two teacher-selected organizers based on Peter Rabbit. They selected two of the remaining five organizers; although they were encouraged to use the second story at least once, all reported on Peter Rabbit exclusively. Each organizer was selected at least once. Although students were allowed choice in the tasks they designed for the organizers, all participants elected at least one character analysis. Other areas of interest included story sequencing, setting analysis, plot analysis: Peter’s problems, and vocabulary development. Peer coaches aided with computer use and with selection and use of organizers. Future replication of the project will include a change in the use of the two assigned organizers. The story map will be assigned for one student-read book and the story sequence organizer for the other. Peter Rabbit will be used for modeling only.

Abstract: This poster demonstration will show different learning activities for mother tongue education using information and communication technologies from a communicative perspective. The demonstration will show video, audio and the writing process for the students. This paper gives an overview of the project and offers a list of resources used in the project to be shown.

Sec21 Project: Information and communication technologies in secondary education in Mexico

Sec21 is a national project that promotes and supports the use of information and communication technologies (ICTs) for teaching and learning in secondary school (junior high school). Sec21 means secondary for the XXI century and suppose the integration of two components to regular activities: video and informatics. They are implemented through a local area network with (a) two servers, one for digital video, the other one for telecommunication and other facilities sharing, (b) computers and televisions in each subject room, and (c) one or more computer laboratories. The project has developed materials and courses for some of the subjects, particularly mathematics, physics, biology, geography, history, civic and ethical education, and Spanish (mother tongue) and offers some specific equipment or materials in each particular subject. For example, programmable calculators are offered for mathematics or audio materials for Spanish language. The national project includes the technical support for the initial installation and training for the personal in the school, including principals and teachers of all the subjects involved.

In Spanish language the activities and materials are design within a communicative and functional perspective to allow the participation of students for the development of communicative competencies. The videos are less than ten minutes long and offer mini-classes, propose activities or can be used inside an activity developed by the teacher for written or oral activities. The audios are less than three minutes long and can be used in several ways. There are two series: Sec21 for the (stand up) ears (a play on words in Spanish) and Voices of the literature. In the informatics component, the proposal offers activities for using the word processor for writing, the presentation generator for supporting students’ conferences, the navigator for visiting selected sites on the web for supporting initial research activities, the sound recorder for oral activities and the local area network for sharing products.

The resources to be shown

The demonstration will show up some videos, some audios and the strategies for integrating the work in the classroom with the work in the media classroom. The strategies include the computer accessories and general-purpose software, the local area network facilities, and Internet resources.
Teacher Education for Mother Tongue Teaching and Learning Using Information and Communication Technologies

Abstract: This paper presents the teacher education process inside a project that uses information and communication technologies for mother tongue teaching in secondary school (7th to 9th grades) and the research project that is starting. The paper has three parts: an overview of the development project, the teacher education process inside the project, and the research project. The development project is founded on a communicative and functional perspective on language teaching, according to the national curriculum in Mexico. The materials developed in the project include video, audio, and integrated activities between the Spanish classroom and the media laboratory. The teacher education process has been face to face, with some support by e-mail. The research is oriented to the comprehension of how do teachers appropriate of information and communication technologies for mother tongue teaching.

Sec21 Project: Information and Communication Technologies in Secondary Education in Mexico

Sec21 is a national project that promotes and supports the use of information and communication technologies (ICTs) for teaching and learning in secondary school (junior high school). Sec21 means secondary for the XXI century and suppose the integration of two components to regular activities: video and informatics. They are implemented through a local area network with (a) two servers, one for digital video, the other one for telecommunication and other facilities sharing, (b) computers and televisions in each subject room, and (c) one or more computer laboratories. The project has developed materials and courses for some of the subjects, particularly mathematics, physics, biology, geography, history, civic and ethical education, and Spanish (mother tongue) and offers some specific equipment or materials in each particular subject. For example, programmable calculators are offered for mathematics or audio materials for Spanish language. The national project includes the technical support for the initial installation and training for the personal in the school, including principals and teachers of all the subjects involved.

In Spanish language the activities and materials are design within a communicative and functional perspective to allow the participation of students for the development of communicative competencies. The videos are less than ten minutes long and offer mini-classes, propose activities or can be used inside an activity developed by the teacher for written or oral activities. The audios are less than three minutes long and can be used in several ways. There are two series: Sec21 for the (stand up) ears (a play on words in Spanish) and Voices of the literature. In the informatics component, the proposal offers activities for using the word processor for writing, the presentation generator for supporting students' conferences, the navigator for visiting selected sites on the web for supporting initial research activities, the sound recorder for oral activities and the local area network for sharing products.

Teacher Education

Teacher education in the project has been has not been very successful, particularly because of the duration. The local support varies from state to state, although in some of them there is an effort on supporting in situ and the central team efforts have not been enough to follow teachers' processes of learning. Therefore teachers do not use the equipments and materials with the frequency expected or even do not use them at all.
The training they receive lasts two days and, generally without a focus on the use for language teaching and learning.

The Research Project

The question to which the research aims to answer is: How do teachers appropriate of ICTs for mother tongue teaching? The sense of the term “appropriation” comes from the sociocultural perspective, as we will see below. The central question involves many other questions like: How do teachers use ICT’s? How do they interpret their activities? How do they explain their work? How do they organise the work in the classroom and in the media classroom? What kind of a community do they integrate, if they work inside isolated classrooms? How do they perceive themselves as teachers? How do they participate in the processes of change? How do they learn in all these processes?

The approach will be qualitative, this means in depth investigation of the processes of teachers participation in the school, teaching mother tongue and using ICTs. The case study will focus on a group of teachers that integrate one school in one turn. In this way, as “the case is studied in its own right” (Robson 1993) the project does not aspire to arrive at generalisations. On the contrary, it will intend to have a depth understanding of a school community and of the ways in which each individual person participates in it. The readers of the results will make “generalisations” or comparisons with their other “cases”.

For approaching to school, sociocultural perspectives, particularly activity theory (Engeström et al., 1999), offers a starting point to the comprehension of teachers’ actions in context, and the process of teachers’ appropriation of ICTs for teaching mother tongue in secondary school. On the one hand a sociocultural approach allows researchers to transit from the social to the individual in two senses. Firstly, this perspective do not isolate the individual subjects, reduce the subjectivity to biology or mental activities, nor attribute to them a sense of omnipotence on the context in which they act. Secondly, this standpoint can explain how the agent acts in a context that opens a limited number of options among which the individual subject decides. In other words, the conditions in which the individual or group moves has two aspects: opening possibilities and setting up limits to action. The agent is not only determined by the situations. However change is not a process from willing, but a process where different perspectives, dependent on the own place in the social context, interplay to construct options. In this way, the starting point for the understanding of human beings, and specifically of teachers’ processes of changing, remaining, learning, felling willing, engaging, being creative: acting in the world, would be the processes of participating in communities of practices (Wenger, 1998). Particularly, teachers act in the social world of the school and in the particular social world of the communities to whom each school serves.

The concept of appropriation, the social comprehension of learning (Newman, Griffin et al. 1989), implies two aspects of the same process (Cole et al., 1999). The first one is that the subject appropriates something that does not belong to him / her in the first moment. In the case of the teachers, they have to make computers their property, which means to make them useful tools for their activities. However, to make this possible, they need to make them appropriate, adequate, to their own purposes. This aspect of appropriation implies the transformation in use of the tools they “receive”. Thus, the process of appropriation of a tool is an active process. This active process is what is going to be investigated.

Abstract: Lack of student access to computers in the classroom (or lack of adequate computer lab access) has limited the computer's usefulness in the writing process to the "publish" stage. Although publishing an attractive, professional-looking document as a result of the writing process is important to the development of good writers, it should not overshadow the real need—developing thoughtful writers who can appropriately use technology during the revision process. Teachers of writing understand that the real work of the writing process comes during the creative brainstorming, drafting, editing, and re-writing stages. Handheld PDA devices may hold the key to integrating technology into the creative work of the writing process.

Introduction

Surveys regarding the current state of technology use in classrooms indicate two important facts. First, although more students have access to computers, either in the classroom or at home, than ever before, 78% of classroom teachers still view access to computers in the classroom as a barrier to their efforts to integrate technology into their daily teaching practices (U.S. Department of Education, 2000). Secondly, teachers who do use technology within their instruction most frequently assign the use of word processing technologies to their students for purposes of keyboarding and formatting their writing projects (Becker, Ravitz, & Wong, 1999; U.S. Department of Education, 2000). The challenge, then, to educators responsible for providing preservice and inservice teachers with the skills necessary to infuse technology into their daily teaching practices is to provide teachers with options to overcome the access barrier as well as inform them of practices that strengthen writing skills of students throughout the writing process, not just during the final publication stage of keyboarding and formatting writing projects. Meeting this challenge may have received a helping "hand" with the recent drop in prices of the Personal Digital Assistant (PDA), a handheld device that allows a portable and relatively inexpensive means of gathering, recording, and organizing information into meaningful forms of communication. For under $200 per student, the teacher is able to provide a student with a PDA and a keyboard that will enable the student to take notes, jot down ideas, record thoughts, memories, words, and responses to readings/experiences, and collect "scraps" of life that can later be used for writing purposes—all of which are important procedures necessary to the writing process. This paper will explore the Writing Workshop, a process of teaching writing that has gained acceptance throughout the United States as an authentic means of not only teaching the art of writing but creating a community of writers, and will demonstrate how the use of PDAs within this workshop approach enhances the establishment of conditions necessary in the creation of student writers.

The Writing Workshop: The Process

Lucy McCormick Calkins has stated that the student act of creating written pieces in the classroom is often "little more than a place to display—to expose—(students') command of spelling, penmanship, and grammar," rather than a process of growing meaning from "real, human reasons to write" (Calkins, 1994, p. 12, 13). The use of the Writing Workshop to provide students with opportunities to view the world with a "writer's eye" and develop those views to express ideas and communicate perceptions to others is a powerful and authentic learning experience designed to develop students who view themselves as writers. The writing process then becomes an important part of participating in a learning community. Briefly stated, the Writing Workshop is structured
so that a block of 30-60 minutes (two to five times a week) is scheduled on a regular basis for students to write on projects of their own choosing. During the writing block, students work independently on pieces of writing in various stages of progress according to the writing process, share this writing with peers through participation in small group peer review sessions, participate in individual teacher-author conferences, and listen to tips or writing strategies shared by the teacher as “mini-lessons.” An essential ingredient for the success of the Writing Workshop is for the students to understand the writing process: the cyclical processes of prewriting, drafting, revision, and editing, that are the necessary stages of development in taking a piece of writing from an idea, memory or thought bouncing around in the head of the author to the published finished product.

The PDA and the writing process

Introducing the PDA into this workshop experience is a true illustration of seamless integration in which the technology not only supports the learning experience, but also enhances the process. For example, the initial stages of the writing process, called prewriting or rehearsing, involve the collection of ideas, the jotting down of memories, thoughts, or words, brainstorming things to write about, drawing pictures or collecting pictures that the individual likes, doodling, making lists, reading aloud, talking to others, and capturing thinking responses to readings or experiences in text notes. These kernels of thought may or may not find their way into a writing draft, but the collection process is crucial to the foundational development of the idea that writing evolves from life experiences, not from the story starters or motivational activities supplied by the teacher. Experts in the field of writing and authors who have written about their writing experiences, such as Donald Graves, Lucy Calkins, Betsy Byars, and Donald Murray, suggest gathering these ideas into a “container” such as a notebook, journal, box, or file that can be carried with the author as they go about their daily experiences. This is the basic purpose of the PDA. The note taking capabilities through such software as Memo Pad, TakeNote!, Thought Manager or word processing applications, such as QuickWord, FreeWrite, or Documents to Go, allow the individual to make such collections easily with the added capacity of organizing these files into categories for later retrieval of files on the same topic—the next necessary step in the process of topic generation.

In addition to helping students collect and organize their thoughts and bits of writing into categories, the PDA can support the student’s need to visualize the relationship between the topic once it is chosen and possible subtopics through the use of concept mapping tools, such as PicoMap. The limitation of screen size for mapping purposes creates a need for the student to visualize no more than three to four possible relationships or subtopics to the central topic, which in many cases, is an appropriate management technique for leading the student from collection of related “bits” to understanding the relationships between the “bits” and writing about those relationships.

Even the drafting process is enhanced for beginning writers with the use of PDAs because often students new to the writing process are more concerned with the way the text looks on the page than getting the ideas recorded. Viewing the text on the small screen focuses the writer's attention on the text and its meaning rather than the way the text looks as it shapes into a paragraph. And, the use of formatting tools in most of the word processing applications for the PDA is limited to Cut, Copy, Paste, and Delete, which allows the student to use the power of the word processor to move and re-arrange text as needed for clarification of expression, but prevents the student from “making the page look neat” or inserting cutey graphics and WordArt. As student writers mature in their abilities to concentrate on and value the process of drafting thoughts into cohesive statements, the need for focus becomes less of a concern; however, the use of the PDA for drafting purposes remains valid.

And, finally, the sharing of writing with others is an integral part of the workshop experience. Participants in the workshop share drafts of stories, poems, and thought pieces with other individuals or small groups or in conferencing with the teacher, soliciting feedback, encouragement, and suggestions for improvement. The PDA supports this process by making it simple for participants to share files by beaming the draft file from the author’s PDA to the reviewer’s PDA. Reviewers are then able review and comment on the piece, and beam the file back to the author complete with added comments and suggestions.

Conclusion

For teachers interested in integrating technology seamlessly into their daily practices, the challenge remains how to use the technology so that the tools become an invisible support structure for the learning process. The use of PDAs within the writing process of the Writing Workshop is indeed an instructional design that builds upon the natural learning processes and scaffolds the learning processes in ways appropriate for the technology. In addition to the appropriateness of the technology to the learning process, the ability to provide all students with the technology in a relatively inexpensive manner addresses the desire of teachers for all students to participate in the learning experience in the same way. Pretty handy!

Abstract: In the premises of the educational reform across Europe, many countries have funded teacher training programmes regarding the integration of the Information and Communication Technologies (ICTs) in all areas of the curriculum, in the primary and secondary education sector. Apart from the infrastructure required, it is essential to focus on the human resources of education and to train teachers in order for them to acquire the skills necessary to integrate ICT into their courses and help their students attain knowledge in a constructivist way. Greece is also fostering educational reform and is running a number of projects towards this direction. One of these projects, EPENDYSH (http://www.ithaca.uom.gr) aims among other things in the postgraduate training of 40 secondary education teachers of all disciplines, who will be distributed to schools in order to train their colleagues. They are being trained to use ICT in the teaching of their subjects. The paper firstly states the overall philosophy and main issues regarding teacher training on ICT. We support a constructivist approach to teacher training, focusing on the training of a sub-group of trainees, teachers of foreign languages. The aim of this paper is to present the attitudes of this sub-group, based on the results of a questionnaire handed to them after completing their training at the University of Macedonia (http://www.uom.gr). It is therefore desirable to investigate how successful the actual training was viewed by teachers of foreign languages, whose subject matter is not affiliated with computing and computer science. These results are subjected to further discussion for future improvements on teacher training.

INTRODUCTION

Information and Communication Technologies (ICTs) have become indispensable in all educational environments. Firstly, ICTs have changed the way people access and process information. Nowadays, information is not a static entity, given ‘as such’ to those interested, but it is dynamic, ever-changing, characterized by diversity and subjectivity. Knowledge is not built behavioristically, but it is a cognitive process built constructively that includes searching for information and evaluating it in order to solve problems. Students have access to an open bank of knowledge and information that needs critical thinking skills in order to be fully exploited. Secondly, ICTs have opened new communication channels, both synchronous and asynchronous, for students, teachers, administrators and parents, which are global, multicultural and multilingual in nature. To keep new generations up-to-date with these developments, major changes need to take place in public schools regarding the integration of ICTs in all curriculum subject-areas. Apart from the infrastructure required, it is essential to focus on the human resources of education and to train teachers in order for them to acquire the skills necessary to integrate ICTs into their courses and help their students attain knowledge in a constructivist way. It is therefore the aim of this study to investigate how successful current initiatives in teacher training are from the teachers’ point of view and particularly from teachers of disciplines that, though not affiliated with computer science, are highly promoted and enhanced by ICTs, such as foreign languages.

TEACHER TRAINING

Apart from equipping schools with the appropriate infrastructure, it is mutually important to affiliate the staff with the suitability and usability of ICTs in education. Teachers need to believe in the supportive use of technology, in order to fully exploit the capabilities of ICTs and motivate their students to actively participate in the learning process. Similarly, teachers need to acquire the computer skills necessary in order to be able to operate ICTs. Finally, teachers need to develop an autonomous approach to life-long learning and construct their own understanding from the stimuli and experiences they gather from their immediate environment.

Current European initiatives [1,3,5,7] invest billions in teacher training (TT) and have common grounds and objectives. The organisation, the content, and the outcomes of a TT course are of major importance and different trends seem to exist. Especially in the field of course content, there is rivalry...
between those persisting in the instruction of educational packages and those following a more 'open' training strategy [4].

We assume that the teachers' objective should not be the mastering of one or more computer programs but the development of critical thinking skills and global perspectives on educational technology. The teacher should not be a passive recipient of new knowledge but he/she needs to be actively enrolled in the learning process. Therefore, as long as the training takes place, the trainee should assume the role of the learner in order to develop the thinking skills required to act in a constructivist way. A TT program as such should include courses from the disciplines of Education, Educational Psychology, Informatics, Learning Theories, Computer Networks and e-Learning, and should prompt the trainees to critically interrelate and construct the knowledge acquired by each discipline in conjunction with their prior experience and their students' needs. Thus, teachers will be able to consciously identify their target group's needs, in order to adapt new technologies to their schools/institutions. Similarly, the optimal assessment tool for teachers should be project-based in the form of authentic case studies or problem-solving activities that trainees need to explore, process and evaluate in order to propose possible solutions.

Specifically, regarding the training of foreign language (FL) teachers, we propose the following strategic points. The theoretical academic background of FL teachers necessitates initiatives that increase teacher motivation and teacher attitude, and promote technical expertise. It is generally accepted that the teacher's attitude is a central element and it is highly influenced by the lack of technical knowledge [6,14]. This fact is partly due to a certain degree of technophobia among those teachers who share a positive view towards new developments but lack the technical knowledge and infrastructure to practice computer skills. What is therefore highly suggested, is substantial, high-level TT as well as the providence of a PC to each trainee for home practice. TT programmes need to focus on both directions and promote teachers' attitude as well as ICTs actual use. However, TT in ICT's should always preserve its pedagogical orientation, as the ultimate goal is not to build computer experts but 'IT Pedagogy specialists' [8,13].

Finally, TT initiatives need to focus on their own target group needs, considering variables such as trainees' nationality, cultural background, age, computer literacy, and target areas of interest (higher, secondary, or primary education). Trainees' attitudes regarding the training program's success can be officially measured by means of interviews or questionnaires. Though numerous similar TT programs are currently running worldwide, the methodology used and the needs that ought to be covered are literally depending on the aforementioned variables and may be divergent.

To sum up, we propose that TT initiatives should focus on a specific target group, such as 'FL teachers from the Greek secondary education sector'. In this case, the structure of the program proceeds as follows. In the first phase, trainees focus on basic computer and Internet skills, while at the same time they rehearse some major educational subject areas (e.g. methodology, learning theories, curriculum design). In the second phase, they proceed with the e-learning philosophy and principles, focusing on Computer Assisted Language Learning (CALL). Parallel to this, they learn authoring skills, and the use of authoring tools. Finally, they should be given adequate time for practical training, in order to become dynamic participants instead of passive recipients. Overall, teachers need to develop a new philosophical perspective and a flexible pedagogical approach, rather than confine their training in the operation of ready-made packages.

THE PROJECT

Greece, together with the rest European countries, runs a number of educational projects focusing on three directions: construction of fully equipped computer labs in public schools, development of educational software and TT [10]. The project EP.E.N.D.Y.SH (Training of Trainers in the Modern Network and Information Systems) focuses on the third direction and provides one-year postgraduate training courses for in-service secondary education teachers, who are trained to provide in-school training for their colleagues. In 2000, the University of Macedonia undertook the postgraduate specialization of 40 teachers from the following disciplines: Computer science, mathematics, FL, and economics.

The training programme consisted of 'horizontal' tutorials to which trainees (Ts) of all disciplines were participating and 'vertical' training for trainees of each discipline separately. Specifically, the FL domain received 72 hours of vertical training that covered theoretical and practical tuition.

METHOD

Page 1898
The Trainees (Ts)
The Ts of this study were five FL teachers who were selected on the basis of their 'personal qualities [and] intellectual abilities' [9] regarding their background, teaching experience, postgraduate studies and involvement in pedagogical activities, that was viewed in their 'expression of interest' application form and during a personalized interview. Their age spanned between 30 and 50, while their affiliation with new technologies before the programme ranged between very good and average. Therefore, we assume that they were motivated to participate in this programme, due to the fact that they were responsible of expressing interest and they were computer literate, at least at an initial stage.

The Questionnaire (Q)
The Ts' training at the University of Macedonia officially ended with a graduation ceremony on 27 June 2001, the date when the questionnaire (Q) was handed in. The Q was structured on the basis of Q construction standards in the field of educational research [18]. It had four sections that were comprised of 31 closed-ended questions and one to three open-ended questions at the end of each section. The over-use of closed-ended questions was due to the fact that they produce more accurate and measurable results, and they do not require long time to be completed by the Ts avoiding the Ts' loss of patience or frustration and the resultant improvised completion of the Q. The questions were short, direct, carefully structured and focused on one topic, in order to avoid ambiguity and to ensure that Ts fully perceived the author's queries. The first three sections regarded the quality of the lectures during the 'vertical' training, the quality of the learning materials and the evaluation of the expertise gained by the Ts, and they had five scale point closed-ended questions. The last section dealt with the trainees' capability to instruct other teachers in ICTs and had three scale point closed-ended questions.

Results
The first section asked Ts to evaluate the knowledge they gained from the 'vertical' lectures regarding the pedagogical use of the ICTs in FL teaching. The overall impression was good. The Ts declared that they received good training in the subjects ‘General Teaching Principles’, ‘FL Teaching Models’ and ‘Special Teaching Problems per Language’ but they also stated an average to poor level of competence gained from the lectures on ‘The Use of Multimedia in FL Teaching’ and ‘Teleteaching of FL’, which are the subjects that directly apply to use of ICTs in language learning (LL). In the open-ended question that followed and regarded recommended changes, the Ts stressed the fact that they were not taught Xenios, an e-slate learning environment and authoring tool, developed by the Computer Technology Institute [2] in order to be taught to in-service FL teachers and to be distributed to all Greek secondary schools. In a privet talk with the Ts, we noted a feeling of insecurity regarding their competence in training other teachers on the specific piece of software without having initial training on it themselves. One trainee characterized as 'loss of time' the instruction of old authoring programs, such as WIDA, and suggested a more ‘up-to-date’ approach, while other Ts stressed the absence of model teaching scenarios that integrate ICTs. This attitude is indicative of the fact that the Ts showed an implicit indifference regarding the general pedagogical values of ICTs in education and the history of educational technology. Instead, they complained that they were not trained on a specific piece of software and they were not given ready-made teaching scenarios. We deduct that our Ts were not in a position – or did not want – to function autonomously and constructively.

The second section dealt with the quality and quantity of the learning materials presented and offered to the Ts. Three types of materials were presented and evaluated: printed materials, software and web-based software. Ts were trained in how to use, integrate and evaluate such learning materials. As regards the materials' quality, Ts' opinions were divergent. According to the them, the quality of printed materials ranged from very good to average and the quality of software from good to below average. The web-based software together with the overall estimation regarding materials' quality was evaluated as average.

Concerning the quantity of learning materials, the Ts agreed that they received a satisfying amount of printed materials, but their opinion on software and web-based software quantity ranged from good to below average. In the open-ended question, asking Ts to identify the best piece of software that would be serviceable in the Greek secondary education sector, they all named English Discoveries and Xenios. This unanimity in an open-ended question is indicative of the fact that either the Ts did not receive training on a large number of foreign language teaching packages or they only focused on the very limited number of the packages that were going to be distributed to public schools.

The third section of the Q measured the degree of attaining the objectives of the programme and specifically the skills acquired on the general use and integration of ICTs in a FL environment. The Ts considered as average the skills they acquired in multimedia applications, pedagogical applications of
the ICTs and strategic pedagogical planning. In the open-ended question, they stressed the necessity for more hours of training in the above areas.

Regarding ICTs integration in the FL environment, the Ts had divergent opinions. Answers ranged from good to below average regarding the skills acquired in the production and development of ICTs-supported language activities, in the design and support of interactive LL activities and in the selection and evaluation of the appropriate CALL materials. However, the Ts considered that they received good theoretical tutoring and good to average ‘hands-on’ training. On the whole, we assume that the Ts admitted receiving good training, but they tended to be skeptical when it came to specific subject areas.

The last section of the Q dealt with the level of the Ts’ ability to transmit the expertise they gained to their colleagues. This section had unanimity, and all Ts answered that had acquired the skills needed to inform, motivate and familiarize their colleagues in the use of ICTs in education, as well as to train their colleagues in ICTs integration and in the design of electronic or web-based learning materials. Thus, if we exclude some degree of dissatisfaction regarding certain areas of the training, we can assume that the TT project managed to develop competent teacher trainers, that are conscious of the knowledge they gained and feel competent to deliver it to their colleagues.

At the end, there were three open-ended questions in order to investigate the Ts’ overall opinion on what went well, what went wrong, and what changes should be considered for the future. To sum up, Ts praised the computer lab, which was designed and equipped to fulfill the needs of the particular group, and stressed how facilitating the spirit of cooperation among them was. Discussion, questioning and ideas exchange between people of the same status can accelerate the process of turning the outside stimuli into acquired knowledge. To this end, some teamwork projects were extremely helpful.

The lack of homogeneity regarding the Ts’ level of computer literacy frustrated all of them, as the less competent could not easily acquire what they were being taught, whereas the more competent felt hindered to proceed to more advanced activities. Apart from that, the Ts criticized the great emphasis given to informatics, which, as they claimed, impeded the saving of extra hours dedicated to subject-specific aspects.

**FUTURE CONSIDERATIONS**

Based on the aforementioned results, we can draw up some conclusions for future FL TT initiatives. The relatively high degree of divergence is mainly due to the fact that all Ts received the same training, regardless of their level of computer literacy at the beginning of the course. Therefore, the Ts perceived the training course differently, according to their prior experiences and computer competence. This problem has been also noted in other similar programmes [11]. One solution could be to split Ts in groups on the basis of their computer competence. Yet, the small number of Ts per subject matter prohibits such initiatives. For this reason, it is preferable to offer extra hours of optional training as well as to provide all trainees with personal computers for autonomous training. Finally, TT courses need to administer constructivist group-work projects that will give Ts the opportunity to exchange ideas and share their own understandings with their colleagues, in order to have gains from each other’s knowledge.

Additionally, in order to avoid the Ts’ frustration and insecurity, their training should include model teaching scenarios that integrate ICTs in the educational process. Ts will thus feel more competent to train their colleagues. On the other hand, Ts should also be exposed to numerous educational software packages in order to be able to think critically, make their own judgments and learn how to evaluate, compare and contrast existing and future electronic learning materials. To accomplish this, TT programmes should also invest on learning materials and equip TT labs with relevant resources. They also need to create a library sector with print learning materials, stand-alone software, networked software, journals, case studies, and worldwide research project deliverables, in order to keep the Ts and the staff up-to-date with new developments.

Moreover, TT initiatives should dedicate equal number of training hours for both technological and pedagogical aspects. It is important for Ts to develop a deep understanding of the actual effects of ICTs in the learning process. In order to familiarize Ts with the use of ICTs in education, TT programmes could also integrate ICTs for course delivery. Telematics and computer-conferencing systems can help to this end, as they can guarantee synchronous and asynchronous learning as well as autonomous and group work. Ts will then be able to evaluate these systems from the learner perspective.

Finally, we believe that every new TT initiatives should be tailored to its target group’s needs. Collecting and implementing ideas and findings from similar projects is also legitimate but it needs careful selection and monitoring, based on the current situation. Though TT courses have some
parallel attributes, there are also culture-, country-, infrastructure-, subject-, and trainee- specific variables that explicitly affect and determine the outcomes of such initiatives. We strongly advocate trainee needs analysis and careful budget management.

CONCLUSION

The aim of this study was to investigate the degree of success of the one-year foreign language instructors' training programme on ICTs in education at the University of Macedonia, according to the trainees' point of view. The results were gathered by means of a questionnaire handed to them at the end of the course. We assumed the subjects' motivation from the fact that they expressed interest for participation in the programme. In total, the results showed that the course fulfilled its main objective, which was the successful training of in-service instructors from the secondary education sector in order to train their colleagues. The subjects declared that they felt competent to instruct other teachers on how to use and integrate ICTs in the classroom, and how to design and evaluate learning materials. However, they also criticized some aspects of the course and suggested future changes, which can be taken into consideration for the next group of trainees. Therefore, we aspire to optimize the instructors' training course not only by keeping up-to-date with current international initiatives and studies but also by actively focusing and adapting our programme on the specific needs of our target groups of trainees.

NEXOS - A Language Portal for Cultural Learning and Collaboration

Josef Hellebrandt, Santa Clara University, US
David Armstrong, Santa Clara University, US

Foreign language teachers have been lacking an open web platform in support of learning and collaboration. This interactive session introduces participants to NEXOS, a web language portal for teachers and learners of Spanish. It will be facilitated by a Spanish professor and an instructional resource expert, who will familiarize the audience with the main features of NEXOS as well as its pedagogical and technological aspects.

The main goal of NEXOS is to promote learning exchanges among university students, teachers, and community members in the US and abroad through shared cultural information and resources. Traditionally, schools, colleges and universities have been offering Spanish teaching and learning in a top-down fashion to the student or to the community. Only recently have Spanish teachers begun to re-evaluate the focus of teaching and to explore collaborative learning formats using technology. The key features of NEXOS—a database-driven platform and multiple communication and collaboration channels—will dramatically enhance technology-enhanced collaborations. It is designed for the sharing of a variety of resources among users and contributors around the globe, specifically for the education community.

The NEXOS portal supports three types of resources within its data banks: images, audio/video and general resources. The latter consists of links to information that can be found in the community and on the web, as well as information posted by NEXOS members on a variety of categories and types including: Events, Organizations, Teacher / Student Resources and much more. In addition, it allows for Real Video and web-based graphics. Members of NEXOS can communicate with other members of this portal via its Webboard or through topic-specific mailing lists.

Both design and usage of NEXOS support numerous learning outcomes, which aim at:
1. enhancing student learning about cultural products, perspectives and traditions
2. engaging campus and off-campus groups in mutual collaborations
3. promoting learning and professional collaborations among students and teachers
4. increasing access to technology
5. establishing electronic communication as a viable form for university and community collaborations.

The project will be made available to the membership of The American Association of Teachers of Spanish and Portuguese in November for evaluation including a request for possible modifications.
Abstract: Askov and Gordon (1999) recognize the need to write effectively in an electronic context as important to literacy programs. The goal of situated learning is to create a context that is meaningful and relevant. When an instructional approach is developed based on principles of situated learning, instructors acknowledge the fact that adult learners bring already existing knowledge and skills to workplace literacy programs. Askov and Gordon (1999) suggest that the integration of work-related materials and instruction in basic skills builds on workers’ background of experience and knowledge while developing their abilities to use communication and computational skills more effectively in the workplace. This paper discusses the importance of integrating electronic writing into workplace literacy programs, describes an approach to instruction based on reciprocal teaching, situated learning and strategy instruction, outlines the data analysis process used to assess the impact of the instruction, and discusses the findings.

Introduction

The definition of workplace literacy is shifting to encompass much more than the traditional interaction with text, as the idea of text itself is continually transforming with the onslaught of new technologies; there is now an essential focus on written communication within the boundaries of workplace literacy. Heath and Mangiola (1991) suggest that literacy is a mix of content, process and context by differentiating between 'literacy skills' and 'literate behaviours'. Literacy skills they define as “mechanistic abilities that focus on separating out and manipulating discrete elements of text” (p.40), while literacy behaviours refer to being able to “communicate ... analyze[se] and interpret ... through extended text .... [They are] ways of going about learning that treat language as both the medium and the object” (p.40). This distinction is central to this study; by concentrating on improving electronic writing our goal was to focus instruction on literate behaviors and literate skills that may be necessary in the workplace.

Writing in electronic spaces has changed most workplaces. For example, the impact of e-mail has recently overwhelmed the workplace. A poll conducted by Kopp (1998) estimates that ninety percent of large companies, sixty-four percent of mid-sized companies, and forty-two percent of small firms currently use e-mail systems. The same poll found that more than forty million employees correspond via e-mail, and the number is expected to increase by about twenty percent each year. In addition to the significant presence of e-mail in today's workplaces, there has been an escalation in the use of electronic discussion in
many environments (Bonk, Appelman & Hay, 1996; Hemming, 1999; Kuehn, 1994; MacKinnon & Hemming, 1998). Electronic discussions provide adult learners with opportunities to reflect, pose questions, and examine problems (Brett, Woodruff & Nason, 1997). Given the growing need to be able to communicate effectively, exposing adult learners to computers is not sufficient preparation for the workplace. Communicating through the use of computers must be distinguished from simply using computers. Workplace literacy programs must be founded on research that focuses on understanding methods of teaching individuals to use literacy skills effectively within a technological context and to support the development of literate behaviors for interaction with electronic texts. In this research project we developed and examined an instructional approach designed to teach adults strategies for writing effectively in an electronic context. The instructional approach was developed based on a reciprocal teaching framework and the goal was to situate the learning within a meaningful work-related context through electronic discussions.

Reciprocal teaching has been used extensively in previous studies designed to examine the effectiveness of teaching cognitive strategies (Collins, Brown & Newman, 1990; Lysynchuk, Pressley & Vye, 1990; Palinscar & Brown, 1984). Results in many studies suggest that reciprocal teaching has potential to be an effective instructional approach to teaching workplace literacy skills (Rosenshine, Meister & Chapman, 1996; Spivey, 1995). Reciprocal teaching involves providing instruction over several sessions beginning with the instructor modeling strategic approaches to tasks. Gradually, from session to session, the instructor shifts more and more of the responsibility to the learners for using strategies. The gradual transferal of responsibility allows learners to ask questions, clarify the approach, and receive feedback before being required to complete the task independently. Reciprocal teaching supports an ongoing dialogue between student and instructor; various instructional strategies including teacher-led discussion, explanation, and modeling of strategy use may be effective ways of scaffolding participant attempts to employ the strategy.

Askov and Gordon (1999) suggest that because situated learning involves contextual instruction, based on real-world knowledge and experiences, it encourages transfer of knowledge and skills from the classroom to the job. To enhance the relevance of the writing strategies to the participants involved in this study, hypothetical case studies were created to reflect real-life situations and provided the context for the electronic writing. The cases were based on real-life issues that often surface within many workplace situations. Also, workplace settings found in local communities were used within the cases to enhance the relevancy of the material. The context of the cases enabled participants to explore important issues that often arise in workplace settings, bring and build on their prior knowledge and experiences, and increase awareness of various perspectives, which may encourage a re-examination of their viewpoints and beliefs with regard to many workplace situations and therefore enhance their ability to transfer their new way of thinking and problem-solving skills to future places of work and other areas of life.

Electronic discussion groups as a medium for writing has the potential to promote a collaborative writing environment. Further, Askov and Gordon (1999) suggest that computer-assisted instruction is one approach that educators may take to customize instruction to suit the needs of adult learners. To be prepared for the demands of electronic communication there must be opportunities to engage in writing within this context. Electronic discussions may provide an environment for more reflective responses as they enable participants to work at their own pace. Electronic discussions offer flexibility given their asynchronous capability; this makes the learning medium one that may be provided at a time when the adult learner is available and able to participate. Further, this environment allows learners to use their prior knowledge, reflect, and revise their writing within the context of an electronic learning community.

The Study

This study focused on the development of an instructional approach and the subsequent assessment of the approach used for teaching writing strategies important in electronic communication based on a reciprocal teaching model of instruction. Twenty-two participants, ages 18-48, at the Annapolis Valley Work Centre (AVWC) participated in the study. AVWC is an organization, which provides support to adults who have difficulty finding and/or maintaining employment due to various obstacles including academic, emotional, or behavioural barriers. Regardless of their unique challenges, all participants who
were involved with the study experienced varying levels of computer experience as well as difficulty with literacy skills.

Each participant completed a computer usage survey prior to receiving instruction as a method of gaining information regarding participant previous experience with computers and participant attitudes toward computers. In addition, to gather baseline descriptive data each participant was asked to complete a written sample based on the content of a selected case study, without the use of a computer. A baseline score was assigned to the written samples using a modified version of the TOWL. Basic computer instruction was provided to the participants using the IBM Thinkpads that they would continue to use throughout the study. When the participants felt comfortable using the laptop computers, they completed an introductory session prior to instruction, which involved making an entry into the electronic discussion group based on a case study. The instruction was based on a reciprocal model of instruction and consisted of eleven forty-minute sessions that focused on three specific writing strategies used when making electronic discussion entries. The instruction was also designed to situate the teaching and learning in context relevant to workplace preparation.

Throughout the instructional phase of the study, three sessions were designated to each of the three writing strategies: explaining/expressing a viewpoint, asking pertinent questions, and writing effective responses. Participants received instruction in heterogeneous groups during their regular class schedules at the AVWC. The first session consisted of an introduction to the strategy where the strategy was modeled; the second session (application A) involved participants working through the strategy with some guidance; during the third session (application B), participants used the strategy independently. Worksheets and study guides were provided to participants during each session, which were used as guidelines for making entries into the electronic discussion groups. Participants were also required to complete two additional sessions, which involved working through a case study using all three of the writing strategies. During the first of those sessions, participants received guidance and support from the research assistant while participants used all three strategies independently during the second session.

After the instructional phase was completed, all data collected throughout the study was archived for analysis. In addition to the computer usage surveys and written samples completed prior to instruction, the worksheets used during instructional phase and participant electronic discussion group entries were documented for later analysis. Additionally, detailed qualitative data was gathered throughout the entire phase of instruction.

Findings

To gain better understanding of participants' experience with computers prior to instruction, the computer usage surveys were examined. 15 of the 22 (68%) participants had used e-mail while 9 (41%) had used chat groups prior to this study. Only 3 (14%) of the participants categorized themselves as heavy computer users (many hours per day), another 3 felt they were light computer users (approximately once per week), and 3 of the 22 considered themselves to be infrequent users (rarely use the computer). These findings reveal that there was diversity among participants with regard to computer use. It is also interesting to note that although fifty-nine percent of the participants had used a computer within seven days prior to participating in the study, sixty-two percent of those participants had used a computer for playing games while only thirty-eight percent used a computer for word processing and forty-six percent for writing an e-mail message. These findings suggest that the participants enrolled in the workplace literacy program at AVWC do not frequently use computers for electronic writing when compared with using computers for entertainment purposes such as playing games. Further, only fifty percent of the participants used a computer for any purposes within the context of their workplace literacy program within one week prior to the study.

The overall goal of the instruction was to improve the quality of electronic writing with more specific goals of having the participants use the strategies taught while writing. To assess the change in writing quality after instruction, we compared the electronic discussion entries created during an introductory session to entries made during the final independent session. These data are summarized in Table 1. The number of words that participants used before and after instruction did not differ, \( t(20) = 1.77, p = .092 \). However, participants used an increased number of sentences after instruction than they did prior to instruction (\( t(20) = 3.24, p = .004 \)). This suggests that writing processes were changing; it appeared
as though participants started to make more thoughtful, planned decisions about their writing. Further, when comparing these two groups of entries it was also found ninety-five percent of participant entries showed an increased amount of explanation provided to support viewpoints generated. This data suggests improvements to participants' written communication; they were carefully explaining the viewpoints with regard to the cases rather than simply stating isolated opinions that were not relevant to the cases. The overall quality of participants' writing was compared using a modification of the TOWL. Results suggest significantly higher scores following instruction, \( t(20) = 2.43, p = .024 \). We also compared the explanatory quality of the arguments made by the participants on a 5-point scale. This reliable scale indicated that the participants' arguments were better after instruction than before, \( t(19) = 12.58, p = .001 \).

</table>

Table 1: Descriptive statistics of pre- and post-instruction writing measures

Specific to the goal of using the strategies in the electronic postings, we assessed participant worksheet/study guides to see whether there was evidence of strategy use. Ninety-five percent of participant entries revealed some evidence of using worksheets and study guides, which were important components of the strategy learning throughout the instructional phase.

Throughout this study, there was evidence of change in attitudes toward writing. At the beginning of the study, thirty-six percent of the participants specifically identified writing as a significant barrier for them with regard to finding and maintaining employment. During the pre-instructional session, which required participants to write in response to a case study without using a computer, eighteen percent of participant written responses did not accurately reflect thoughts verbally expressed within the group discussion. Many written responses were very brief, used basic words, contained unconventional spelling and letter formation.

There were additional changes in the participants' literate behaviours throughout the duration of the project. Participants began to think about their writing, as well as the conventions of writing particularly spelling, punctuation, and capitalization. For example, one participant stated that she now read her work “over and over again” to make sure that “it makes sense” before she published it. Further, participants began to use each other for resources in the process of writing. Also, when reading the entries of others, participants would often make editorial comments. As a result of this feedback, one participant gained increased awareness of the importance of spacing between words.

Conclusions

Computer exposure is not sufficient to prepare adult learners for the workplace. Communicating through the use of computers must be distinguished from simply using computers. Electronic discussion groups (EDGs) have the potential to promote a collaborative learning environment that enables learners of various abilities to exchange ideas and thoughts, extend their learning, and ultimately grow as a community of learners. Thus, electronic discussion groups may provide an appropriate learning atmosphere that allows for the diversity of adult learners enrolled in workplace literacy programs. If workers are to be prepared for the demands of electronic communication, instructional approaches must reflect the authentic process of
communicating electronically to promote growth in the areas of literate behaviours and skills. Adult
learners require an instructional approach that will address their diverse needs and will guide them to
independent use of the various strategies learned so they can then be transferred to future situations.

CoBaLTT! Content-Based Language Teaching through Technology

Marlene Johnshoy
Center for Advanced Research on Language Acquisition
University of Minnesota
United States
johns484@tc.umn.edu

Abstract: The CoBaLTT project includes two primary components: the delivery of a professional development program for K-16 world language teachers that will enable them to create content-based lessons and UNITS that incorporate technology in order to improve students' language proficiency; and the construction of a Web Resource Center for language teachers that will provide instructional modules based on the face-to-face instruction in the professional development component and additional practical resource "rooms."

The purpose of the CoBaLTT project is to provide professional development and practical resources for K-16 world language teachers in content-based instruction supported by appropriate uses of technology. The CoBaLTT project has two primary components: a Professional Development Program and a Web Resource Center.

Professional Development Program

The purpose of the CoBaLTT professional development program is to provide intensive professional development for world language teachers on the use of technology in the second language classroom to support and enhance content-based language instruction. Participating teachers gather authentic materials and create content-based lessons or units that motivate students to develop higher levels of proficiency and cultural awareness, thus enabling them to meet challenging standards.

Each year, a cohort of world language teachers is selected to participate in a year-long program that includes a week-long summer workshop and three two-day workshops during the academic year. The program focuses on:

- content-based curriculum development and teaching strategies,
- best uses of technology for teaching and learning,
- creation of authentic tasks that meet national foreign language standards, and
- assessment of student language proficiency and content knowledge through performance-based assessment.

The program begins with a one-week intensive summer workshop held at the University of Minnesota. The CoBaLTT summer workshop sets the stage for the program by helping teachers understand the theoretical principles that link standards with content-based language instruction and curriculum development. Participants also become familiar with selecting and using technology to enhance content-based language instruction.

We are currently in the third year of the professional development program. The 25 K-16 teachers in the current CoBaLTT program have completed the week-long institute in the summer of 2001. Support and additional learning sessions will be held three more times during the 2001-2002 academic year. Between sessions, participants are involved with developing lesson plans to be added to the website, offering feedback and suggestions to peers, and trying out new ideas with their students.

Web Resource Center
The CoBaLTT Web Resource Center serves both as an integral part of the CoBaLTT Professional Development Program and as a stand-alone learning resource for language teachers. The Web Resource Center has two main areas:

- instructional modules for language teacher professional development in key subject areas important to the CoBaLTT program
- practical resource rooms for teachers related to the topics in the instructional modules

The instructional modules support the face-to-face instruction, but will also serve as independent learning modules for those teachers who are not able to attend the face-to-face instruction with a cohort. It is intended that these instructional modules will eventually form the core of a credit-bearing independent learning course.

The instructional modules will include the following:
- National standards
- Content-based curriculum development
- Content-based teaching strategies
- Technology-enhanced instruction
- Performance assessment (connected to the Virtual Assessment Center)

The practical resource "rooms" will contain a large collection of practical resources for language teachers. These resources will support and expand both the face-to-face instruction and the online modules:
- lesson plan room has (many first and second year cohort lessons/units now viewable)
- discussion rooms (Year 3 cohort is using a bulletin board to discuss readings)
- rubric room (connected to the Virtual Assessment Center)
- technology room

Please visit the CoBaLTT website modules and resources. Any comments or suggestions would be appreciated.

This project has been funded in large part by the USDE Title VI Language Resource Center Program. The CoBaLTT project is directed by Professor Diane Tedick of the Second Languages and Cultures Education Program, Department of Curriculum & Instruction, University of Minnesota.
Using Technology to Present Mathematics Lesson Plans That Integrate Children's Literature

Virginia Keen, Bowling Green State University, US

It is not uncommon for preservice early childhood/elementary school teachers to acknowledge having some level of mathematics anxiety. In an effort to establish a comfortable learning environment in which to both deal with mathematics content and learn good mathematics pedagogy, I assign the creation of mathematics lesson plans which integrate children’s literature. By approaching the teaching of mathematics through the more attractive realm of the reading of stories to children, preservice teachers gain a sense of security in the planning of a mathematics lesson.

Students are required to present their plans to their peers in the mathematics methods classroom using some means of technology. The technology options range from chalk and chalkboard to a digitized whiteboard system, including a networked computer providing access to all University-keyed software. The students choose the level of technology they wish to use, just as they select the literature and mathematics content for their lessons.

Several students have chosen to put the ideas and knowledge gained through their program preparation in classroom technology to excellent use as they have developed presentations that capitalize on the power of presentation software like PowerPoint® and HyperStudio®. In addition, some have incorporated opportunities to use the digitized whiteboard (SMART® Board) to make their presentations more interactive. In this SITE presentation, I report on the experiences I have had with student products and, if possible, have a preservice teacher co-present, sharing the product they created as a part of this assignment.

The objectives of this session include:
1. Sharing a vehicle for getting students to use their learning from classroom technology course work in subsequent courses,
2. Providing an opportunity for colleagues to see examples of student work, using technology to show how students integrate children’s literature in mathematics instruction, and
3. Initiating a preservice teacher into the professional world of conference presentation.

The intended audience is teacher educators, not restricted to those in classroom technology. The software of concern includes PowerPoint®, HyperStudio®, Inspiration®, SMART® Notebook, and AppleWorks® graphics.
Preservice Teachers’ Use of WebQuest to Construct Literacy Events

Kimberly Kimbell-Lopez, Ed.D.
Department of Curriculum, Instruction, and Leadership
Louisiana Tech University
United States
Kklopes@latech.edu

Abstract: Preservice teachers taking a Reading Methods course as part of their elementary program requirements were asked to complete a WebQuest on a topic of their choice. The students were shown how to create the WebQuest through use of Netscape Communicator, which contains the web page editor Netscape Composer. As part of the process, the preservice teachers incorporated elements of reading as well as other elements of the language arts.

Introduction
It has become increasingly apparent that teachers must enter the classroom with knowledge and expertise in the use of technology resources. In the Report to the President on the Use of Technology to Strengthen K-12 Education in the United States (March, 1997), the President’s Committee of Advisors on Science and Technology stated that:

As schools continue to acquire more and better hardware and software, the benefit to students increasingly will depend on the skill with which some three million teachers are able to use these new tools. In order to make effective use of educational technology, teachers will have to master a variety of powerful tools, redesign their lesson plans around technology-enhanced resources, solve the logistical problem of how to teach a class full of students with a smaller number of computers, and take on a complex new role in the technologically transformed classroom.

A major point made by this report is that teachers currently do not receive enough support in the way of administrative, technological, or pedagogical resources. In addition, graduates of teacher preparation programs are not adequately prepared to use information technologies in their teaching. Subsequently, most teachers are left largely on their own as they attempt to integrate technology into their curriculum.

The National Center for Educational Statistics (Cattagni and Farris, 2001) reported that in fall 2000, 77 percent of classrooms were connected to the Internet. Developments concerning connectivity are especially critical when considering information reported by The United States Department of Education Office of Education in its Progress Report on Educational Technology. This report (November, 2000) stated that the proportion of teachers using the Internet in teaching continues to climb along with school connectivity from 65% in 1998 to 85% in 2000. With this increase in access to the Internet, there is a need for teachers to have explored potential uses of this resource within teaching and learning activities used in the classroom.

The International Reading Association’s position statement on Integrating Literacy and Technology in the Curriculum (December, 2001) emphasizes that students must become proficient in the new literacies of information and communication technology in order to be fully literate in today’s world. The role that teacher preparation institutions play becomes increasingly important, since the preservice teachers that are trained must be able to support these students in the development of new literacies. Teacher educators must integrate effective instructional models that use the Internet and other technologies into preparation programs in literacy education (IRA, 2001).

The Study
A major purpose of this study was to investigate possible ways to model the infusion of technology within classroom instruction using the WebQuest project developed by Bernie Dodge and Tom March out of San Diego State University (Dodge, 1997). Questions that were explored included: (a) What technical problems do preservice teachers encounter when using technology resources, and (b) How do preservice teachers incorporate reading and language arts curriculum elements when using the technology resources to develop an Internet-based Inquiry project (i.e. WebQuest)?
Participants

Participants in this study were twenty-three female preservice teachers enrolled in a Reading Methods class. This class was a course that must be completed prior to the student teaching component of their degree requirements. Students are usually around a junior level status when enrolled in the reading methods course. The university calendar is arranged in Quarters with classes taken in ten-week cycles, and this particular class met two times a week for one hour and fifty minutes each class for a total time of three hours and forty minutes. During weeks four through nine, students met on one of those class days at an elementary school to participate in the field experience component of the course.

Data Sources

Qualitative data collected for this project included the final WebQuest product completed by the students, a questionnaire, and email correspondence. Required elements for the final WebQuest product included pages that addressed the Introduction, Task, Process, Evaluation, and Conclusion (Dodge, 1997). In addition, the preservice teachers were asked to complete a three item questionnaire that addressed the following areas: (a) What was the hardest part about doing the WebQuest, (b) What helped the most during the process of creating the WebQuest, (c) Do you think the WebQuest is a good project to do with your students? Why or Why not? The preservice teachers were also asked to write a response to complete two open-ended questions: (a) I wish..., (b) If I could do it all over again, I would....

Introduction to the Project

Through their involvement in the course, preservice teachers were introduced to the concept of a “WebQuest” as a way to construct meaningful literacy events for teaching and learning activities in the elementary classroom. This model was developed by Bernie Dodge and Tom March at San Diego State University in 1995, and it is defined as:

...an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web. WebQuests are designed to use learners' time well, to focus on using information rather than looking for it, and to support learners' thinking at the levels of analysis, synthesis and evaluation. (Dodge, 2001c)

In order for students to have an adequate amount of time to create and develop the WebQuest, the project was introduced at the beginning of the quarter. Students explored WebQuest Building Blocks (Dodge, 2001), and a WebQuest about WebQuests (Dodge, Byles, and Brooks, 2001) to learn more about what is involved in the project.

Technical Aspects of the Project

Students entered the class with varying degrees of expertise and experience regarding use of technology. Many had not used any type of web page editor at all much less used such software to develop instructional materials for use in the classroom. In order for the software to be made available to all students, it was recommended that they use Netscape Communicator 4.7x. Since this is a free software program they could download to their home computer, which made it more readily accessible when working on the project. This software was also available in all of the computer labs on campus therefore accessing the software to work on the WebQuest project should not have been an issue.

Support Outside of Regular Classroom Instruction

In addition to class time where the project was discussed, a three-hour support session outside of regular class time was provided by the instructor for those students wishing to receive instruction regarding how to use the web page editor. Students also sought support through office visits with the instructor or through email correspondence.

Providing a Template as Support

Students were provided a working template on diskette that included already created “base” pages for: (a) WebQuest Home, (b) Introduction, (c) Task, (d) Process, (e) Conclusion, and (f) Evaluation. Each page also had a navigation bar with links between the pages. The purpose in providing the template was to help students concentrate on the curriculum component of the project versus becoming mired down in technical problems. Students had to still input selected graphics and links, so they did get experience in working with these technical aspects of the project.
Selection of Topics

The topic selection for the WebQuest was based on an area of interest or grade level range in which the preservice teachers were interested. Students were directed to the web site of Bernie Dodge, which provided a Matrix of Examples (Dodge, 2001a) of different WebQuests that were organized by contents and grade levels. This web site had been found to be a good resource in helping students narrow the instructional focus for their own WebQuest project.

Incorporating Reading/Language Arts

During the course of the quarter, discussion topics and activities in the Reading Methods course cover such skill areas as word recognition and identification, vocabulary, and comprehension. When developing the WebQuest project, students incorporate various aspects of these skill areas in to the learning activities. Since students were also enrolled in the Language Arts Methods course while enrolled in the Reading Methods course, they were encouraged to embed aspects of the language arts within the WebQuest project (i.e. speaking, listening, reading, writing, viewing, and visually representing).

Results

The preservice teachers had the option of developing the project individually or they could work with one to two partners. Five students chose to do the project alone, six other students chose to work in groups of two (three groups of two), and twelve students opted to work in groups of three (four groups of three). Students were free to select the topic and grade level for their Webquest. Grade levels that were targeted in these twelve projects included the following:

Table 1
Distribution of grade levels for WebQuest Projects

</tbody>
</table>

The topics selected by students for their projects were geared toward content area reading primarily in the area of science (10 of 12 projects). Topics selected included broad areas such as Zoo Animals, Discovering Plants and Animals, Endangered Species and Introduction to the Solar System. Some projects narrowed the focus to address topics that included Creepy Crawly Spiders, The Bald and the Beautiful highlighting the North American Bald Eagle, Pumpkin Time, Only You can Build the Zoo focusing on African animals and their habitats, or a specific city as in Landfill Overload or Clean up your City. Two projects had a social studies emphasis that targeted Orville and Wilbur Wright and A New National Monument.

Responses from Questionnaire

Two major themes that emerged from the analysis of the questionnaire included concerns with the technical aspects of the software and appreciation of support services. A minor theme noted included students wishing they had prior knowledge about how to create web pages.

Technical Aspects of the Software

Comments from students when responding to the questionnaire mainly dealt with technical considerations. Many considered the hardest part of the project was finding appropriate links and graphics to build into the pages of their project. Since Netscape Composer is a “bare bones” web page editor, it does not allow much room to manipulate such features as font size, placement of graphics, or to incorporate audio/video elements within the pages of the WebQuest. As a result, many of the problems encountered with the project were more technical in nature versus problems related to how to organize the teaching and learning activities incorporated within the actual project. Specific comments included notes about problems encountered in keeping the font style and size consistent,
getting the links to work properly, anchoring the graphics in a particular place on the page, or disappearing graphics. The biggest issue noted by students was the idea of learning how to use Netscape Composer while also learning how to incorporate effective elements of lesson design with the Webquest project.

**Support services**
Accessing support services was another theme that emerged from analysis of the questionnaire. The three hour support session provided outside of regular class instruction and the use of the template with navigation bar were found to be helpful to the majority of students. In addition, students commented on how helpful it was to use each other as a resource in areas that were technical as well as curriculum oriented.

**Previous Experience with Web Page Design**
Some students included comments in the questionnaire that indicated a wish to have had previous experience with web page design before actually developing their own WebQuest. Prior to taking teacher education methods coursework, students are required to take a general technology course that covers such areas as word processing, presentation, draw/paint, database, spreadsheet, and telecommunications. The depth that these areas are explored is usually dependent on the instructor of record. For example, those instructors having expertise and experience with web page design have required the development of basic web pages. Students who did not have instructors who considered this to be important, therefore would not have this previous experience before taking the Reading Methods course.

**Analysis of Final Product**
Analysis of the final WebQuest projects centered on the areas of reading that were targeted such as word recognition/identification, vocabulary, and comprehension. Each project was also analyzed to determine the types of activities that were included in reference to the language arts (i.e. reading, writing, listening, speaking, viewing, and visually representing.

**Reading Skill Areas**
The twelve projects created by the preservice teachers incorporated a variety of activities that included an emphasis on vocabulary and comprehension skill areas. In all of the projects, the vocabulary focus related to the content area topic or theme of the WebQuest. For example, the project on Landfill Overload included attention to the science vocabulary terms landfill, reduce, reuse, recycle, and solid waste. The word study activities that were included focused on the meaning of particular words and the relationships that existed through the common theme that was being studied.

Through the process section of the WebQuest, the preservice teachers scaffolded learning activities so that the elementary students the project was designed for would be successful in completing the required comprehension elements of each WebQuest. For example, activities focusing on comprehension would build on a basic literal level of information (i.e. What is the Statue of Liberty? Where is it located?), gradually expand to a broader synthesis of information (i.e. Why is the Statue of Liberty considered a National Monument?), to finally include an evaluative component (i.e. What should be the next National Monument for the United States? Why?). As part of these activities, the preservice teachers would activate prior knowledge, guide elementary students to determine what is important in a web page from which they seek information, ask questions about what they would be reading, create visuals and other images as part of the activities, synthesize information drawn from multiple sources, and summarize the most important elements about the topic.

**Language Arts Elements**
The most represented elements of the language arts were reading, writing, speaking, viewing, and visually representing. Although students incorporated activities that requested students to turn around and present information to the class (i.e. speaking), there were no activities that focused on the listening component that would also be necessary for those students who are receiving the information from their peers. For example, students might be required to present the information to the rest of the class, but the audience listening to the presentation was not required to make notes or record this information as they listened to the presentation.

By far the most represented element of the language arts was writing. Activities that focused on this element included the writing of stories, persuasive essays, report writing, how-to guides, journal writing, email correspondence, and the development of books. The element of visually representing was another category of the language arts that was well represented. Elementary students who would complete these activities would be encouraged to create posters, complete charts or concept maps, develop diagram, and construct 3-D models.
Final Thoughts

The development of the WebQuest as a potential use of Internet resources required a certain level of knowledge and expertise using a web page editor software program. Preservice teachers who had less experience with such software felt that they were at more of a disadvantage than those who had previous experience in the development of basic web pages. The comments made by those students related to technical problems that were encountered. They also tended to be more easily frustrated and panic-stricken when such problems were encountered (i.e. font style, size, inserting images, linking to web pages, etc.).

Those students who were technologically proficient were much more confident during the planning and development phase of the entire project. Comments made by these students reflected a level of confidence that enabled them to concentrate on the construction of meaningful literacy events. These preservice teachers were comfortable in their ability to incorporate elements of reading and language arts to plan effective teaching and learning activities for elementary students. The overall consensus from the preservice teachers was that they believed the WebQuest to be a worthwhile project to use when constructing literacy events with elementary students.

Abstract: It is the intent of this paper to share the framework (e.g., pre-writing, writing workshops, peer-editing, etc.) for integrating various technologies into freshman composition, ENG 101. Review of the objectives for ENG 101 and the rationale for integrating various technologies will be discussed. Examples of applications of the technologies with emphasis on the appropriateness of the technology for the writing process (curriculum) will be addressed. Reflection by one of the professors of the effectiveness the technology tools is provided as well as barriers to successful integration of some of the technology tools.

Overview of the Preparing Tomorrow’s Teachers to Use Technology (PT3) Grant Objectives

The Preparing Tomorrow’s Teachers to Use Technology (PT3) implementation grant at Eastern Kentucky University is a unique, collaborative effort between the College of Education, College of Arts and Sciences, and P-12 partners with a focus on transforming the education of future teachers through the infusion of technology throughout the general education and the teacher education program. Implementing the grant is a campus-wide priority through which content areas, pedagogy, and instructional technologies are fully integrated. One of the major goals of the grant includes creating "clusters" of both Education and Arts and Sciences faculty, as well as pre- and in-service teachers, to work together to integrate content, pedagogy and technology through the redesign of technology-rich general education and educational foundations courses for future teachers.

Preparing technologically skilled pre-service teachers begins in their freshman year during their English general education course, ENG 101. Two English professors, one Education professor, one P-12 teacher, and a sophomore student formed an English cluster. During the first year of the project, the cluster rewrote the syllabus for the course. Objectives of the university’s freshman writing courses were revisited along with discussions of appropriate technology tools. Implementation of the revised syllabus occurred in the second year.

It is the purpose of this paper to share the instructional philosophy and strategies for teaching composition, and how the selection of the technologies for the course was guided by these instructional principles. A major criterion for applying technology tools in the course was to promote the learning of the writing process. A guiding question that influenced these decisions was “what can we, as professors of English, do better and differently in class as a result of using of technology?"
Instructional Philosophy and Strategies

The guiding philosophy of the PT3 English 101 composition course was based on the social constructivist model of learning. This model promotes the use of "collective knowledge and skills" within a course so that individual knowledge and skills can be supported. The focus is on building communities of learners within a failure-safe learning environment. This environment involves taking risks by sharing pieces of writing. Providing a supportive environment for taking these risks encourages learning about writing.

The instructional strategy forming the basis of the ENG 101 course was to facilitate the recurring processes in writing by monitor the planning, writing, and revision stages within the process. The English professors assumed the roles of monitors in the writing process. This role entails reflecting, coaching, and evaluating the performance of students (McNabb & Smith, 1998). As monitor, the individual professor becomes a collaborator while focusing on the written piece. At all times, the professors, of the cluster, maintained the positions of the expert and evaluator. With the professor as a collaborator, the richness of the classroom context is taken into account and a community of learners is built. The focus is on centered on implementing different classroom activities as a result of using technology resources. The teacher enhances the classroom with in-depth, and critical thinking conversations focusing on the process of writing. The teacher focuses on the metacognitive strategies for assessment allowing for the self-monitoring of progress. Assessment probes include open-ended questions, exploratory cues, and dialog. As a community of learners, mature writers share their knowledge and skill in the writing process and immature writers are provided with appropriate contextual strategies that engage them successfully in the process of writing. In class, conversations centering on writing allows mature and immature writers to revise links in their mental schema concerning the topic and delete, add or edit their paragraphs within the paper.

Objectives, Technology Selection and Application

The objectives of the English Department and The National Council for Teachers of English (NCTE) guided the rationale for selecting and applying various technologies into the course.

Academic Writing

The English department's main objective for the course is to increase the focus on academic writing. Students are required to write critical responses to short readings rather than writing for narration, description, or definition. The specific objective reads as follows. "Learn about the variety of outside sources, including print and electronic resources, available for developing and supporting one's own ideas in writing, and use of outside resources in at least one essay." (This does not mean students are required to write a formal research paper).

NCTE's objectives state that pre-service teachers “use major sources of books, periodicals, reports, videotapes, electronic and non-electronic databases to understand the relationship between reading and writing”, and "examines, evaluates, and selects resources, such as print materials, video recordings, software, websites which support different viewpoints" these objectives supports the departments position on academic writing in Freshman composition courses.

With these objectives, it became evident that the course would increase its emphasis on researching and documenting information. The objectives are closely relate to the concept of information literacy; that is, locating, accessing, and citing references as well as evaluating information available from textual resources and web-sites. The technology that was the best fit with this objective was online search tools; i.e., the University's electronic databases, on-line catalog, and web-sites. The class shared articles and visual information found during the search process in order to support ideas and thoughts concerning specific topics. The concept of identifying and using keywords was emphasized.
Peer Sharing and Evaluation of Writing

A second objective set forth by the University’s English Department read as follows. “Read and respond critically to materials relevant to writing, including student writing, writing intended to guide the composition process, and writing which serves as a model or stimulus for the students’ own work.”

The selection of technology, guided by this objective, was to employ software for courseware authoring such as Blackboard or Web-CT. The rationale for including a courseware authoring system was based on the premise that discussion forums provide equality among students and democratizes classroom discussions (Eckman, 1996). Students often feel less restrained in posting a writing piece, reading the posted writing prior to class, and in preparing comments on each other’s works prior to class time. The shift is from the use of technology to preparing for classroom activities. Students come to class prepared to discuss the writing piece. It is at this point that the teachers become the monitor of the writing process.

Classroom technologies: peer sharing and evaluation of writing

Keeping in mind the objective of reading and responding critically to student writing, a classroom equipped with a Smart Board and video projector became a necessity. These technology tools became imperative in that the success of any technology implementation depends largely on class activities, which is determined by teachers. The Smart Board and video projector allowed the professors to carry out the crucial role of monitoring student writing. Within small groups, students decided which piece of writing would be used as a model for class activities.

Prewriting Activities

NCTE’s objective states pre-service teachers, “use writing, visual images, and speaking for a variety of purposes and audiences” guided the selection of the visual thinking tool, Inspiration, for brainstorming activities. The software was selected for its attributes of using graphic organizers and outlines. After a demonstration of the software, students used either the graphic organizer or outline to display their schema for the topic. The selection of the graphic organizer or outline aspect was based on students’ personal learning preferences. While students worked on the software, the professors were able to clarify any problems with the assignment, coach students while engaging in a performance task, and provide strategic prompts for the students. Use of keywords for concepts, ideas and thoughts and providing links among the ideas were emphasized during instruction. The “notes” feature of the software was used to embellish and elaborate upon a keyword or concept.

Collaborative Writing

Applying NCTE’s objective, “produces different forms of written discourse”, provided the direction for including a written piece created collaboratively among small groups of students. Technology tools available in the courseware authoring software appropriate for implementing this assignment included discussion forums and use of e-mail. Individuals were responsible for posting single paragraphs to the small group discussion forums based on one thesis statement. The group had to agree on a thesis statement, and, then each individual posted a separate paragraph supporting the thesis. The group was responsible for making organizational decisions concerning the collaborative paper and then suggesting transition statements. Small groups used e-mail for this purpose. One individual was responsible for preparing the final piece, and then e-mailing the paper to the members and professor.

Use of Visual Images to Support Writing

Two other NCTE objectives state that students “will demonstrate the influence of language and visual images on thinking and writing”, and “recognize the influence of media on culture and on people’s actions and communication”. These objectives suggested that the analysis of visual images in print materials was appropriate for ENG 101. Throughout the semester students analyzed visual and text images as they wrote their pieces of writing. On the final paper students were required to support their thesis on youth culture and denim by incorporating one or more appropriate visual images.

Finally, University’s English department objective that students “engage in inquiry – such as class discussion, critical reading, speaking with others, observing, and using technology – appropriate for writing tasks”, and NCTE’s objectives that the student “displays an understanding of the role of technology in communication” and “demonstrates how reading, writing, speaking, listening, viewing, and thinking are interrelated” provided the direction for the final project of the course. Students were to present a Power Point Presentation based on their thesis paper concerning youth culture and denim. This medium was
selected based on its attributes of changing the manner in which writing was directed, and its communication purposes. Students were required to use effective presentation guidelines that included using keywords, phrases, concepts in bulleted format so that the ideas could be elaborated and embellished during their presentation.

Reflection: The Process of Integrating the Technology

I, Kevin Rahimzaden, began the first semester of PT3 course implementation as perhaps the English service unit’s most stubborn skeptic. While much of my skepticism had to do with my own anxieties over teaching and using technology in the classroom, part was also due to the fact that during the year-long planning process for the course, I found it difficult to see how, exactly, the various technologies we included in the course benefited either the learning or teaching process in Freshman Composition. I feared, in fact, the worst: that students would walk away from the semester having learned more about the mechanics of posting to an electronic discussion board than they would about how to construct a careful piece of college-level rhetoric.

Still, some advantages of our PT3 design seemed clear. It was easy to see, for instance, that the course’s BlackBoard site would allow students to distribute drafts and share revision suggestions with unusual ease. This aspect of the course would be especially useful at Eastern Kentucky University, where we have a large number of commuting students who find it difficult to meet with their classmates in the evenings or on weekends. The BlackBoard site also seemed well suited to posting updated ancillary materials such as the course schedule and assignment questions so that students could have easy access to them. Powerpoint presentations have become so pervasive in academia and business that students would be well served learning how to do them. Email and the various communication functions of BlackBoard would clearly facilitate communication between myself and my students. Library databases would be an essential component of learning how to conduct research. Although I could not see the advantage of Inspiration, an idea-organizing software, over, say, a blank sheet of paper and a sharp pencil, I was willing to give it the benefit of the doubt, if only because my cluster colleague from the College of Education, MaryAnn Kolloff, was so enthusiastic about this software’s possibilities. Nevertheless, in the end it remained unclear to me how any of these technologies would have a real impact on the writing process, or, for that matter, on our secondary goal of pre-service teacher training.

Now that our inaugural semester has ended, my central fear, that students would be more absorbed in the technological aspects of the course than they would in learning how to write, has proved groundless. My freshmen were on the whole unfazed by the technologies we used. While I expected such a reaction from those who arrived at the beginning of the semester already comfortable with email and discussion boards and the Internet, I was surprised that even those students who had to learn along the way didn’t demonstrate much by way of interest, either positive or negative, even in something as flashy as Powerpoint. Nor did these students seem especially anxious about their initial lack of technological ability, despite the fact that they were so obviously behind the slight majority of students in this area. They simply learned what I asked them to learn as a matter of course, because their instructor expected this of them.

Whatever technological enthusiasm the PT3 aspect of the course generated among my students was focused on the Inspiration software. Despite my thoroughgoing skepticism while we were planning the course, this electronic brainstorming tool ended up a clear improvement over the handwritten charts and outlines I usually demand, at least if the student evaluations turned in at the end of the semester are any guide. Class member after class member indicated that Inspiration really did help them generate and sort out their preliminary essay ideas. And while I cannot say that I saw any noticeable leap in the quality of student writing—or quantity for that matter, for text generation remained an oddly stubborn problem all semester long—I will note one important thing: our hour-long Inspiration sessions forced the class to analyze assignments carefully. Composition students typically “under-read” their assignment questions, especially as they brainstorm and create early drafts. Because one cannot get anything out of Inspiration without first putting quite a bit in, students were quick to learn that they must be speedy and systematic in “figuring out” the what the assignment requires if they are to have a document to turn in as part of their grade by the end of the period. For this reason, Inspiration seems to create a fairly good conceptual and organizational foundation for subsequent drafts. In the past, in-class brainstorming sessions have mostly
functioned as an excuse for students to shut down intellectually for an hour or so; Inspiration, it seems to me, prevents this from occurring, and so may mark an advance in the composition learning process. Nevertheless, despite a pleasant surprise here and a disappointment there (the classroom's Smartboard, for instance, was not at all useful) I think that my central assumption going into the semester proved largely correct: Though the PT3 technologies we used smoothed out the operation of the course a bit, especially by way of student-to-student and instructor-to-student communication, and by way of better idea-generating sessions through the use of Inspiration, they did not have a meaningful impact on teaching and learning processes in the composition classroom.

Conclusion

When evaluating the effectiveness of the various technologies in the freshmen composition course, based upon the observations and reflections of the course professors, it is clear that students' attitudes towards the technologies were favorable. Also, the professors indicated that using a visual thinking tool such as Inspiration provided many benefits to using class time effectively in the writing process. Other implementations of technology provided students with access to course information and file sharing. On the other hand, Dr. Rahimzaden's initial assumption and resulting conclusion that the technologies "did not have a meaningful impact on teaching and learning process" needs further investigation. Other variables may influence the students' performance in the area of text generation. These variables include students' previous writing abilities, perceiving assignments as authentic and meaningful, desire to become a better writers, willingness to take risks in sharing writing during discussion of written work, and investigating professors' monitoring strategies during class time. These variables guide the basic question that continues to direct the PT3 clusters' discussions: “What can we, as professors of English, do better and differently in class as a result of using the technology?”

Integrating Technology into Reading Instruction: A New Course Development and Implementation

Leping Liu, Ph.D.
Assistant Professor of Instructional Technology
Towson University, U.S.A.
Email: lliu@towson.edu

Abstract: This paper will present the development and implementation of a new course that prepares reading-major students to use technology to enhance reading instruction. Emphasis is on integrating current computer technologies and software applications into reading curriculum. Course content includes design of reading segments on phonemic awareness, vocabulary development, comprehension, and writing, using presentation, graphics, and multimedia authoring software. Issues, problems we had when developing and teaching this course, the progresses students made, the effects of this course will be discussed.

Introduction

Through our experiences of technology integration projects, we have come to realize that an important part of effectively integrating information technology into classroom is to systematically train the pre-service and in-service teachers in a regular fashion, equipping them with the necessary theoretical foundation and technical skills of the integration. The idea is that we need to have certain courses to prepare them for this. In our general education programs, we are offering certain computer literacy teaching basic computing skills; but very few of the course contents systematically deal with theory or technique of technology integration. Although the courses in the instructional technology (ISTC) programs are well developed to integrate technology into learning and teaching from different perspectives, they are mostly for our ISTC major students, and inappropriate for other students who do not have a background of using technology for various reasons: for example, (1) to take one ISTC course, they may need several prerequisites, (2) the course could not be counted into their original program, or (3) even though they finally get into the course, it may not focus on the particular subject areas they are/will be teaching. After all, it is quite clear to us that courses of technology integration focusing on certain areas might be a good solution. This paper will introduce the design and implementation of such a course—Integration Technology into Reading Instruction.

Purposes of the Course

Overall, this course was designed to help teachers develop technology-based reading instruction. Emphasis was on integrating current computer technologies and software applications into reading curriculum design. Course content included designing reading segments on phonemic awareness, vocabulary development, comprehension, and writing, using presentation, graphics, and multimedia authoring software. It would prepare students to use technology as a tool to enrich reading instruction at all levels.

Specifically, after taking this course, students would be able to use technology as an assisted tool to develop reading instruction on related topics. They would: (1) Develop understanding of various technologies, including basic computing, presentation software, and authoring tools. (2) Use Web resources in reading instruction design, including information search, evaluation, and documentation. (3) Evaluate and use selected reading software packages. (4) Be familiar with the general principles and processes of system design/courseware design. (5) Design appropriate reading instruction with the above mentioned technologies and software on four reading topics (Phonemic Awareness, Vocabulary Development, Comprehension, and Writing).
The Structure of the Course

Course was structured in three dimensions: (1) Lecture, including theories, concepts, instructional designs, and demonstration of the designs, (2) Cooperative learning, including class/group discussion, group activities and team projects, (3) Lab work, including a series of lab modules from which students learned the basic computing skills, the use and teach of educational software, and multimedia courseware designs.

Course Work

The course work focused on five major projects that were paralleled through the entire semester. The first project was a research project in which students were supposed to search the current trends and issues in the area of using technology in reading instruction, develop research interests on certain topic, and write a research paper. The research questions formulated from this research project should relate to their integration design projects. The second project, parallel with the first one, was an information search project, from which students would learn skills of Web search and online database search, develop information evaluation criteria to determine the quality of the information that they could use for their research and the courseware. An information resource Web site also was developed on the related topics as a whole group project. The third one was to develop a technology portfolio including 12 pieces of basic computing work with the concentration on how they could be used to enhance learning and teaching. The portfolio consisted of the work on word processing (including the uses of table and mail merge), digital graphing, communication skills, spreadsheet and database applications, multimedia presentation, and simple Web page design. The portfolio should have an electronic copy and a hard copy, and Online copy as option. In the fourth project, students were supposed to develop four short lessons using different reading software. They need to (1) determine the topic of learning or teaching; (2) select and evaluate the software; (3) develop a lesson plan to arrange the procedures of the lesson, when and how to use the software, task, activities, or materials necessary for the lesson, and evaluation methods; and (4) present the lessons to the class and be evaluated by the class. The last project was to design a unit of multimedia courseware using authoring tools on selected topics. Students were supposed to go through all the processes of courseware development form the stage of planning, through analyzing, designing, implementing, evaluating, and revising. The authoring tool used for the reading major students was HyperStudio. Overall, the five projects, together, developed a framework of integrating technology into reading instruction.

Teaching the Course

The author has taught this course twice and found out: (1) we should employ different instructional strategies to teach those majoring in reading than the instructional technology majors. (2) The component of research in this technology-reading course is especially important for students to understand “integration of technology”. (3) Coursework such as computer-based instruction program design that focuses on the reading instruction has great potential to be used in classrooms to enhance reading achievement. Some students had already used their self-developed program to their classrooms and obtained very good responses. (4) The assessment strategies and instrument used in this course differ from that used in instructional technology courses, which makes a useful input into another course (Assessment in Instructional Technology). (5) Student-products from this course, such as on-line portfolio, multimedia courseware, and Web resources, can be used to show their technology strength when they go out for a teaching-job interview. Some of the students had already found good positions or been promoted in schools because of their strength of using technology.

Some issues that need to be considered when teaching this course are: (1) the students need extra lab-time to work on their project, and some individuals even need extra help. Therefore, the schedule of computer lab and the availability of the instructor are important issues. (2) The access to necessary educational software is another issue. In this course, students need to learn, evaluate a variety of reading software, and use the software to design a series of short lessons. We only have limited copies of the software and they were installed in our classroom, which was not always available because of all other course schedules. (3) The instructor needs to prepare the lab instruction materials in the way that is appropriate for computer-beginners. The solutions and how everything worked out will be presented on site (because of the length limitation of a short paper).
Preparing Teachers to Use Technology, MI Theory and TESOL Standards

Ines Marquez-Chisholm, Arizona State University West, US
Carol Beckett, Arizona State University West, US

With the increasing cultural and linguistic diversity in classrooms most teachers have or will have students who are in need of English language skill development. In addition to the cultural and linguistic diversity in today's classrooms, teachers must also address the diversity of cognitive strengths that students bring to the learning environment.

In order to ensure that students receive optimal educational opportunities, teacher educators must prepare pre-service and in-service teachers with strategies that will accommodate these cultural, linguistic, and cognitive differences. Teacher educators can provide professional development opportunities for teachers to experience learning activities that support the diverse needs of their students. Merging Multiple Intelligences (MI) Theory with language objectives found in the ESL Standards for Pre-K-12 Students (TESOL, 1997) provides teachers with instructional strategies that accommodate a range of cultural, linguistic, and cognitive skills. Applying these strategies through the use of technology provides equitable educational opportunities for all students while developing their technology competency.

This interactive session offers participants the opportunity to experience a hands-on computer integrated learning activity that combines MI Theory and TESOL standards. The activity is a multi-disciplinary lesson including language arts, social studies, and mathematics. The activity provides for verbal/linguistic, logical mathematical, visual/spatial, and intrapersonal intelligences. TESOL standards addressed are Goal 1, Standard 3, "To use English to communicate in social settings: Students will use learning strategies to extend their communicative competence (p.39)." The activity includes gathering information on the Internet, cut and pasting graphics, word processing, and presentation software. Handouts will include information for downloading the TESOL standards from web, on-line references for MI Theory, and additional adaptations for the classroom.
The Sky IS Falling:
Language Arts Methods, Technology, and a Cleveland School Facilities Crisis

Kristien Marquez-Zenkov, PhD
Cleveland State University

k.zenkov@csuohio.edu

James Harmon, MEd
Lincoln-West High School
United States
j.harmon@prometheus.ed.csuohio.edu

Abstract: This paper describes a literacy education professor’s and a middle school technology specialist’s pedagogical responses to a Cleveland school facilities crisis. The decrepit conditions of Cleveland’s schools offered an opportunity to engage language arts teacher candidates in a authentic, multidisciplinary, performance-based research, writing, design, and presentation language arts methods curricula that integrated tools of technology. The authors suggest implications for language arts, technology, and democratic education.

Introduction

On October 6, 2000, the roof of the gym at Cleveland’s East High School collapsed onto the basketball courts below, injuring no students or staff, but sending a loud message to the Cleveland Municipal School District and the city of Cleveland. In the ensuing months, the then-Mayor of Cleveland, Michael White, and the Mayor-appointed Chief Executive Officer (CEO) of the District, Barbara Byrd-Bennett, formed a temporary citizen’s council (the Facilities Assessment Commission) which appealed for broad public input at several forums held around the city. These roundtables offered a chance for residents to vent their frustrations, express their fears, and contribute their ideas about the state—both physical and academic—of the city’s schools.

The city and its district clearly no longer had a choice about addressing the facility needs of its schools: significant investments would need to be made immediately, merely for the physical safety of the students and staff. While the Commission was necessarily concerned with the state of the physical plant of each of the District’s 122 buildings, the larger symbolic significance of the conditions of a district’s schools was then and still remains an underlying issue. What are the implications of such a decrepit physical state for the state of the academics and the morale of students and teachers? Can these conditions be indicators of the expectations that a community has for its youth? Might the physical and aesthetic environment of a school building serve as a starting point for a language arts curriculum that is highly relevant, project-oriented, and appropriately technology-infused?

These were the questions that this article’s authors—a literacy education professor and an educational technology specialist—asked as they planned the teacher education curricula on which they would collaborate during the 2000-2001 academic year. This article describes these educators’ pedagogical responses to this facilities crisis and details a language arts methods curricula that integrated tools of technology.
curricula that is uniquely multi-disciplinary, technology rich and performance-based, energized by an immediate and authentic citizen concern, but still honors the traditional writing, reading, and presentation components of a language arts methods course. This course provided authentic opportunities for the teacher educator, technology specialist, and future classroom teachers to utilize tools of technology that are not usually considered relevant to or viable in a language arts setting. These tools provided unique, tangible, cross-curricular strategies for making the “recreation of our classrooms” the focus of a language arts experiences.

Perspectives and standards

This language arts methods course began with a collective role-playing activity that is part of the vernacular of “process drama” (O’Neill, 1995), through which all teacher candidates engaged with numerous constituent perspectives. Who were the members of the city district’s hastily called Facilities Assessment Commission (FAC)? The commission’s members and the attendees at the various public forums included a broad cross-section of the Cleveland’s schools constituents—business leaders, foundation representatives, grandparents, community service agency workers, pastors, union activists, teachers, students, parents, engineers, artists, etc. The language arts teacher candidates adopted these and myriad other points of view, using these perspectives to consider a range of standards by which to judge language arts curricula, their own teaching practices, their achievement in our course, and the design and function of schools in general.

Using the process drama method of role-playing developed by Dorothy Heathcote (Heathcote and Bolton, 1995), these teacher candidates frequently took on these constituent perspectives collectively; rather than each student adopting an individual point-of-view, the entire class considered the ongoing school building events from a single perspective. At the beginning of most of the 15 evening class sessions the teacher candidates were provided a news article, Facilities Assessment Commission draft report, photograph of a current Cleveland school building, or another artifact to quickly and concretely focus their attention and provide an impetus for the selection of a constituent perspective. These artifacts became the lenses through which students imagined and described the events that resulted in these reports, etc.

In addition to the important process of allowing students to understand the range of perspectives on a school, the primary use of this early role-playing was in the development of a class set of standards and objectives for all classrooms. For first course writing assignment students adopted these roles in order to conduct and transcribe interviews with friends and family about their experiences in schools, translating these into their own “Standards Recounts” about what the expectations of school had been over previous generations. For this initial assignment, it was important that the class consider the broadest definition of “standards,” as the instructors hoped to build a bank of potential expectations and outcomes for classrooms and schools before narrowing the class focus to a set of standards to which the students and instructors could commit professionally.

These standards served several purposes throughout the course. First, they were used as set of guidelines that established some ground rules for engagement amongst the students and instructors of this course. Secondly, they were meant to provide these future teachers with an example of a standard-setting process that they might use in their future classrooms. Thirdly, they required these teacher candidates to research and discuss the proliferating “standards” (especially technology standards, such as the NETS for teachers touted by the International Society for Technology in Education [ISTE]) with which K-12 teachers are supposed to be
conversant and to which they are being held accountable. Finally, these standards were used as a set of outcomes against which students in this course assessed themselves and by which they were assessed by the university instructor through a semester-long portfolio development project.

Students started this standard-setting process by looking at the College of Education model that drives the curriculum in the teacher education programs at Cleveland State University. They then described the lists of classroom rules and expectations that they had encountered in their various field experiences, practica, and student teaching, as well as the rules and guidelines they might have for students in their future classrooms. To these lists they added any expectations that the students believed community constituents might have for the schools, based on the role-playing activities in which they'd engaged. They shared this list of more than 30 potential guidelines with each other via web-based email accounts.

With a bank of almost three dozen potential standards for language arts classrooms, one might expect that the instructors would have wanted to begin the winnowing process, paring this almost overwhelming list down to a manageable number. While they felt a strong pedagogical urge to do this, they decided instead to have the students sit with and even add to this catalog through the use of some visual explorations. Rather than begin a decision-making process, students built on this list of standards through the visual brainstorming by completing a “Photo Essay” assignment where they shot pictures (both 35mm and digital) of the city schools in which they were currently completing a practica.

As well, the class visited the Cleveland Public Library’s digital photo archives to study the history of school architecture in the city, and toured the recently renovated seventy year old middle school where the technology specialist worked to document the aesthetic and design features of the building and classrooms. Students again used both digital and 35mm cameras to document the features of the middle school, while for their own photo essays students shot color 35mm film. At the photo archives they used an optical scanner to view and print photos of school and community buildings stored off-site, and compared these archived photos with their up-to-date images of the same school structures.

These analog and digital photographs provided the final, compelling, design-based (Taylor, Vlastos, and Marshall, 1991) component of this standards generation and discussion process. While students’ previous school experiences and the various lists of standards from professional organizations afforded a substantial overview of relevant curricular and community guidelines, the students’ use of visual tools with which they had less experience provided a unique perspective on how these standards are fleshed out in the very designs and structures of our classrooms (Uline, 1997). Consequently, their ideas for the standards that should guide their teaching expanded to include guidelines that considered these environmental elements. To support their understanding of the connection between the visual evidence to which they were being exposed and the standards for schools and curricula that this evidence represented, the instructors provided them with a T-chart that allowed them to graph these connections.

When the language arts methods class visited and toured the technology specialist’s school, they were able to use one of the school’s computer labs to submit these broader perspectives on standards to a discussion board on the course Website. They could then view each others’ ideas immediately and begin to consider the full range of these ideas as they prepared to select their final list of course standards or outcomes. Additionally, because of this asynchronous environment, students could engage in each other’s ideas in settings outside of class, where the traditional pressures of classroom discussion did not factor. It is the opinion of
the authors that the discussion board format allowed students to carefully formulate new threads and operate at a level higher than what was commonly experienced in class.

Over the course of the semester the class used the final class list of standards to support and assess all course projects. The roles considered in building this final list of standards provided the class with the rich perspectives that educators should regard when they construct their language arts curricula. While technology is explicitly mentioned in one of the language arts curricula standards, it is the authors’ opinion that technology is implicit in all of the standards. While this process required class time during each of the first four weeks of the course, it allowed for a deep, multi-disciplinary, and authentic consideration of the idea of teaching standards and the development of a set of standards to which each student was personally and professionally committed. It provided the students with numerous opportunities for discussion, debate, reading, and writing in both traditional and electronic modes—the basic skills of language arts—and required that they engage in the very activities they might use in their own middle grades classrooms in the future.

As well, this standards development process relied upon an integration of technology that supported and extended the reading, writing, brainstorming, and professional discussion emphases of this process. Because students were asked to use these tools in order to generate ideas and to build a store of potential classroom guidelines, their reluctance to use these new tools was mediated. The instructors’ modeling of integration also demonstrated the importance of bringing technology in when it was appropriate and had an explicit impact on the content off students’ learning. Finally, and perhaps too obviously, this process placed the question of classroom design and aesthetics at the center of any curricular, pedagogical, technological or behavioral consideration. It communicated to these future teachers that the design factors are interwoven with—though most often silent in—the everyday choices of language arts educators.

Conclusion

One of the realities of teaching and teacher education work is that educators are typically so bombarded with discrete tasks that they rarely have the chance to gain a broader perspective on these tasks. What is the relationship of these tasks to each other? How do they fit with the field in which educators are working? How do they relate to the overarching curriculum concepts a particular class is supposed to address? Often, educators at all levels plan for a class, devise most of a semester’s outline for a course, and then delve into these daily and weekly responsibilities, only to surface for air at the end of a semester. Or a career.

The focus of this integration of design-based projects and technology into a language arts methods curriculum was a deliberate attempt to challenge this myopic tendency. Teacher candidates often hear about the importance of their educational philosophies, only to have any time or capacity for contemplating the larger purposes of their professional work squeezed out of them in the first years of K-12 public school experience. This essay suggests that if our society wants educators to continue to contemplate the grander implications of their teaching practices, then it must provide them concrete—as in the bricks and mortar of our school buildings—ways of exploring the relationship between their daily lessons and school’s broader purposes.

This essay opened with questions about the effects of a school’s decrepit physical condition on the state of the academics and the morale of its students and teachers, and about the extent to which these conditions might be indicators of the expectations that a community has for its youth. The answer is to these questions is obvious and requires no elaborate research study to prove: students and educators will default to what they see; their expectations and ideals are
rooted in what they experience daily. If kids learn in crumbling, forgotten schools, the first lesson they will learn is that the value of their educational endeavor is an afterthought in the minds of their community.

Much like students in schools, teacher candidates will resort to what they see and experience in their model instructors. In this case, they witnessed instructors who engaged them with not only a technologically enriched, standards-based curriculum, but also with sense of “eventness” and social justice. As the evidence of this course demonstrates, the physical and aesthetic environment of a school building can serve as a starting point for a language arts curriculum that is highly relevant, project-oriented, and technology-infused. This article suggests explicit strategies and projects that classroom teachers, teacher educators, and curriculum specialists and theorists might use to make the study and design of educational environments cross-curricular, democratic education projects. This project has the potential to alter significantly current language arts teacher education and language arts curricula, as well as history curricula and the state of our city schools nationwide. One unique implication of this project was its use of “parallel practices”: in order for teachers to understand the importance of their language arts lessons, they must engage in and be legitimately affected by the projects they require of their students. Design-based activities lend themselves to this sort of “practice what you preach” ideal.

Of course, a teacher or teacher educator must be very comfortable or proficient with her or his content, before using tools of design or technology with this content. But the content of language arts—and other subject areas, as well—can be supported and extended by these tools of design and technology. All of these activities began with “doing” rather than “learning”: students engaged in these projects largely without recognizing that they were simultaneously engaged in learning about teaching.

The authors suggest that an explicit focus on the authentic project of considering and altering the design and aesthetics of educational environments might both enliven students’ language arts education and provide immediate opportunities for democratic engagement. The public artists who are language arts and English teachers might help the rest of us—artists of the public, all—find our way as we engage with our school lessons, our immediate communities, and our broadest political contexts. They might begin by calling upon their students to recreate the very classrooms in which they are learning.

Abstract: This paper identifies and analyzes four markers significant in assessing the impact of Web-based delivery on the teaching and learning of literacy. The paper describes how Web-based instruction is questioning assumptions about course delivery models and is re-casting boundaries between human interaction and texts. It adds to the discourse on the ways in which Web-based instruction supports critical thinking and reflective writing, as well as learner engagement.

Introduction

Three years ago, the Reading Education program at Marshall University Graduate College experimented with Web-based delivery as a means of serving the needs of students in our distance education program. We now find ourselves in the midst of a sea change. What began as a venture to cut down on traveling time for students and faculty triggered an interrogation of course delivery models, and of the influence of technology on conceptions of literacy and of literacy education. Four markers have emerged as significant in this re-charting of the terrain of literacy and of literacy education in the wake of cyberspace:

1. A need to marry web-based delivery with a face-to-face delivery model
2. The shifting relationships of literacy processes in Web-based teaching and learning
3. Web-based learning presents unique opportunities for student engagement
4. Web-based learning communities can actualize the reading-writing connection

Marrying web-based delivery with a face-to-face delivery model

Mission and structure propel the change to Web-based instruction

Prior to the introduction of Web-based course delivery, the Reading Education program enjoyed a positive reputation for being both rigorous and student-friendly. Why mess with something that was working? As program director, this was my initial take on Web-CT. Although our program was working well, the outreach mission was limited to two sites in southern West Virginia. Forays beyond these sites resulted in small classes, and occasionally interrupted programs. The program was restricted to fewer than 75 students per semester, some of whom dropped-out completely or meandered through their course of study in ways that threatened program cohesiveness. What was needed was a means to extend the program to underserved areas of the state. The three courses that were the hardest to schedule, due to being housed in other
programs, were the first revised into Web-CT deliveries. This, along with recruitment of students into regional cohorts, allowed the Reading Education Program to expand to 11 sites and serve from 200-300 students each term. During the past year, we have averaged over 400 students per term.

Scheduling considerations

Before Web-CT, my major scheduling concern was to make sure the program faculty had sufficient number of students in their courses and that a balance of students per course was reached. This has changed. My concern now is to hold down the numbers to where they are manageable. We have found that Web-CT is much more labor intensive than first thought. Students expect and need quick feedback regarding their assignments and inquiries. This means that the instructors craft hundreds of responses during the semester, in addition to grading assignments. Through trial and error, we have learned that a class that exceeds 20 students will need additional instructional support.

Marrying Web-based delivery with face-to-face delivery

My first reaction to Web-CT was that it was a complex copy of the instructional modules that were attempted in the mid-to-late '70's. After some disappointing experiences, I abandoned their use. Module responses were based upon the analysis of program defined information sources such as a textbook and journal articles. Collaboration supporting the student's analysis was sparse, even from the instructor. It was expected of the student to form answers to several questions related to the readings. In comparison, Web-CT courses both address 'propositional knowledge' (knowing what) and 'procedural knowledge' (knowing how). Web-CT can stretch learning beyond producing a final product by enabling the learner to access feedback at numerous points in the learning experience. The feedback may come through collaboration, coaching, and questioning, and it can come from the instructor, network of classmates, Internet resources, and, most importantly, reflection. Although further analysis and review are underway in regards to the quality of all Web-CT course delivery, our four field-based reading courses are not being considered at this time for Web-CT delivery. Careful instructor supervision is required for two of the courses (Polanyi, 1958) and instructional resources that depict student-teacher interactions are required for the other two. Web-CT technology will be more useful in these courses once a more comprehensive video clip library is formed, but it will likely be used in conjunction with individual, group, and whole class face-to-face delivery formats.

Considering the shifting relationships of literacy processes in relation to Web-based teaching and learning experiences

Web-based courses share this much in common with traditionally delivered courses. Students need to know what to read, what to do with the readings, and how to proceed with the task. New electronic forms of reading and writing (e.g., e-mail), however, "point to fundamental changes in the way we communicate and disseminate information, the way we approach the task of reading and writing, and the way we think about helping people become literate"(Reinking, 1995, p., 17). A unique challenge faced by those who teach Web-based courses, then, relates to supporting students' efforts to use new electronic forms of reading and writing to learn. The challenge: Instructors must reconsider how literacy process such as reading and writing should be used to help students relate information from course learning materials (e.g., readings) to course learning experiences (i.e., assignments) when working within Web-based learning contexts.

Recasting the boundaries between human interaction and written text

Historically, within traditional delivery contexts (e.g., the classroom), teachers and students have relied primarily on speaking and listening to facilitate human interaction, while the reading of written text has been used to facilitate interpretation and reflection (Bruner, 1972). Students often rely on the processes of speaking and listening to understand the instructor's expectations in relation to course assignments. For example, students may use verbal illustrations provided by the instructor or ask questions to clarify their
understandings in relation to assignment criteria. In contrast, students often use the process of reading to comprehend and interpret relevant ideas presented in the readings, using the text later as a reference point for reflecting upon connections to course assignments. When a Web-based delivery system is used, the traditional/historical boundaries between human interaction and written texts are recast. Through electronic environments such as bulletin boards, chat rooms, listservs, and e-mail, "human interaction now takes place in a text-based form" (Warschauer, 1999), reducing student reliance upon the processes of speaking and listening to understand instructor expectations. In addition, the use of Web-based documents, hypertext links and multimedia effects (e.g., graphic images, sound, and streaming video) changes how students approach the reading process. The reading process becomes less fixed and linear (Reinking, 1995), and more extensive (Birkerts, 1994) in nature, as students use hypertext links and use multimedia effects to comprehend and interpret course learning materials.

The instructor's role in defining processes and procedures

While it is clear that the nature and emphasis on literacy processes that contribute to student learning shifts within Web-based contexts, it is less clear how those who design and deliver instruction through Web-based courses should use this information to help students learn. One alternative that considers the shifting relationships and nature of these literacy processes with respect to teaching and learning emphasizes the use of process-based procedures and criteria. Initially, Web-based instructors should provide students with several sources of information to consider beyond the course syllabus in relation to course assignments. A description of each assignment should be provided, specifying what the student should do to complete the assignment successfully. Web-based instructors should also specify criteria for each assignment, suggesting the cognitive acts students should engage in to demonstrate their understanding of course content (e.g., summarizing information from course reading materials and/or critically evaluating information from course reading materials). The assignment criteria serve as a means of communicating the benchmarks or goals that the student should achieve. In addition, procedures for completing each of the assignments should be specified. These procedures will help students understand how to achieve the criteria for each assignment. Together, these sources of information will help students grasp how the process of learning information from course materials intersects with the process of completing course learning experiences.

Weaving a web for learning: student engagement

The old call for "time on task" has been with us for decades as one of the few measures that relate closely to real learning. Yet too often classroom attention to this can lead to superficial and unimportant learning. Our attempts to identify "competencies" such as the IRA standards helps somewhat as we develop educational environments and activities based on targeted learning goals. Still this too can result in piecemeal and isolated skill-based learning which is too narrow and limited to support the development of thoughtful and reflective literacy professionals prepared to make important decisions about students, classrooms, and reading programs. How can we create the student engagement necessary to support the learning needed (Schön 1983)? Mindful of this need, our reading program has experimented with Web-based delivery of courses. As we develop Web-CT delivery, we gain greater opportunities for some forms of student engagement in meaningful learning as we also lose other opportunities. Gains are represented by new and extended opportunities for students to interact. Through reading, writing, and thinking in email exchanges and bulletin board sharing students find themselves interacting more than they did in traditional classroom settings. Through instructor guidance and feedback these forms of engagement are directed towards meaningful and important learning experiences. The necessity for writing to replace "classroom discussion" in Web-CT courses, for example, leads naturally to a greater opportunity for students to engage in writing activities. Although our reading students sometimes balk at a writing requirement, over time they come to recognize the merits of this added focus on writing and thinking. These benefits seem to arise from needs that are inherent in Web-CT's format, needs that lead naturally to greater place for writing, and the cognitive demands this entails, as well as extensive exchanges between student and teacher.

In contrast, the reduction of "face to face meetings" in Web-CT courses leads to the loss of some important serendipitous opportunities for learning. Many forms of demonstrations and classroom engagements cannot
be easily duplicated in a Web-CT learning environment. What kinds of experiential learning from these interactions are lost by web delivery? Can optimizing time during a small percentage of “live” meetings replace this loss, or are we faced with changing how we represent learning and learning goals for our students in the future as we move more substantially to web delivery? These issues need addressing.

**Actualizing the reading-writing connection in Web-based learning communities**

Research on reading and writing has confirmed that they follow parallel and interconnected paths (Brozo & Simpson, 1995) and, that their regular integration sharpens participants’ awareness of the social and communicative nature of literacy (Shanahan, 1990). Practical constraints often lead to a separation of the two in face-to-face classes in which the instructor’s primary role is to deliver content. Students often report reading without comprehending texts or neglecting regular, weekly reading. Many writing assignments are used to show learning rather than "to discover or create new knowledge" (Foote, p. 211, 1999). The rethinking of literacy processes, essential in Web-based delivery, provides an opportunity to integrate reading and writing in ways that extend the literacy development of graduate students.

**Moving reading and writing to the center of the course**

The bulletin board is an asynchronous, interactive communication system that allows course participants to respond to postings of one another. When used in conjunction with carefully crafted learning activities, it can promote student engagement with core readings. Journal activities linked to the bulletin board were central to the conception of CIRG 621 Issues and Problems in Reading Education, a Web-based Reading course at Marshall University Graduate College. Participants composed weekly journals that related to central issues in weekly readings and responded to the journals of other participants. Completion of eleven sets of journal activities per semester has been over 99% throughout the six sessions of the course. Participants reported spending an average of 1.5 hours on the reading, 1 hour composing the journal, and 30 minutes responding to the journals of other participants. When provided with a viable structure, participants connected reading and writing and quickly sharpened critical reading skills. A preliminary analysis of the journals and responses by an outside observer confirmed that journals became more rigorous, more grounded in the text, and more integrated with professional experience. Bulletin board discussions encouraged active learners who read less on ‘automatic pilot’ (El-Hindi, 1997).

**Moving participants to the center of knowledge-making: the on-line learning community**

A unique feature of the journaling activity is that, in essence, participants collaborated in the task of making meaning with weekly readings. Unlike the discourse of traditional classes dominated by the voices of a few, the discourse of the bulletin board identified the voice of every participant. Over time, the bulletin board discussions established a ‘learning community’ whose goal was to construct meaning with the weekly readings (Wells & Wells-Chang, 1992). The responses of other participants heightened awareness of personal learning processes (El-Hindi, 1997). Instead of private responses journals written on ‘automatic pilot’ that often surface in traditional classes, the bulletin board postings reflected the positive influence of being responsible for communicating one’s ideas to others and for responding to the ideas of course participants. An independent observer assigned to read the journals noticed a pattern of changes in the bulletin board postings. Journals became longer, more specifically grounded in the ideas of the weekly readings, and more critically reflective. They referred to specific ideas and insights of participants; they drew heavily from personal, professional experience to construct meaning from texts and to respond to the ideas of other participants; they constructed action plans; they ‘questioned ideas’ (El Hindi & Leu, 1998). The bulletin board postings validated the expertise of the community members as literacy specialists whose identity had shifted from seekers of knowledge to makers of knowledge.

**De-centering the instructor**

The bulletin board activities in CIRG 621 that encouraged participants to integrate reading, writing, and communicating pointed out a fundamental fact of web-based course geometry. Student tasks and
interactions move to the center of the course. Instructor tasks and interactions operate more behind the scenes. Web-based instruction makes the instructor responsible for creating the on-line learning environment and this entails careful alignment of anticipated outcomes and learning experiences.

Conclusions

Web-based instruction recasts the boundaries between human interaction and written texts, and this in turn, establishes new roles and challenges for instructors of Web-based courses. Web-based delivery makes possible the integration of reading and writing activities in a social context that is advocated by current literacy research. However, the positive engagement of students in reading and writing activities cannot substitute for learning that is better achieved in face-to-face settings. The communication tools of cyberspace and the simulation possibilities of virtual reality cannot replicate all of the ways of knowing involved in becoming a literacy specialist. Rather than choosing between Web-based and face-to-face delivery models, instructors may operate with blended class formats that respect the domains of knowledge that are balanced differently in each course. This balance will influence the manner and degree to which web-based instruction can be integrated with face-to-face delivery. It is our hope that these four markers will serve as lightships in charting the contours of literacy and literacy education in the labile medium of cyberspace.

Using Technology to Address Demographic Change and to Integrate Meaningful Assessment in a Writing Program.

Rosemary K. O'Donoghue, Director, Writing and Reading Program, Western New England College, United States, rodonogh@wnec.edu

Abstract By using technology to teach the basic concepts of composition instruction, and by utilizing technology to produce assessment requirements, a college or school system can effect change in a writing program without traumatizing students, faculty, or administrators.

Today, there are two critical issues that college Writing Programs face: 1) how to address demographic change in students and faculty and 2) how to integrate meaningful assessment measures with traditional pedagogy. If as administrators and teachers we relate these issues to technology, we can revitalize composition instruction without sacrificing essential content.

Schools are experiencing demographic change in their student bodies and their faculties, not the least of which is technological expertise. Administrators are requiring increasingly more program assessment. Faculty across the curriculum are demanding that students be able to write academic papers. Furthermore, because there is not a uniform standard of excellence, the "good paper" is a nebulous thing. Complicating these issues is the fact that composition studies have become a discipline, a significant evolution in the past 20 years, and, as is the case in most disciplines, because the field has developed many threads, writing programs often must overcome resistance to change and/or inertia. That most schools have faculty from a range of backgrounds and technological experience only serves to further complicate these issues. However, once having identified the basic goals of a writing program, if we make it easy to use technological innovation beyond the use of a computer as a glorified typewriter, students can have a program tailored to their needs; faculty can stress a common core and can learn to incorporate technology painlessly; and administrators can compile the required program assessment.

In the Classroom

Incoming freshmen typically arrive with inconsistent writing skills. They have varying degrees of proficiency in conducting and documenting research, constructing cogent arguments, and applying rhetorical and grammatical standards. Faculty often have developed "pet" ways of dealing with these heterogeneous classes; some are measurably effective; others are less so. We have found that by making technology a major part of each course, we can provide a common core of instruction. Furthermore, by distributing the common core to the faculty at large, we can help them to develop expectations for the caliber of academic writing their students will produce.

Among the methods that have worked for us in the classroom are:

- Meeting each class in a computerized classroom once a week.
- Constructing a common core of instruction
- Developing core lessons that can be used in a computerized classroom
- Creating PowerPoint lessons that can be individualized by faculty
- Using a LAN to create faculty directories for in-class work
- Establishing an Internet connection and using it for in-class work
- Crafting a Departmental Web page that has many resources
- Providing meaningful CAI for a writing class (handbook, full dictionary, links to web sites, etc.
- Establishing grammar, EFL, and reading drills and pointing students to them on an individualized basis, as needed.
- Using WORD features (for instance highlight changes, compare documents, track changes.)
Assessment

Administrative units are requiring more detailed assessment of students, courses, and programs. To assess courses and programs properly, we should identify specific, assessable goals; stipulate what constitutes success in reaching those goals; evaluate whether or not the goals were reached; and feed the results back into the program. The assessment of students in a course or program should be related to those goals.

We have found it meaningful to:

- Compile data about academic indicators and student background and provide faculty with individual class profiles in the aggregate.
- Develop grading rubrics or standards for grades that are tied to the goals of the course and to the degree of accomplishment as related to the common core.
- Provide faculty with comparisons of indicators and mid year and final grades.
- Develop portfolios for each student and assess them according to the goals of the course.
- Distribute results of assessment to the faculty at large.

Conclusions

By thus relying on technology to implement a common core, we can assure that students receive standardized instruction, and we have not infringed on the traditional professorial right to an individual teaching style. By developing rubrics that are determined by the common core of instruction and assessing portfolios according to those rubrics, we can provide meaningful assessment of the course. By telling faculty across the curriculum what the results of the assessment are, we can provide them with meaningful expectations of the academic writing they will receive. The students enjoy using technology. The faculty are not frustrated by their varying degrees of technological expertise. The administration has assessment that is pertinent.
The 3D Term Paper: Putting Virtual Reality into the Writing Process

Carl L. Reynolds, Professor
College of Education
University of Wyoming
Laramie, WY 82071
Aged@uwyo.edu

Christine D. Reynolds
Language Arts Instructor
Rock River School
Rock River, WY 82083
Creynolds@sage.ac1.k12.wy.us

Abstract: In order to meet a need for an enhanced approach to writing term papers using MLA format, the secondary ELA teacher in an isolated rural school in southeastern Wyoming integrated web-based technology into the process. Students acquired communication skills that are traditionally a part of standard ELA instruction, as well as meeting district standards and benchmarks, while incorporating advanced technology to complete the project in a highly motivating manner. The assignment motivated students to think for themselves, to solve problems, and to read, interpret and apply complex operations in what previously had been a common, mundane, "boring" assignment. The students had fun, the teacher had fun, and ELA standards and benchmarks were mastered.

Introduction:

In order to stimulate new interest in the old, English-Language Arts standby, the term paper, the instructor searched for ways to utilize advanced technology to enhance the students' annual term paper efforts. The students were asked to incorporate appropriate web site URLs in the body of their work. Not only were they asked to use the web as a source for information to document their research on selected topics, but the URLs also became a part of the paper itself. In addition, students were asked to embed multimedia sites, such as movie clips, sound clips, action cam sites, and virtual tours to enhance their message and to create a third dimension to their work.

Background:

Prior to integrating technology in the writing process, students would dutifully complete the annual term paper assignment, using standard, hard copy material found in the library. They copied out of the encyclopedias, magazines, and periodicals, in spite of repeated warnings of the evils of plagiarism. In addition, because of the size of the school library in a K-12 school in rural Wyoming, much of the hard copy resources available were sorely out-of-date. Or, they would enlist the assistance of mom, dad, a friend or the Internet, to create the paper for them. In the past, money had been spent to purchase the term paper assignment. Something had to be done to encourage the students to want to complete the assignment themselves, as their best work, and to create a document of which they could be justly proud. By creating a new "third" dimension to the assignment, students were motivated to take pride and ownership in the project. It became fun to write a term paper.
Implementation:

The instructor utilized time-tested writing process instructional procedures, as well as integrating web-based technologies to augment the students' annual term paper writing experience. In collaboration with university personnel in the College of Education, the teacher and university faculty member demonstrated the use of Internet sites and selected citations to prove the validity of the paper's thesis. Traditional research methods were taught to students who ranged in age from 12-18, in grades 7-12. The teacher demonstrated the use of the MLA format, a traditional research tool, for all students to ensure quality results. The teacher demonstrated, through the use of paragraphs with imbedded URL's, the impact of multimedia in providing additional emphasis and impact to prove the thesis of the paper. Demonstrations were conducted, through analysis and the application of critical judgement of several sites, the rationale for selecting a particular site. Finally, the students were instructed in ways to establish the reliability and validity of the chosen sites. As a final step to the project, the students projected their work (in addition to handing in a hard copy for archival purposes), using Microsoft Word and the school's computer display projector, and they gave a speech about the results of their research.

The combined project was archived as a part of their "body of evidence" to prove competency in the ELA state standards of Reading, Writing, Listening, Speaking, and Integration.

Conclusion:

Because of a need to enhance, through technology and multimedia, the required but often mundane assignment of the annual term paper, students were given the chance to create a 3D term paper. The project featured URL's embedded within the paper, that were hyperlinks to sites that featured movie clips, sound clips, action cam sites, and virtual tours to enhance their message and to create a third dimension to their work. The multi-dimensional project stimulated increased creativity and interest in the term project, which usually caused groans from the students. Instead, comments during class from students included such comments as, "Come see what I just found!"

Follow-up interviews with students indicated clearly that students were more motivated, collaborated with each other more, and shared in each other's work much more than when the traditional term paper writing project was conducted. Comments such as "I don't care much about writing, but this project was more like putting a show together", and "I enjoyed seeing what other kids came up with" were common. By adding the "third dimension" students were taught, Traditional English standards were accomplished, as well as integrating advanced technology skills in the English curriculum. Most of all the project became "fun" for students and the teacher alike, while at the same time accomplishing the ELA standards and benchmarks mandated by the state and local district.
Lessons Learned: Twelve Years of Actively Integrating Technology into the Teacher Education Program

Susan Ramp Ridout, sridout@ius.edu
Carl deGraaf, cdegraaf@ius.edu
Jane E. Riehl, jriehl@ius.edu
Indiana University Southeast, New Albany, IN, USA

Background
Twelve years ago, an overwhelming feeling of remiss fell upon the two teachers of the Language Arts/Reading Methods Block at Indiana University Southeast in New Albany, Indiana. Why? We kept hearing about the power of technology in the classroom and the backwardness of any teacher preparation program that ignored this idea. From whom did we hear this? From national publications and “future experts.” But even closer to home, we heard it from a colleague in our own School of Education.

After facing up to the fact that our forward-thinking colleague was right, we decided to try to change our current modus operandi to make room for technology within our methods courses. But, there was one major problem. Neither of the two methods teachers knew much about technology for our own personal uses, let alone had enough confidence to require students to teach lessons using technology while we supervised. So, we did the only thing we knew how to do, we asked our colleague who was so interested in seeing an infusion of technology into methods courses, if he would help us.

During the first years of this project, our students had very little computer savvy coming into their Language Arts/Reading block. Some had been in a 1-hour computer course, but really did not know the software they would be using with children. Therefore, our colleague trained the university students by holding workshops to learn the software we would be using at Galena Elementary School, the site of our practicum. Now our students come to the Language Arts/Reading Methods block having had a 3-hour college course in educational computing, and are fairly comfortable using technology themselves.

While the technological ride continues to evolve, after twelve years we have learned several valuable lessons. Here are a few of them:

Lessons Learned
One: The university is not in charge of all decision-making. At first, we at the campus selected the software, delivered the workshops to our students, and shared our limited expertise in an authoritative way. But, as time has marched on, not only have the Language Arts/Reading teachers become more comfortable with technology, the teachers at Galena have, too. Now, the school has requested the software packages we use. Together, we plan our projects, attend conferences, and give presentations.

Two: Programs housing technology must be in a constant state of evaluation/change. While it would be easier to stick with software packages and the present “way of doing things,” the program has needed to be in a constant state of change. For example: we have gone from desk top computers in a lab, to lap tops in various locations in the school, back to desktops, but this time not in a lab, but in the actual classrooms. Numerous times we have changed software packages, e-mail transport systems, and the way children respond to e-mail. This notion of constant change has not been easy for the two methods teachers who like to feel more organized and prepared than advances in technology will allow. Indeed, hard work is the constant companion of technological innovation in schools, and there is little time to “coast and enjoy the ride.”

Three: All participants are the teachers of technology. It no longer is one teacher at Indiana University Southeast and one teacher at Galena who hold the keys to incorporating technology. Now, the IU Southeast students share their knowledge with the children, with Galena teachers, and with the IU Southeast faculty members. Likewise the teachers at Galena and the methods faculty share technology tips and help students and children problem-solve. And, often most helpful, the children at Galena continue to instruct all of the adults involved in this project.
Four: The availability of hardware determines how fluid the infusion of technology is. A few years ago when we first heard that the computer lab at Galena Elementary School was being dismantled, we almost cried! What? How were we going to actively incorporate technology into the program without a lab? And...what about glitches? Who would help with the glitches? (All of the adults might have to know a bit more because the most technology-proficient Galena teacher and IU Southeast faculty member could not be everywhere at once.) As it turned out, this change was exactly what we all needed. It forced us all to become more diligent in our efforts to become proficient with technology and it enabled our students to really use technology in a fluid manner. Having the hardware readily available in the classrooms has allowed children to look up questions, write on the word processor, or create hyper cards when they are ready, not necessarily during the 30 minutes they were previously assigned to the computer lab.

Five: The Internet truly enhances the power of literacy lessons. We are watching our students teach literature-based lessons that include skimming, scanning, and note-taking skills and strategies being taught as the children gather research from Internet sites. The children enjoy engaging in purposeful reading activities on the Internet, all the while improving their understanding of the logical organization of websites. This, in turn, is helping them with their reading comprehension skills.

Closing
The lessons we have learned during this twelve-year experience have been perhaps the most rewarding of our professional careers. We have truly felt like a total community of learners, and eagerly look forward to the next few years to see what new lessons we will be fortunate enough to discover.
The Lektor system for the creation and reading of electronic books

José L. Rodriguez Illera
Universitat of Barcelona
jlrodrig@ariadna.d5.ub.es

`E-books ' have had a prominent position in the media over the last years, always tied to the possibility of partially substituting the reading in paper for the electronic reading. This topic has several possible approaches, in this presentation we will basically cover the possibilities and demonstration of a new system for the edition and reading of electronic books based on pedagogical approaches.

The current situation of electronic books.

The electronic books started as a new technological possibility, derived from the improvement provided by user's graphic interfaces, as well as of the new portable reading devices, always adding the advantages of the digital edition in the treatment of the text. However, it cannot be said that there is a standard system, as it is the case for the operative system in conventional computers. Although there are several types of programs that generate electronic books, there is only a few widespread. (but incompatible to each other):

Acrobat Ebook Reader (and its variants)
Microsoft Reader
Diverse proprietary formats of the different portable devices.

One of the few standards proposed for the ebooks, the denominated Open Source, promotes that the text of the electronic books be in a variant of XML, although such a format is not compatible with Acrobat. Microsoft Reader has its own format and it can be used in platforms with Windows and Windows CE operating systems. The different devices (Rocket, Pocket, etc) use their own operating systems or Windows CE, incompatible with each other.

This situation is normal in an emergent market sector, thus the suppliers of electronic books opt for converting the originals into one or several of the already existing systems, offering two or three formats for the same title so that the readers choose the one suitable for their reading system. The use of electronic books, in the sense of 'ebooks ', is at the moment almost limited to novels, historical and literary works, although the use of electronic documents is widespread for any content type.

The electronic books have some important disadvantages. The main one is the scarce screen resolution. This is a problem that will be solved with screens offering more resolution, but this will not be immediate. Microsoft has created an improved antialiasing system, ClearType, that allows a better visualization of small size type fonts. Acrobat has also created its own system that uses a similar system to colour antialiasing and that shows very good results. Both systems will be incorporated in the operating systems, and improve the reading on screen.

The Lektor system
Lektor is a new system to create and read electronic books that started dedicated especially to the educational and training sector, and now covers the most general electronic edition. It emphasizes the reader's possibilities like a fundamental issue in the reading process, at the same time that makes it simple to the teachers the creation of electronic texts with instructive aims.

Its current position, shortly described, is as follows:

- It uses a basic and universal creation standard: files in format text (.txt), as well as Html with limitations.
- The creation of books is very easy: it is enough with specifying a text file, adding the data about the author, title, etc. and the program carries out the rest automatically.
- The books can be read in conventional computers (desktop, laptops) and in different operating systems: Windows 95,98,2000, Me, NT, Macintosh 8.5 and 9.x, and Linux and Macintosh X in the next version.
- The interface is multilingual, and the user can choose the language and change it in any moment. In version 1, Lektor supports the following languages: Catalan, English, Spanish, French and Portuguese.
- It offers advanced capacities of search: quick search of words and sentences, as well as complete indexing with chart of frequencies and contextual occurrences of each word.
- Lektor has a group of tools that the reader can use to work with the text: specific notepad for each book, possibility to mark the text with colors, highlight reading pages, and write down commentaries.
- The author can decide to re-export the contents of books created with Lektor, so that the text is always recoverable.
- It allows inserting graphics or commented diagrams.
- Impression in text and graphic modes.
- The electronic books remain in the user's library, in their local hard disk. New books can be downloaded with any navigator and incorporated to the library.

Besides these general features, Lektor offers a series of facilities for the use of ebooks in schools and educational institutions, by means of a module, denominated Scola, that allows the teacher or the author to associate to the book questions of understanding and tasks related to the reading. Scola allows the student to write a comment on the reading document, as well as to send the professor its own questions or suggestions by means of a module that incorporates electronic mail.
Developing EFL collaborative and communicative writing skills on the Web:
An evaluation strategy proposal

Janete Sander Costa, Universidade Federal do Rio Grande do Sul/CNPq, jtscosta@uol.com.br

Silvana Zardo Pacheco, Faculdades Integradas do Instituto Ritter dos Reis, silvana@portoweb.com.br

Dra. Cleci Maraschin, Universidade Federal do Rio Grande do Sul, clecimar@adufrgs.ufrgs.br

Porto Alegre, Brazil

Abstract: This paper reports a study, which aims at evaluating the development of written communicative competence of a group of college students in a Language Course in Brazil, majoring in English as a Foreign Language, during three academic semesters. Students have been utilizing EquiText, a collaborative writing tool on the Web, as a vehicle to improve their linguistic competence in text productions. This tool provides future teachers the opportunity to build a textual interaction on the Web as an alternative means for the face-to-face current practices. Texts written collectively provide the material for this evaluative analysis, which ultimately investigates whether the participants' communicative strategies represent significant indicators of their learning progress in this peer text construction.

Introduction

Digital technologies have been used in the education of future teachers of English as a Foreign Language (TEFL), opening new teaching fronts to Computer Assisted Language Learning (CALL), especially in the linguistic competence learning field. The Brazilian Ministry of Education and Culture (MEC) as well as private educational institutions encourage research in applied technology for collaborative work. Collaborative writing systems available on the Web have been created, such as Col-laboració, REDUCE, EquiText, WikiWiki Web, BSCW, which certainly can be utilized in TEFL programs to enhance learning language skills in response to growing demands for new digital resources as alternative means to teaching/learning conventional materials.

EquiText®, a Groupware tool that uses the Web as a word processor model, developed by a multidisciplinary team at the Post Graduate Program in Computer Science and Education at the Federal University of Rio Grande do Sul, according to socio-constructionists concepts, including Vygotsky's “zone of proximal development” (Rizzi et al., 2000a), allows any peer interactive written task in any language including EFL. Its layout favors the writing and rewriting of texts asynchronously by several remotely located people, allowing a constant text edition - during a limited time granted by the task mediator to the participants - in a friendly and accessible manner, displaying an immediate screen visualizations of actions. EquiText educational applications have been carried out in Brazilian academic programs and findings presented in local, national and international events2. As a CSCL resource, it promotes collaborative learning supported by the Web tools, and open space for production and sharing of knowledge, also among EFL learners.(Chapelle 2001).

A pilot project utilizing EquiText to improve linguistic competence in future teachers of EFL has been developed at the Faculdades Integradas do Instituto Ritter dos Reis, Porto Alegre, Brazil, for three consecutive academic semesters. It aimed at analyzing mainly the process of writing in future teachers of EFL according to the communicative competence construct mentioned in Canale & Swain (1980) and Canale (1983), now in its preliminary evaluative stage. Written communicative competence of a group of 10 EFL voluntary students has been evaluated mostly from their interactions in the co-construction of the text entitled Short Story (second text), a negotiated and reflected result from their first experience with EquiText during the writing in collaboration of the Collaborative Writing text, specially created for their free use and learning of the tool. For analytical purposes just their interactions taken place in the second text - Short Story - will be considered. See Costa et al. (2001a,b) for further detail.

The Study

The communication model used here for analyzing collaborative writing in Equitext and its possibilities of improving language skills, according to Canale & Swain (1980) and Canale (1983) concepts of communicative competence are based in three main communicative competences for the teaching of ESL: the grammatical, which registers the domain of the linguistic code, through the vocabulary, pronunciation rules, word formation and sentence structures (essential for students to reach higher proficiency level); the discursive and the sociolinguistic competence, which encompasses the capacity to combine ideas to reach cohesion in the form and coherence in the thought, and to use the grammatical forms adequately in several contexts, expressing the communicative functions in descriptions, in narratives, to persuade, to thank, to invite, etc.; and the strategic, especially used either in the proper process of communication or to express flaws in the knowledge of the code to negotiate meaning, recognized in paraphrases, aid requests from peers, etc. (Schlatter et al., 1998). It is emphasized that the written communication under analysis in Equitext is based on interpersonal interactions, in a sociocultural context, with inherent unpredictability, creativity, purpose, final result and authenticity of the language used. In this particular group, writing and rewriting by the 10 volunteer students in Equitext took place both synchronously (students met in the same Lab room and could interact face to face) as asynchronously (students contributed to the text in other moments, elsewhere). The students were attending various disciplines of EFL in a Language Course, and had different levels of language proficiency. They all worked for this project knowing that there were no evaluation implications involved.

During our study, we could easily find two of the communicative competences described in Canale & Swain: the grammatical and the socio-linguistic (here in conjunction with the discursive communicative competence) in its paragraph layout. The strategic competence, essential to compensate flaws in the communication, turned up less frequently in the Short Story than in the Collaborative Writing text, as a result of the students’ discovering the free writing exercise and still counting with peer and teachers-mediators support, according to Costa et al. (2001a), as they negotiate the topic for the second text, Short Story, mentioned in Costa et al. (2001b). In fact, the tool itself makes the strategic competence possible because all contributions there are open to interference of any other participant: the strategic request for help is implicit throughout the task. Communication happens in spite of the limits imposed by the virtual environment, as human beings are flexible and adjustable. The final result or text production works as an integral part of the complex discursive process, where the written language used by the participants, independently of their linguistic competence level, is preceded by reflection and correction, is (re)organized logically in paragraphs, proper of the EquiText layout. Speakers/writers act more or less coordinately while elaborating the collective text, creating a new multi-territorial and multi-authorial space. The resulting cognitive processes can improve the students’ fluidity in the use of their linguistic knowledge (Swain, 1998).

The set of paragraphs submitted during the text construction was a more or less communicative text. However, this evaluative study of the students' collaborations - based on the communicative competence approach - concentrates in the paragraphs stored in the "History" function and not in the final text production. Actually, the "History" function displays individual participations, corroborating to the whole text, i.e., a space that exposes to the user all the contributions made in the text in chronological order. For each contribution the accomplished action is indicated (inclusion, alteration, exclusion), its author, date and time the action was executed. The final product is collective, but it is in the function “History” that all the procedural register is stored, all individual contributions are displayed, revealing rich and peculiar meta-linguistic (Swain, 1998), and meta-cognitive processes (Ridley, 1997).

The students volunteering in this project were all taking different levels of EFL courses, were considered intermediate to low advanced proficient in EFL, according to the ACTFL Proficiency Guidelines (Hadley, 1993, p.13). Their openness to learning with each other in a different means - without the evaluation ghost haunting their souls - perhaps made it simpler at first. Actually, Collaborative Writing text interactions were their first collaborative writing experience in text construction on the Web and that was possibly the reason why they seemed to be at ease in sharing ideas for co-constructing Short Story, their selected topic for the second text. EquiText became then an interesting and democratic environment, an opportunity for them to learn English and eventually teach, collaboratively. It motivated most of them to overcome difficulties, to take risks, to recognize their own mistakes and those of others and to correct them eventually, turning this activity into a dynamic and productive learning experience. This peer text construction generated solidarity and mutual responsibility (Ushioda, 1996) improving their EFL linguistic abilities, especially reading and writing.

Short Story collaborations (from November/2000 to July/2001 mostly) represent the material for our preliminary evaluative analysis. An arbitrary evaluation scale has been created to measure all the collaborations
stored in the “History” function of Short Story text, in a scale of 0 to 10, varying from maximum (10), medium (7) and minimum (4), for all paragraph contributions: Insertion before or after, Alteration, and Exclusion, according to the EquiText functions shown in its menu of collaborations. Participations are computed according to the degree of relevance to the text development, according to the grammatical, sociolinguistic – discursive, and strategic communicative competence model. The grammatical and lexical inadequacies shall be considered if they modify the text course somehow, hindering its clarity, and receiving, in result, the corresponding degree.

Findings

This preliminary analysis of the data collected through the function “History” leads naturally to the idea that Equitext as a communications tool offers good resources in aiding to the reading and writing process in a text written in collaboration task. Illustrations 1 and 2, below, show the percentile of the participations by student as well as the three types of collaboration accomplished by those 10 students in the Short Story.

Insertions of new paragraphs to the Short Story text were in smaller number than Alterations to the ideas already submitted. Students seemed to be either more involved with turning the text clearer or simply correcting grammar episodes. The Exclusion of paragraphs, with the intention of turning the sequence more fluent, coherent or logically connected, was very small, however significant. Female students accomplished more alterations than men, an interesting finding for a gender analysis. (See Figures 1, and 2). However, a contribution by Carla, for instance, that didn't modify the text in course and to which punctuation was not attributed (neither 7 nor 4), even having the contribution been registered in the function “History”, a type of database of the text in process. Contributions like Carla’s were not computed for they did not present significant value, neither to the textual movement, nor to the proposed analysis. We tried to maintain the analysis under the perspective of the quality and of the relevance of the contributions to the narrative, and considering the communicative competence, grammatical, sociolinguistic – discursive, and strategic, which actually revealed somehow the students linguistic improvement.

Communicative competence: Insertion

Figure 3: Demonstrative Graph of the three communicative competences in the Insertion function by student.
Communicative competence: Alteration

Figure 4: Demonstrative Graph of the communicative competence in the Alteration function by student.

Figures 3 and 4 above present two graphs built from data raised out of the Short Story “History” storage functions: the Insertions, Alterations and Exclusion listed in the collaborations menu came from the 10 students Short Story production, arbitrarily valued as 10, 7 and 4, though qualitatively attributed. They show the total of participations and their authorship, as well as the nature of their collaborations. Also, they bring referring data to the nature of the insertion and the corresponding communicative competence, as well as their degree of relevance to the textual weaving. Therefore, they reveal the importance of the participation to the process of the text construction. In addition, results show that Alterations (Fig. 3) and Insertions (Fig. 4) largely surpass Exclusions and that grammatical and sociolinguistic – discursive competence were close in intensity, either in their frequency as in the text alteration. The strategic competence due to its interactional and more dialogic nature was apparently less present in the Short Story than in the first text Collaborative Writing, where students had to negotiate for topic and learn to handle the tool, having therefore to ask for help – a clear case of a strategic communicative competence. On the other hand, EquiText itself potentializes this kind of competence in virtue of its design: it could be implicit in the participants’ minds and actions while being receptive to any alteration in their paragraphs. At this very moment, each paragraph author also uses insertion strategies from the others in their own texts. There’s a permanent linguistic feedback on the Web and those participants later reported that their experience in Equitext while writing texts in EFL collaboratively contributed considerably to their easiness with the language and with the learning processes there involved, an important gain in their education: “we think that collaborative writing is very important to English students because we can change ideas and work together.” (Danilo/Jö, in 11/22/01).

Conclusions

The unprecedented diffusion of the Internet resources, the urge for friendlier and easier educational software to aid to current classroom didactics, in addition to the ever growing challenges that (future) teachers of EFL are facing today in their educational formation, necessarily forces us to a reevaluation of the paradigms towards the teaching of foreign languages, especially English, in Brazil in view of its being the current lingua franca. Sustained basically by the theoretical foundations of Canale & Swain’s communicative competence model we feel confident to suggest that the communicative competences found in the text construction of the 10 EFL students analyzed in this pilot project have somehow developed if not improved considerably while writing collaboratively in Equitext during the three academic semesters studied. We agree with Hirvela (1999) that writing collaboratively [in Equitext] will not solve all the problems, nor will it work for all the students, in the same way as any other teaching approach. However, producing a text collaboratively may create significant opportunities for the practice of other linguistic abilities: participants of a group that carry out a task [e.g. in Equitext] negotiate meaning while constructing their text. As a result, they develop group attitudes, which sustain more affective and consequently more effective language learning strategies. Positive peer interactions mediated by a constructive teacher can create high levels of motivation and promote more constructive learning. And this has been verified throughout our students’ collaborative text construction, in both Collaborative Writing and Short Story texts. Thus, the interactions through the Web studied in Equitext produce a group articulation with meta-cognitive peculiarities that retroact and enhance the analyzed communicative competences.

Finally, we believe that other EFL teaching strategies in conjunction with the digital technology available on the Web may generally improve Brazilian learning levels. Thus, Brazilian students’ communicative competence in EFL can improve by EquiText environment layout as it facilitates the construction of communicative strategies in collaboration with other peers in order to produce shared knowledge while the text writing movements takes place. Moreover, the construction of a collective that enhances EFL writing skills among (future) teachers in Brazil is possible and provides their users with other more autonomous, reflective...
and co-responsible means of teaching. EquiText proved a helpful group knowledge construction tool, with considerable benefit to the education of Brazilian teachers.

Write to Learn with Journal Zone

Peter Skillen, Educational Consultant, peter@peterskillen.org

Abstract: Journal Zone is an online 'journal' that supports reflective learning within a social context. It is a classroom tool that integrates three common practices of exemplary teaching—journal writing, collaboration, and cognitive scaffolding. These encourage students to think more deeply, not only about the task at hand, but also about their own thinking and learning processes. Journal Zone is designed to support and encourage the development of both expertise in learners and of 'collaborative knowledge building' communities (Salomon et al, 1991; Bereiter et al, 1992; Scardamalia et al, 1994). How can novice learners become more like expert learners? What role do journal writing, collaboration, and scaffolding play in the development of learning?

Novice versus Expert Learners

'Intentional' or 'mindful' learners are learning to become expert at becoming expert (Scardamalia et al, 1983). They are learning not only subject matter and skills, but are acquiring valuable metacognitive knowledge as well. Current pedagogical models acknowledge that 'learning to learn' is central to education (Perkins, D.N., 1995). Journal Zone is designed to help novice learners acquire many expert strategies and behaviors through their purposeful engagement with peers and with the support of the scaffolding features.

Journal Writing

A Place to Think

The very presence of a journal acts as a tool that predisposes people to think— to plan, monitor, and reflect. This helps overcome the difficulties of not even thinking about performing these tasks. Sometimes it is not that the student doesn't know how to plan, it just does not come to mind to do so. The journal, therefore, reminds students to think and gives them the opportunity.

Thinking About Thinking

Journal writing allows for the externalization of knowledge through language. Language plays an important role in making knowledge explicit by objectifying experience. So as students engage in writing about their knowledge they are indeed exploring, stating and questioning what they know (Britton, J., 1970).

Understanding Subject Matter Through Writing

Writing has been widely accepted by educators and researchers as a significant means of learning subject matter more effectively. Countryman (1992) says, "Knowing mathematics is doing mathematics. We need to create situations where students can be active, creative, and responsive to the physical world. I believe that to learn mathematics, students must construct it for themselves. They can only do that by exploring, justifying, representing, discussing, using, describing, investigating, predicting - in short by being active in the world. Writing is an ideal activity for such processes."

Journal writing, as a form of writing and 'thinking out loud,' seems to assist in initiating, supporting and encouraging intentional learning. What role might collaboration, cognitive prompts and computers have in designing an effective journal writing environment?
Collaboration

Central to knowledge construction is the recognition that learning is a social process. Social interactions allow for concepts, vocabulary and processes to be made explicit. Learning has been said to be “less as the socially-facilitated acquisition of knowledge and skill and more as a matter of participation in a social process of knowledge construction” (Greeno, J.G., 1997).

Journal writing, usually a personal event, may also be more public or collaborative. This collaborative form of journal writing leads to unique experiences that have qualitatively different results than individual journal writing. Students not only reflect on their own thoughts and processes, but also exchange information about both the subject content and the processes and strategies used by others. This leads to more comprehensive knowledge building and results in both better reports and increased metacognitive skills.

Journal and Elaboration Prompts

Both journal writing and collaboration offer opportunities for students to think deeply about their tasks. Specifically, students may engage in a great number of thoughts related to planning, monitoring and reflecting. But, they also may not. Prompts, questions or sentence starters may provide the necessary scaffolding for this to occur.

Journal starters encourage the change of normally covert procedures into ones that are overt. They help students to consider one’s own higher level strategies and they promote the active decontextualization of knowledge. They may allow the user to decenter from personal thoughts and think about other considerations. They facilitate an internal dialog when no other partner exists to “bounce ideas off”.

Summary

Journal Zone is an online tool for reflective collaboration. Journal writing, collaboration, and scaffolding support and encourage the development of students’ expertise in learning.

Literacy Junction: Exploring Adolescent Identity and Social Agency on the Web

Hiller A. Spires

Abstract: This paper describes Literacy Junction, an interactive web site for middle school teachers and students. Using an interdisciplinary approach to learning, Literacy Junction offers three unique features: technology-enhanced experiences with outstanding young adult literature, a virtual middle school environment replete with student-created cybercharacters and cybermodels, opportunities for critical analysis of contemporary social issues. Our ongoing research suggests the motivational value of an interactive, literary cybercommunity to support high reader/text engagement. Through their membership in this unique online community, students are challenged to develop a sense of their own social agency.

Literacy Junction, (http://www.ncsu.edu/literacyjunction) an interactive web site for middle school students and their teachers, takes a unique approach to connecting young adult literature to young adult audiences. Recent research suggests that adolescents are spending more time reading on the web and less time reading traditional print-based texts. Rather than attempting to reverse this natural adolescent learning trend, we are capitalizing on it by providing technology-enhanced learning opportunities to accompany young adult literature. Literacy Junction offers features that both peak the interest of adolescents and simultaneously augment the need for rigorous and engaging reading experiences in middle school. In order to accommodate the needs of both teachers and students, Literacy Junction includes the following features:

- Teacher-generated lessons tied to the NC Standard Course of Study
- Technology tutorials for teachers and students
- Publication of student-generated work
- Community of cyberpeers who model academic products
- Student-created cybercharacters
- Critical analysis of contemporary social issues

By offering the opportunity for both face-to-face and virtual meetings, this networked professional community provides the mentoring and continued support that teachers need to initiate and sustain new
teaching practices. Additionally, *Literacy Junction* offers unique opportunities for students to creatively express themselves as they grapple with contemporary social issues that are prompted from young adult literature.

As we designed *Literacy Junction*, we kept one basic premise regarding adolescents in mind—“for middle schoolers, school is primarily a place for making friends... and figuring out just who you are. Somewhere after all of that, it’s also a place for learning” (Beers, 1998). The three conceptual tiers underlying *Literacy Junction* take full advantage of this well-established understanding of what engages and motivates adolescents. First, there is Cyber Heights Middle School (CHMS), *Literacy Junction*’s virtual learning center. CHMS cybercharacters typify the idiosyncrasies of real world adolescents and teachers. These “virtual” characters serve as our cybermodels, demonstrating academic approaches to the literature-related activities offered at *Literacy Junction*. After getting to know the resident cybercharacters, our “actual” (or real world) student visitors are then invited to create their own cybercharacters to attend CHMS. These student-created characters, who form our second tier, immediately become part of the cybercommunity and are invited to participate in online learning opportunities through the genius of the students who created them. A third and final tier of the site is comprised of our “fictional” CHMS characters, who include the many protagonists from the books featured on *Literacy Junction*.

After getting acquainted with and creating cybercharacters, *Literacy Junction*’s student visitors “go to class” at CHMS in what might be best described as the *Literacy Junction Impact Zone* (Fig. 1). In this theoretical zone, actual, fictional, and virtual worlds converge as students grapple with contemporary social issues signaled from young adult literature. Through their own perspectives, as well as the unlimited perspectives of the cybercharacters they create, students negotiate their evolving identities and embrace their emerging roles as socially responsible citizens. Within the *Literacy Junction Impact Zone*, students experience unique learning opportunities that potentially include: text immersion and critical web consumerism; intellectual rigor and creative expression; perspective-taking and identity negotiation; personal efficacy and social responsibility.

![Figure 1. Literacy Junction Impact Zone](image)

Over time, we expect *Literacy Junction* to help teachers integrate technology, to increase students’ capacities to use technology as a learning tool, and to enhance students’ academic and personal growth as they develop a sense of their own social agency. By using young adult literature as an elemental and engaging platform, *Literacy Junction* provides an appealing technology-enhanced environment for adolescent cognitive and social development.

Assessing the Process and Efficacy of Moving Literacy Education Classes Online

Matt Thomas, Ph.D.
Assistant Professor of Literacy Education
Department of Curriculum & Instruction
Central Missouri State University
United States
mthomas@cmsu1.cmsu.edu

Abstract: This paper reports on successful efforts to bring a teacher education course in content area literacy into an online-only environment. It delineates the research-based planning of the course development, course efficacy relative to other forms of delivery, and some of the implementation challenges. The course planning was based on an emerging collection of best-practices in online instruction coupled with the embedding of new online versions of best-practices in traditional content area literacy instruction. Course efficacy is evaluated by comparing quantitative data and anecdotal information from the online course with the same course taught in hybrid and traditional formats. Simple conclusions are drawn in order to advance current understandings of the process and efficacy of moving literacy education classes online.

Introduction

In summer, 2001, the researcher was awarded an online course development grant for $9,000. The purpose of the grant was to move a teacher education course, taught previously by the researcher in both traditional and hybrid formats, into a completely on-line course. This was done by utilizing BlackBoard course delivery software, subscribed to by the researcher's university. The course title was “Teaching Reading in the Secondary School” and is taken for undergraduate or graduate credit. The main content of the course is targeted toward helping pre-service and in-service teachers acquire understandings of student literacy development and teaching methods for best helping their students to learn from their many content area reading, writing, and thinking assignments.

Research-Based Course Development

The backbone of the course structure was a series of thirteen Learning Modules built, by the researcher, around the course text, a content area literacy textbook by Manzo, Manzo, and Estes (2001). Each Learning Module was a Microsoft Word document that the students downloaded and on which they completed the work assigned within the Learning Module. The Learning Modules were designed around a synthesis of best-practices research regarding both traditional literacy pedagogy and online course delivery (c.f. Manzo, Manzo, & Estes, 2001; Thomas & Grigsby, 2001; Dwyer, Sunal, Geisen, Sunal, & Trundle, 2001; Thomas & Hofmeister, in press). Each Learning Module contained the following distinctives: an agenda and task list; a lecture essay to introduce the material; a chapter of the text to be read; a set of Microsoft PowerPoint notes over the chapter; an application activity utilizing journal writing and online discussion board interactions or small group collaborations; three levels of “reading the lines” (reading the lines, between the lines, and beyond the lines, or activities that required reading comprehension, inferencing, and higher-order literacy); transmission, transaction, and transformational models of instruction/learning; three different types of structured interactions (student/text, student/student, and student/teacher); a carry-out thought or quotation; and a checklist to ensure all of the Learning Module tasks and activities were completed. Additionally, in the chapters of the text a selection of content area reading strategies were presented. In subsequent Learning Modules then, key teaching strategies, modified for an online/Learning Module environment were employed as the main strategies used within the Learning Modules themselves. Content area reading/literacy methods or strategies embedded in the Learning Modules included: Listen-Read-Discuss (Manzo & Casale, 1985); Three-Phase Graphic Organizer (Manzo,
Efficacy of Online Course, Implementation Challenges, and Conclusions

Since the summer of 2001, approximately 75 students have completed the online course. Quantitatively, according to test scores, assignment grades, course grades, and course evaluations, the online course compares equitably to the traditional and hybrid format offerings of the same course taught by the researcher. Anecdotally, based on reflections in their course notebooks, discussion board interactions, and e-mail conversations, students learn a good deal, read their texts more carefully, think critically about the course topics, and find the course to be valuable. However, while some students seem pleased with the flexibility afforded by the asynchronous course delivery, others express that they miss the face-to-face interactions of a traditional course. The primary practical implementation challenges faced by the researcher have included: the time-consuming nature of Learning Module creation and monitoring and participating in many discussion board threads; helping students with needed technology skills; and managing a very great increase in the number of e-mails from students. Future course upgrade goals include adding video streaming, developing more small group collaboration activities, and developing a web-based environment for housing student work for future use by themselves and by colleagues.

Abstract: With the arrival of technology’s presence within classrooms around the world, the responsibilities of the teacher quickly become redefined. Technology itself cannot automatically provide learners with an enhanced education; thus, teachers are encouraged to critically examine how technology is used in their classrooms. It is essential for teachers to actively question issues surrounding technology’s ability to support constructivist teaching and learning approaches. This paper will offer a discussion around the successful implementation of an electronic learning environment, supported by CSILE/Knowledge Forum®, in a Northern Canadian classroom and educators’ views on the impact on literacy learning.

Introduction

Using computer based technology to support literacy learning has been embraced enthusiastically by some, outwardly rejected by others and examined cautiously by many. What remains a concern is how to ensure that the computer is used in a pedagogically sound way to support learners as they use language in functional ways to construct meaning. One of the challenges for educators is making computer learning experiences culturally relevant while supporting literacy development. This paper examines educators’ perspectives on the challenges and possibilities for literacy development created when CSILE/ Knowledge Forum® (Scardamalia, Bereiter, McLean, Swallow and Woodruff, 1987) software was used by educators in Iqaluit, an isolated, Northern Canadian community of approximately 6000 people where 85% of the students are Inuit.

Theoretically, the learning process embedded in the CSILE/ Knowledge Forum® learning environment should support the creation of a learning environment which parallels that advocated by leading literacy educators. For example the software is created in a manner that learners read and explore content which is self-selected, use existing background knowledge as a base for learning, are in control of their learning, use language in meaningful ways to build knowledge and solve problems. The role of the teacher is one of facilitator. The infrastructure of the software makes explicit some thinking strategies. Participants explore specific areas of interest under the umbrella topics introduced, choose one of several scaffolds to frame their discourse, such as the process of devising a problem, developing theories, posing additional questions, planning, researching new information from a variety of sources, representing new learning through text and graphics, devising a better theory, etc. or through focused discussion topics. Topics are tailored to meet specific local curricula and interests/needs of the students as each site starts with an empty database on their server. In Iqaluit, topics have ranged from Marine Environment to Indigenous People of the World, from Weather and Space to Northern History, Geography and Resources, with special interest areas such as Suicide and Racism explored in between. Users contribute to the database on client...
computers to construct knowledge as a community, allowing for continual modification, building on each other's ideas, constructing knowledge, whether individually or in groups. Using the technology of Knowledge Forum® to build knowledge that is culturally relevant while promoting a world-view has the potential of being motivating for young Inuit children. Such software could enable students to start with what they know, and from where they are in their language development in their first and second languages, thereby enabling a comfort level with learning and technology that is not readily available in most commercialized resources for Northern youth.

The Study

This research project focused on analysing perspectives of educators regarding the relationship between the knowledge building technology of Knowledge Forum® and literacy development for Inuit students. Data was collected through interviews, observation and examination of the data base. The choice of a qualitative framework was adopted primarily due to the emphasis on social context. Since qualitative research is “rich in description of people, places and conversations” (Bogdan & Biklen, 1992, p.2) means that the context formed an integral part of the research.

Five major informants were selected using purposive sampling: 1) a bilingual Inuk first grade teacher whose students are taught totally in Inuktitut, 2) a consultant who was responsible for bringing the software to Baffin, 3) a veteran northern teacher, 4) a bilingual Inuk third/fourth grade teacher, and 5) a fourth grade English First Language teacher.

Findings

According to all the informants, all the questioning, theorizing, researching, dialoguing integral to the used of Knowledge Forum technology encouraged students and teachers to engage in literacy learning which was meaning focussed. In the classroom these processes were not something practiced but were a natural part of the literacy learning. Further, the creation of various forms of texts which requiring thoughtful question posing, reflection on the need to communicate with an audience, clarifying an ideas and editing were all viewed as authentic literacy events. The fact that the software was viewed to be driven by process, and that content focus was developed by participants, was thought to create a literacy learning framework that supports cultural relevancy. As the informants identified, rather than the teacher controlling the evolution of content exploration students had an opportunity to have control over identifying content that had personal relevance. Further, given the flexible nature of the software students were able to engage in knowledge building communities at a variety of developmental levels. Consequently, the diverse range of literacy levels within classes were thought to be accommodated.

Knowledge Forum® technology offers an electronic medium for literacy learning which educators involved in this study suggest can create a meaningful context for literacy learning. In classrooms, teachers are challenged to create literacy learning curricula which are meaning-centred, emphasize process, allow student control, support a variety of learning levels, and embrace cultural relevancy. In northern communities where English is frequently not the first language the challenge of creating a curriculum, which is relevant and builds on the existing language base of the students was viewed as challenging. The experiences of the informants in this study suggest that using knowledge-building technology in Iqaluit, a Northern Canadian community provided a curricular structure which in their views supported meaningful literacy learning and pedagogically sound teaching.

Abstract. There are thousands of software applications available to educators, but one application in particular is an essential tool for teaching and learning. It is a graphic organizer program called Inspiration. Inspiration is a program that can be used by teachers and students to organize ideas graphically or textually. Advanced features of the application allow for linking both to the Internet and other documents thus demonstrating the relationship of ideas and concepts.

In these days of national standards there is a tremendous need for on-going training among pre-service and practicing teachers in the use of technology. Students are entering pre-school having utilized technology more than many of the educators that they will encounter. There are thousands of software applications available to educators, but one application in particular is an essential tool for teaching and learning. It is a graphic organizer program called Inspiration. Inspiration is published by Inspiration Software, Inc. and allows for the organization of ideas either graphically or textually. It is user friendly, stimulating, and easily adopted by both students and teachers. Advanced features of the application allow for linking both to the Internet and other documents thus demonstrating the relationship of ideas and concepts.

Research is clear that graphic organizers assist greatly in improving instruction, increasing reading comprehension and improving creative writing. (Culbert et al. 1998; Bowman et al. 1998; Meyer 1995; Quist 1995). In addition, graphic organizers assist with conceptual understanding, higher-level thinking and retrieval of information (Monroe 1997). Most importantly, Inspiration’s ease of use assures that it does not interfere with the creative process or the sometimes frustrating use of technology.

Inspiration software allows teachers to turn complex thoughts into meaningful displays whether pictorially, in text, or back and forth between the two. Brainstorming, concept mapping, and diagramming in all subject areas are essential to inspire creative thinking. Educators utilizing this program can easily survey a class and then demonstrate the similarities and differences among the concepts. A class of primary students could quickly contribute verbally about a variety of topics and instantly see a graphic representation of their session. The idea of classifying pets, foods, or games could turn into a meaningful beginning for young minds to see relationships within the group. The teacher could then provide links for concepts either to the Internet or other similar documents. This would provide a springboard for writing or reporting within the classroom. Furthermore, this visual graphic helps to retain knowledge. It also helps to connect prior knowledge to new knowledge in a meaningful way, supports different kinds of thinking and can assist with formative assessment. Inspiration has a brainstorming rapid-fire feature that allows thoughts to flow quickly. There is no longer a need for messy boards and copying because Inspiration has made the connections and display. The organizer can then be printed out and copies run for all participants. Inspiration can also be used by the teacher for his or her own writing. Lastly, the modeling of the creative process for students can be powerful.

The Inspiration program can help students with the development of concepts, demonstrating and understanding sequencing or chain of events, cycles, cause and effect, problem solving, comparing and contrasting, analysis, classifying, finding main ideas and part to whole learning. In addition, the program can be very motivating for reluctant writers. Besides the students having a copy of the organizer to study for a test, the actual process the student goes through with Inspiration can demonstrate and be used for
alternate assessment purposes. For example, if the students make visual representations of what they know
the teacher can then quickly check for this understanding.

Inspiration can be used by teachers and students alike. It is a fun, easy and motivating program to
use. Best of all, it allows for the integration of technology and contributes to learning in many ways.

Children's Literacy Initiative’s Message Time™ CD-ROM

Alicia Wilson, Children's Literacy Initiative, US

Children's Literacy Initiative (CLI) is a non-profit organization dedicated to ensuring that children living in high-poverty areas have the best possible opportunity to become successful at reading. Children's Literacy Initiative’s goal is to prevent the need for remediation by helping children who are perceived to be educationally “at risk” achieve at national norms on literacy assessments. CLI's programs address many of the causes of reading difficulties in the early grades, which very often lead to continued school failure, and ultimately to economic disadvantages. CLI has served public school and Head Start teachers nationally, with a focus on the eastern states. Large-scale projects include Baltimore City Public Schools, the Philadelphia School District, Newark Public Schools, and the Camden Board of Education, with other projects in Los Angeles, New York City, Washington D.C., and Pittsburgh. Through years of work in entire school districts and with the community of teachers within individual schools, CLI has established itself as an effective professional development model.

CLI’s approach is to provide primary teachers (pre-Kindergarten through 3rd grade) with intensive training in proven literacy instruction practices. CLI coaches, mostly teachers themselves, work with new and veteran teachers in their classrooms assisting them to the level of mastery in these practices. Moreover, essential to CLI’s working with teachers in low-income, under-resourced areas, is its commitment to setting up individual classroom libraries, as well as home lending libraries, and provides other literacy supplies such as individual student writing boxes equipped with a myriad of fun and essential writing tools.

As CLI develops and addresses new demands in primary education for the 21st century, its mission is expanding to reach an ever growing population of new teachers who are replacing the thousands heading for retirement. With the hopes to train larger numbers of teachers in effective instructional strategies, CLI has adapted the use of CD-ROM technology to its program. As an alternative to its intensive training component, CLI will be providing shorter training sessions on one of its instructional strategies and supplying teachers with a CD-ROM to give them a thorough demonstration of an effective method in teaching writing skills. By taking advantage of the multimedia format, teachers will be able to view multiple video, audio and graphical samples that will provide them essential supportive illustrations and information.

By using CD-ROM technology, CLI has reformatted one of its central training models, namely, the use of video demonstrations and text support into a more dynamic and interactive medium giving teachers opportunities for multiple viewings and personalized engagements. CLI plans to use this format as a supplemental as well as an alternative training program offered to schools throughout the country and to those not able to purchase the entire CLI training package.

CLI hired twentyonedesign (http://www.21xdesign.com) to develop a CD-ROM that would demonstrate the step by step procedure for conducting a daily writing lesson called Message Time™. Developed by Dr. Janice Stewart of Caldwell College in New Jersey, Message Time™ is a basic instructional approach which explicitly models the writing process to primary students learning the initial skills in literacy. Message Time™ is not a direct-instruction approach, nor is it a script for teachers to follow. Rather, it is a simple approach to writing which allows early learners to first comprehend that writing is a process of communication. Message Time™ increases children's knowledge of print conventions such as differentiating between words and letters and punctuation. It also acquaints children with written language in a meaningful context and provides opportunities for children to respond at their own level of reading and writing comprehension.

The SITE conference offers CLI an optimal platform to launch a debut of its CD-ROM to the education community and interact with colleagues who have also developed technology-based educational formats. CLI is interested in demonstrating its CD-ROM to educators who can use it as well as to those who can offer critiques and suggestions of its use. During a two hour poster session, CLI will offer demonstrations of its software, displays of images from the CD-ROM and pamphlets about the product and about the CLI program in general. A raffle of free CD-ROMs will also be offered during this time.
The Q-folio in Action: Technology Integration in Inquiry-Based Language Learning

Carl Young, Virginia Tech, US

Abstract:

Presenter will share an approach to re-inventing the pen and paper portfolio and the traditional research project with the Q-folio, a web-based electronic portfolio designed for language pedagogy courses taught at the University of Virginia and Virginia Tech.

The "Q-folio" courseware tool was originally designed for use in portfolio-based writing instruction. The principals employed in that design include: (1) a web-based platform for communication; (2) a "user-centered" approach in which users of the tool are invited to participate in the design of the interface; and (3) "day one productivity," meaning the tool should require a minimum of training before it can be used productively. The Q-folio acted as a robust document management system both for delivering content to the students as well as archiving drafts of their work. The system also allowed them to build multimedia files with full HTML capabilities for presentations. The tool was built in a web-database environment using Cold Fusion, allowing administrators to develop the tool rapidly and make changes easily. Cold Fusion's close adherence to HTML standards and its relatively straightforward commands for manipulating databases were found to be effective for instructors with little knowledge of programming.

In supporting the Heuristic Quest research project in "Language, Literacy, and Culture," the Qfolio provides students the opportunity to develop their own research agenda and to use inquiry to teach themselves and their classmates in an authentic research process. Using hypertext, interlinks across heuristics, and web links, students create a sophisticated road map of inquiry into the nature of language and effective language instruction. They document their process and their findings, which are being archived for future students and eventually for public access. Although customized for this course, the Q-folio is being used in other courses at the University of Virginia as well as Virginia Tech. Ultimately, the tool can be used to support any content area and grade level where teachers want to enhance and integrate the research, writing, language, and conversational practices of their students.

Comments:

The evaluation study informing this presentation was conducted on the electronic portfolio mentioned and examined students' experience of the tool to support both their research processes and products. This study sought to address the need for information regarding: 1) how preparing teachers perceive the technology they are being asked to use; 2) the extent to which electronic portfolios enhanced content learning for these students; 3) how students might collaborate with instructors and technicians on the design of the technology intended to support their work; and 4) how experiences of technology in teacher education affects student plans for integrating technology in subsequent learning environments.

The data (from surveys, interviews, lab and classroom observations) derive from a course focused on language, literacy and culture, wherein the subjects used the specific electronic portfolio tool to further a research question of their own choosing related to language pedagogy in the English classroom. The case study method and analytic induction were used to arrive at the findings regarding students' perception of the tool and associated tasks, the impact upon content learning, the potential for collaboration on instructional design, and the impact upon student technology use. Findings were used to revise the course and refine the tool for this course as well as additional course settings.

I had difficulty in deciding on a presentation category. The presentation would include a talk integrated with a demonstration of the tool and some of the student work archived there. I am open to suggestions for altering the presentation category should this be a concern.

Possible co-presenters may include Margo A. Figgins, Associate Prof. of English Education at the University of Virginia, and Yitna Firdyiwek, Faculty Instructional Technology Advisor at the University of Virginia.
Technology use in teaching and learning has come to be regarded as essential for the future of educational institutions at all levels. Researchers strive for a better understanding of technology's effects as it continues to gain prominence in education. This year's SITE conference papers contribute to this understanding. The quantity of submissions has more than doubled this year attesting to a deeper recognition of the need for critical evaluation of Instructional Technology (IT). This section includes papers addressing the comparison of online and traditional methods for instruction, technology use in practice, competence with and use of technology, perceptions related to technology, as well as theoretical and methodological issues related to research in IT.

My perception is that research in IT has often begun with the unexamined assumption that technology use is inherently good. As such, I find a need for more research comparing technology to traditional methods. This type of research highlights the idea that various forms of technology should only be used if they are more effective tools. I would like to see more of this type of research in future SITE conferences thereby helping educators to determine both when technology is appropriate and what forms of technology are likely to be most beneficial for meeting their goals. This year's contributions include papers that compare online and traditional or face-to-face methods. Jerry Galloway works with middle school students studying African American cultural heritage and Merry Boggs focuses on high school computer science students while the rest of the authors work at the university level. Yusef Koc, in mathematics, and Barbara Coppola, in teacher education, each focus on how discussions can be influenced by IT, while Sherri Restauri and Rosa Ponce each do broader campus-wide comparisons.

The papers dealing with the effects of technology use in practice without making comparisons to traditional methods describe the effects of a wide variety of technologies, in several educational contexts, and from many different theoretical perspectives. Papers in this category include those by Simon Mochon, David Lane, Donna Russell, Tiffany Koszalka, Marino Alvarez, Kimiko Isono, Tianguang Gao, Yahya Mat Som, Neal W. Topp, Sue-Jen Chen, Margarete Juliana, Max Louwerse, Therese Laferriere, Robert Bracewell, and Isil Kabakci. IT such as spreadsheets and simulations, web-based methods, discussion lists, electronic journals, intelligent tutoring systems, and networked learning communities, are examined among others. These technologies are predominately examined in math and science education, but there is also an interesting piece on music education. Readers of this section should appreciate the emphasis on empirical data combined with a diversity of theoretical backgrounds including socio-cultural and ecological perspectives, constructivist theories, action research, and inquiry-based education.

Papers focused on the level of competence with and use of technology help describe the current level of computer, Internet, and software use by elementary and secondary students, as well as the level of computer literacy and technology use by pre-service and in-service teachers. These include offerings by Myka Raymond, Pamela Petty, Donna Ferguson, Toni Jones, Helen Brown, JoAnne Davies, Kay Gibson, Nan Li, Gerald Knezek, Rhonda Christensen and Yu-mei Wang. Some of these papers include discussion of attitudes and beliefs related to technology, but not as the primary focus.

The papers dealing with perceptions related to technology include research on perceptions, beliefs, and attitudes of a wide variety of stakeholders on a diverse set of topics. This category includes articles by David Dean, Jesse Foster, Amy Staples, Mary Lane-Kelso, Beth Coghan, Glenda Rakes, Kathy Bohley, Dale Magoun, Debra Sprague, Seung Jin, Kimberly Berg, Rita Dobbs, Melissa Mohammed, Prentice Baptiste, Christian Penny, David Pratt, and Misook Ji. These articles discuss research on perceptions related to the Bill and Melinda Gates Foundation's Teacher Leadership Project, the "Digital Divide" and "Digital Schools", integrating technology into teaching, PT3, using interactive television environments and the Internet, as well as other timely topics. The perceptions
of pre-service and preschool through university in-service teachers, kindergarten through university students, and university administrators are focused on to better understand the effects of IT across many educational contexts.

The papers categorized as theoretical and methodological issues related to research in IT include those by Betul Ozkan, Fidel Salinas, Steven Dickey, David Moursund, Tammy McGraw, and Chih-Hsiung Tu. These authors cover wide-ranging issues including statistical applications, ethics, online presence, and future directions for research in IT.

Dr. Reagan Curtis completed his Ph.D. in Education at the University of California at Santa Barbara and is currently an assistant professor in educational psychology at Northwestern State University. He currently teaches courses in human development, research methods, and statistics. His research interests include the development of quantitative knowledge from infancy, cross-cultural mathematical development, online teaching and learning, and teacher education.

Two Professors Share Their Thoughts and Feelings with Their Students

Marino C. Alvarez
Center of Excellence in Information Systems, Tennessee State University
United States
malvarez@coe.tsuniv.edu

Michael R. Busby
Center of Excellence in Information Systems, Tennessee State University
United States
busby@coe.tsuniv.edu

Abstract: Lecture dominates the medium that is used to communicate facts and concepts to college students. Often these facts and concepts are either misunderstood or take on meanings not intended by the lecturer. Unfortunately, there are very few avenues that students can pursue to clarify misconceptions other than infrequent question-asking or a visit during office hours. Likewise, professor feedback is delayed until end-of-the-year student evaluations that does not remediate faulty logic and serves little purpose in reclaiming clarity of thought and negotiation of meaning of the curriculum. This paper describes how electronic dialogues can illuminate the degree of student understanding with course content.

Introduction

Exploring Minds is an active electronic venue for professors, teachers, and students to reflect, negotiate, and evaluate the teaching/learning process that enables systemic changes to occur under meaningful and thoughtful circumstances. Ideas are revealed in narrative and visual formats through electronic journals, mapping conceptual arrangement of ideas, and V diagrams so that metacognitive tasks such as self-monitoring, reflective and imaginative thinking, and critical analyses are a crucial part of the learning process. The basic premise that underpins Exploring Minds is that the mind deals with meaning and meaning is the basis for conceptual understanding of facts and ideas. This paper describes the dialogic exchanges that took place between two professors and their undergraduate students during a semester via journal entries in a teachers education methods and a physics class.

Knowledge that is isolated into compartmentalized units of study does little to advance the interest and curiosity of teachers and their students. This type of learning reduces knowledge into capsules that are sorted by topic with the ultimate purpose of retrieval by testing. Nowhere does this type of compartmentalized knowledge occur than in college classrooms where the professor lectures and students dutifully take notes for later retrieval on an examination. Facts become valued over ideas due to expediency and an attitude of getting through the required course at minimal expended thought. Understanding is sacrificed for knowing in this type of classroom setting with little professor/student exchanges taking place outside the walls. The professor relies upon end-of-the-semester student evaluations to determine student perceptions of course content and delivery of information; however, in many cases these comments cause minimal, if any, changes in course preparation, adjustment, or course restructuring.

This paper focuses on electronic interactions between two professors and their students during the course of a semester. For this study, we used the action research paradigm grounded in the reality of classroom culture and under the control of teachers. In this study, the events consisted of electronic exchanges that were initiated by the students who were asked to reflect and enter narratives that expressed their thoughts, feelings, and questions resulting from the class session and their assigned readings. These entries took the form of a mental task similar to a diary entry where students were asked to carry on a dialogue with themselves concerning the happenings during class and assigned readings.

Theoretical Framework

Teaching is an exchange of facts and ideas engaged under meaningful circumstances in an environment that goes beyond simply telling and assigning. These facts and ideas should relate to topics,
problems, situations, and contexts of a given discipline that take into consideration the experience and world knowledge of the students. However, our position is that these facts and ideas should not be confined to one subject discipline in which the teacher and students are assigned, but rather serve as the anchor from which other disciplines are incorporated so that relationships among them can be readily ascertained, acknowledged, and assimilated.

Our view is predicated on our belief that monitoring student progress and understanding keeps us better informed about our teaching practice, the value of our course content, and takes into consideration Gragg’s (1940) warning that “wisdom can’t be told.” It is also consistent with Gowin’s (1981) theory of educating and Ausubel’s (1968) theory of meaningful learning. Our theory guides us when interpreting the findings of our research projects and others so that better communication and understanding of the key concepts occur with the “live” audience who weigh the merits of their learning derived from these discussions, assigned readings, assignments, and their applications.

Faculty and Student Use of Computers in the Classroom

A case study involving faculty at Stanford University indicated that computer use by professors primarily consisted of preparing documents used for instruction (e.g., handouts, email listservs), and when researching for personal writings. However, using this same technology in their daily teaching was negligible (Cuban, 2001).

We should also note that professors who teach using distance learning labs or classrooms are not engaging in faculty use of technology for instruction rather it is a way to dispense information “live” rather than tape-delayed through video (although we acknowledge that this method is sometimes also disseminated through distance learning classrooms). These uses of technology become methods of conveyance rather than uses of technology to monitor self-learning. Instead we depict a network that provides teacher/student monitoring of classroom practice with journaling, and student use of metacognitive tools of concept mapping and V diagrams.

Computer access does not necessarily equate to computer classroom use, but it does indicate that students having computer access to the Internet does imply engagement for personal use and induces student learning brought about by the societal, informal, curriculum than by the formal, school curriculum. For example, Cuban (2001) found that students’ use of computers were peripheral to their primary instructional tasks, and that less than 5 percent of the middle and high school teachers integrated computer technology into their regular curricular and instructional routines. When teachers in their classrooms used computers these computers did little to alter the existing teaching practices already in place (see Cuban, Kirkpatrick, & Peck, 2001).

Perhaps it should be noted that technology systems that have been developed for school use are done so by persons who have little knowledge or experience of what it is like to teach at elementary, middle, secondary, or postsecondary schools. This position also encompasses the social, cultural, organizational, and political factors of the school environment that shape the complexities of what people do in this milieu.

Our Exploring Minds Network was developed at the Center of Excellence for Information Systems, Tennessee State University, from a teacher’s perspective with classroom experience at the middle, secondary, and postsecondary levels that includes management, interactive communications, monitoring, and metacognitive tools (Alvarez, 1998). The network includes collaborations with researchers, parents, coordinators, and guests as deemed necessary by its users.

Finding Out What Our Students Know and Understand

Keeping abreast of how our students perceive the course content is a key component of pedagogy. How are we, as professors, to know the extent to which our students are processing new information in meaningful ways that are deemed to be acceptable rather than in ways that may be either misconceived, confusing, or relegated to rote memorization?

In order to promote learning and understanding that go beyond the walls of the classroom and result in reflection, we used electronic exchanges with our student to reveal their feelings and thoughts as well as our own to the course content over a semester period. The processes involved are social, political,
and organizational when negotiating the curriculum, adhering to politically driven mandates, while working within the organizational structure of the school.

**Dialogic Exchanges**

Two full professors and their undergraduate students participated in this action research study. Thirty-six students, freshmen through seniors, enrolled in an introduction to physics class in the College of Arts and Sciences, and twenty-one senior, preservice teachers, enrolled in a secondary methods class, College of Education, participated in this electronic journaling. Students in both classes utilized the Exploring Minds Electronic Network.

Exploring Minds is an interactive electronic network that is password protected and contains provisions for teachers, researchers, and students to communicate about their class work and/or research agendas. This unique network is designed as a venue for professors, teachers, and students (middle, secondary, and postsecondary) to reflect, negotiate, and evaluate the teacher-learning process almost exclusively over the Internet (Alvarez, 1998). Exploring Minds is a self-contained system in component form that encapsulates transactions between students and learning stakeholders over the Internet interactively. Although this network contains many features, for this study, the focus was on the journal component that provided students in the respective classes to enter their thoughts, feelings, and questions following each class session that met twice a week for sixteen weeks. Students also posted reactions to their assigned class readings.

Students were asked to react after each class session in their journal by carrying on a dialogue with one’s self. In other words, students were to reflect on the content of the class session and express their thoughts about the facts and ideas that appealed to both their cognitive and emotional state. A rehashing of what transpired during the class session was discouraged and clearly not intended to appear in the journal other than in those instances that a specific notion or feature was referred to in the writing.

**Informing Practice**

After each class session and before our next meeting each of us read the journal entries that were posted by our students. Our responses to the students were predicated on the type of entry posted. For example, we were interested in the ways our students reflected upon what was being taught both in their affective and cognitive responses as well as how well they understood the facts and concepts of a specific lesson. Three levels of reflection were classified:

1) How important the facts and ideas were perceived by our students;
2) If they reported that the facts and ideas were part of their prior knowledge and/or experience; and,
3) If they applied the facts and ideas of a topic to another relevant situation.

As part of the analysis we also read each posting to determine if any misconceptions related to the lesson or reading assignment were reported in these entries.

Reviewing the responses of our students indicated that a few students maintained a continuous dialogue with us as opposed to the others who primarily maintained a running record with themselves. The majority of the postings were entries that posed either direct questions about the clarity, their understanding or specific questions, or about their interpretations of the material.

Seldom we didn’t respond to a students’ entry. The primary reason being that the postings were worded in such a way that “asked” either directly or indirectly for a response. Our responses took the form of answering a direct or indirect question/statement, offering encouragement, or asking to share their concerns, revelations, and/or materials with the class. Many of the postings by the students contained embedded questions that were explicitly stated or took the form of comments that were written similar to “thinking out loud.” One can question the sincerity of these postings since the students knew we were reading them. However, the overall postings by the class, as a whole, together with their in class discussions indicated that their remarks were consistent with their thoughts and feelings of the course content and their interactions with us.
It was clear that students maintained a dialogue with themselves and also with us that better enabled them to understand and retain important facts and ideas. Simultaneously their electronic entries informed us of their level of understanding of each class session, and also alerted us to be more cognizant of forthcoming lessons and reading assignments so that they could be better learned and understood. Based on the students completed assignments, in class discussion, and their journal records, each of us changed the format of our course and final examination making it more applicative.

Conclusion

Electronic journaling created shared and mediating learning contexts and invited multiple connections across contextualized information. Questions, thoughts, and feelings were exchanged after students had an opportunity to reflect on each class activity and assignment through electronic journals that took place beyond the walls of the classroom. Student reflections were dependent upon how important they perceived the lesson, whether they had experienced the lesson itself in their world experience and/or knowledge of the facts and ideas being studied, and/or their ability to apply newly learned methods to other situations. Their queries informed us of any information that needed clarification or elaboration to which we could respond directly and, if warranted, make the rest of the class aware of an issue, fact, or concept that needed further explanation at our next class meeting.

This study confirmed an earlier one that concluded that it may be that when you ask students to conduct journal entries as a “dialogue with oneself” that the entries are written in such a way that evokes within the person a reflective stance that differs from when one is asked to record what transpired during the class session. This kind of posting results in a “report-like” response that is similar to a notetaking type of entry (Alvarez, 2001). This type of “report-like” entry does little to stimulate thought or evoke feelings since reflection of the class session is minimized and relegated to writing down the information and then repeating it again either from notes or memory into a journal entry.

The Exploring Minds Network facilitated teaching and learning of our course content. It also provided a means whereby meaningful learning of ideas were shared, negotiated, and continued beyond the walls of the classroom. These electronic exchanges helped us and our students negotiate the curriculum in ways that traditional lecture and college teaching does not entertain.

Gulsun Kurubacak, Ed. D.
New Mexico State University, College of Education
kurubagu@nmsu.edu

Natashia Hill, MA.
New Mexico State University, College of Education
hill@nmsu.edu

Abstract: This is a qualitative ongoing case study. The main purpose of this study is to describe
and analyze faculties’ reflections toward online learning. Through purposeful sampling techniques,
six faculties in the College of Education at a large Southwest State University were selected as
participants. Video-typed interviews have been conducting to explore and evaluate faculties’
reflections toward online learning in its natural environment. This study is exploratory in order to
allow insights to emerge from a recursive data analysis process. The variables in the site of the
research are highly complex and extensive. The research data are very dependent on context and
needed to be collected in its natural environment with no controls and manipulations.

Overview of the Study

This study has been taken a grounded theory approach to allow the researchers to explore and
discover the faculties’ reflections toward online teaching for two reasons. First, today, different academic
institutions offer teacher education graduate courses online. Therefore, online learning and faculties’
reflections toward online teaching are relatively new phenomena. There is a lack of theoretical or empirical
research base on this topic. Only a few researchers have focused scholarly attention on investigating or
working in this field.

Finally, before entering the study, the researchers tend to analyze the research data inductively
rather than to prove or disprove hypothesis. The main focus in this study is: 1) to obtain investigate,
understand and the insider’s views toward teaching online courses on different subject area, and 2) to
expound on this study participants’ perspectives and interpretations rather than researcher imposed
categories.

Research Design

This study is a qualitative case study. The purpose is to investigate the faculties’ reflections
toward a particular phenomenon of online teaching on different subject area experiences.

Research Site

The site of the research is a large urban university at Southwest in College of Education. It is in
the Fall Semester 2001. The College offers many B.A., M.A. and Ph.D. programs online.

This College was chosen to study faculties’ reflections toward enhanced online teaching for three
major reasons: First, today’s, the most of the faculties have been strongly interested in using the web as an
instructional tool to make possible communication between regular class sessions. Each week students
would post their assignments and any questions, concerns, ideas online. The students could read, receive,
post, exchange and/or share information on the discussion topics of each week before and after the class hour. Sometimes students would email the course professor’s account directly, when they had particular questions, suggestions and/or comments any time. Second, the most of course curriculums in the College of Education have been included both computer-based learning activities into classroom and web-based learning activities. WebCT have been used for posting the students’ massages and papers via electronic mail (email) and electronic bulletin board. Finally, at the future, the most of the faculties in the College of Education are considering to teach their courses totally online in the near future whereas the few of them have been delivering their courses online.

Instrumentation

This study utilized both qualitative and quantitative data to provide detailed information to the researchers for analysis. Therefore, qualitative instruments and qualitative instruments are designed due to collecting and analyzing data on the faculties’ reflections toward online teaching on different subject areas. Video-typed interviews have been qualitative instruments whereas the faculty survey instrument has been a quantitative instrument in this study. Each instrument was developed and modified according to investigating the focus of this study.

Another crucial issue in this study is the validity of each research instrument. To provide the validity of these instruments in this study, the researchers have been collaborating the experts, the other faculties and the students from the other courses. These people have been asked to provide opinions regarding the following three issues: 1) readability and clarity of the questions in the faculty survey, 2) length of the instruments, and 3) other general impressions.

Data Collection

The researchers have been collecting data from different sources to investigate faculties’ reflections toward teaching online. Although the qualitative case study approach has been used to obtain information on the focus of study, both qualitative and quantitative data have been collected from the research setting. Utilizing qualitative and quantitative data together in this study have been provided a more complementary and different aspects of this complex phenomenon.

Researchers have been following a careful data management process to ensure high-quality and accessible data, documentation of data collected, and associated after the study will be complete. For these reasons, the researchers regularly record and systematically store both qualitative and quantitative data into the researcher computers and videocassettes. They have been recording each collected data on the floppy diskettes and CD-ROMs every day as well as printing out each datum twice and filling them into separate folders. The researchers also regularly send all collected data into their FTP sites via WS_FTP Pro 6.02 ftp client software everyday.

The researchers have been writing short notes on these data from different sources in folders to show where related data in another can found. The researchers also index all data by using number and letters as locaters in each data being collected.

Data Analysis

This research is being operated with a qualitative case study approach. The analysis of the faculties’ reflections toward online learning on the different subject areas is ongoing process, which will be started at the end of the Fall Semester-2000, through written the final report. The data analysis process in this study is analytic and recursive to inform further decisions on data being collected. It also is restructured, flexible and open to the discussions with the stakeholders and reviews of related literature.

During the data analysis procedure, the researchers briefly will followed these steps given in a logical order: 1) transcribe each video cassettes, 2) write field notes from the class and all WebCT activities, 3) identify patterns, 4) analyze the content of each class observation and the student survey, 4) work on qualitative data, 5) triangulate all qualitative and quantitative data, and report results in descriptive and narrative form.
Integrating Technology into Preservice Teacher Education: Comparing a Field-Based Model with a Traditional Approach

Krista Glazewski, Kimberly Berg, Thomas Brush
Educational Technology
Arizona State University
United States
kglaze@asu.edu

Abstract: This study comprises one component of a PT3 funded investigation into the effectiveness of combining technology integration techniques with field-based preservice teacher methods courses. One data collection instrument, the Technology Attitudes and Beliefs Survey, is described. Attitude and belief differences between preservice teachers in the field-based model and those enrolled in the traditional, one-credit course are identified and discussed.

Over the past decade, rapid advancements in technology have created expanding possibilities for enhancing instruction. As a result, there remains a growing need for augmenting the instructional technology skills of both practicing and preservice teachers (Hill & Somers, 1996; Northrup & Little, 1996). Meeting those needs, however, has proven to be a struggle for many teachers (Strudler & Wetzel, 1999). Siegel (1995) reported that most K-12 teachers are generally not receiving sufficient time, access, and support to become comfortable with computers, while others have found that although some teachers have positive attitudes toward technology, many do not consider themselves competent to teach with technology (OTA, 1995; Schrum, 1999; Strudler & Wetzel, 1999).

Researchers have advocated integrating technology training throughout the preservice teacher education program (Brush, 1998). However, most teacher preparatory programs offer stand-alone technology courses. Many of those courses have curricula that fail to adequately prepare teachers for technology integration (OTA, 1995). This is especially true in states lacking specific computer competencies for teacher certification. Therefore, many preservice teachers are still entering the classroom with minimum exposure to technology and the techniques for integrating its use into instruction in real world settings (Strudler & Wetzel, 1999).

With the support of a three-year Preparing Tomorrow’s Teachers to Use Technology (PT3) grant, one university is attempting to improve the way it prepares preservice teachers for technology integration. Until recently, preservice teachers enrolled in the existing program have been required to complete a one-credit, stand-alone technology course; the curriculum thus remains isolated from the environment in which it is to be applied. The primary goal of the PT3 grant shifts the focus of this experience away from skill development to means for integrating the technology with authentic teaching experiences (Brush, Igoe, Brinkerhoff, Ku, Glazewski & Smith, 2000). To achieve this, the on-campus preservice teacher course is being eliminated in favor of integrating this content into field-based courses covering instructional methods. This field-based model, also known as job-embedded learning (Loucks-Horsley, Hewson, Love, & Stiles, 1997), focuses on providing preservice teachers with authentic training experiences in real classrooms prior to their student teaching experience.

Currently, preservice teachers enrolled in the field-based program are elementary education students who follow a sequential block system in their coursework. The technology component is incorporated in the first two block semesters which cover instructional methods for teaching language arts / social studies and math / science. These courses are taught at local elementary schools where the preservice teachers are placed in K-6 classrooms. Within the technology component, each student attends workshops where he or she observes and participates in models of technology-rich lessons integrated with the given content areas. After the observation workshops, each student designs, implements and evaluates an instructional lesson for one of the content areas that effectively and appropriately utilizes technology.

The purpose of this research project focuses on collecting comparison data regarding their beliefs and attitudes related to technology integration from two groups of preservice teachers: those enrolled in the field-based model and those enrolled in the on-campus course. The data collection process is aimed at addressing the following research question: Are there differences in attitudes and perceptions toward technology integration between preservice teachers in the field-based model and those in the campus-based course?
Method

Participants

Participants were 133 preservice teachers. Of these, 24% (n=33) were completing their computer requirement on the university campus, and 76% (n=100) were participating in the field-based model. Over 90 percent were female. The majority of students (74%) were enrolled in the elementary preservice teacher education program, 11% were enrolled in the secondary education program, and 15% were enrolled in a different education program, such as English as a second language, bilingual, or special education.

Procedures

Survey data collection occurred during fall of 2001. Those preservice teachers enrolled in the field-based model completed the survey during the final class session of the technology component related to their respective methods course. Those preservice teachers enrolled in the traditional, one-credit course completed the survey during their final class session.

Materials

Materials consisted of one survey: the Technology Attitudes and Perceptions Survey. The survey was developed as a means of measuring attitudes toward technology integration as well as the degree to which the preservice teachers hold prevalent misconceptions as identified by the methods and educational technology university faculty. The survey consists of three sections: Background Information, Attitudes Toward Integration, and Environmental Resource Barriers. The Background Information section contains eight items covering such things as future teaching goal, academic year, frequency of computer use, and basic demographic information.

The Attitudes Toward Integration section includes 18 Likert-style items measuring attitudes and beliefs related to technology integration. Example items in this section include “A variety of technologies are important to enhance student learning,” and “I feel that my technology course(s) has prepared me to integrate technology into my content area specialization.” Participants rate all items on a four-point scale from “Strongly Agree” to “Strongly Disagree.”

The final section, Environmental Resource Barriers, contains 16 items asking participants to rate their perceptions of potential technology integration barriers. Example items include “There isn’t enough time in class to implement technology-based lessons,” and “It is easier to use technology with smaller class sizes.”

The overall Cronbach Alpha coefficient of the Technology Attitudes and Perceptions Survey is relatively high ($\alpha = 0.81$), indicating it is a fairly consistent measure.

Data Analysis

Data analysis consisted of calculating means and standard deviations of scores obtained for each item on the two surveys. A one-way multivariate analysis of variance (MANOVA) was performed to determine if a significant difference in overall reported scores between preservice teachers in the field-based model and those in the campus-based course is evident. A follow up one-way analysis of variance was performed on the survey data in order to identify significant differences between the two groups on individual survey items.

Results

Table 1 displays the means and standard deviations for the five items with which the on-campus preservice teachers most strongly agreed and most strongly disagreed. The numbers represent responses on a four-point Likert scale ranging from one (Strongly Agree) to four (Strongly Disagree).

Discussion

Currently, technology training is a major focus of many preservice teacher education programs. That training is provided through a variety of approaches, most of which are stand-alone technology courses. This research describes the initial comparison results of a PT3 grant designed to move technology training of preservice teachers from the university classroom to a field-based setting in which students observe lesson models integrated within their methods courses, and are expected to plan and implement a technology-integrated lesson.

Overall, results from this survey are encouraging. Both groups perceive that they are responsible for teaching students to use technology, and express agreement that a variety of technologies are important for enhancing student learning. However, both the on-campus and field-based groups also tend to disagree that a successful technology-integrated lesson is possible using one computer. They also perceive that it is easier to deliver a technology-integrated lesson in a computer lab. These generally positive attitudes regarding the importance of technology coupled with the perception that technology is easier to integrate with more computers represent an opportunity for teacher preparation programs to make an impact. Because these teachers are more likely to have 1-4 computers rather than regular access to a lab, instruction should focus on what is possible with the resources they are more likely to possess.

Results also reveal differences between preservice teachers participating in the field-based experience when compared to those enrolled in the on-campus course. Specifically, the field-based preservice teachers feel more unprepared for technology integration than their counterparts in the on-campus courses, while expressing stronger agreement with the statement that a teacher with novice technical skills is able to deliver an effective technology-
rich lesson. This suggests that providing preservice teachers with a more authentic experience may result in differing perceptions regarding what a teacher needs in order to integrate technology. Preservice teachers in the field-based model, many of whom consider themselves novices, were required to plan and implement a technology-integrated lesson; therefore they are more likely to agree that it is possible for teachers to integrate technology, even if they do not have advanced skills. However, these preservice teachers also recognize a greater need for more preparation, which may result from experiencing directly what is involved with planning and implementing a technology-based lesson.

In addition, those participants in the field-based model were more apt to recognize that planning for technology-integrated lessons requires more time, and their responses showed stronger agreement that there is not enough time to implement technology-based lessons. This reflects a more accurate perception of the time that is involved in planning and implementing technology-rich lessons. During the initial data-gathering phase of this PT3 grant, methods and educational technology faculty expressed that the preservice teachers who participated in the traditional model of instruction held an unrealistic perception of the time involved in technology integration (Glazewski, Brush, & Ku, 2000). It is encouraging to see that those experiencing the field-based model hold a more accurate perception of time.

The limitations of this study, however, should not be overlooked. The small number of participants enrolled in the on-campus course who completed the survey may not adequately reflect the attitudes and perceptions of this group as a whole. For this reason, further research should attempt to obtain a larger sample. Doing so should increase the power associated with the statistical results, and, thus, account for a larger percentage of variance related to technology attitudes and perceptions.

Abstract: This paper presents specific findings based on a three-year campus-wide student attitude survey of web-delivered learning. Since 1998, the University of Indianapolis has utilized Blackboard to augment and web-deliver courses. The survey collects demographic data and several attitudinal questions scored on a 5-point Likert scale. Additional open-ended questions are included. The survey consists of a web-based form administered anonymously institution-wide in all courses that have integrated the web into teaching and learning. Findings indicate that as time passed, students perceived their computer skills were more sufficient and that their computers were more adequate for the course requirements. Data indicate a negative correlation with the term in which the course was taken chronologically and instructor-student interaction, course pace, learned more, and required more time. Correlations among the data provide information for developing a useful distance learning attitude survey.

Introduction

The University of Indianapolis is an independent, comprehensive university affiliated with the United Methodist Church. Approximately 1,900 undergraduate day division, 900 graduate and 1,200 non-traditional students pursue credit in undergraduate, graduate, and continuing education programs.

The presenters have analyzed data collected from a student survey based on three years of institution-wide web-enhanced, web-based and distance learning courses using Blackboard. The online survey consists of demographic data and several attitudinal questions scored on a five point Likert-type scale (see end of paper). Additionally, open-ended questions are provided to the students. Anonymous responses are used to improve course offerings in the web-learning environment at the university. Implications of the data analysis reveal valuable information for colleges whose faculty and administrators have concerns about changing the traditional university interaction of faculty and students in a classroom.

The university utilizes Blackboard to support three types of web instruction: those using the web to augment instruction (web-enhanced), courses that have significantly reduced seat time (web-based) and courses delivered entirely via the web (distance learning). For the purposes of this paper, data have been aggregated by term. Further data analysis will be presented in the session.

Scope of Research

A total of 1410 students responded to the survey over the three-year period. Table 1 shows the breakdown of the respondents by semester. As indicated in Table 2, the number of male respondents was approximately 30%, and the number of female respondents was approximately 70%. This is representative of the university demographics. As indicated in Table 3, approximately 45% of the respondents were under
Moreover, almost 85% of the respondents are under the age of 30. Less than 7.8% of the respondents were over the age of 41.

Table 3: Age

When asked if they understood the computer requirements before enrolling in the course, approximately 50% of the students agreed or strongly agreed. Approximately 30% of the respondents did not understand the computer requirements upon enrolling in the course. A large portion of the 30% occurred in the first year of offering the course in the web-based format during which the web-based requirement was not indicated in the schedule and the students were not informed of the format of the course when registering. As indicated in Table-4, understanding computer requirements is positively correlated with the term for the course; hence the students understand computer requirements more now than when the university first employed web-based learning. One reason for the correlation between understanding computer requirements and the term could be due to the following reasons: the web-based format was listed on the schedule after the first year and informal communication amongst students increased.

The next two variables addressed whether students had a sufficient computer and whether they had sufficient computer skills when enrolled in the course. Eighty-nine percent of the students reported to have use of a computer that was sufficient to meet the course requirements; however, almost 7% of the students did not have a computer or it was not sufficient for the course. Not only is the computer sufficiency variable important, it is essential to analyzing whether the students had the computer skills to take a web-based course. Over 90% of the students agree or strongly agree that their computer skills were sufficient for this course. Conversely, only 4% of the students did not feel that their computer skills were sufficient for this type of course. As indicated in Table-4, understanding computer requirements, having sufficient computer skills and having a sufficient computer are positively correlated with the term for the course, thus
the longer the university employed courses in this format the more likely the students were to agree or strongly agree that they understood the requirements, their computer was sufficient and they had sufficient computer skills.

Besides computer variables, interaction variables (instructor available, sufficient instructor interaction, and sufficient student interaction) must be addressed. As in all courses, it is imperative to determine the student's perception of the instructor availability. Less than 8% of the students did not feel that the instructor was available to provide assistance. When evaluating the interaction, it is imperative to evaluate the student-to-student interaction and the student-to-faculty interaction. Eighty percent of the students reported the interaction with the instructor was sufficient. On the contrary, 9% of the students did not feel that the interaction with the instructor was sufficient. Sufficient instructor interaction was negatively correlated with the term; hence, students perceived that the instructor interaction was much greater when the web-based courses were first offered. The expectations and the numerous course offerings of courses in this type of format could be the reason for the negative correlation. The majority, 75%, of the students enrolled in this course believed that the student-to-student interaction was sufficient, however 7% of the students did not feel that the interaction with other students was sufficient.

In addition to computer and interaction variables, course variables were analyzed. The course variables analyzed in this paper are appropriate pace, appropriate delivery approach, organized material, learned more, required more time, enroll in more, and recommend this type of course.

Over 77% of the students reported the pace of the course was appropriate; however, 11% of the students did not feel that the pace of the course was appropriate. The course pace was negatively correlated with the term; hence the students reported that the course pace was not as appropriate as it was when the web-based course was first offered. The change in technology and expectations could be reasons for these results.

Over 70% of the students enrolled in the course reported the delivery approach was appropriate. On the other hand, 10% of the students did not believe that the delivery approach was appropriate. Moreover, the majority of the students, 75%, believed that the course material was well organized. The key questions, “Did you learn more than a traditional course?”, “Would you be interested in enrolling in more courses offered via this technology?”, and “Would you recommend other courses delivered via the same technology?”, were also analyzed. Over 44% of the students reported that they learned more in this course than a traditional course. Moreover, 43% of the students reported they spent more time in this course than a traditional course. However, the number of students reporting that they learned more and the courses required more time have declined over the three years, hence the negative correlation between term and these variables. The expectations and the numerous course offerings of courses in this type of format could be the reason for the negative correlation. The majority, 68% of the students reported they would be interested in taking another course in this type of format. As indicated in Table 4, there is a positive correlation between term and enrolling in more courses; hence, the students are more likely to enroll in web-based format courses now than three years ago. Finally, over 70% of the students reported they would recommend this type of format.

Table 4: Correlation with Term

List of Variables:
CR = Understood Computer Requirements
SC = Sufficient Computer
CS = Sufficient Computer Skills
IA = Instructor Available
II = Sufficient Instructor Interaction
SI = Sufficient Student Interaction
PA = Appropriate Pace
LM = Learned More than a Traditional Class
MT = Required More Time than a Traditional Class
DA = Appropriate Delivery Approach
OR = Course Material Organized
EM = Enroll in More
RE = Enroll in More
type of course
TE = Term, Year of course
The majority of the students agreed or strongly agreed that they understood the computer requirements, their computer and computer skills were sufficient. Moreover, the majority of the students agreed or strongly agreed that interaction was sufficient; however, there is a negative correlation between instructors to student interaction. The majority of students agreed or strongly agreed that the course pace was appropriate, the delivery approach was appropriate, and the course material was organized. However, course pace was negatively correlated with the term. The majority of the students reported that they spent more time and learned more than a traditional class; however, there is a significant decline in students reported this over time. Finally, students would enroll in more courses in this format and they would recommend web-based courses to others.

Recommendations:

Data analysis indicates that the survey items contained useful information. The exceptions are the items “On average, how much time did you spend in a week accessing course materials?” and “On average, how much time do you spend per week with a traditional course?” Student responses were vague and of little meaning. More data need to be collected to determine why there is negative correlation with the term and instructor-student interaction, course pace, learned more, and required more time. Otherwise the only survey additions we plan to make in the future will assist in collection of more specific demographic data such as department and school in which the course is offered, student’s major, and full-time or part-time student. We also plan to add items asking each instructor what technologies they are using with their courses in addition to Blackboard. These may affect student responses to items relating to technology.

Distance Learning Assessment

Bio/Demo Information:
What is your gender?
☐ Male ☐ Female

What is your age?
☐ Under 20 ☐ 21-30 ☐ 31-40 ☐ 41-50 ☐ Over 50

Country of residence? (International students, please provide your country): (fill-in the blank)

Computer-related Questions:

Which computer did you use most frequently?
☐ Macintosh ☐ Windows 95/NT ☐ Windows 3.1

Which Web browser did you use most often?
☐ Netscape 4.0 or later ☐ older version of Netscape ☐ I don’t know
☐ Internet Explorer 4.0 or later ☐ older version of Internet Explorer

How did you most often access course materials?
☐ University computer lab or residence hall ☐ Direct dial-in to university
☐ IndyNet ☐ Other Internet Service Provider (AOL, GTE, etc.)

What is the speed of your modem?
☐ 28.8K ☐ 33.6 K ☐ 56 K A direct connection ☐ I don’t know

How much memory is installed on your computer?
Less than 16MB 16MB 32MB 64MB or greater I don’t know

### Likert Scale:

I understand course requirements before I enrolled: 1 2 3 4 5 6
My computer was sufficient to access the course materials: 1 2 3 4 5 6
My computer skills were sufficient for this course: 1 2 3 4 5 6

### Technical Issues:
I did not encounter any technical problems when I tried to access course materials: 1 2 3 4 5 6

If any, what types of technical problems did you encounter while trying to access course materials? Please give error messages if you recall them. *(Short answer)*

### Course Information:

Course being evaluated: *Student selects course from a drop-down menu*
In which term are you enrolled? *Student selects term from a drop-down menu*

What is the level of the course?
- □ Undergraduate
- □ Graduate
- □ Continuing Education

The course briefing/orientation (if you received one) explaining how to use the software was helpful in making the most of the course: 1 2 3 4 5 6
The instructor was available to provide assistance: 1 2 3 4 5 6
My interaction with the instructor was sufficient: 1 2 3 4 5 6
My interaction with other students was sufficient: 1 2 3 4 5 6
The pace at which the course progressed was appropriate: 1 2 3 4 5 6
I learned more in this course than in a traditional course: 1 2 3 4 5 6
The course required more time than a traditional course: 1 2 3 4 5 6
The delivery method used in this course was appropriate: 1 2 3 4 5 6
Course materials were well organized: 1 2 3 4 5 6
I would be interested in enrolling in more courses offered via this technology: 1 2 3 4 5 6
I would recommend other courses delivered via the same technology: 1 2 3 4 5 6
Was your Internet access to the course adequate? Please explain: *(short answer question)*
What are the strengths of offering a course via this technology? *(short answer question)*
What are the weaknesses of offering a course via this technology? *(short answer question)*
What would you change about how this course was taught? *(short answer question)*
On average, how much time did you spend in a week accessing course materials? *(short answer)*
On average, how much time do you spend per week with a traditional course? *(short answer question)*
Please list any additional comments you may have: *(short answer)*
Optimizing informal learning experiences in the home and school

Helen Brown
Research Project Manager
British Educational Communications and Technology Agency (BECTa)
helen_brown@becta.org.uk

Abstract: This paper describes an array of research projects that explore the use of ICT within the home and other informal settings to enhance motivation, learning outcomes and contribute to the attainment of children in school.

It is important for teachers, researchers and policy makers to be more aware of the ways children are using computers in the home. New evidence from longitudinal research projects in the UK suggests that effective integration of ICT within the school environment is constrained by:

- an underestimate of children’s experience and facility with ICT
- a lack of appreciation of the power of collaborative environmental environments made possible by ICT
- a narrow conception of knowledge and its construction
- lack of time and opportunity for teachers to explore the Internet and engage in purposeful but playful activities that contribute to confidence and vision.

This paper reports on the findings of major longitudinal studies commissioned by the UK Government. The impact of informal learning on pupil attainment at school will be discussed in the light of important issues identified as subjects for current and future research.

There is untapped potential in greater home-school linkage and collaboration. The wider learning environment in which children can flourish needs to be understood more fully. In the UK research projects are currently exploring the possibilities of raising pupil attainment through new forms of home-school collaboration. Such research recognises the undervalued knowledge and skills of parents, peers, extended family and global www communities.

Recent longitudinal studies have found that the ways children learn to use computers at home are markedly different from the ways they use them at school. Alongside a huge investment of UK Government funding in the National Grid for Learning (NGfL), new technologies are being adopted very rapidly in a majority of homes. Schools are currently coping with children who have an increasingly broad range of computer skills and very high expectations of ICT.

Traditional approaches to schooling may not optimize the exciting possibilities offered by ICT such as the development of higher level conceptualization, better problem solving, more complex collaborative learning in small groups. The British Educational Communications & Technology Agency (Becta) is engaged in several research projects to seek reliable measures for identifying and documenting the impact of home based informal learning activities in relation to attainment in school.

Becta is managing the largest and most comprehensive national study of the impact of ICT on the attainment of pupils from 1999-2002. This study, known as ImpaCT2, involves 60 schools in England and over 2000 pupils. The researchers indicated in their early finding that exposure to networked technologies may impact on learning in ways that are not reflected in formal tests of attainment in Mathematics, Science and Literacy. Nevertheless the skills and attitudes acquired in informal settings may well be essential to developing effective learning strategies.
ImpaCT2 has five specific aims to:
- identify the impact of networked technologies on the school and out of school environment
- determine whether or not this impact affects the educational attainment of pupils aged 8-16 years
- provide information that will assist in the formation of national, local and school policies on the deployment of ICT

To do this the researchers
- devised innovative new methods of assessing pupil attainment and
- devised a framework for measuring the ICT environment.

The ImpaCT2 study makes the assumption that there are new empirical and conceptual challenges involved in attempting to identify a causal relationship between children’s use of ICT and improvements in their attainment. The findings show widespread use of ICT across all school age children, with those who use computers at home tending to use them more frequently and confidently at school:

- 80% of UK school pupils now have a computer at home
- primary school children (aged 8-11 years) spent three times longer on ICT at home compared with school and secondary pupils (aged 11-16 years) spent four times longer.
- 52% of primary and 67% of secondary pupils had e-mail addresses
- 14% of primary and 67% of secondary pupils had created their own web page

The research suggests that schools with greater ICT resources may provide more opportunities for children to create web pages, encourage children to have an e-mail address and may have a positive influence in persuading parents to buy a home computer.

Although many children and young people are positive about using computers in the home, many are disillusioned with school ICT. Often they find the restrictions on Internet access frustrating and the speed of individual PCs or networks are less efficient than they experience in the home. Although it is recognised that important forms of learning take place both in homes and classrooms, teachers and parents and children rarely have the opportunity to share, discuss and use their experiences and skills.

There are some important differences emerging in the ways in which adults and children experience this new technology. When children and young people use the computer for pleasure they learn by playful discovery and experimentation. They ask family, friends and use electronic help frequently such as chat rooms and web sites. Their use of computers at home tends not to include educational software but they do choose to write, design and play games (often in group situations on or offline).

Teachers are increasingly being asked to develop innovative ways of teaching with ICT. In particular they are asked to use the Web to develop new ways of communicating with parents, children and colleagues. There is a growing concern that teachers have little time to integrate ICT meaningfully into the school curriculum and ironically they feel that pressure of work prevents them for ‘surfing’ and exploring the www. Their experience of learning via the web is thus very different from that of children who tend to find serendipitous links and spend a lot of time discovering interesting resources and passing on links to friends.

Many schools are utilizing ICT by integrating it into subject teaching, and an increasing number are encouraging pupils to carry out Internet-based research out of school. Schools are also using the Internet and e-mail to make global links within class time. There is a growing challenge for teachers who are then asked to mark computer produced homework. They are also facing the consequences of differential access in the home which can make it difficult to know how best to compensate for the digital divide within the school environment.

Previous research has strongly indicated the beneficial outcomes of using ICT in education. Factors such as learner engagement, enhanced enjoyment, increased commitment to the task; increased autonomy and self-esteem are frequently mentioned (Cox 1997, Someck 1996, Bonnet et al 1999, Davies & Somekh 1997 and Cole 2000). However there is a complex web of social, cultural and economic factors impacting on educational standards and attainment. This makes it very difficult to isolate or extrapolate the direct effects of ICT on teaching and learning.
The ImpaCT2 study has so far found a strong relationship between access to computers and the Internet at home and socio-economic status. The high cost of UK Internet access and software packages means children in less affluent homes are prevented from using information technology to its fullest potential, while those in wealthier families are able to enhance their learning with a treasure trove of online information at their fingertips.

Both children and teachers took part in this research, which used innovative methods of data collection. Sixty schools took part in the research and in each a teacher researcher was given a laptop computer to help them record and communicate data. In each school pupils carried out independent research by keeping weekly logs of ICT usage and interviewing fellow pupils. Pupil questionnaires were used to collect data on ICT activity at home and school, and concept mapping was used to gain insights into children's ideas about how they visualize the current use and future potential of networked computers.
Instructional Design Strategies for Summer Online Courses

Sue-Jen Chen
Department of Specialty Studies, Watson School of Education
University of North Carolina at Wilmington
United States
chensj@uncwil.edu

Abstract: One may think that a summer online course is just a condensed version of a regular semester online course. If the instructor squeezes an 18-week semester of course material into a 6-week time frame, and the students triple their time and efforts studying online, then the outcomes of learning should be the same. In fact, due to the nature of online learning, different instructional strategies should be used for the design and delivery of short- and long-term online courses in order to maintain the quality of learning without reducing the amount of instruction. A combination of objectivist and constructivist instructional methods was used for the design of a short-term summer online course. It yielded positive results.

With the rapid growth of technology and the widespread concept of lifelong learning, academic institutions are rushing headlong into the distance education arena and are offering a variety of online courses not only during regular semesters but also during summer sessions. One may think that a summer online course is just a condensed version of a regular online semester course. It works the same way as face-to-face classroom instruction. If the instructor squeezes an 18-week semester of course material into a 6-week time frame and the students triple their time and efforts studying online, the results of learning should be the same. In fact, due to the nature of online activities, usually both teachers and students invest much more time on online learning tasks compared to the same course taught in a traditional classroom. Besides the time factor, long-term and short-term online courses work very differently in many ways; consequently, different instructional strategies should be used for the design and delivery of summer online courses in order to maintain the quality of learning without reducing the amount of instruction.

The positive value of employing constructivist learning theories in the design of online learning environments and activities has been supported by the educational literature (Hannafin, Land, & Oliver, 1999; Palloff & Pratt, 1999, 2001). Recently, with the move of constructivism into education, there is a growing interest among teachers and instructional designers in adopting constructivist philosophy of teaching and learning in the design and delivery of their online courses. However, constructivist-based learning activities require more time and effort from both the instructor and the students. There will be no problem if a constructivist-based online course is offered during the regular semester. Students have sufficient time to work collaboratively with their peer learners to construct knowledge or to solve assigned problems through authentic learning activities. However, it would be a challenge for the instructor to implement the same instructional method in a summer online course given that he/she only has one-third of the regular semester hours to cover the same amount of course material and to achieve the same objectives.

The effects of traditional objectivist instructional design theories derived from behaviorism and cognitive psychology have long been acknowledged and commonly used by educators in various learning environments. The objectivist instructional design models advocate systematic planning of instructional materials and learning activities so that students can follow through the prescribed steps to obtain the desired learning outcomes. This school of theories grants to instructors the control of learning such as environment, materials, students, activities, and time. Efficiency and predictability are some of the strengths of objectivist-based instruction.

If time is the essential factor affecting the success of short summer online courses, instructional designers may consider using a hybrid approach for the design of the summer online course, which combines the strengths of objectivist and constructivist methods of teaching and learning. The intention of this paper is to share my experiences of designing and teaching long- and short-term online courses in the past year.

A short 6-week summer online course was designed based on the constructivist learning environment design model suggested by Jonassen (1999). The course was offered during the summer I session. The result of implementation was far from expected due to insufficient time for communication and collaboration, which are
essential for constructivist learning. A decision was made to employ both objectivist and constructivist instructional methods in the revision of the course, which was offered again during the summer II session. The revision included:

Course orientation

- Instead of asking the students to go through the entire tutorial in order to learn how to use the course management system to take the course, selecting only those tools that would be used in the class.
- Developing a step-by-step job aid.
- Including the job aid in the course resources.
- Integrating a practice of these tools into the course orientation activities and made the practice as an assignment prior to the start of the course. For example, asking the students to post an introduction of themselves to the forum, send an e-mail about their expectations of the course to the instructor, upload their digital picture to the online folder, etc.)

Instructional design of the units - The course contained four units.

- Selecting a unit pertaining to the potential for problem-based learning, but the level of difficulty and complexity of the problem was manageable and accomplishable within a 2-week time frame to be the group project, and using constructivist approach to design this unit.
- Applying objectivist instructional design principles to design the rest of the three units.
- Prescribing detailed instructions on content, class activities, and assignments.
- Providing detailed assignment procedures, rubrics, and criteria for grading.
- “Clarity” was the key for designing the units using the objectivist approach.

Class activities or learning community - Although the objectivist approach was employed in the design of the majority of the units, most learning activities were designed based on the constructivist learning theories. A big learning community involved the entire class members and four sub-communities consisted of only the members of the groups were formed. Students were advised to work collaboratively not only on the group project but also on the individual projects. The goal of collaboration was for the students to assist each other in obtaining a better quality product. Students were also made aware that their contribution to the teamwork would be graded.

The revised course was well received and highly rated on the students' evaluation at the end of the class. On the exit reflection, most students indicated the following as the most helpful features of the course: clear instructions on how to use the tools to take the course, the assignment criteria and rubrics, quick response from the instructor, and the in-time feedback on draft assignments from the instructor and the classmates. In conclusion, a short summer course, in order to be effective, should employ a combination of objectivist and constructivist instructional design approaches.

University of North Texas
gknezek@tenet.edu

Abstract: Stages of Adoption of Technology are used in conjunction with other assessment instruments to determine attitude, skill and technology access changes that assist in moving a teacher further along in his/her level of classroom technology integration. Prototypical characteristics are used to formulate strategies for professional development in advancing teachers toward higher stages of adoption. This paper summarizes characteristics at each stage of adoption and address issues faced in promoting transitions from one stage to the next. Example strategies that could foster transitions are also provided.

Introduction

Stages of Adoption (Christensen, 1997) is a self-assessment instrument of a teacher's level of adoption of technology, based on earlier work by Russell (1995). There are six possible stages in which educators rate themselves: Stage 1 - Awareness, Stage 2 - Learning the process, Stage 3 - Understanding and application of the process, Stage 4 - Familiarity and confidence, Stage 5 - Adaptation to other contexts, and Stage 6 - Creative application to new contexts. These six stages form an ordered continuum that has been shown to function as a reasonable interval-level measurement scale (Knezek & Christensen, 1999).

Teacher attitudes can be differentiated according to levels that characterize each stage of adoption. Instruments used for skill and attitude assessment are described in the following section.

Attitude/Skill Measurement Scales

Several information technology attitude instruments were developed and validated by the authors during 1995-98. One of these instruments, plus a second authored by Ropp (1999) with a focus on technology proficiency, form the core of the stage classification data presented in this paper. Each instrument used in this study is briefly described in the following paragraphs. More detailed information is available in the book Instruments for Assessing Educator Progress in Technology Integration (Knezek, Christensen, Miyashita, & Ropp, 2000).

The Teachers' Attitudes Toward Computers Questionnaire (TAC) (Christensen & Knezek, 1998) measures seven major indices regarding teacher attitudes. These scales are: 1) Enthusiasm/Enjoyment, 2) Anxiety, 3) Avoidance/Acceptance, 4) E-mail for Classroom Learning, 5) Negative Impact on Society, 6) Productivity, and 7) Semantic Perception of Computers. Internal consistency reliabilities for these scales typically range from .87 to .95 with K-12 teacher data (Christensen & Knezek, 2001).

The Technology Proficiency Self-Assessment Instrument (TPSA) was included to gather data on teacher competencies (Ropp, 1999). This instrument was selected because it has good reliability and measures skills recommended by the International Society for Technology in Education (ISTE) for all K-12 teachers. Four of
Ropp's measurement scales (with five items each) were included: Email, Integrated Applications (IA), Teaching with Technology (TT), and the World Wide Web (WWW). Respondents rate their skills on a scale of 1 (strongly disagree) to 5 (strongly agree). Reliabilities for these four scales ranged from .78 to .88 for K-12 teacher data gathered from 417 respondents in Texas during 1999.

**Study 1: Relationship of Attitudes to Stages of Adoption**

In an initial study conducted using the Stages of Adoption instrument in 1998, the average Stage of Adoption value across a sample of 1,135 educators was 4.13, with educator representation falling in each of the six stage categories (see Fig. 1). High correlations were found between stages of adoption and computer anxiety ($r = .67, p < .0005, N = 973$), in the direction of higher stages being associated with reduced anxiety. Higher stages of adoption were also strongly associated with increased computer enjoyment ($r = .60, p < .0005, N = 973$). Background information was gathered regarding home access to computers and the Internet. To determine whether use of a computer at home or access to the WWW at home made a difference in a teachers’ stage of adoption, t-tests were carried out. Findings were that both home use of a computer and home access to the Internet were very strong discriminators for high or low stages of adoption (Knezek & Christensen, 1999). The nature of the relationship appears to be that home access makes a large contribution to technology integration advancement at the higher stages.

![Figure 1. Distribution for stages of adoption of rural Texas educators, 1998.](image)

**Stage One Teachers**

As shown in Tab. 1 and Fig. 2, teachers who were in Stage One (awareness) rated themselves lowest (among those in the six stages) in computer enjoyment, computer avoidance, Email, productivity and overall perception of computers. They rated themselves as being more anxious toward computers and more negative in their feelings about the impact of computers.

*Table 1. Attitude factors by stage of adoption of technology for 1141 rural Texas teachers, 1998*
Stage Six Teachers

Teachers who reported being in the sixth stage of technology adoption had the highest mean scores among the six stages of adoption category groupings in computer enjoyment, Email, productivity, and semantic perception of computers. This subset of teachers also rated themselves the lowest of all the groups of teachers in anxiety, computer avoidance, and a negative feeling toward the impact of computers.

Study 2: Attitudes by Stage and Home Access

In spring 2000, data were gathered from 344 teachers in a west Texas urban school district near the international border with Mexico. As shown in Fig. 3 attitude profiles by stages were similar to those previously reported for the 1998 rural sample.
Influence of Home Access

In a 2001 study in the same urban district with a sample of 117 teachers, almost 85% reported having access to a computer at home while only 57% reported having access to the Internet at home. Tab. 2 and Fig. 4 show the near linear relationship between stages and computer access at home.

Discussion

As shown in Fig. 3, many Stage One and Stage Two teachers appear to have high levels of anxiety toward computers (F2). However, when teachers reach Stage Three they begin to become less anxious and continue to become less anxious progressively throughout Stages Four, Five, and Six. Teacher education might focus on these Stage One and Stage Two teachers to reduce their anxiety by educating teachers in something that will apply immediately and then move on to classroom integration after they lower their anxiety and gain confidence in using technology.

Profiles of characteristics of educators in various stages of adoption allow the formulation of strategies for promoting advancement to the next higher stage. The concepts of will (attitudes), skill (competencies) and information technology tool access are conjectured to be essential parameters determining whether or not smooth transitions occur from stage to stage. However, simultaneous improvement in all three areas may not be necessary. These findings have ramifications for decision makers seeking to plan the most efficient and productive professional development growth path for technology-using educators.

Abstract
As school administrators increasingly see the importance of teachers using technology, there is a demand for technology related professional development for in-service teachers. As an on-going evaluation of a federally funded technology innovation grant, the researchers conducted a case study of a week long summer training session for teachers involved in the grant. The goal of the workshop was to help teachers integrate technology into their own curriculum plans. This study was designed to examine the development of relationships between the teachers and the trainers.

The researchers found characteristics of trainers associated with more teacher involvement and interest in technology use. Trainers who view themselves as learners and understand the difficulties of learning technology skills are more productive with teachers. On the other hand, trainers who present themselves as experts on technology often develop negative working relationships with teachers. This case study provides practical implications for successful professional development.

Introduction
There is an ever-increasing demand for more effective ways to deliver instruction in the classroom. Technology use is an avenue that many education professionals are exploring to address this demand. To promote the enhancement of delivery of instruction in middle school classrooms in four schools in Mississippi’s second congressional district, the CREATE for Mississippi project was implemented. A federally funded project, CREATE for Mississippi, is a technology innovation grant originally intended as a five-year grant that is being funded on a yearly basis. The project’s main goal is to support the educational technology initiative in the state of Mississippi. CREATE addresses four main areas that have been identified in the literature as barriers of technology infusion instruction. These barriers are lack of time, training, equipment, and support. The barriers of lack of training and support are addressed in the 2001 Summer Training Session of new CREATE core teachers.
In the summer of 2001, the second year of the project, a group of teachers from the Congressional District 2 (CD2) of Mississippi attended a workshop for a week on the campus of Mississippi State University as part of their obligation as core teachers or as educational technologists. The new CREATE core teachers were a group of 16 teachers from the Delta area of Mississippi. These teachers are mostly veteran educators in economically challenged school districts. The summer training session aided the teachers in improving their method of instructional delivery through technology integration. Four teachers and one ET from three of the four schools from CD2 involved in this project participated in the workshop. Only three teachers from one of the schools were at the workshop.

The goal of the workshop, as well as the CREATE for Mississippi project, was to help teachers integrate technology into their own curriculum plans. The training available at this training session was provided through the CREATE staff and teachers and an ET from CD1. The barrier of lack of support is addressed by the presence of the CREATE staff and core participants from CD1 who will serve as mentors during the 2001-2002 school year. The workshop trainers focused on teaching the teachers basic computer skills while assisting them to create lesson plans infused with technology. Throughout the year, each teacher will be expected to create at least three more technology-infused lesson plans to be published on the CREATE website (www.create4ms.org) in conjunction with using technology in their teaching. The goal is that these teachers will become comfortable enough with technology to mentor other teachers in their schools to use technology in their teaching plans as well. The interactions and relationships developed among the teachers from the four core schools and between the new core teachers and training staff will be explored in this paper.

CREATE for Mississippi

CREATE is an acronym for Challenging Regional Educators to Advance Technology in Education. CREATE for Mississippi is a federally funded Technology Innovation Challenge Grant (TIGC) that is presently in operation in three congressional districts in the state of Mississippi. The major thrust of the CREATE project is to provide training and support for participating schools in order to advance their technological capabilities.

Four core subject area teachers were chosen by the school administrator at each school. The four core teachers will receive on going training on technology equipment and software. The core teachers are responsible for mentoring other teachers in the school and for developing lesson plans to be submitted to the CREATE staff. The core teachers are allotted one hour a day to work on technology integration. This one hour is designed for the teacher to find useful websites, write lesson plans, work with the ET, or perform any other task that is related to their growth in technology.

The CREATE project includes a component that addresses technology availability in the school. Through the project the core teachers have access to technology equipment designed to enhance classroom instruction. Teachers are provided with a technology support cart with components such as: (a) computer, (b) wireless keyboard, (c) scanner, (d) digital camera, (e) flex camera, (f) video editing hardware, and (g) digital video camera. The teachers also have access to a fifteen-unit wireless laptop cart in addition to a laptop strictly for teacher use.

Another component of the CREATE project is the support provided to the core teachers. This support is provided through the availability of the Educational Technologist (ET). The ET is responsible for providing teachers with technology training and just-in-time support. The ET serves as a liaison between the teachers and the unfamiliar technological grounds that they may tread. The ET is also responsible for the development of the student technology team.

The student technology team is monitored and trained by the ET. The student technology team is responsible for correcting problems that the teachers may encounter while infusing technology in lesson delivery or planning. The technology team is also available to train teachers and to be trained on new software that is available. The ET provides professional development sessions for the core teachers in the school as well as the non-participating teachers.

2001 Summer Training Session

During the week of June 11-15, 2001, 15 core teacher and 3 ET's from 4 schools in CD2 received technology training at Mississippi State University. The training sessions were conducted by the staff of CREATE for Mississippi as well as teachers and an ET from CD1. The teachers attended sessions on the
use of Microsoft PowerPoint, Microsoft Excel, Microsoft Word, digital cameras, scanners, printers, and laptop computers. The sessions were eight hour sessions during the day with additional two hour sessions at night. The teachers were given the opportunity to create permanent products for personal use or for school use during the day sessions. The evening sessions were designed for the development of technology infused lesson plans to be presented on the final day of the week-long session.

Mississippi Delta

The Mississippi Delta is a region of the state that is marked by casinos and cotton fields and set to the rhythm of the blues. This region of the state is known for its rich soil and its flat land. The major source of employment for Deltans is industry and catfish farming. With a very slow economy, many Delta school districts are desperate to improve the quality of the schools in order to improve the quality of life in the Delta. Many Delta school districts face a critical need for teachers. There are two universities located in the heart of the Delta. Both of these universities have teacher education programs that offer teacher certification for graduates. Despite the fact that these universities produce the teachers, the graduates opt to leave the Delta for more attractive economically desirable locations. Technology is not very prevalent in the Mississippi Delta schools. The schools struggle to operate on a yearly basis just to meet the demand for required material for the teachers. Many Delta schools receive technology assistance through educational grants that offer equipment to school teachers and school districts.

Despite such a bleak appearance, the Mississippi Delta has a creative legacy that includes more than the music of the blues that was born in the Delta. Playwright Tennessee Williams spent his childhood in the Delta and modeled many of his characters and locations after real people and places. The annual Tennessee Williams Festive includes tours of these locations as well as performances of the playwright’s work. Thomas Harris, author of Silence of the Lambs and Hannibal, was also a Delta native. Southern writer Willie Morris grew up in Yazoo City and immortalized his hometown in the book My Dog Skip. Morris is buried 13 paces from the grave of the Witch of Yazoo, a site made famous by a film version of his memoir.

Participants

The participants of the summer teacher workshop were teachers and ET’s from four schools located in CD2 and the Delta. The sizes of the school districts range from 944 students to 7942 students. According to the state accreditation rating ranging from one (lowest rating) to five (highest rating), the four school districts have an accreditation level of two. The participants were four math teachers, three social studies teachers, four language arts teachers, three science teachers, one gifted teacher who is the science representative for the school, and 3 ET’s. The teachers’ years of experience as a certified teacher range from none to 30 years.

2050
The Study

In CREATE’s first year of operation there was extensive and continuous communication between the teachers in the core schools and the CREATE staff. During this year, there were many visits made to the schools by the staff, and the teachers made visits to Mississippi State University for training. Because of the long distance e-communication that existed between these two entities, there was some miscommunication along the way the ultimately there were elements of mistrust that arose.

The lack of trust that existed between the staff and the teachers manifested itself in the form of weak relationships between the two. This manifestation hindered the excellence of the project on the part of the teachers and the CREATE staff. The teachers were not comfortable with presenting their problems to the staff or asking for assistance with problems related to their optimum achievement in their participation in the project. The staff was at a loss because they were unsure of how to communicate with the teachers to find out where their weaknesses were and how to help the teachers solve these impending problems.

The researchers were members of the evaluation team during the first year of the project which included schools from the Mississippi Congressional District 1 (CD1). They have discovered that the development of trusting relationships is vital to the growth of the teachers as a result of the project. Since a major component of CREATE for Mississippi is the mentor-model, the researchers examined how the teachers from CD2 felt about the training staff during the one-week workshop.

Findings

When working with teachers, the researchers have found characteristics in the trainers that help create effective relationships between the trainers and teachers. The trainers who understand the situations that teachers face in the classroom are more productive when instructing the teachers how to integrate technology into their curriculums. The trainers who view themselves as learners and understand how difficult learning new technology can be are also more helpful to the teachers. On the other hand, the trainers who see themselves as experts on technology while viewing the teachers as less intelligent or less capable of learning technology are often viewed negatively by the teachers. These trainers are less effective with the teachers and eventually develop a negative working relationship with these teachers. These trainers have become frustrated with the teachers and eventually stop attempting to help the teachers learn about topic discussed.

The researchers found that the week-long training session was instrumental in helping to start the relationship development process. The teachers seemed hesitant to communicate at first, but as the week progressed, many relationships developed. Teachers from different schools developed relationships with each other, and the teachers developed relationships with the training staff.

The teachers were very open, down-to-earth people with one common goal which was to gain valuable experiences through technology training. The CREATE staff was very receptive and open to the teachers and made themselves readily available to the teacher at all times. Although during the training sessions the teachers sought help from any staff member available, there were two staff members in particular that the teachers relied on heavily on for assistance. These two staff members were Jimmy and Rose. Jimmy and Rose are two the newest members of the training staff. One interesting observation made about Jimmy and Rose is that many times teachers would pass up another staff member to get help from one of the two.

Rose is a young, energetic European American female. Rose has had experience teaching in the public schools as well as experience working with teachers in a grant-related position. Rose is responsible for serving as a liaison between the staff and the teachers in the schools. This position with the staff has offered her invaluable experience in knowing how to communicate with the teachers and developing and maintaining trust. The only problem that arose during the first year of the project with Rose was teachers associating her so closely with the other staff members. When the teachers were dissatisfied with the other staff members, they also felt negatively about Rose although she had nothing to do with the problem. As the year progressed, the teachers began to feel more comfortable with Rose.

Not only did the teachers at the workshop develop a professional relationship with Rose, but they were beginning to establish semi-personal relationships with her as well. Through the week, Rose used very personable language to communicate with the teachers, and she dressed in a very comfortable teacher-
like fashion. She could often be observed practically running around the room wearing tennis shoes and her hair pulled back in a ponytail trying to answer the call of everyone who requested her help.

Jimmy is a young, technologically-gifted European American male. Unlike Rose, Jimmy does not have teaching experience. Jimmy has, however, used his savvy technology skills to conduct technology training workshops for several agencies. In addition to Jimmy's training experience, he has been a part of the business world. In this capacity, Jimmy's position was comparable to customer relations. This experience has offered Jimmy the skills needed to be a people centered person. Jimmy has also worked with the project for close to a year in a multifaceted capacity. The bulk of his responsibility was to go to the schools and conduct professional development sessions with the teachers. This experience has been a plus in helping Jimmy to effectively communicate with the teachers and in earning their trust. Jimmy, like Rose, could often be found throughout the week scurrying about offering assistance to the teachers during sessions.

The rest of the staff during this week were effective in their roles but did not establish a connection with the teachers like Jimmy and Rose. The teachers did not seem to respond to those staff members who were more formal in their manner and dress. The complaints from the teachers about these persons were that they were too serious, often boring, and not personable. Teachers complained that these trainers seemed to be unable to relate to them on their level of knowledge of technology and teaching.

On the last day of the session, the researchers used a questionnaire to discover how the teachers felt about the relationships that they built with the staff during the week. Through conversations, the teachers revealed that there were members of the training staff that they preferred not to ask for assistance. In direct contrast to this fact, all of the responses on the questionnaires were positive. On the questionnaires, none of the teachers mentioned being uncomfortable with anyone on the training staff. This may be attributable to the fact that the project manager was in direct contact with the teachers as they were completing the questionnaire. The teachers may not have felt comfortable enough to reveal their true feelings or the feelings that they expressed during casual conversation.

The researchers concluded that there were positive relationships developed between the staff and the teachers during the training session. The researchers believe that the working relationships between the staff and the new teachers for the upcoming years will be more beneficial to everyone involved for the success of the grant. It is the belief of the researchers that the teachers will relate better to staff members who are open and appear to be friendly. This study has shown that positive interaction fosters relationship building. Relationship building, in this case, creates the environment for a productive year for the CREATE project.
Assessing and Predicting ICT Literacy in Education Undergraduates

craig.montgomerie@ualberta.ca

Abstract: This study developed computerized testing procedures for selected procedural and declarative knowledge and skills of undergraduate students in an introductory, required instructional technology course. Examination of participant demographic information shows ICT skills seem to be rising as a function of increased exposure to technology in K-12 schools, but it is insufficient for mastery. In addition, a multiple regression model of predicting success based on intellective and non-intellective variables was tested. It was found that the intellective variable computer experience and the non-intellective variables gender and computer self-efficacy predicted ICT skills. The intellective variable general academic ability predicted declarative skills only (not procedural skills). Implications for individualized assessment and instructional programs are presented.

Introduction

In recent years, the view that Information and Communication Technology (ICT) is vital in K-12 education has become widespread. ICT use in schools has increased and various professional bodies have set ICT standards for students and teachers (e.g., ISTE, 1998; Alberta Learning, 2000).

When "embedded within practices and activities that realize its functionality for specific purposes and situations" (Réginald Grégoire inc. et al., 1996), ICT may contribute to various aspects of teaching and learning such as: (1) greater motivation, attention span and concentration, (2) stimulation toward deeper investigation of subjects, (3) cooperation and collaboration, (4) more authentic learning environments through simulations, virtual experiences, and graphic representations, (5) increased teacher interaction and mentoring, (6) more demanding forms of assessment, (7) better teacher access to learning resources, and (8) more collaborative professional development.

Questions abound as to whether teachers have the skills that their students are expected to attain (Milken Exchange on Educational Technology & ISTE, 1999) Schools of education are under pressure to produce teachers who are able to effectively integrate technology into their teaching. However, many teacher education programs do not adequately prepare teachers in ICT, nor assess candidates relative to ICT standards.

The Study

The objectives of this study were to: (1) develop a computerized system which assesses ICT declarative and procedural knowledge and provides a profile to the participant, (2) gather baseline information on the ICT Literacy of undergraduate Education students, and (3) determine whether there are characteristics associated with students with greater ICT expertise.

This study tested 713 undergraduate students at the start of an educational technology course (whose major focus was learning computer technical skills) and found generally weak ICT Literacy, with less than 10% of the students achieving a mastery level (80%). The students took the tests again at the end of the educational technology course and the results indicated a significant increase in the ICT Literacy level of the students. However, still only about half of the students achieved a mastery level on the tests. These results imply that teacher education programs should continue to take measures to increase the computer technical competency of
students, as part of preparing pre-service teachers to teach with technology, and that a single computer technical course is not sufficient to raise all students to an adequate level of ICT technical competency.

This study also sought to identify characteristics associated with students who enter education studies with greater ICT expertise. A multiple regression analysis (Ma, 1997) revealed that pre-course ICT Literacy could be positively predicted by: variety of previous computer experience, amount of post-secondary computer-related studies (higher for students with science/technology focus rather than humanities), amount of ICT exposure in K-12 schooling, ownership of a home computer, general academic ability, gender (male), computer self-efficacy, and recency of high school graduation. Both declarative knowledge and procedural knowledge were predicted fairly similarly, with just one major difference. General academic ability was not a significant predictor for procedural skills, while recency of high school graduation was a significant predictor. Since academic ability is normally tested in a manner more similar to the declarative portion of the test (multiple-choice questions) than the procedural portion (practical hands-on tasks), it is not surprising that this variable significantly impacted declarative but not procedural scores. Recency of high school graduation likely impacted procedural skills because more recent graduates have had more opportunity for hands-on practice with computers in school than earlier graduates did.

## Automated Assessment of ICT Skills

There was no existing instrument or data available which would have suitably assessed the ICT skill level of the post-secondary students who participated in this study. Commercial automated products such as SAM 2000 (Course Technology, 1999) are available for assessing individual expertise with particular application programs. These products offer an authentic type of assessment, in which the student must demonstrate skill acquisition in a live application environment or in a very realistic simulated environment. However, these products were not suitable for use in this study because they were limited to use on the Windows platform and to one particular version of applications such as Microsoft Word 2000 or Excel 2000 (Microsoft Corporation, 2000b); the computer facilities used in the study included both Macintosh (Apple Computer Inc., 2000) and Windows (Microsoft Corporation, 2000c) computers and various versions of software. There was also very little content in these products that addressed entry-level skills, and they generally did not allow for multiple methods for the student to produce a correct result for a given task.

In addition, various tools for self-assessment of ICT skills are available to pre-service or in-service teachers. Examples are the California Technology Assessment Profile (California Department of Education, 2002) and the Professional Competency Continuum (Milken Exchange on Educational Technology, 1999). Such tools are based on student self-reports and general checklists. This study required data from an objective, consistent test, in addition to student self-reports (this study collected some self-reported data concerning previous computer experience). For example, this study assessed what a student understands about using spreadsheets, by asking direct questions that require experience with various aspects of using such a tool, including performing particular operations using an actual spreadsheet program. It did not simply ask "Have you used a spreadsheet?" or "How well do you know how to use a spreadsheet?", which is what most self-reports would ask. Students may not be aware of how much they do not know about software tools. The lack of suitable tools for evaluating student ICT skills in this way justified development of new instruments.

Part 1 of the ICT literacy test developed in this study was called the ICT Knowledge Test. This test was a multiple-choice 30-minute test intended to measure declarative knowledge on ICT terminology and concepts. This instrument was presented to the students as a web-based HTML form and responses were collected via the Internet using an Active Server Page (Microsoft Corporation, 2000a) process. This process recorded their responses in a Microsoft Access (Microsoft Corporation, 2000b) database stored on a Windows server and returned a confirmation message to the student's web browser. In addition, responses were compared to the correct answers and the total score was automatically computed and stored in each student's database record.

Part 2 of the ICT literacy test was called the ICT Performance Test. Students completed a number of hands-on computer tasks which required a total of about an hour to complete. Each student was provided with a task list and a set of computer files that they were required to modify. The tasks were a sampling of the practical skills covered in the course and were limited to those requiring commonly available software and operating system functions (e.g., text/word processor, spreadsheet, copying/moving files). When the student completed the test, the modified files were then transferred via the Internet to the server. An automated scoring program immediately analyzed these files and stored the student's results in the database.
The Performance Test was a much more technically complex instrument than the Knowledge Test since it required automating the analysis of files that participants have manipulated on their local computers. There were many different programming methods which were considered prior to developing this instrument - the decision concerning which tools to use were based on criteria such as time constraints for the initial instrument development, minimizing problems in collecting data, and allowing the Performance Test to occur on either the Windows or Macintosh platform and with varying versions of application software. The solution chosen was to create a Visual Basic for Applications (VBA) (Microsoft Corporation, 2000d) procedure within the same Access database described earlier. Web-based (especially client-side) programming techniques were avoided because of variable client computer setup and security issues involved in attempting to examine files on a client computer over the Internet. This part of the system required uploading a set of files (combined into a single compressed archive) over the Internet to and from each participant’s computer and the database server. During the Performance Test, the VBA procedure was continually running, monitoring a certain file directory every 60 seconds for arriving submissions and executing an automated scoring routine. The VBA scoring procedure implemented programming techniques (e.g., use of Microsoft Automation objects, methods and properties) which enabled automated execution of file system commands (e.g., file searches and directory listings), reading of text stream files, interfacing with external applications (e.g., Microsoft Word and Excel), opening files in these programs, and examining their object hierarchy.

After completing the tests, students were able to view their profile privately by entering their ID and password on a web-based form. The profile displayed their scores along with detailed information concerning the responses and correct answers to every item on the tests. After the post-test, the profile displayed both the pre-test and post-test information so that the student could assess their progress.

Conclusions

Regarding exposure to ICT in K-12 schooling it should be noted that the results only reflect the situation in the limited geographic area covered in this study. It was found that integrating ICT into a larger number of school subjects and starting ICT exposure earlier in school appear to have a positive impact on ICT Literacy, and this is increasingly evident in more recent graduates. Thus, one would expect that if ICT use in K-12 schools continues to increase, the ICT Literacy level of students entering post-secondary studies (in particular those entering teacher preparation programs) will continue to rise. K-12 schooling must be expected to provide a significant portion of a student’s exposure to ICT, and the current situation (as per the baseline pre-course assessment) is that students overall do not appear to have enough exposure to ICT in their K-12 education. However, if the apparent trends discussed above are real, this situation should ameliorate with each passing year.

K-12 programs should also be aware of the characteristics associated with individual differences in ICT Literacy that have been identified in this study or in the literature. K-12 schools should continue to take measures to ensure that both boys and girls, both humanities and science-oriented students, and all students regardless of academic ability or family SES (especially access to a home computer), have ample opportunity for ICT experience. K-12 schools also have an important role to play in fostering positive attitudes and self-efficacy regarding the use of computers.

It is clear and perhaps obvious that exposure to computer technology in a variety of school contexts, homes and elsewhere is related to higher entry technical skills and knowledge. This raises some interesting issues. For example, to what extent is there a self-selection factor at work? That is, it might be hypothesized that students who have some sort of predisposition to work with computers are attracted to those courses that involve computers to the extent they have choice. If so, the suggestion of increasing the number of courses which use computers in order to increase literacy may have limited effect. An analogy to this logic is the argument that we reduce the sales of ice cream cones in the northeast because of the known correlation between ice cream cone sales and deaths by drowning. The fact that being male was a significant predictor in the multiple regression equation and that males tend to be more attracted to technology provides support for this hypothesis.

This study has demonstrated an applicability of automated testing to assess students’ knowledge of ICT skills and procedures. Note that in the course, not all ICT skills were tested in an automated fashion: some were tested using conventional formats. One question to be raised is the reliability, validity, and usefulness of the automated testing process. Another is scalability: to what extent can a larger number and type of skills be successfully assessed using automated procedures? Increasing numbers of students and shrinking resources
provide a practical impetus to this line of questioning. Potential benefits might include scalability, freeing of instructors' time to engage in assessment and instruction that demands more complex human judgment, and individualizing programs for improved learning and greater efficiency.

The age-old question arises, should every student in an instructional technology class be required to complete exactly the same assignments? Could we not create a system of individualization in which students would be directed to those learning assignments where their skills and knowledge is weak and in turn away from those learning assignments where their skills and knowledge is strong? Of course, this concept works well in theory but there are practical limitations. First, how does an instructor identify, among all the required basic skills and knowledge, which each student has acquired or not? Given hundreds of students and dozens of skills quickly renders this a task of unreasonable proportions. However, were all or the majority of the skills able to be assessed automatically, and via distance learning technology to boot, the logistics, operational problem could be solved. A second barrier is how to communicate, to each student, his or her profile of skill acquisition, that is what skills have been mastered and what skills have not? Individual student-instructor consultations with hundreds of students, some who may be studying as distance students is also prohibitive from a logistics point of view. However, results of automated testing can be generated through web-forms and delivered, individually, tailored to each student.

A third problem is remediation. For any given skill deficiency, what is the student to do to overcome it? Once again, if a specific learning activity with specific learning resources can be identified which will lead to a removal of a skill deficiency, the reporting system can also inform each student what they need to do in order to remove the deficiencies. Obviously such a system works best when the learning resources are available to students on a 24 X 7 basis.

Finally, there is the question of verification of acquisition of skills by students, so they can decide whether or not they need more study or can proceed to the next skill set. Because the assessment program has been automated, it can also be used by students to perform self-checks to determine what they have learned and still need to learn. In terms of using an individualized and computerized assessment system, it has been shown that (1) students' judgments about their own learning progress is often erroneous and (2) having access to an objective computerized testing system increases learning (Tennyson, 1981). These and other benefits of computer managed instruction systems are well documented (e.g., Szabo and Montgomerie, 1992). Plans for expanding the automated testing described herein into a full-blown CMI system are currently underway.

Further Research

Further research should be done on individual variations in computer usage. Cuban, Kirkparick & Peck (2001) identified 'open door' students whose computer competence enhanced their motivation and self-confidence to do well in school and opened doors to learning. These students were predominantly male, from diverse ethnic backgrounds, and all had gained computer experience outside of school.

Another area identified for further research is adapting the instruments developed in this study for use in K-12 school environments for the purpose of longitudinal studies that would assess the ICT Literacy of students and determine if there is a trend towards increasing ICT use and ICT literacy in the geographic area covered by this study, in other regions in Canada and in other countries. Such K-12 studies may also be able to identify additional variables regarding ICT use in schools that will provide greater understanding of individual differences in ICT Literacy. This study only examined two simple variables related to the earliest grade of computer use and a count of the number of high school subjects that used computers. There are likely a host of other school-related variables that may increase our understanding of K-12 ICT Literacy such as school SES, school type, attitude of principal and other teachers regarding technology, expenditures on technology (e.g. hardware, software, and support), professional development opportunities, teacher ICT Literacy, student-computer ratio, level of Internet access, amount of time students have access to computers, level of sophistication in the use of particular software tools, and the complexity of projects completed using technology.

Further research should also be conducted into developing and implementing models for covering ICT in teacher education programs. Teacher education programs must help pre-service teachers increase their level of ICT knowledge and practical skills along with their understanding of integrating ICT into teaching. Improving the coverage of ICT in teacher education programs is a complex challenge; coursework is only one aspect of incorporating ICT into these programs. There are many factors that impact technology in pre-service teacher programs including faculty professional development, faculty incentives, funding, technology
infrastructure, technical support, leadership, long-range planning, accreditation standards, technology use in K-12 schools, and technical competency of incoming students (Bielefeldt, 2001)

Assessment of the Impact of the Gates Foundation's Teacher Leadership Project (TLP) as Reported by TLP Graduates, Their Principals and Teaching Peers

Dr. David E. Dean
Information Resources
Eastern Washington University
United States
dave.dean@mail.ewu.edu

Abstract: The Teacher Leadership Project (TLP) is a technology infusion effort funded by the Bill & Melinda Gates Foundation. The TLP provides K-12 teacher participants with technology infusion training and technology funding for participants' classrooms. This presentation describes a study of the impact the TLP has had on its participants as reported by the TLP "graduates," their building Principals, and some of their teaching peers. This study was designed to learn about some of the "ripple effects" of the Teacher Leadership Project. Are TLP graduates sharing their technology integration skills and techniques with others teachers in their school and district? What leadership roles have TLP grads assumed in the district? How has participation in the TLP impacted graduates' desire to pursue additional schooling or certification training? Are their broader district-wide impacts that are occurring because of the influence of activities of TLP graduates?

Introduction

This report describes results from a study designed to discover the impact Teacher Leadership Project graduates are having on their schools and school districts. This study solicited the input of the 407 teachers who graduated from the Bill & Melinda Gates Foundation's Teacher Leadership Project (TLP) between June 1998 and June 2000. Current TLP participants (graduates in June 2001) were excluded from this study.

Included in this report are: (1) background information on the TLP, including its goals and methodologies; and (2) results from quantitative and qualitative analysis of graduate impact surveys.

Background on the Teacher Leadership Project

In the summer of 1997, 27 teachers from public and private schools, in Washington State, came together to determine how best to use technology in their classrooms. These teachers developed a vision, mission and a staged model for implementation of technology as a learning tool across the curriculum. The model emphasized the relevancy of computing in the context of elementary education. It encouraged teachers to capitalize on integrative strategies. It encouraged teachers to plan, manage and reinforce computer activities as they would their other lesson plans and materials. It utilized a "teachers teaching teachers" development model.

In the fall of 1997, these teachers began to test their plan. The addition of new computers to participants' classrooms brought the student-computer ratio down to 4:1; each received a printer and a presentation device; and they began to infuse technology into their lessons. Not only were these teachers learning about using technology, they also had the equipment to begin testing the strategies for learning with their students.

A new environment emerged in the classrooms of TLP participants. Teachers reported that students often became teachers, and teachers learners. Students were engaged, curious and interested in active inquiry. TLP participants began collaborating with each other and serving as peer mentors. Participants adopted a mentoring, collaborating style of interacting. And through regular meetings and workshops, teachers had the opportunity to share and learn from their peers' new strategies.
As of June 2000, this program, the Teacher Leadership Project, had concluded its third year and had reached more than 400 teachers. These graduates are the population included in this study. The Teacher Leadership Project Impact Study was designed to learn about some of the "ripple effects" associated with participation and then graduation from the TLP.

Teacher Data Collection

Research participants in this study were teachers (mostly grades 4-8) who had attended and graduated from the Teacher Leadership Project (TLP). Participants came from public and private schools (K-20) located across the State of Washington.

Survey design took place during January and February 2001. The eight TLP Regional Coordinators who worked with the first three years of TLP participants (graduation years 1998 - 2000) were contacted via phone and interviewed. Regional Coordinators were asked to identify ways that TLP teacher participants were impacting their schools. Regional Coordinators' input fell into four impact areas: (1) training and development activities, (2) leadership activities, (3) personal development activities, and (4) other impacts to the participant or the school district and community. Two impact assessments were designed around these four impact areas.

Data collection took place throughout the state of Washington between April 3, 2001 and April 30, 2001. One hundred and forty five completed graduate impact surveys were returned to the researcher and used in this study. Two hundred and seventy one completed principal and peer surveys were returned to the researcher and used in this study.

Summary of Quantitative Data (Graduate Surveys)

The majority of TLP graduates who responded to the impact survey were female (73%) and over 40 years of age (63.8%). Most of the respondents teach grades 4 - 8 (90.8%) and have, on average, 15 years of teaching experience. Teachers indicated there were between 6 and 7 graduates in their school district; however, the respondent was typically the only TLP graduate in his/her school building.

Research Question Number 1

To what extent are TLP graduates engaged in training and development activities and to what extent is their level of activity linked to their participation with the TLP?

Survey data indicate that graduates are active in a majority of the identified training and development activities. In most cases, participants perceive that their participation in the training and development activities is strongly linked to their TLP experiences. Respondents most uniformly report they are engaged in the following training and development activities:

- Presenting informal technology training sessions for teachers in their school (94.4 percent participation)
- Engaging in informal peer mentoring activities (92.4 percent participation)
- Developing instructional materials, which are utilized by other teachers — tip sheets, integrative lesson plans, webquests, etc. (82.1 percent participation)
- Presenting formal technology training sessions for teachers in their school (70.3 percent participation)

Each TLP graduate trains, on average, 57 teachers in a typical school year. Courses taught fall into three categories: Microsoft Windows / Office / and other productivity software (49% of all courses taught); Integration / Curriculum topics (38% of whole); and Multimedia topics (13% of whole).

Research Question Number 2

To what extent are TLP graduates engaged in technology leadership activities and to what extent is their level of activity linked to their participation with the TLP?

Each of the technology leadership activities showed some level of participation by TLP graduates. Scores indicate that a majority of respondents are active in two of the listed technology leadership activities. A strong linkage was indicated between participant's involvement with the TLP and their participation in the listed technology leadership activities. Teachers most uniformly reported they were engaged in the following technology leadership activities:

- Led or assisted with development of district technology plan (56.9 percent participation)
Research Question Number 3
To what extent are TLP graduates engaged in personal development activities and to what extent is their level of activity linked to their participation with the TLP?

While there was some level of participation by respondents in all of the listed personal development activities, a majority of respondents did not indicate their participation in any one of these activities. However, participants did indicate a strong linkage between their involvement with the TLP and their participation in the listed personal development activities. Teachers most uniformly reported they were engaged in the following personal development activities:

- Applied to participate in additional (post-TLP) grant funded technology training opportunities (46.2 percent participation)
- Received grant-funded training (other than 1st year TLP participation) (28.7 percent participation)
- Pursued formal schooling at university / community college pertaining to integration of technology into the curriculum (27.1 percent participation)
- Served at professional conference (22.5 percent participation)

Research Question Number 4
To what extent have respondents observed or experienced "other impacts to the TLP graduate or the school district and community" following their completion of the TLP and to what extent do they perceive a link between these "other impacts" and their participation with the TLP?

Survey data indicate that graduates agree that these "other impacts" are occurring in their schools and school districts. In most cases, participants perceive that the "other impacts" are strongly linked to the presence of TLP graduates in the district. A majority of respondents agreed to all six of the "other impact" statements:

- TLP graduates are viewed as role models by building or district administrators due to the graduates' technology infusion skills (95 percent agreement)
- TLP graduates are noticeably more enthusiastic and energized individuals after their TLP experience (94.9 percent agreement)
- TLP graduates are viewed as role models by many teachers in the building due to the graduates' technology infusion skills (94.3 percent agreement)
- TLP graduates are viewed as role models by many parents due to the TLP graduates' technology infusion skills (73.7 percent agreement)
- Parents have become more involved in the classroom and with their student's learning activities because of the TLP graduates' effective use of technology and discovery learning activities (60.3 percent agreement)
- The school or district's scope and sequence has changed due to the impact of TLP participants' technology infused discovery learning activities and TLP-funded technology rich classrooms (58.1 percent agreement)

Summary of Qualitative Data (Principal and Peer Surveys)

Two hundred and seventy one completed principal and peer surveys were returned to the researcher and used in this study. Individual comments, provided by principals and teaching peers appear below. Information in these comments that would identify the graduate or the graduate's school district has been changed to respect the anonymity promised to respondents by the researcher.

Principal & Peer Survey Question Number 1
"Please identify any changes in the individual's involvement with training and development activities that you believe can be attributed to his/her participation in the TLP."

Responses were clustered into the following themes:

TLP graduates have a significant positive impact on the school and community: For example, "The TLP is a wonderful blessing to small, rural schools. This TLP graduate is a visionary and yet practical,
always involved in training in our building, district, and across the state and nation. This TLP graduate is a chief advocate for change and development of our technological resources and skills.

**TLP graduates provide training and other assistance:** For example, "As a result of the TLP, Kate has become a confident technology trainer for teachers in our building and our district. She has provided training sessions in the areas of Microsoft Word, PowerPoint, and Excel. She has demonstrated ways to integrate technology into the curriculum and acted as a Master Teacher and mentor for novice technology users."

**TLP graduates are peer mentors:** For example, "On a personal basis Janelle has been available always, for me to receive training on programs, which are coming on newer computers I'm receiving through the levy funds. She has done staff inservice demonstrations on School Kit, PowerPoint, and Word and hands-on workshops with the computers in her room (middle school staff of 8 teachers). Had she not shown how simple it was to use PowerPoint (for instance) I might not be using it."

**TLP graduates model the principles of the Teacher Leadership Project:** For example, "Sara offered a school-wide inservice for classified and certificated staff, all functioning at various levels of computer competency. She led us through a variety of activities, including those which involved scaffolding techniques to build lesson plans and curricular structures using templates and introduced us to Schoolkit and other invaluable programs. Each of us, with Sara's leadership and guidance, came away with increased understanding and lesson structures individualized to the specific needs of our own classroom."

**TLP graduates have a significant impact on students and student learning:** For example, "Ms. Hall did lots of computer training and development activities with her students. Her 6th grade social studies class did Western Hemisphere MS PowerPoint presentations, while her 7th grade social studies created Eastern Hemisphere PowerPoints, Siberia brochures using MS Publisher, and constructed and read graphs in preparation for the WASL. Her 8th grade social studies did a yearlong research paper written in a magazine format, which used MS Word documents and Internet research. The students also used Word to write reports, which were presented, to the public."

Principal & Peer Survey Question Number 2

"Please identify any changes in the individual's involvement with technology leadership activities that you believe can be attributed to his/her participation in the TLP."

Responses were clustered into the following themes:

**TLP graduates have a leadership role in the school district:** For example, "She has been vocal in decisions being made in the district. Because of this training, the district listens to her ideas. She is our school's technology leader and is also a leader at the district and state level on the use of instructional technology."

**TLP graduates model the principles of the Teacher Leadership Project:** For example, "It was Janet who first raised the idea of an in-district version of TLP. She and two other TLP teachers have taken the lead in planning and instructing at our in-district session."

**TLP graduates have a significant impact on students and student learning:** For example, "Sara has almost single-handedly developed a core of students whom she has trained as "tech kids," literate in a variety of computer skills and competencies and able to troubleshoot problems and difficulties which might arise in the computer lab or in the computers in our classrooms. These students have a helpful and problem-solving approach and a sense of pride in what they do. This program is a direct result of Sara's instruction. In addition, Sara works collaboratively with our computer lab instructor and the other TLP participant in our school, in developing a scope and sequence and Essential Learnings in Technology, both in terms of committee work at the district level and site decisions at our school."

Principal & Peer Survey Question Number 3

"Please identify any changes in the individual's personal or professional development activities that you believe can be attributed to his/her participation in the TLP."

Responses were clustered into the following themes:

**Many TLP graduates pursue additional training due to their TLP experience:** For example, "With the leadership role she has evolved into, she is now convinced that she should complete her Masters Degree with a major in administration. She will make an excellent principal!!"

**The TLP energizes many of its graduates to continuously renew their skills:** For example, "Mr. Flynn continues to grow through reading and participation. His teaching practices will be even better next year than they were this year—high praise for a state finalist for Teacher of the Year. I'm sorry if I sound like his mom, but this guy is unbelievable!"
TLP graduates model the principles of the Teacher Leadership Project: For example, "I believe as a professional educator, Jim promotes technology through leading by example. His professional involvement in school district activities has shown others that technology can and does work well with our existing curriculum that is required to be taught."

TLP graduates have a significant impact on students and student learning: For example, "Claudia intentionally looks for appropriate use of technology as she crafts her lessons and units. She leads a Science Team and has incorporated robotics into her program. She was anxious about the PCs her first year but has grown by leaps and bounds over the next 2 years. It takes time to develop skills in using tech—and Claudia keeps growing!"

Principal & Peer Survey Question Number 4
"Please identify any impacts to the school district that you believe can be attributed – either wholly or partially – to the influence of TLP graduates in the district."

Responses were clustered into the following themes:

- **TLP graduates have a significant positive impact on the school and community:** For example, "It is hard to say where we'd have been without it. However, I do know we have entered an exciting world, and a great deal of that is due to Rachel. Thank you so much for the opportunity."

- **TLP graduates model the principles of the Teacher Leadership Project:** For example, "We have had others teachers apply for the TLP. Teachers at our school, along with teachers from other Catholic schools in our city took the course offered this past year on technology integration in math and science. Her expertise is recognized in the classroom and as part of the technology committee. Debbie has been a very positive influence for technology."

- **TLP graduates have a significant impact on students and student learning:** For example, "WOW! For the kids it has been a HUGE impact. They are creating projects, researching, and gaining computer skills that enhance their learning. As each school has sent people to TLP, parent groups and other staff members have seen the benefits of TLP and are seeking out training in their buildings. This is a GREAT program!"

- **Parental and Community impressions of the school district is enhanced due to TLP graduates:** For example, "Many parents have expressed a concern about the minimal use of technology in our district. Because of the teachers who have participate in this project, the administration has seen a HUGE number of teacher request from parents who wish their children to be in one of the “classrooms with all the computers in them” as a result, the district is increasing budgets to provide more computers and software for all the buildings – something we have had little support for in the past."

**Summary**

Both quantitative data, collected from TLP graduates, and qualitative data, collected from their principals and teaching peers, indicate that TLP graduates are having a dramatic positive impact on their teaching peers, their schools and school districts, students, parents, and other members of the community. The impact is significant as shown via this study.

Graduates are engaged in a variety of activities in the areas of training and development and technology leadership. They continue to enhance their professional credentials via schooling and other professional development activities. Administrators, teachers, and parents perceive TLP grads to be technology leaders. Graduates are more enthusiastic in their teaching following their involvement with the TLP. Participants contribute greatly to the technology integration efforts in their schools and school districts.

Respondees have stated that TLP participation has, in fact, been a life-changing experience. The Bill & Melinda Gates Foundation, and the teacher-founders of the TLP, can be assured that the impact of the TLP is being felt in many ways beyond participants' initial involvement with the program.

Schools, universities, and other organizations across the country who wish to implement a technology-infusion program that produces demonstrable and measurable long-term impact on teacher participants, students, schools and school districts should consider the example of the highly successful Teacher Leadership Project in Washington State.

For Additional Information: The full Teacher Leadership Project – Impact Study (Spring, 2001) and other technology infusion evaluation reports can be found at: http://www.gatesfoundation.org/education/evaluation/default.htm
Simulating and Evaluating the Yekioyd Methodology

JoAnna Dickey, Dept. of Curriculum and Instruction, Eastern Kentucky University, USA, joanna.dickey@eku.edu

Steven Dickey, Dept. of Economics, Eastern Kentucky University, USA, steve.dickey@eku.edu

Kevin Zachary, TRIS Unit, Eastern Kentucky University, USA, kevin.zachary@eku.edu

Abstract:

The Yekioyd family of statistics provides a method of evaluating the consistency of test items with overall test scores. Their purpose is to aid an educator in developing tests by identifying weak test items. This simulation study at hand provides an analysis of these statistics in a variety of circumstances reflecting the concerns of the educator. We find that the statistics have highly desirable properties under all circumstances.

The relationship between the Yekioyd statistics and the literature on item analysis has been covered elsewhere (Dickey and Zachary, 2001). The only tools of item analysis that are in any way related to the Yekioyd statistics are the homogeneity indices proposed by Long (1934) and Loevinger (1948). The statistics analyzed in this paper are the product of taking the alternate direction to the Long/Loevinger approach. Assume that the information set consists of a binary for the test item for each student and overall student scores. The Long/Loevinger approach orders the data by the binary and counts contradictions occurring in the corresponding sets of scores. The Yekioyd statistics order the data by overall scores and count contradictions in the order taken by the binary. Given the current state of development of the homogeneity statistic, the Yekioyd statistic offers advantages. It features an exact interpretation because of its mathematical formulation. In our previous paper, we demonstrated that Yekioyd procedure is readily subjected to natural weighting schemes that increase its functional value to the educator. These weighted statistics are the upper Yekioyd, YU and the lower Yekioyd, YL. The basic Yekioyd statistic, YB, is unweighted.

n is the number of test questions, p is the proportion of students answering correctly, and q is the proportion of students answering incorrectly. The weighting scheme built into these statistics is based on ordering student responses to a test item by their overall scores in column style with scores declining as one moves down the column. A division line (boundary or B value) is created between the upper np students and the lower nq students. For each range, the deviation variable D is constructed. Its value is one for all upper range students who answered incorrectly and all lower range students that answered correctly. Otherwise, its value is zero. For each student, a value of the weighting variable W is constructed from the student's score and B. In the upper range, B is subtracted from the student's score. In the lower range, the student's score is subtracted from B. W is not a weight in its own right. The actual weight given to a deviation occurring with a particular student is the W value associated with that student divided by the base for the weighting. In each range, the base for weighting will be the summation of W values in that range.

The resulting construction is a weighted statistic that reflects the greater undesirability of deviations that occur far above or far below the line of division between the upper and lower ranges. Such weights should reflect the distance from the line of division to the number line location at which the deviation occurred. This division point will be calculated by the average of the scores of the two students on the boundary of the np/nq division. This average serves as the boundary value, B.

In order to achieve comparability across questions with varying p values, both statistics will be scaled by a factor reflecting the number of locations for deviations divided by the number of possible deviations. The maximum number of possible deviations in each of both ranges is the smaller of np and nq.

Our notation will represent this smaller one of the two values with (np:nq).
Let \( i \) be the index of the rank order of student scores, with 1 assigned to the highest student score and \( n \) assigned to the lowest student score. The basic Yekioyd and the weighted statistics are:

\[
Y_{B} = \frac{\sum_{i=1}^{n} E \, D_i}{n} \quad \text{the smaller of } 2n_p \text{ or } 2n_q
\]

\[
Y_{U} = \frac{\sum_{i=1}^{n_p} E \, W_i(D_i)}{n_p} \times (n_p \div n_q)
\]

\[
Y_{L} = \frac{\sum_{i=n_p+1}^{n} E \, W_i(D_i)}{n_q} \times (n_p \div n_q)
\]

Interpretation of these statistics is based on the following table. The table applies the assumption that \( n_q < n_p \). Otherwise, \( n_p \) would appear instead of \( n_q \), with no change in implications.

<table>
<thead>
<tr>
<th>Yekioyd Value</th>
<th>Deviations Not Occurring</th>
<th>Deviations Occurring</th>
<th>Net Contribution To Consistency</th>
</tr>
</thead>
<tbody>
<tr>

<td>2n_q</td>
<td>0</td>
<td>2n_q</td>
</tr>
</tbody>
</table>

The weighting in \( Y_U \) and \( Y_L \) precludes a simple analysis of their properties. For this reason, simulations were performed to display their properties. Two conditions were imposed on the simulations to achieve neutral comparability. These conditions are that \( Y_B \) is constant across the questions and that the locations of deviations in the rank order of student performances be comparable across questions. The simulations will have 20 student scores ranging from 98% to 60% in increments of 2% in consecutive numbers. This distribution of grades makes it possible to perform exact interpolation in several instances. There will be 9 questions labeled Q1 through Q9 with \( p \) values ranging from .9 to .1 in increments of .1.

In order to be evaluated on mathematically comparable locations of deviations, case definitions will be framed in terms of given \( Y_B \) values. The \( Y_B \) values of .25, .50, and 1.0 are interpreted in the case definitions as 1/4th of a range, 1/2 of a range, and the whole of a range. The concept of centering used here means that the deviations are clustered about the middle of the range segment with equal numbers of deviations equally spaced on either side. The case definitions are:

**High Concern Case:** When all deviations are centered in the upper \( Y_B \) portion of the \( Y_U \) range or centered in the lower \( Y_B \) portion of the \( Y_L \) range.

**Low Concern Case:** When all deviations are centered in the lower \( Y_B \) portion of the \( Y_U \) range or centered in the upper \( Y_B \) portion of the \( Y_L \) range.
Intermediate Case: When each range contains its deviations centered around the middle of the range by rank order.

Three sets of simulations were performed on the nine questions. These corresponded to YB values of .25 for set one, .50 for set two, and 1.0 for set three. With the case definitions provided earlier, all questions examined exhibited identical YU and YL statistics. These statistics are shown below.
The weighting scheme is intended to cause a decrease in sensitivity to deviations near the boundary and an increase in sensitivity to deviations far from the boundary. The results of the simulations confirmed the characteristics just noted. For any value of $YB < 1$, $YU$ and $YL$ will be above $YB$ in the high concern case and below $YB$ in the low concern case. In the intermediate case, the weighting is neutral in its effect, producing values for $YU$ and $YL$ that are equal to $YB$. In sets 1 and 2, the effect of the weighting between high concern and low concern cases appeared to be symmetric, e.g. $(.438+.063)/2=.25$ and $(.750+.250)/2=.50$. When $YB = 1$, $YU$ and $YL$ were forced to 1 either because all locations in a range had deviations or because the centering as set forth in the case definitions induced the same result via the mean of the weights at the centered location.

The operating principle in the preceding simulations was that the educator’s concern with a deviation is indicated by its distance from the boundary measured by overall scores. If this view is accepted, then the cases are comparable on the basis of the educator’s concern as well as mathematically comparable. In the measurement of $YU$, the high (low) concern case is a worst (best) case scenario if $p < .5$, but not if $p > .5$. This means that when a question has a $p > .5$, a condition can occur that is worse or better than is possible for questions where $p < .5$. In the measurement of $YL$, the parallel is when $p < .5$. In terms of the educator’s concern, questions with different $p$ values have different potentialities. $YU$ and $YL$ can reflect the extent of these differences. In order to explore this question, the simulations were repeated with case definitions that were not comparable situations across questions with different $p$ values. These case definitions were:

Worst Case: When each range contains its deviations located as far from the boundary as possible.

Best Case: When each range contains its deviations located as close to the boundary as possible.

Set One: $YB = .25$ (i.e. 25% of all possible deviations occur) Questions 1, 3, 5, 7, and 9 are intractable because 25% of $np$ and $nq$ are not integers and deviations must occur in whole units.

Worst Case:

</tbody>
</table>
Best Case:    

YU   .028 .063 .107 .167 .250 .250 .250 .250 .250
YL   .250 .250 .250 .250 .167 .107 .063 .028

Set Three: $Y_B = 1.0$ (i.e. 100% of all possible deviations occur)

Worst Case:    

YU   1.89 1.75 1.57 1.33 1.00 1.00 1.00 1.00 1.00
YL   1.00 1.00 1.00 1.00 1.00 1.00 1.00 1.00

Best Case:    

YU   .111 .250 .429 .667 1.00 1.00 1.00 1.00
YL   1.00 1.00 1.00 1.00 .667 .429 .250 .111

As $Y_B$ goes to 1.0, the effect of the weighting scheme diminishes to 0 for all situations where a deviation will occur at every location. The $Y_U$ statistic for a high $p$ question and the $Y_L$ statistic for a low $p$ question do not have this limit property. In these situations, the weighting scheme continues to function even at $Y_B = 1.0$. This allows $Y_U$ and $Y_L$ to provide an indication as to the severity of differences in questions. When $Y_B$ is .25, the difference in high $p$ questions and a question with a $p$ value of .5 was very small with observed differences ranging from negligible to as much as .046. As $Y_B$ increased to 5, the observed differences rose to as much as .222. When $Y_B$ reached its limit at 1.0, a difference of as much as .89 was observed. This means that the worst (best) case for a question with a $p$ value of .9 can be 89% worse (better) than the worst (best) case for a question with a $p$ value of .5.

Overall, we are left with the perspective that high or low $p$ questions do little good for or harm to a test's consistency in terms of the number of deviations occurring or not occurring. None the less, such questions can do either considerably more harm or considerably less harm per occurrence of a deviation than questions with $p$ values near .5 if $Y_B$ is high. $Y_U$ and $Y_L$ indicate whichever the situation is and provide a useful measure of its extent.

Effects of Training in an Interactive Television Environment

Rita L. Dobbs
Department of Technology
The University of Texas at Tyler
United States
rdobbs@mail.uttyl.edu

Abstract: The purpose of this study was to determine if formal distance education classroom training or classroom training combined with laboratory experiences would affect the concerns of college faculty and administrators about the implementation of interactive television (ITV) in their institution. Twenty-seven faculty and administrators employed full-time in the fall semester at Texas State Technical College-Marshall participated in the study. The instrument used to collect the data was the Stages of Concern Questionnaire (SoCQ). The quasi-experimental study utilized a pretest posttest control group design utilizing three groups with Analysis of Covariance (ANCOVA) used to analyze the data. The results of this study indicated that classroom training and laboratory experiences were effective in assisting college faculty and administrators in progressing more rapidly through the stages of concern when confronted with teaching in an ITV classroom.

Introduction

In 1997-1998, 54% of the public two-year and four-year higher education institutions in the United States offered courses via two-way interactive television (ITV). At that time, 61% of the respondents indicated that distance education delivery utilizing two-way interactive video would start or be increased by their institution within the next three years (National Center for Education Statistics [NCES], 1999). However, only about a quarter of higher education institutions offering distance education courses required faculty to have training in distance education instructional methodologies (NCES, 1999). The implementation of two-way interactive video classes can be an expensive venture for an institution, yet the research indicates that training does not seem to factor into the process.

ITV instruction presents a change in teaching methodologies for traditional face-to-face teachers. In their groundbreaking work on change, Hord, Rutherford, Huling-Austin, and Hall (1998) wrote, "the single most important factor in any change process is the people who will be most affected by the change" (p. 29). Even though the technology and the institution are important to the successful implementation of a distance education program, the faculty, staff, and administrators utilizing the system are the most important factors in successful implementation (Hord, Rutherford, Huling-Austin, & Hall, 1998). Moore and Kearsley (1996) suggested that success of a distance education program in an institution is dependent upon the internal commitment by the teachers and others within the organization. However, training for faculty utilizing ITV systems is seldom offered.

As institutions begin to utilize distance education technologies, it is important that instructors have the advantage of training in the new instructional approaches. Implementing a successful distance education program, in this case, ITV, for the institution is critical to the sustainability and expansion of the college. Because change is a process, administrators and faculty must embrace the new innovation for a successful and profitable distance education telecommunications program (Hord, Rutherford, Huling-Austin, & Hall, 1998). Personnel must be given the necessary training to alleviate their stages of concerns about the new innovation, ITV, so that the change process can be accomplished and successful implementation of the innovation can occur. These premises provided the bases for this investigation.

The Study

This research was conducted at Texas State Technical College-Marshall (TSTC-M), which is located in Marshall, Texas, a rural East Texas town of approximately 25,000 people. The college is part of the TSTC system, the only state-supported technical college system in Texas and new to the use of ITV for instructional purposes. Twenty-seven full-time faculty and administrators of the college volunteered to participate in the study. The participants were divided into three groups with the first group receiving classroom instruction and hands-on activities in ITV.
methodologies. The second group received classroom instruction only. The third group served as the control group for the study and did not receive any training.

Each participant in all three groups received the 35-item Stages of Concern Questionnaire (SoCQ) on the first day of the scheduled classroom training. The control group attended the first fifteen minutes of the first scheduled classroom training to complete the survey. Once their survey questionnaire was returned, the control group members were dismissed from the classroom training session. Respondents indicated on a Likert scale the degree to which each concern was true and circled a number from 0 to 7 on the printed scale. Respondents were given as much time as necessary to complete the survey before actual classroom training began. Each series of the questionnaire consisted of items that are important at a certain stage of concern, according to the Hall, George and Rutherford (1986) concerns theory. Each of the seven stages of concern was represented by five questions on the survey. A scale score was obtained for the peak score and for each of the stages of concerns on the questionnaire.

After the SoCQ was completed, the researcher presented nine hours of classroom instruction in distance education methodologies to the 18 participants in groups two and three. Each group met one day every second week for three hours of instruction. Classroom training consisted of three, three-hour sessions over six weeks of instruction. Participants took part in discussion and hands-on activities that familiarized them with the technology and the necessary skills for teaching in an ITV classroom. At the conclusion of the last classroom session, the participants who elected to end their training with the classroom portion were administered the SoCQ as a posttest. The classroom and laboratory group was comprised of the faculty and administrators who wished to receive college credit for their participation in the classroom sessions. In order to receive credit, this group participated in 18 hours of individual, hands-on practice in the distance-learning classroom in addition to the classroom instruction. Logs were maintained by the participants and kept in the ITV classroom. Logs were reviewed by the researcher and by the Dean of Instruction for TSTC-M to ensure that each participant completed the required 18 hours of practice. Participants presented a 15-minute lesson in the ITV classroom to a remote site as part of their course requirements for credit at the conclusion of the training and hands-on experiences. Upon completion of the presentations, the SoCQ was administered to the classroom and laboratory group and to the control group.

Findings

When using the SoCQ, Hall, George and Rutherford (1986) recommended two methods of dealing with group data. The first method tallies the number of individuals that score high on each stage to obtain the range of peak stage scores within a group. Peak scores are related to the stage definitions in the questionnaire. The authors noted that “the higher the score, the more intense the concerns at that stage. The lower the score, the less intense the concerns at that stage (p. 31). The second method, and the method utilized in this study, is to "aggregate individual data by developing a profile that presents the mean scores for each stage of the individuals in the group" (p. 32). The aggregate score was derived from the sum of the responses given to the five questions addressing each stage of concern. The total stage raw scores for each of the participants in each group were used in the ANCOVA test to determine differences among the groups. The results of the study are presented in Table 1.

The initial pretest score on the Stages of Concern Questionnaire was used as the covariate in this study. Analysis of covariance (ANCOVA) was used to adjust for initial differences between groups before a comparison of the within and between groups was made. Gall, Borg and Gall (1996) suggested “the preferred statistical method is analysis of covariance in which the posttest mean of the experimental group is compared with the posttest mean of the control group with the pretest scores used as a covariate” (p. 496). Independent t tests of least squares means, Tukey, were conducted on the comparison results of the groups to determine which differences between and among groups were significant.

Results of the data analysis for the experimental populations in this study indicated that significant differences favoring the experimental strategy for the classroom combined with laboratory experiences group occurred in four of the seven stages of concern at the p < .01 level of confidence.

Concerns research shows that concerns change over time in a developmental manner. Because this is true, professional development for faculty and administrators should address the stages of concern in a progressive manner if the innovation is to be effective. The sum of the responses to the five questions addressing the seven stages of concern should show the progressive development of an individual or group moving from a high awareness or self concern to the refocusing concern that indicates acceptance and willingness to implement an innovation (Hall & Hord, 1987).

When evaluating the classroom and laboratory group in this study, the analysis of the data indicated that this group had shifted its focus away from concerns primarily about self and had begun to evaluate the management, consequence, collaboration, and refocusing stages that are essential for the new innovation, distance education, to be successful at TSTCM.
High concerns in stage 3 for the classroom and laboratory group indicated that this group was concerned about logistics, time and management concerns. The highest adjusted mean score for the classroom and laboratory group occurred in stage 4. This indicated that the group had concerns about the effects of distance learning on students. Their next highest adjusted mean score was in the adjacent stage 5, collaboration. This indicated that the group had concerns about the collaborative efforts of distance learning. The high score on the refocusing stage, with a low score in the awareness stage, indicated that the individuals who had participated in classroom and laboratory experiences were concerned about its effects on students. They were also concerned with collaboration efforts to make distance education more effective for students involved in the process.

The analysis of the data of the classroom group in this study showed a significant difference at the p < .01 level of confidence in two stages of concern. The highest adjusted mean score for the classroom group was in stage 5, collaboration. A significant difference between the classroom and the classroom and laboratory groups appeared at this stage. A significant difference between these two groups also occurred in the consequence stage. These differences indicated that classroom training was beneficial to both groups but the actual laboratory experiences helped the faculty and administrators feel more comfortable about distance education. The classroom group also showed a significant difference from the classroom and laboratory group in the impact dimension. This shows that the classroom training made the group more aware of distance education but faculty and administrators need the additional laboratory experiences before beginning instruction in the distance learning classroom.

The control group profiles in this study align with that of the nonuser in the stages of concern. The concerns of nonusers are typically the highest on stages 0, 1, and 2, and typically lowest on stages 4, 5, and 6. The highest adjusted mean score for the control group occurred in stage 1. This indicates that the group was more concerned with personal position and well being in relation to the change. With the second highest adjusted mean score falling in stage 5, the results of the ANCOVA suggested that the control group was also highly concerned with working with others. The “tailing-off” stage 6 indicates that the group did not have ideas that compete with the distance education innovation. The responses for the control group followed the typical pattern of a nonuser of distance education. This group appeared to have little interest in distance education.

The classroom and laboratory group progressed steadily through the Stages of Concern with the aid of training and laboratory experiences. The classroom group made some developmental moves but adjusted means were not significant. The graphic view of the control group results resembled the profile of the typical nonuser described by Hall, George, and Rutherford (1986).

The results of this study should not be generalized to extend to other institutional groups without comparative data. The findings must also be viewed with limitations specified by the experimental design, the participating faculty and administrators, the researcher, the questionnaire, and the statistical analysis.

Conclusions and Recommendations

Based on the findings of this study and recognizing the limitations stated in the previous section, the following conclusions were drawn:

1. The classroom training combined with laboratory experiences strategy was more effective than classroom instruction only or no treatment for addressing concerns of college faculty about the innovation of distance education.
2. The classroom training combined with laboratory experiences strategy was more effective than classroom instruction only or no treatment to prepare faculty and administrators for teaching in a distance education classroom.
3. The classroom training combined with laboratory experiences strategy was more effective than classroom instruction only or no treatment to help faculty and administrators move from the early stages of concern, awareness, informational, personal, to the task and impact stages of concern of management, consequence, collaboration, and refocusing.
4. The SoCQ was an effective instrument for evaluating faculty and administrator concerns about the innovation of distance education.
5. Classroom and classroom combined with laboratory experiences are important to the successful implementation of distance education platforms.
6. Faculty and administrators will be more willing to accept and institutionalize the new innovation of teaching in a distance-learning environment as a result of classroom instruction and classroom instruction combined with laboratory experiences.
7. Professional development in distance education methodologies should be offered to faculty and administrators to address their concerns, about the new innovation and to
increase institutionalization of the innovation.

8. The results of this study corroborate the evidence found in the review of the literature that classroom training combined with laboratory experiences should be provided to all users of telecommunications systems.

9. Training in distance education methodologies is a critical component for successful institutionalization of an innovation.

Determining if classroom training and classroom experiences aid in the smooth acquisition of the innovation of interactive television classes provides pertinent and useful data on how higher education administrators and faculty embrace and adapt to change as measured by the SoCQ. This study was conducted under the assumption that personnel implementing distance education programs desire a smooth and successful acquisition of the innovation.

New Teachers and Technology: Positive Factors

Judith Duffield, University of Colorado at Denver, US
Myka Raymond, Englewood Public Schools, US

Each of us involved in encouraging technology for learning can list factors that inhibit the use of technology in schools. The lack of skills, confidence and tools are the usual suspects. When all these are present, many teachers still choose not to use technology. This study looks at five first year teachers who are using technology in order to determine the factors that encouraged them to be active technology users.

The subjects were selected from a pool of recently licensed teachers from eleven teacher education programs who are members of a PT3 consortium in a western state. Each program nominated teachers who were believed to be using technology in their first teaching position. Those nominated were selected based on their self-described use of technology, location in the state, grade level taught, and the students they served. The five subjects selected all are high technology users and represent the range of grade levels, locations, and settings.

The subjects will be observed twice, once in the fall and once in the winter. During these observations, the teachers, their colleagues, and their supervisors will be interviewed. The data will be analyzed to determine which factors lead to the teachers using technology in their first year. The ISTE/NETS list of Essential Conditions will serve as a starting point. We will also consider factors from the literature on the adoption of innovations and compare the strategies used to teach these teachers about technology.

Data collection will be completed before the SITE Conference. The purpose of this short paper will be to share our preliminary findings and receive feedback from the session participants.
An Analysis of the Influence of Gender, Grade Level, and Teachers on the Selection of Mathematics software by Intermediate Students

Donna Ferguson, Ph.D.
Department of Educational Technology
University of Northern Colorado
United States
dferguson@coe.unco.edu

Abstract: The purpose of this study was to investigate the relationships between gender, grade level, teachers, and the selection and use of mathematics software as measured by the type of mathematics software chosen, time-on-task, and reasons given for selection. Research data were collected from 202 third, fourth, and fifth grade students in a single elementary school located in northeastern Colorado.

This study investigated gender preferences of intermediate level elementary students. The overarching research question was: What relationship is there between gender, grade level, teachers, and the selection and use of mathematics software as measured by the type of mathematics software chosen, and time-on-task?

Results from this study add to the gender bias knowledge base and provide suggestions for software developers for improving movement toward gender equity in software design. The future for women in the field of technology is tenuous at best (Harrell, 1998). The obstacles females face eventually translate into highly paid men dominating the engineering and computer science arenas while women are relegated to data entry and word processing (Hakansson, 1990; Henwood, 1993). This study gave insight into factors that may influence this trend during the age range where females begin to lose their interest in computing, between third and fifth grade (Harrell, 1998; Hopkins, McGillicuddy-DeLisi, & DeLisi, 1997).

Research Design
The study population was 235 elementary students at the intermediate level from a school district in northern Colorado. One piece of mathematical software was chosen from each of four categories: drill and practice, instructional game, simulation, and tutorial. Students were taught how to use each of the four pieces of mathematics software and then asked to choose their favorite during a free selection time. They recorded both their time on task and the title of the software they chose.

Discussion
The analyses of this study revealed few significant differences for gender and grade level selection of software. However, the individual teacher was found to play a significant role in student choices. These analyses both confirm and dispute prior research on software selection which noted girls prefer drill and practice software, while boys prefer gaming software. The results for time-on-task by gender, grade level and teachers all showed significant differences which also disputes earlier findings.

Software selection by gender, grade level, and teacher variables was a primary focus of this study. Students in this study chose the drill and practice/tutorial mathematics software less often than either the instructional game or simulation mathematics software. The instructional game and simulation mathematics software were both more interactive than the drill and practice/tutorial software and allowed the students to select from a variety of activities within the software. It is possible students in today's classrooms have reached a level of sophistication where traditional software no longer satisfies their needs or expectations.

Girls (n = 15) were significantly more likely to use drill and practice/tutorial software than boys (n = 6). Studies conducted by Huff & Cooper (1987), Laurel (1998), Malone & Lepper (1980), and Sanders (1995) all found boys are more likely to prefer gaming software than girls. Results from the statistical analysis of this study dispute these former results, as the proportion of girls (n = 40) and boys (n = 43) who chose instructional game software was not significantly different. Differing results, however, could be due to the fact the software in this study was an instructional game as opposed to a recreational game or perhaps because these students had been taught to use the software during the study. The simulation software used in this study was composed of two distinct sections. The first section asked students to work in stores to solve problems and earn money. Previous studies (Malone & Lepper, 1980; Laurel, 1998) have indicated
girls prefer working with problem solving software. The second section of the simulation software allowed students to spend the money they had earned in the shops, playing arcade games. The proportion of girls (n = 45) and boys (n = 53) who chose simulation software was not significantly different. There is a void in the literature concerning student selection of simulation software. It is possible, however, the two very different sections in the simulation software (gaming and task-oriented skills) counterbalanced each other. Had the simulation software not included both sections, results may have differed.

Statistical analyses from this study indicate grade level had no effect on students' selection of mathematics software. The proportion of third, fourth, and fifth grade students who chose a particular type of software differed only by classroom teacher.

Apple Classrooms of Tomorrow (ACOT) research (Sandholtz, Ringstaff & Dwyer, 1994b), as well as work completed by Lohr, Ross and Morrison (1995) indicate the type of instructional delivery in a classroom affects the way students interact with their own learning process. Perhaps the software students selected as their favorite was a reflection of the instructional approaches used by their teacher. Statistical analysis from this study indicates a significant difference between teachers and the type of mathematics software their students selected as their favorite.

This study clearly demonstrated a difference between the time girls and boys spent working with their favorite type of software, with boys consistently spending more time-on-task regardless of software choice than girls did. These results seem to contradict previous findings (Martin, 1991; Murphy & Gipps, 1996) noting boys were more comfortable with computers because they generally had greater access to them at home (Gressard & Loyd, 1987; Mandell & Mandell, 1989; Moe, 1984). All but one student in this study reported having a computer at home and more students reported the primary user of that computer as female rather than male. Although computer use in the home may be a predictor of attitude (Aman, 1992), it does not appear to be a predictor of software selection or time-on-task.

There were significant differences in time-on-task by grade with fourth and fifth grade students consistently spending more time-on-task than third graders. These results are most likely an indication of student maturity level or perhaps a reflection of instructional methods used in their classroom.

While this study did not show significant differences for software selection by gender or grade level, it did show a difference by individual teacher. Further research into the factors underlying these differences is recommended. What methods are these teachers employing in their classrooms that may affect the choices students make when working with software?

**Conclusion**

Although data from this study indicate no gender significance for software selection, it did illustrate the impact teachers can have on students' time-on-task and software choices. It is important for teachers to be good consumers and evaluators of software like their students. Many teachers have not experienced the technology rich background their students now inhabit. Teachers need instruction on how to seamlessly integrate technology into their classrooms, thoughtfully evaluate software, and be willing to share the responsibility of teaching and learning with their students.

Abstract: For too long now, we have been attacking the digital divide with a "Field of Dreams" mentality; if we build it they will come. We have tossed money at the divide under the auspice that it will magically disappear if we sprinkle it with the pixie dust of corporate funds and government resources. This paper examines the assumption that the digital divide is not merely about computers, modems, and hardware. Instead the researcher asserts that the key to solving the digital divide is inside the individual users. The paper is the result of qualitative and quantitative research conducted in and around Tuscaloosa, Alabama. The qualitative methodology included interviews, classroom observations, and surveys of African American and European American students in two post-secondary institutions, and a series of technology workshops for middle and high school aged students. This paper is composed of the literature review, as well as the primary theoretical framework behind the research.

Digital Divide

Hoffman and Novak (2000) in their paper, "Bridging the Digital Divide," concluded that European Americans were significantly more likely than African Americans to have a home computer in their households (44.2% vs. 29.0%). European Americans were also more likely to have access to a personal computer at work (38.5% vs. 33.8%), although this difference was not statistically significant (p=.087). In terms of Internet access, European Americans were more likely to have ever used the Web (26% vs. 22%), and the gap between European Americans and African Americans became proportionally larger the more recently the respondents indicated they had last used the Web. Further investigation revealed that 12.9% of European Americans vs. only 5.8% of African Americans used the Web 1 week before their survey response date. According to Hoffman and Novak, this roughly translates into 5.2 million (+/- 1.2 million) African Americans and 40.8 million European Americans (+/- 2.1 million) who have ever used the Web, and 1.4 million (+/- .5 million) African Americans and 20.3 million (+/- 1.6 million) European Americans who used the Web in the past week. European Americans and African Americans also differed in terms of where they have ever used the Web. Most notably, European Americans were significantly more likely (14.7% vs. 9%) to have ever used the Web at home. African Americans were more likely to have ever used the Web at school, and European Americans were more likely to have ever used the Web at work and at other locations (such as friends' houses, libraries, etc.), but these differences were not statistically significant (Hoffman & Novak, 2000).

The Divide is Getting Wider

Over the course of the last 10 years, researchers have offered numerous and varied solutions to crossing the digital divide. Voelker (2001) reported that the World Health Organization has joined with a number of public and private partners to improve access to high-quality scientific information for research centers. They are upgrading connections and adding new equipment, and the divide is still widening. The American Library Association (Kranich, 2001) noted that libraries offer not only access to computers and networks, but also the content, training, and expertise crucial to ensure widespread participation in our information society. The ALA has identified equity as a priority action area for the next 5 years and has attempted to articulate how local libraries can ensure equity in the digital age. Yet, the divide continues to grow. Roach (2000b) cited the conventional approach by non-profit groups and corporations to digital divide initiatives which is to provide computers, Internet access and technology training to people in disadvantaged communities, an approach that has been generally unsuccessful in bridging the divide. Despite all of these warnings, and all of the programs designed to address the digital divide, it is still present. More importantly, headlines tell of a widening gap between upper- and lower-income groups and between single-parent and two-parent families. Falling through the Net: New Data on the Digital Divide, a report released in 1998 by the Commerce Department's National Telecommunications and Information Administration (NTIA), noted that although access to communications technology is "soaring," the "digital divide ... is actually widening over time" and has "turned into a "racial ravine."
There is something seriously wrong with the ways we presently address the digital divide, beyond the fact that they are blatantly ineffective. Perhaps Ramon Harris, executive director of the Executive Leadership Foundation's Technology Transfer Project, was right when he suggested that the digital divide is not about the technology (Roach, 2000). It is possible that Harris was very close to the right answer when he suggested that the digital divide is about access to information as well as placing value on that information.

Social Perceptions of Computers and Computer Users

The truth about technology, at least as far as computers are concerned, is that regardless of how useful they are, their users are consistently viewed in an undesirable light. Computer savvy people are often perceived as, and referred to as "nerds" or "geeks." It happens on the playgrounds, in private conversations, and even among researchers. Coolidge (1998) entitled his article, which investigated high technology companies in the United States looking to teenagers to fill jobs testing software, designing Web sites, and writing computer programs, "Teen geeks ride to tech rescue." Fotheringham's (1999) article on the year 2000 date conversion problem for computers and why the first computer programmers were directly responsible for the magnitude of the problem, was entitled, "Behold the Y2K bug--Revenge of the Nerds and Geeks." Monroy (2000) referred to women who were becoming competent in information technology jobs as "girl geeks." A group of volunteers that taught Java and Unix programming languages in Ghana referred to itself as Geekcorps (Dewan, 2000). Morse (2000) noted that one of the nation's premier computer repair companies is Geeks2Go. Cohen's (2000) article in the New York Times, discussing the Internet as a tool people can use for revenge on another person, referred to such an action as "Revenge among the Nerds." Whitmore (2000) reported that the gatherings of Internet and Information, an association of Internet business pioneers were nothing more than "a gathering of geeks." There is a defined and definite social perception of computer users. Bill Gates, with his small body frame and large glasses, is the personification of this image. Lohr (2000) even went so far as to suggest that this image problem is the reason for the shortage of computer programmers in the United States.

Research has suggested that negative attitudes and unfavorable perceptions of computers may adversely affect computer literacy (Marcoulides, 1988). Similarly, limited computer experiences were related to computer anxiety and lack of confidence in computer use (Huang, Waxman, & Padron, 1995). This information should be viewed in light of Marriott's and Brant's (1995) assertion that the way cyberspace is marketed to America contributes to negative perceptions by many minority students. They cited the fact that 'surfing the Net' is a foreign language made up of foreign ideas. Most African Americans do not surf. Watson (1996) noted that the "Big Brother is watching you" belief that some African Americans have toward technology also contributed to the negative perception of technology held by many African Americans. Marriott and Brant (1995) agreed with the idea that paranoia plays an important part in the equation. They asserted that computers evoke a deep-seated fear, perhaps even paranoia, among African Americans youth. It is possibly something about the machine's ability to be in every component of your life that scares them (Marriott & Brant, 1995). Many African Americans have said they do not want computers in their homes because they worry those faceless functionaries might use them to spy (Marriott, & Brant, 1995). Finally, Marriott and Brant (1995) contended that young African Americans are the hardest to sell on technology. To them, computers and computer people are the epitome of White nerdiness. Technology is "too much Bill Gates and not enough... Bill Bellamy" (p. 62).

Impact of Social Perceptions

Self-concept

The notion of the self-concept extending both backward and forward through time appears in the literature in diverse forms. James (1890) used the term "potential social Me" and distinguished it from the "immediate present Me" and the "Me of the past." Freud (1925) wrote about the "ego ideal," which referred to the child's conception of what the parents consider morally good. For Horney (1950), neurosis occurred when the idealized self became the focus of the individual's thoughts, feelings, and actions. The concept of the "ideal self," the individual's view of "how I should be," was important in the work of Rogers (1951) who claimed that the individual's self-regard depended on the discrepancy between the actual self and the ideal self. The notion of potential selves also intrigued Gergen (1967). He has argued that their range and complexity have been ignored in the focus on the "central tendencies" of the self (p. 64). Similarly, Gordon (1968) analyzed the retrospective, current, and prospective elements of the self, and Schutz (1964) discussed tenses of self, noting the difference between the Present Tense (acts in progress) and the Future Present Tense, which includes anticipated or imagined acts.
More recently, Levinson (1978) has described "the Dream" and has been concerned with the imagined possibilities of the self as motivating forces. The Dream is a personal construction that contains the "imagined self" associated with a variety of goals, aspirations, and values, both conscious and unconscious. With maturation, the Dream becomes cognitively refined and more motivationally powerful. Levinson, however, has focused on dreams; he has not analyzed nightmares or negative possibilities. Similarly, Cummings (1979) wrote of a personally salient "lost dream or hope" that, when reinstated, can serve as a powerful therapeutic procedure to overcome problems such as addiction, negativism, and lack of caring.

Recent reviews of the empirical literature on the self-concept from both the psychological and sociological perspective (e.g., Epstein, 1984; Gecas, 1982; Greenwald & Pratkanis, 1984; Suls, 1982; Zurcher, 1977), reveal that, except for some limited attention to the "ideal self," the content of conceptions of the self, other than those of the current self, have not been emphasized. There have been a variety of efforts to empirically explore individuals' understanding of the future (e.g., Davids & Sidman, 1962; De Volder & Lens, 1982; Goldrich, 1967; Lessing, 1968; Teahan, 1958; Wallace, 1956), but this work has rarely been concerned with how the future is represented in the self-concept.

The link between the future and the self-concept is implicit in the writings of the symbolic interactionists who argue that the self as an organizer of behavior is always anticipating, always oriented to the future (Lindesmith & Strauss, 1956; Stryker, 1980). To Mead (1934), having a self implied the ability to rehearse possible courses of action depending on a reading of the other person's reactions and then being able to calibrate one's subsequent actions accordingly. Whenever individuals engage in this type of role taking, they are in the process of creating potential selves, and there can be as many of these selves as there are times when the self is the object of definition, expectation, or evaluation. Other sociological theorists extended Mead's idea and tackled directly the relation between the self (or identity) and motivation. Foote (1951), for example, believed that all motivation was a consequence of the individual's set of identities. The individual acts to express his or her identity: "Its products are ever-evolving self-conceptions" (p. 17), and "When doubt of identity creeps in, action is paralyzed" (p. 18). When action does manage to proceed with an uncertain identity, it is completely robbed of its meaning.

Self-concept has revealed the great diversity and complexity of self-knowledge and its importance in regulating behavior (cf. Carver & Scheier, 1982; Gergen, 1967; Greenwald & Pratkanis, 1984; Higgins, 1983; Kihlstrom & Cantor, 1984; McGuire & McGuire, 1982). Until recently, however, one specific domain of self-knowledge has remained relatively unresearched. This domain is commonly referred to as "possible selves." This specific domain of self-knowledge refers to how individuals think about their potential and about their future (Markus & Nurius, 1986). Possible selves are the ideal selves that we desire to become. Possible selves are also the selves we could become, as well as the selves we are afraid of becoming (Markus & Nurius, 1986). The possible selves that are hoped for might include the successful self, the creative self, the rich self, the thin self, the alcoholic self, the unemployed sle, and the total, complete failure self (Markus & Nurius, 1986).

According to Markus (1986), an individual's repertoire of possible selves can be viewed as the cognitive manifestation of enduring goals, aspirations, motives, fears, and threats. Furthermore, because possible selves provide the specific self-relevant form, meaning, and direction of these dynamics (Markus & Nurius, 1986), they provide the essential link between the self-concept and motivation. The graduate student who fears he will never finish his dissertation carries with him a personalized fear. Furthermore, the graduate student is likely to have a well-defined possible self that represents this fear—the self as having failed, as bitter, as a poet who can't publish her poems.
Possible selves arise from representations of the self in the past and they include representations of the self in the future (Markus & Nurius, 1986). They are different and separable from the now selves, yet they are intimately connected to them. Markus and Nurius pointed out that possible selves are individualized and personalized, but they are distinctly social. For the most part, possible selves are the direct result of previous social comparisons in which the individuals own thoughts, feelings, characteristics, and behaviors have been contrasted to those of salient others. This is where the problem begins for many African Americans. Whereas, an individual is free to create any variety of possible selves, the pool of possible selves derives from the categories made salient by the individual's particular sociocultural and historical context and from the models, images, and symbols provided by the media and by the individual's immediate social experience.

Possible selves, therefore, have the potential to reveal the inventive and constructive nature of the self, but they also reflect the extent to which the self is socially determined and constrained (cf. Elder, 1980; Meyer, 1985; Stryker, 1984). Young African American females who are track participants no doubt absorbed the victories of Marion Jones into their own possible selves. Stories of people dying from the effects of smoking serve to create negative possible selves for smokers. In this same manner, images of savvy computer users as geeks and nerds may create negative possible selves for many youth. This is, however, more detrimental to the possible selves of African Americans in general and African American males in particular, because there are very few positive models to aid in the creation of positive possible selves to combat or counteract these negative possible selves.

It has been suggested that possible selves are important components of motivations, because they function as incentives for future behavior (i.e., they are selves to be approached or avoided), and because they provide an evaluative and interpretive context of the current view of self (Markus & Nurius, 1986).

Markus & Nurius (1986) further contended that the function of possible selves derives from their role in providing a context of additional meaning for the individual's current behavior. Individuals' self-knowledge of what is possible for them to achieve is motivation as it is particularized and individualized; it serves to frame behavior, and to guide its course. In short, possible selves serve to select among future behaviors (i.e., they are selves to be approached or to be avoided).

Self-efficacy

One of the fundamental components of this study is self-efficacy. Self-efficacy theory is an important component of Bandura's (1986) more general social cognitive theory, which suggested that an individual's behavior, environment, and cognitive factors (i.e., outcome expectations and self-efficacy) are all highly interrelated. Bandura (1978a, p. 240) defined self-efficacy as "a judgment of one's ability to execute a particular behavior pattern." Wood and Bandura (1989) expanded upon this definition by suggesting that self-efficacy beliefs form a central role in the regulatory process through which an individual's motivation and performance attainments are governed. Self-efficacy judgments also determine how much effort people will spend on a task and how long they will persist with it. People with strong self-efficacy beliefs exert greater efforts to master a challenge while those with weak self-efficacy beliefs are likely to reduce their efforts or even quit (Bandura & Schunk, 1981; Schunk, 1981; Weinberg, Gould & Jackson, 1979). Efficacy beliefs help determine how much effort people will expend on an activity, how long they will persevere when confronting obstacles, and how resilient they will prove in the face of adverse situations—the higher the sense of efficacy, the greater the effort, persistence, and resilience. Efficacy beliefs also influence individuals' thought patterns and emotional reactions. People with low self-efficacy may believe that things are tougher than they really are, a belief that fosters stress, depression, and a narrow vision of how best to solve a problem. High self-efficacy, on the other hand, helps to create feelings of serenity in approaching difficult tasks and activities. As a result of these influences, self-efficacy beliefs are strong determinants and predictors of the level of accomplishment that individuals finally attain. For these reasons, Bandura (1997) argued that "beliefs of personal efficacy constitute the key factor of human agency" (p. 3).

Self-efficacy theory (Bandura, 1977) suggests that there are four major sources of information used by individuals when forming self-efficacy judgments. In order of strength, the first is performance accomplishments, which refers to personal assessment information that is based on an individual's personal mastery accomplishments (i.e., past experiences with the specific task being investigated). Previous successes raise mastery expectations, while repeated failures lower them (Gist & Mitchell, 1992; Saks, 1995; Silver, Mitchell & Gist, 1995). The second is vicarious experience, which is gained by observing others perform activities successfully. This is often referred to as modeling, and it can generate expectations in observers that they can improve their own performance by learning from what they have observed (Bandura, 1978; Gist & Mitchell, 1992). Social persuasion is the third, and it refers to activities where people are persuaded, via suggestion, into believing that they can cope successfully with specific tasks. Coaching and giving evaluative feedback on performance are common types of social persuasion (Bandura, 1977; Bandura & Cervone, 1986). The final source of information is physiological and emotional states.
According to theory and research (Bandura, 1995), individuals with low self-efficacy also have low self-esteem and harbor pessimistic thoughts about their accomplishments and personal development. In terms of thinking, a strong sense of competence facilitates cognitive processes and performance in a variety of settings, including quality of decision-making and academic achievement. When it comes to preparing action, self-related cognitions are a major ingredient of the motivation process. Self-efficacy levels can enhance or impede motivation. People with high self-efficacy choose to perform more challenging tasks (Bandura, 1995). They set higher goals for themselves, and are more apt to persevere in their pursuit of said goals. Actions are pre-shaped in thought, and people anticipate either optimistic or pessimistic scenarios, depending on their degree of self-efficacy. When setbacks occur, they recover more quickly and maintain commitment to their goals. Self-efficacy also allows people to select challenging settings, explore their environments, or create new environments. Researchers (Maddux, 1995; Schwarzer, 1992, 1994) have suggested that a strong sense of personal efficacy is related to higher achievement. This concept applies to such diverse areas as school achievement, career choice, and sociopolitical change. It has become an essential variable in clinical, educational, social, developmental, and personality psychology (Bandura, 1997; Maddux, 1995; Schwarzer, 1992, 1994).

This Research

Attitudes do matter. If African American students are proficient with technology, but do not believe that technology has a use in their lives, or offers a positive future possible self, they will probably not work with technology despite their proficiency. In this respect, attitudes and beliefs about technology serve to "make or break" the cycle of computer avoidance among African Americans in general. On the other hand, African American students who believe in the utility of technology in their lives, and that computers offer a positive future possible self, may persevere through challenges that face novice technology users.

Researchers have investigated the relationship between computer attitudes and computer adoption or uptake (Cox, Rhodes, & Hall, 1988; Davidson & Ritchie, 1994; Kay, 1990). The importance of attitudes and beliefs for learning to use new technologies is widely acknowledged (Bandalos & Benson, 1990; Dupagne & Krendl, 1992; Francis-Pelton & Pelton, 1996). Several studies have found that individuals' attitudes toward computers might improve as the result of instruction (Kluever, Lain, Hoffman, Green, & Swearingen, 1994; Madsen & Sebastiani, 1987; Woodrow, 1992). In other studies, attitude scales comprised of component subscales were developed. Subscales measured attitudes toward the social issues relating to computer use (Francis & Evans, 1995; Popovich, Hyde, & Zakrajsek, 1987); computer liking, computer confidence, and computer anxiety or comfort (Delcourt & Kinzie, 1993; Loyd & Gressard, 1984b); achievement (Bandalos & Benson, 1990); and usefulness in education, personal usefulness, and value (Francis-Pelton & Pelton, 1996). Like other individual characteristics hypothesized to play a role in the continued growth of technology proficiency, attitudes and beliefs are not easily taught and must be developed by individuals over time.

The driving force behind this study was the slow, yet constant marginalization of African American students based on their "inability" to academically match their European American counterparts. This is particularly alarming when one considers the power of information technology and the generalized demand for Americans to be proficient at this task, if they are to be successful. As a collective group, African American male and female students have scored significantly lower on standardized achievement tests than other populations for far too long. Research suggests that this condition is widespread (Oakes, Gamoran, & Page, 1997; Steele, 1997). African American students are under-represented in programs for gifted and talented students, tend to be over-represented in special education programs and are consistently underrepresented on the honor rolls, which represent academic achievement based on grade point averages. Such observations are consistent with those of Gibbs (1989), Ogbu (1987), and Shapiro et al. (1993) regarding the educational plight of the African American student in our society. These observations are also consistent with those of Harter and Jackson (1992) on effects of intrinsic motivation on academic achievement, learned helplessness (Maier & Seligman, 1976), and the role of protective factors on academic achievement in African American students (Crocker & Major, 1989). Therefore, it is possible that motivational variables may influence African American students' computer usage differently than European American students. If these motivational variables and their effects can be determined for African American students, then it may be possible to develop instructional strategies to improve the integration of computers into their lives, and begin to use the technology as the powerful information tool it is.
Using Technology to Encourage Motivation and Achievement in Academically At-Risk Secondary Students

Kay L. Gibson
Department of Curriculum and Instruction
Wichita State University
United States of America
kay.gibson@wichita.edu

Abstract: This paper reports research efforts to establish how successful use of technology relates to achievement and motivation of at-risk secondary school students; and to identify aspects of technology use that appear to have a positive effect on these students' learning outcomes. Using school records, academically at-risk students were identified in one middle school situated in a mid-western city. These students were interviewed and observed in technology classes. Interviews were also conducted with the technology teacher concerning how the curriculum was designed and taught. Initial findings in this study, were inconclusive. In anticipation that a larger number of participants will begin to reveal categories and patterns of responses, data from a group of high school students will be included with existing data. It is hoped that eventually results from research such as this will help teacher educators better prepare pre-service teachers to choose effective technology teaching strategies and to integrate them into their classrooms.

Introduction

It is generally believed that the wise use of technology in teaching can lead to enhanced student motivation and achievement (Becker 2000; Chen & Looi 1999; Mistrler-Jackson & Songer 2000). One reason that the use of technology can increase the learning achievement of students has to do with the very nature of technology (Kozma & Croninger 1992). Cognitive psychology suggests that learning is an active process in which the learner uses existing cognitive resources to construct new understanding from information provided by the environment and knowledge from prior experiences stored in long-term memory. Obviously, then prior knowledge has a major impact on current learning. Knowledge is best remembered when it is stored both as a mental image as well as a verbal description (Paivio 1990). Technology is complementary to cognitive learning in that it provides the means by which visual and verbal representations can be constructed and can model or perform certain processes such as problem solving that facilitate successful learning (Salomon 1988).

The literature provides numerous examples of improving the retention rate of at-risk secondary students as well as enhancing motivation through the use of technology (Chen & Looi 1999; Gan, 1999; Mistrler-Jackson & Songer, 2000; Wishart & Blease, 1999). In part, technology is motivating because it is a hands-on approach that allows students to take charge of their own learning (Candon 2000, Taylor-Dunlop & Norton 1997). Not only did technology motivate at-risk students to learn when they were at school, it was also a major reason that at-risk students came to school due largely to the kinesthetic nature of interactions with technology (Taylor-Dunlop & Norton 1997). Dewey (1900) proposed that the use of hands-on activities provided intellectual stimulation for students that in turn increased learning. Considering Dewey’s theory in an educational technology perspective, Herschback (1998) observed that technology demands of students an interaction with the learning environment and therefore was useful “in designing integrative and higher-order learning” (p. 55).

However, simply using technology in the classroom does not automatically result in improved learning and teaching (Mecklenburger 1990). To be truly effective, technology integration into classroom practice must recognize students’ abilities, needs, and learning styles as well as the content structure of the
discipline (Dunn, Dunn, & Price 1989). Additionally, the Laboratory of Comparative Human Cognition (1989) suggested that technology use with at-risk students is more effective when it is used in conjunction with collaborative groups of students with a well defined learning goal; involves complex simulations that require higher-order thinking; and connects students with their family, community and other cultures.

Background

When the National Educational Technology Standards (NETS) were incorporated into the program goals of the undergraduate teacher preparation program at Wichita State University, teacher educators began to examine effective uses of the integration of technology into classroom practice. Faculty worked in teams across four semesters to describe ways in which technology was currently being used in the program and to look for additional ways to effectively integrate technology into the various program courses.

The undergraduate teacher preparation program has a strong field component in all semesters of the program. Over forty public schools in the city school district provide field placements for students in the teacher preparation program. This gave rise to the opportunity for informal discussions with teachers in the field regarding their beliefs about the link between the use of technology and learner motivation. These discussions revealed that in-service teachers too were seeking possible ways in which they could effectively integrate technology into their existing curriculum to better facilitate successful learning.

Further these classroom teachers pointed out that they had become aware of a number of students who were only making a passing grade in their technology class while failing all of their other classes. They wondered if there was a connection between technology usage in the classroom and an increased level of student motivation to learn. These observations led to the question, “What types of technology integration most effectively encourage and motivate students to learn and achieve?” Answers to this question can help pre-service teachers, teacher educators, and classroom practitioners to provide a more responsive learning environment for all learners. The informed technology integration decisions of practicing teachers ultimately enhance all students’ learning experiences and increase positive student outcomes (Kauchak & Eggen 1998). Teachers need to know what factors of technology use are crucial for consideration as they develop curriculum delivered at least in part through technology. This research sought to establish how successful use of technology relates to achievement and motivation of at-risk secondary school students; and to identify aspects of technology use that appear to have a positive effect on these students’ learning outcomes.

Method

For the purposes of this study, at-risk students were those who did well in technology classes but who were receiving Ds or Fs in all or most other classes. The technology teacher using school transcripts identified a list of possible participants. The parents of these students were sent a letter explaining the research and a consent form to return should they wish for their child to participate. A total of 12 of the 16 possible participants returned consent forms and therefore, were included in the study.

An interview schedule was developed for use with the students that consisted of eight questions. Additionally, probe questions were written for five of the eight questions. The interviews were conducted in the technology classroom during class time. One researcher asked the interview questions while the other recorded responses. Interviews were also taped to insure accuracy and thoroughness of recorded responses. Most (9) of the students were interviewed during their technology class, however, three were given permission to come for the interview during another class. Once students were interviewed, they were observed working in the technology class. The two observers informally discussed the student’s technology project with him/her, which helped to verify the student’s responses to the interview questions. Informal interviews were also conducted with the school administrator and the technology teacher.

Individual student interviews, observation data, and the administrator and teacher interviews were coded using the constant comparative method (Maykut & Morehouse 1994) to establish themes, categories, and issues across the data. Additionally, the two researchers and a research assistant independently coded the data and then discussed the data, coding and recoding it until 100% agreement was reached. Through
the multiple types of data gathered and researcher agreement, triangulation of the data was obtained and reliability established.

Findings

This paper reports the data results and findings concerned with the student interviews. The schedule of interview questions was constructed guided by the researchers' assumptions that technology was motivating a) because of its novelty, b) because the class was organized in a more appealing way for the learners than were other academic courses, and c) because technology activities required less reading and writing for completion of class assignments.

Responses regarding access to computers and the Internet other than at school did not support the researchers' assumption that access to technology was only available at school during technology class and therefore was motivating because it was an uncommon activity. Of the twelve student interviewees, eleven (92%) reported that they had regular access at home (n=10) or at a parent's place of employment (n=1).

The students used the Internet for a variety of activities. The most common use was playing games (n=8, 67%) followed by sending and receiving of email (n=7, 58%). Other Internet activities included research (n=6, 50%), school projects (n=5, 42%), general information searches (n=5, 42%), presentations (n=2, 17%), chat rooms and making birthday cards (n=2, 17%). Students also reported using a total of 10 different applications and software packages including Word, Excel, Adobe Acrobat, Word Perfect, Photo Shop, Paint, Clip Art, Print Master, PowerPoint, and Grolier's Encyclopedia.

When interviewees were asked what they liked about using technology, eight (75%) of the students answered that they enjoyed searching for and learning new information. One student liked "accidentally finding new information on the Internet. There were six students (50%) who responded that they liked the ability to do artwork and other creative things using technology. Responses from six students (50%) also identified the ease of using technology was one thing they liked. Comments such as "It's easy to correct", "I don't have to write", "It's faster", "I can make what I want (so it) looks professional", and "easy to get information faster" were included in the 'ease of use' category.

Responses to a question asking what the interviewee liked about technology class indicated that for several of the students (n=2, 17%) the organization of the class was important especially in terms of self-directedness. Types of responses included in this category were "I can talk with other people", "I get to do more on my own", and "There's just more freedom in our technology class". Two other students (17%) described teacher characteristics of "nice" and "willing to help" as what they liked about their technology class. However, the largest number of students (8, 75%) gave responses concerned with the type of content that was learned in the technology class and indicated that was what they liked about their class. These students enjoyed "the opportunity to learn", "working on a web page", "learning to insert pictures...into documents", and finding "new stuff...like new links and graphics".

The students were also asked if they worked with other students during the technology class. The researchers anticipated that group work might be appealing to the at-risk students. Initial responses do appear to support this assumption. Eight students (75%) reported that they frequently worked with others on projects and seven students (58%) said that they helped other students even if they were not working on the same project. Only three (25%) of the students said that they did not work with or talk with other students.

Interviewees were asked several questions pertaining to the amount of reading and writing required in the technology class because the researchers believed that less use of reading and writing skills would be motivating to the at-risk secondary students. However, a total of seven students (58%) responded that there was "a lot more" reading in the technology class (n=6, 50%) or that there was "more (reading) than (in) other classes" (n=1, 8%). Three students (25%) answered that the amount of reading required was the same as other classes while only two (17%) responded that there was less reading involved in their technology class than there was in other classes. When asked how much writing was required in their technology class, four (33%) said more was required than in other classes, four (33%) said less, and two (17%) said it was the same amount of writing in all of their classes. Two (17%) of the students were undecided.

To conclude the interview, the student interviewees were asked why they thought they did better in technology class than in some of their other classes. Seven (58%) believed that it was partly due to the fact that their technology class was easier for them than other classes; while 3 (25%) of the interviewees
said they did well in technology class because they found it interesting. One student said he thought he did better because “other classes (were) too easy” but technology class was challenging. Two students said they were not sure why they did better.

Conclusions

The initial findings of this study showed that all of the at-risk students who participated in the research, used technology at home and at school on a regular basis for playing games, emailing, completing various type of school assignments, participating in chat rooms and making birthday cards. They had a substantial knowledge of a variety of applications and software. Most of the students (n=8, 75%) enjoyed searching for and learning new information while the same number enjoyed the skills that they learned in their technology class such as constructing a web page, activating external links, inserting pictures, and designing graphics. Most of the students (n=8, 75%) enjoyed the opportunity to work with other students on projects in their technology class. It was found that for these at-risk students the amount of reading and writing required in their technology class was not a factor that influenced their motivation when working with technology. Finally, a majority of the at-risk students believed that they did well in technology class because they either found the work easy (n=7, 58%) or interesting (n=3, 25%).

These findings, though not conclusive, do suggest that technology can motivate at-risk secondary students to achieve when the learning environment allows group work, when the content is perceived by the students as easy to learn and when the students view the content as relevant and interesting. It is anticipated that additional interviews with at-risk secondary students will help to clarify and validate these initial findings.

Acknowledgements

I wish to thank Professor Bryant Fillion in the Department of Curriculum and Instruction at Wichita State University for his contributions to this paper. His thought-provoking questions, particularly in the data analysis phase, brought clarity too much of the interviewees' comments and descriptions.
Process of teacher's buy in and Web design project adopting constructivist model

Misook Ji, University of San Diego, US

Abstract

Current education is facing the challenges of the high standards which the 21st century demands. The new standards emphasize the importance of technology integration as a catalyst for instructional change. Technology integration may offer an active, meaningful, and authentic learning environment for engaging students more in the learning process, and encouraging student ownership of their learning, which are essential parts of the new standards. The need for competent, well-prepared, talented and dedicated teachers in every classroom has been described as the major key to effective technology integration.

Consistent with technology use as the catalyst for instructional change, a paradigm shift from traditional teaching and learning to a constructivist model is critical to accomplish society’s expectations for education. Learning through a Web based design project would be one way of facilitating an authentic learning environment, which includes mastery of basics, inquiry, collaboration, and responsibility as the hallmarks of effective education.

One particular component in the new standards has focused on teachers’ pedagogical beliefs and practices related to technology integration into teaching and learning. The new standards demand a paradigm shift in teaching and learning with technology, and challenge many teachers to modify, transform, and even abandon their traditional model of teaching and learning into an unfamiliar new model to accomplish these expectations. The process of change in teacher’s pedagogical beliefs and practices is often a painful and difficult one, causing teachers a good deal of stress. Teacher educators need to know more about this process to be able to help teachers make the shift smoothly.

In the constructivist view, widely accepted as a legitimate pedagogy, teaching is considered as a "process of helping learners to construct their own meaning from the experiences they have by providing the opportunity for those experiences and guiding the meaning-making process" (Jonassen, Peck, and Wilson, 1999). Teachers must construct their own understanding of this theory and need to design effective and meaningful teaching methods to implement this theory into practice.

An authentic learning environment which is designed to make a connection between meaningful learning and the socially interactive community, is vital to fulfill societal expectations for educational. The environment is the adoption of a constructivist pedagogical approach in a collaborative culture. This might be accomplished within a Web-based curriculum, for example. Such rich learning environments would provide opportunities for learning activities in which “students are engaged in a continuous collaborative process of building and reshaping understanding as a natural consequence of their experience and interaction with the world” (Dunlap and Grabinger, 1996).

Although technology integration and a constructivist approach to teaching and learning hold the promise of promoting meaningful learning in a rich-context learning environment, teachers often have difficulties adopting a new way of teaching, and in changing their pedagogical beliefs and perceptions. These difficulties may not result simply from teachers’ lack of familiarity with combining computer technology and a constructivist approach, but rather may be a result of their failure to recognize a new way of thinking and designing. In the process of applying constructivist concepts, teachers need support and encouragement from educational leaders, researchers, and teacher educators to help them refine their methods and change their teaching practices consistent with a constructivist approach. The process requires that teachers invest more time, effort, and even struggle to cope with conflicts and barriers in their school environments.

Teachers’ changes in instructional approach are the result of a thoughtful process, which is their construction of knowledge about what ‘works’ and doesn’t work in the classroom. It is cautioned that technology integration is not just a matter of “plug and play” from others’ work, and that “tweaking” someone else’s idea isn’t nearly as satisfying, nor effective working out your own ideas for your own classroom. The concept of teachers designing their own activity and curriculum, responding to the dynamic and unique conditions of their classrooms, would be more in keeping with a constructivist classroom.
Therefore, instead of being passive borrowers, teachers need to “buy in” (Perkins, 1991), to become active designers.

The research examined the process of change in teachers’ pedagogical beliefs and practices doing Web based design project and how they struggle and triumph in creating new strategies. This study employed a qualitative research design, using descriptive case study methodology. The teacher participant in this study was a teacher who was engaged in her second project in which her students were designing Web-based projects in order to learn and communicate about a subject matter. Her students designed authentic Web-based projects in which they became technology leaders in the school and the school district, helping the teachers and other students.

This study intended to describe one teacher’s understanding and pedagogical beliefs toward seeking to use a constructivist model of teaching and learning, and the process of change in that direction, and doing so in the context of the teacher's designing Web-based projects with her students. This study described a teacher's pedagogical beliefs and perceptions before and after having her students do a constructivist technology project, in order to understand how these beliefs have changed. The research also focused on understanding the effects of constructivist design on teacher's teaching strategies and constructing pedagogical beliefs. The purpose was to find ways of helping teachers to “buy in” (Perkins, 1991) to becoming an active designer rather than being a “plug and play” (Harris, 1998), passive direction-follower.

The research provides implementation, which enable teacher preparation institutions to better prepare preservice and inservice teachers for active design of buying in constructivist model of teaching which integrates technology.
A Multilevel Analysis of the Relationship between School and Teacher Variables and Students' Usage of Technology

Seung H. Jin

seung.jin@csuohio.edu

Joshua Bagaka's
Curriculum and Foundations
Cleveland State University, United States
j.bagaka@csuohio.edu

Abstract: The purpose of this study was to determine the impact of teacher and school variables on students' usage of computer technology in elementary schools. Participants in the study were 10 classroom teachers and 219 fourth- and fifth-grade students representing rural, urban, and suburban in the Northeastern region of Ohio. The findings in the study show that, teaching experience, teachers' attitudes towards technology, and their school's technological environment were significant predictors of the students' adjusted classroom average technology usage. Teaching experience and teachers' attitudes towards technology had a positive relationship with students' technology usage.

Over the past two decades, there have been significant increases in the use of technology and in access to computer technologies in schools. However, there are important questions of students' competence in necessary technological skills. If students are expected to develop technological fluency for their learning, their teachers must also possess this fluency. If some teachers neglect to use technology in their teaching or to teach the second-level skills of knowledge integration for deeper understanding, students may not be equally prepared to become knowledge workers functioning at higher levels in society.

Many studies investigated students' usage of technology underscore teachers' role in integrating technology. A study about educators' beliefs and technology-related activities revealed that teachers who used e-mail at home, used Internet in classrooms felt technology improved their teaching roles (Norris, Soloway, Knezek, Topp, Young, & Box, 2000). Parr (1998) emphasizes that the beliefs of students and teachers influence the use of technology in their classroom and that the learning context with technology is co-constructed by teachers and learners. Mills (1999) stresses that a successful integration of computer technology in instruction must be approved, accepted, and implemented by teachers. Honey and Moeller (1990) indicate that teachers' educational beliefs play an important role in integrating technology into the curriculum. The purpose of this study was to determine the impact of teacher and school variables on students' usage of computer technology in elementary schools.

Methods

Participants in the study were 10 classroom teachers and 219 fourth- and fifth-grade students representing rural, urban, and suburban in the Northeastern region of Ohio. The subjects were identified to be in two levels of an organizational hierarchy. At the level-1, a short survey is being administered to fourth and fifth grade students to assess their technology-related learning environments and their level of usage of technology such as word processing, drawing, presentation, spreadsheets, keyboarding, game, reading software, encyclopedia, web searching, e-mail, etc. At the level-2, a survey was administered to 10 classroom teachers whose students (level-1) participated in the study. The teachers' questionnaire was designed to assess teachers' technological beliefs, practices and demographic characteristics such as accessibility to computers at home and in the classroom, technological training, gender, teaching experience, and area of teaching.
Students' responses to the survey items were internally consistent with a Cronbach's Alpha reliability coefficient of 0.84. A combined scale of technology usage, created from these eleven items was utilized as the primary outcome variable of the study. Teachers' attitudes toward technology, their perceptions on school technological environment, as well as their usage of technology was used as the primary independent variables of the study. Due to the fact that students are nested within teachers (or classrooms), hierarchical linear model (Bryk & Raudenbush, 1992) was best suited for data analysis of the study.

Results

Table 1 presents the teacher-level model (level-2) results for the prediction of students' technology usage by school contextual and teacher variables. At this level, the outcome variable is the students' adjusted classroom average usage since the students level variables were grand mean centered at the student-level (level-1) model.

Table 1: Teacher-level model results for the prediction of students' technology usage by school contextual and teacher practice variables; * p < 0.05

The findings in Table 1 show that, teaching experience (β = 0.22, p < 0.05), teachers' attitudes towards technology (β = 0.74, p < 0.05), and their school's technological environment (β = -0.59, p < 0.05) were significant predictors of the students' adjusted classroom average technology usage. Teaching experience and teachers' attitudes towards technology had a significant positive relationship with students' technology usage. Surprisingly school's technological environment had a significant negative relationship with students' technology usage.

Conclusions

The findings in the study may suggest that, teachers' attitudes towards technology are more important in enhancing their students' technology usage than school technology environment. A possible explanation for the negative relationship between school's technological environment and students' technology usage may be due to varying teachers' expectations. It is possible that teachers who utilize technology more have a higher level of expectation on their school's technological support and resources. Contrary to other studies which have shown a negative relationship between teaching experience and technology use, the sample of teachers who participated in the study varied only minimally in their teaching experience, from two to eight years.

Deepening the Impact of Technology through an Inquiry Approach to Teaching and Learning: A Cross-Case Analysis of Three Teachers’ Experience

Margarete Juliana, Research Center for Educational Technology, US

INTRODUCTION

Teachers know that in order for students to learn they have to be engaged in the learning process and preferably interested in the topic. Robert Fried takes this a step further as he highlights the need for both teachers and students to become passionate about their learning (2001). This study focuses on three teacher professionals whose teaching practices capitalize on the use of multiple technologies and inquiry method as a means to deepen student learning, engagement, and understanding. Though there are many exhortations to use inquiry to stimulate thinking and learning, it is more easily said than done, given teacher educational models and pressure on teachers to increase student achievement on standardized tests.

PURPOSE OF THE STUDY

The term “inquiry” encompasses many meanings (Short & Burke, 1996) and can have confusing and negative connotations for teachers. Although commonly associated with science education (Ben-Chaim, Ron, & Zoller, 2000; Pierce, 2001), inquiry can be used with any curricular area. This study provides a window into the experiences of three veteran teachers who use inquiry in a classroom equipped with multiple technologies. This study reveals how teachers who ascribe to the inquiry method use technology to support inquiry and learning, and reveals the benefits (and drawbacks) of incorporating inquiry and technology in the classroom. The goal of this study is to determine the differences and similarities in teachers’ beliefs and strategies about incorporating inquiry and technology. Through a cross-case analysis, we will be able to see a broader range of understanding about the use of technology to support inquiry, and the findings can present models of use that other teachers can reflect upon as they think about their own teaching and technology infusion.

BACKGROUND

The Ameritech Electronic Classroom (AEC), a unique research facility at Kent State University and part of the Research Center for Educational Technology (RCET), has been in operation since spring, 1998. One strand of the research focus of RCET is: “Under what conditions can technology be used by students for problem solving, inquiry, and critical thinking, and what are the impacts of such use on student learning?” (RCET, 2000). This question was the impetus for this study.

Area teachers and students call the AEC “school” half a day, every day, for a six-week period. Teachers bring their own units, and are supported by an administrative specialist, instructional specialist and technology specialist during the time they come to the AEC. Teachers who come to the Ameritech Electronic Classroom are identified through a selection process which involves being nominated by their principal. The teachers then participate in a one-week orientation that focuses on the inquiry method supported by a variety of technology.

During the one-week orientation, teachers read about and discussed the issues involved in creating authentic work for students (Newmann & Others, 1996). They created guiding questions as the backbone of their inquiry units (Traver, 1998), and discussed how to design units that involve students in the development of questions that guide their own learning (Short & Burke, 1991). This professional collaboration was continued throughout the year with periodic meetings to discuss topics with teachers and technology, and to share unit plans and ideas as “works in progress”. These meetings were set for one time per month for the first year and changed to quarterly for the second year with online communication and support available.

PARTICIPANTS

The participants in this study were two fourth grade teachers, and one eighth grade teacher from area schools. Nancy*, a fourth grade teacher, who has taught for 11 years, chose a unit on conflict. Sarah, another fourth grade teacher, who has taught for 15 years, chose to continue a unit on immigration that she had begun at the first of the year. Robert, an eighth grade teacher, who has taught for 28 years, focused on oral histories. All units were interdisciplinary, incorporating mostly social studies and language arts as the target curricular areas.
METHODOLOGY

The following methodology was used for each case. In order to assure validity of the data, multiple data sources have been used in this study. Teachers were interviewed after their one-week orientation during the summer, just prior to their turn in the Ameritech Electronic Classroom. They were interviewed once a week with a semi-structured format that allowed us to tailor some questions to issues that emerged from the prior week’s interview and observations. All teachers were observed two times a week in the Ameritech Electronic Classroom and once per week in their home school classroom. This allowed us to see differences between their strategies and orientation to teaching within and outside of the technology immersed environment. All three teachers had technology in their home school classrooms to some degree. A teacher reflection journal was recorded weekly, and unit and lesson plans provided a final data source.

DATA ANALYSIS

The rubric for authentic and intellectually engaged learning (Newmann, Secada, & Wehlage, 1995) will be used to code the data with the software, Ethnograph. Instances of use of technology will be noted, as well as teachers' rationale for using technology, and how they believe it supports student learning. These responses will then be coded for patterns. Categories that emerged will be analyzed to develop a framework of each teacher’s understanding and mental model of the concept of inquiry, how the teacher believes it enriches student learning, and how technology supports teacher and student inquiry in the classroom. These individual cases will then be compared and contrasted.

CONCLUSION

The results of this study will create a picture of how teachers use technology to support inquiry. Our experience with teachers, such as those in this study, shows that they are committed to engaging their students in learning through a multitude of means. Learning, to these teachers, is about delving deeply and broadly into topics that they believe are relevant not just to them as educators, but also of interest to their students. They also know the importance of aligning all learning to state standards and to the objectives of state level standardized tests. This is not an easy tightrope to walk. Even with years of experience in the classroom, these teachers express the difficulty of the balancing act they willingly walk every day. Capturing these teachers’ experiences and reflections can provide an important window into how expert teachers maintain their passion for learning by embracing both inquiry and technology use to deepen the impact of student authentic learning.

[This study is in its final weeks of data gathering. As such, the data analysis has not been completed.

Project Completion Timeline:
• November, 2001 – Data collection completed
• November, 2001 - January, 2002 – Data analyzed and results compiled
• February, 2002 – Study write-up completed]

* Teachers names were changes for confidentiality purposes.

Abstract: Internet, which has entered into our daily life with the rapid changes in data processing, has brought many developments into the educational area through easy access to the information and rapid communication services for users. The use of Internet in training environment has been providing new educational opportunities especially for adults in addition to their main education. Teaching activities through the Internet for various purposes have been organized by institutions which gradually rising in number over the world.

Introduction

Obtaining data in great amounts, easy accessing to information and rich communication possibilities of Internet has formed the idea of Internet for teaching purpose, and this has pioneered the formation of the "teaching activities through the Internet" concept. There are various definitions for teaching through Internet in literature. Khan (1997) defined the “Teaching Through Internet” as a teaching program to form a meaningful teaching environment which will increase and support learning by using the features of the Web and which is supported by computer technology. On the other hand, Reian and Gillami (1997) defined “Teaching Through Internet” as “to create formal and co operational learning environments by using the features and possibilities of WWW, by applying educational strategies to teaching environment” (Henke, 1997, p:1). These definitions for teaching through Internet state that since Internet includes the accessing to information, synchronous and asynchronous communication services, it enriches the teaching environments, supports learning based on cooperation, makes it easier for students to evaluate themselves and for instructors to evaluate the students.

There are various types of use of Internet, which means the use of Internet for the purpose of teaching and it is possible to group the teaching activities through Internet into four groups (Senis, Mutlu & Çetinöz, 1999).

- Providing Internet support for Structural lessons
- Internet based presentation of structural lessons
- Application of virtual University
- Internet based certificate programs

Teaching activities are increasing rapidly through Internet, which can be used in different ways in teaching environments, depending on this, more students in number can continue their educations using these programs free from the place and the time.

Purpose

Main purpose of this study is to examine teaching activities through Internet and to analyze effectiveness of these mentioned applications. As for the aim, the first two units titled as “Introduction to Information Technologies” and “Algorithm Concept and its Fundamental Features” of “Fundamentals of Information Technology” course which is given in order to make the students in all Faculties, Institutions and Vocational Schools using structural education in Anadolu University to gain computer-literacy and which is for one term course was designed as an Internet teaching activity by using WebCT and the success of the students taking this course was determined by using two different Teaching Activities Through Internet (Internet Supported Teaching and Internet Based Teaching) and traditional teaching activity within the presentation of the content.
Methodology

As for the aim, a model with pre-test and post-test control groups was applied in the study. 71 subjects from 2000-2001 Academic Year Spring term students of “Fundamentals of Information Technology” in Anadolu University participated into the study. First of all the content was converted into teaching activities through Internet by using WebCT and then in order to examine the students’ success pre-test and post-test which were consisted of the units that were mentioned was given to the students by the researcher. A subject-success test was applied as a validity and reliability study before the research was conducted. The subject-success test was given as a pre-test to the groups before the units that were mentioned were followed. The first group used “the Internet-Supported Instruction” as teaching activities in the “Fundamentals of Information Technology” whereas the second group was trained by using “the Internet-Based Instruction” in the same course. The last one was the traditional group, which the Internet was not used. At the end of the study, the pre-test was given as the post-test.

Findings and Comments

To analyze the data and its comments, first of all the scores of the pre-test and post-test applications of the experimental and control groups were gained and then each students’ arithmetic average pre-test scores were examined to find out whether there was a significant difference between the scores by using one-way ANOVA analysis. Among the arithmetic average of pre-test and post-test scores of the students in each three groups, it was defined that there was a significant difference in the advantage of the post-test. In order to define the direction of the significant difference in post-tests one of the multiple comparison tests, Tukey’s Honestly Significant Difference Test (Tukey’s HSD test) was used. Table 1 demonstrates the findings gained in the study.

<table>
<thead>
<tr>
<th>Experimental Groups</th>
<th>Experimental Group I</th>

<tbody>
<tr>
<td>Experimental Group II</td>
<td>15.79*</td>
<td>15.57*</td>
</tr>
</tbody>
</table>

Table 1. Tukey’s HSD Test Findings of the post-test scores of the Groups

According to the results of the study, first of all, it was defined that there is a significant difference in the advantage of first experimental group in which Internet Supported Instruction was applied. Additionally, it was found that there is also a significant difference in the advantage of the control group in which the traditional teaching instruction was applied.

Secondly, it was defined that there is a significant difference in the advantage of the control group in which traditional teaching instruction was applied. This finding shows that there is a significant difference in the students’ success level in both traditional teaching instruction group and Internet supported instruction group in the advantage of the first group.

Conclusion

The main findings of this study are:

1) The teaching activities of Internet-Supported Instruction are more effective on students’ success in “Fundamentals of Information Technology” course than the teaching activities of Internet-Based Instruction.
2) The teaching activities of which the Internet is not used are more effective on students’ success in “Fundamentals of Information Technology” course than the teaching activities of Internet-Based Instruction.

kauwell@uiuc.edu

Introduction

Historically, issues such as the retrieval of information have been the problem of Librarians and information scientists and only of ancillary interest to educators. However, we need to consider that current government estimates show that more than 95% of American K-12 schools and virtually all institutions of higher learning are connected to the Internet (National Center for Education Statistics 2000). Indeed, billions of dollars have been spent to provide the infrastructure and equipment to achieve this.

Now that we have all these schools wired it remains to be seen what we are going to do with the Internet. There are many pedagogically sound uses of the Internet and certainly one of them is access to information from around the world. Ultimately, most educators would like to see a day when students can access the limitless collection of media on the Internet and find many relevant resources related to their topic of study. Clearly, the seemingly boundless trove of information, art, music, literature and other forms of media on the Internet is one of its greatest potentials. Information and media that in the past might have been available to only a few, can now be accessed by the many. However, anyone who has tried to find quality information on the Internet, realizes that this is often difficult (Jansen, Spink et al. 1998, Silverstein, Henzinger et al. 1999). This is backed up with personal conversations I've had with teachers, where the most common complaint heard is "I know there is a lot of good stuff on the Internet but, I just don't have time to find it." Yet in spite of the difficulties associated with finding information, students are being called upon to learn from distributed sources of information on the Internet. As many as 30% of K-12 teachers have reported that they required students to find materials on the Web to a large or moderate extent (National Center for Education Statistics 2000). To address this issue in the past there have been many efforts to build static, manually maintained, domain and grade level specific collections of "good" pages. Unfortunately, these repositories are difficult to sustain. What is needed are new methods of finding information, learning from it once it is found, and sharing that information with other teachers and students.

Let's be clear here, the problems we have with finding information on the Internet are not unique only to teachers and is not "just" a training issue for them. Finding and learning from information on the Internet is problematic for teachers, those preparing to become teachers, students, and anyone else desiring to learn from information found on the Internet. To overcome the problems in searching the Internet many advocate teaching better search skills that ultimately rest on the searchers' cognitive abilities to formulate a query, filter information, assess validity, organize results, and generally make sense of what can be a very ill-structured task. Yet cognitive abilities have obvious limits, and mastering search skills takes time on task that many searchers do not have to master often complex query languages that vary from search engine to search engine (Jansen, Spink et al. 1998). Research on information retrieval shows that most well formulated queries involve seven to fifteen search terms and relatively sophisticated query logic (Meadow 1992; Kerthage 1997) yet, the average number of search terms in a Web query is somewhere between 2 and 2.5 words (Silverstein, Henzinger et al. 1999). Furthermore, less than 5% of all Web searches use Boolean operators and of those that do, it's estimated that as many as 50% may be using them incorrectly (Silverstein, Henzinger et al. 1999). When and if information can be found, the teacher must do something with it to make the information available to students and, students must now "do something" with it to construct knowledge. Current search engine interfaces do little if anything to support the knowledge construction process. Studies I am currently conducting indicate that most students (undergraduate students in education, most of whom are preparing to become teachers) use a variety of strategies for selecting Internet sites and learning from them. Often however, they pick the "first" site that appears on the search results or those with a "catchy title." This sadly strikes me as reminiscent of a trip to the library where students pull the first book off the shelf (more often than not the encyclopedia) that seems to have any information on their topic and commence to write a paper. If we are to fully utilize the Internet, we need to prepare teachers and, help teachers prepare students, to find and learn from information on the Internet. Better skills and tools are needed to find and learn from information, better methods for dissemination of information once it is found and organized into meaningful structures, and better ways to maintain repositories of information for use by teachers and students.

Imagine for a moment, a high school history teacher who does a search for "World War II". They are presented with a list of perhaps hundreds of thousands of "hits" from which they have to find the "good" sites. If the teacher uses one of the more popular search engines they will get pages from a sampling from about 16% -30% of the Web and, the validity of these pages is indicated solely by the search engine's relevancy ratings which is highly questionable (Spink and Greisdorf 2000). The teacher must then sort through the hits, determine which ones are good, browse through the sites for other related pages and perhaps they will click through to other sites not returned by the search engine. If this raw information is to be used to prepare a unit on World War II, something must be done with it to make it useful. If the teacher chooses, and knows how, they may be able to make a html list of the sites they found in a hierarchical order for dissemination to other teachers or their students. But, this all requires a good deal of work, lacks the means for easy dissemination and furthermore, the links collected are subject to "link rot". Without constant checking, over a relatively short period of time, many of the links found will be broken.

Alternatively, imagine that the same teacher could search the Web with multiple search engines simultaneously and manipulate the hits in such a way that information about Normandy could be placed on the appropriate location on a world map by simply dragging an icon that represents the Web page. Information about Germany's eastern front could be placed in Russia and information about the Burma Road could be located along the actual route. Instead of printing pages the teacher could easily cut and paste information from the page or make notes that would pop-up whenever a mouse was place over the icon that represents the Web page on the map. When the page icons are clicked on, the entire page could be displayed in a browser for more information. Irrelevant hits could be deleted and new sites that are found while browsing could be easily added to the map. If the entire "search space" information could be saved, map, notes and all, it would be very easy for the teacher, colleagues or students to access the information to use for their own purposes. Such search spaces could be easily made available to other and they could even be collaboratively constructed. Let us further imagine that all who use this search space implicitly contribute to keeping the links updated, help find new links of interest and adjust the
relevancy weightings for sites showing similar information simply by using the search space for their own purposes. Over time, data could be collected that would shed light on other dimensions as well. Such as which sites are best suited for a high school teacher vs. a university researcher. Perhaps patterns could be detected that would allow detection of “misinformation” put out by groups pushing particular perspectives (e.g. groups that advocate there was no holocaust). Or, perhaps patterns that highlight women’s perspectives or a particular country’s involvement in the war could be highlighted. Through normal searching and learning activities, a repository of search spaces, or knowledge structures could be built, maintained and modified simply by users searching the Internet for their own purposes.

Our Approach

We have developed a graphical user interface that applies visualization to Internet search results. Instead of lengthy lists of search results, the Visualization of Information Tool (VisIT) presents the user with a graphical, spatial representation of the search space where each Web site is represented and all of the hits returned are clustered within that site representation. Now the user can “see” the hits returned by the search engine and other pages at the site and, when any of the pages are clicked the appropriate page is displayed in the browser window (Figure 1.). Searchers query multiple search engines simultaneously to construct a search space and heuristic based rules augment search engine relevancy rankings. Upon placing the cursor over any page, a pop-up box appears with search engine comments (if any) and the first ‘n’ characters of text found on the page (Figure 2.). Users can scan text from the page in this manner and they can make a more informed decision as to which pages to explore further by clicking on them. This interface allows users too not only quickly scan hundred of hits at once but, numerous perceptual cues are added to convey more information as well. Arrows are drawn that show which pages in the search space are referencing other pages, the color intensity of pages indicate relevancy weighting, visited pages are marked to enhance navigation, etc.

Once information is found, we need to assimilate it into our existing knowledge structures and graphical representations can help with this process (West, Farmer et al. 1991). To facilitate, VisIT’s graphical displays can be saved, and re-opened later. Users can edit the search space by deleting sites, grouping sites, making annotations on pages, labeling sites and more. Background images can also be inserted allowing users to place information on a meaningful referent (Figure 3). In this manner users can begin to construct a “knowledge space” from their search space, one in which they have taken information from various sources and constructed meaningful external representation or cognitive artifacts (Norman 1991).

Conclusion

Soloway and his colleagues (Soloway, Norris et al. 2000) recently pointed out that some are arguing that computers have failed in education. He shows that the failure is not in computers ability to be an effective tool but, that the failure is in the implementation of computers (or lack of implementation). Now that schools are connected to the Internet, we will soon be hearing debates on its effectiveness as an educational resource. However, unless educators better equip themselves and their students to succeed in learning on the Internet they will fail. Teachers and students need better tools to search and learn from the Internet and the early indications are that VisIT may point to a promising new direction. VisIT will be demonstrated in this session and participants will be able to try out the software for themselves.

Influence of Home Access on Attitudes, Skills, and Level of Use for Teachers and Students in Technology Integrating Classrooms

University of North Texas
rhondac@tenet.edu

Abstract: The interaction of home access and school use of computers has been a topic of discussion among educational researchers for more than a decade. Evaluation of a U.S. Department of Education Technology Innovation Challenge Grant and a Preparing Tomorrow's Teachers to Use Technology Implementation Grant have given the authors an opportunity to address this issue within the context of large scale data sets gathered from several levels of formal education. This paper features findings related to the influence of home access to computers and the World Wide Web on the use of information technology in the classroom. Several positive and some negative indications are presented with respect to teachers, students, and technology at home and in school.

Procedures

Findings in this paper are based on self-reported survey data provided by teachers and students. Paper-based as well as on-line (html) data collection techniques were employed. Attitude and skill data were typically gathered using 5-point Likert type rating scales (strongly disagree = 1 to strongly agree = 5) or 7-point Semantic Differential items pairs (ex: Computers are: friendly unfriendly). Item responses were summed within categories producing reliable, content valid and construct valid measurement scales. Measurement properties of the Teachers' Attitudes Toward Computers Questionnaire (TAC), the Teachers' Attitudes Toward Information Technology Questionnaire (TAT), the Technology Proficiency Self-Assessment Questionnaire (TPSA), the Computer Attitude Questionnaire (CAQ), and the Young Children's Computer Inventory (YCCI) have been reported elsewhere (Knezek, Christensen, Miyashita, and Ropp, 2000).

Home Access to Information Technology for Teachers

Home computer access is associated with positive attitudes, skills, and levels of classroom use for teachers; home access to the Internet is even more strongly tied to positive indicators in these areas.

TAC, TAT, and TPSA data were gathered from 113 elementary and high school teachers in a public school district in Texas during spring 2001. Teachers who reported access to a computer at home had more positive (p < .05) ratings on 11 of 14 information technology indices gathered. Level of interest in information technology, as well as two measures of belief in the utility of electronic mail for classroom interactions, were not significantly impacted by whether or not a teacher had a computer at home. All 4 areas of assessed skill proficiency, including World Wide Web, using Integrated Applications, Teaching with Technology, and skill at using Email, were significantly higher for teachers who had computers at home. In addition, level of use for classroom integration, as measured by self-reported Stage of Adoption of Technology and self-reported Concerns Based Adoption Model Level of Use, was significantly higher for teachers with home access (Christensen and Knezek, 2001).

The analysis of the previous paragraph was repeated for teachers who reported having access to the Internet at home, versus those who did not. All conclusions were the same as those reported for computer access at home versus none, with the exception that the two measures of the belief in the utility of Email for classroom
interaction were both significantly more positive for those with Internet access vs. those without (p < .05). Teachers who had access to the Internet at home were more positive in their belief that Email was useful for classroom interactions. Teachers who only had access to a computer at home, but not access to the Internet at home, were not significantly different in this area from teachers who had neither computer nor Internet access at home (Christensen and Knezek, 2001).

In a third analysis, additional data gathered from 74 middle school teachers reconfirmed these findings for home computer and Internet access versus none, for attitudes and level of use (Christensen and Knezek, 2001). (Skill data was not acquired for these teachers.) It is hypothesized that teachers benefit from home access to a computer and the Internet because together these capabilities extend resources and access into a time and place outside the classroom, where teachers can take time to develop their own competence and confidence. It is also conjectured that if teachers use technology at home more often, then teachers will be more comfortable with technology in school.

**Home Access to Information Technology for Students**

Home access by students is associated with greater skill in using Email and the WWW; however, greater access to information technology at home may also be associated with lower empathy (caring concern for thoughts and feelings of others) in elementary and middle school students.

YCCI data were gathered from 1737 K-6 students during the fall of 1999 and spring of 2000 from the eight elementary schools in north Texas. Analyses of this data from several perspectives indicated that the general impact of technology integrating teachers over several months, across grades 1-6, appears to have been the greatest in the area of Attitudes Toward Computers on students without computers at home. This was evidenced by significant (p < .01) declines in student attitudes toward computers, from fall to spring, among those students without home access to computers who also had low integrating teachers in school (Knezek and Christensen, 2000). Students without computers at home who had high integrating teachers in school showed no significant decline.

In a CAQ/YCCI study involving 218 7-12 grade students from a middle school and high school in a Texas public school system during the spring of 2000, and 113 elementary plus 87 middle school students from the same school system during the spring of 2001, the students with computers at home were found to have lower empathy at the elementary school level (p < .02), and lower empathy (p < .09) as well as higher skills on Email and WWW at the middle school level (skills were not measured for elementary). An additional finding from the same study was that access at home did not appear to be strongly related to (self-reported) student access in school (f = .358, 1x85 df; p = .55) (Christensen and Knezek, 2001).

The finding regarding empathy is worrisome and worthy of further study. The finding regarding home vs. school access is good news in that it implies that schools provide equal access to computers for all students, regardless of whether or not they have access outside of school. Further research is needed to determine if the hypothesized directionality of home access fostering classroom integration is accurate, if desire for classroom integration fosters home access, or if some other phenomenon is responsible for both.

Abstract: The main goal of this paper is to examine how pre-service secondary mathematics teachers, in-service secondary mathematics teachers, mathematicians, and mathematics teacher educators communicated about a multimedia case study through computer mediated communication (CMC). Computer mediated discourse analysis (CMDA) (Herring, 2001) guided the data analysis phase of the investigation. The analysis revealed evidence of individual and group differences with respect to participation in CMC. For example, the average number of messages per day was 2.86 and the average number of words that the participants posted daily was 316.62. These values suggest that the participation rate was relatively high and that the computer-mediated discussion was active. The female participants presented their ideas briefly, and males wrote more. Males appeared to focus on more details, which is an interesting observation because traditionally it is believed that females focus on details more than males.

Introduction and Background Information

A survey of the literature indicates that educators possess a great interest in online environments for teaching. As yet, however, little systematic research is available that compares online communication with face-to-face communication in educational settings. Since Internet use has become widespread in teaching and learning contexts, it is essential to examine how computer mediated communication (CMC) influences human learning with respect to face-to-face communication. Key questions that need to be examined include, “Is CMC an effective tool in teaching and learning?”, “Does CMC affect equality of participation among individuals?” and “Does CMC, in as much as it provides more time for reflection, enhance the sophistication of language used in educational settings?”.

This paper illustrates some applications of Computer Mediated Communication (CMC) in a university-school collaboration project, the Collaboration for Enhancement of Mathematics Instruction (CEMI) project at Indiana University. The CEMI project aims to assist both pre-service and in-service teachers to develop their understanding of mathematics teaching and to create an effective collaboration between Indiana University and Monroe County Community School System of Bloomington, Indiana.
This research examines how four populations of people with a common interest in mathematics teaching and learning -- pre-service secondary mathematics teachers, in-service secondary mathematics teachers, mathematicians, and mathematics teacher educators -- communicate about a multimedia case study, Making Weighty Decisions (Bowers, Doerr, Masingila & McClain, 2000). Each of these populations can be characterized by their status in the mathematics education community because instructor-student relationships exist among them. For example, pre-service teachers are students of both mathematics educators and mathematicians. In addition, in-service teachers might be students of the university faculty. Thus, the participants' status will guide our descriptions of them. These people with varying status met both on-line and face-to-face to discuss the multimedia CD. In this paper, we report the on-line part of the CD discussions. Our goal is to examine how member of the four cultures communicate about the multimedia case study through CMC, making use of computer mediated discourse analysis (CMDA).

The purpose of the CEMI project is to engage members of the four cultures (in-service secondary mathematics teachers, in-service secondary mathematics teachers, university mathematicians and university mathematics educators) in Lesson Study Groups (LSGs) similar to those commonly found in Japan (Lewis & Tsuchida, 1998). Each LSG member was asked to view the multimedia case study CD and related materials individually and then to respond to on-line discussion prompts. Discussion prompts were designed to encourage participants to reflect on the teacher's role in planning for and facilitating classroom activities, the mathematical content of the lesson, and the level of student thinking throughout the lesson. The on-line discussion took place within the Inquiry Learning Forum (ILF) (http://ilf.crlt.indiana.edu) and proceeded for approximately five weeks.

Specifically, this study seeks to determine the following:

- What are diverse members of a professional community (in-service secondary mathematics teachers, in-service secondary mathematics teachers, university mathematicians and university mathematics educators) doing as they talk about mathematics teaching and learning?
- What role and power structures are influential among the participants?

Data Sources

Each of six Lesson Study Groups (LSGs) engaged in two online discussions. The first one lasted two weeks (from 09/11/2000 to 09/25/2000) and then members met face-to-face to reflect on the CD after that. Next, another three-week online discussion took place (from 09/25/2000 to 10/16/2000). Finally, a second face-to-face meeting provided an opportunity for the participants to share their ideas. In this study, we used the transcripts of on-line discussions of the multimedia case study by three LSG as data sources. It should be noted that since each LSG engaged in two online interactions, we analyze six sets of data, three of them are from the first discussion and the other three are from the second one. We selected the three LSGs among six of them randomly. Each of the three LSGs includes one teacher, one mathematics educator, one in-service teacher and three to four pre-service teacher. In addition, two of them include a mathematician. Totally, we analyzed postings of 18 people, 8 males and 10 females. However, two female pre-service teachers only engaged in the second discussion.

In this study, we analyzed regular e-mail messages posted on discussion lists, thus our data is typical form of asynchronous Computer Mediated Discourse (CMD) with one-way transmission (Herring, 2001). Herring characterizes e-mail based systems as asynchronous CMD forms because they do not require that the users be logged on at the same time. She also proposes that e-mail based systems are an example of one-way transmission in CMD because “a message is transmitted in its entirety as a single unit (p.615).”

Methods/Theoretical Approach

Computer mediated discourse analysis (CMDA) (Herring, 2001) guided the data analysis phase of the investigation. Specifically, we obtained descriptive statistics on participation by role and gender, and conducted pragmatic analysis of speech acts. We analyzed participation for each discussion for CMC. This involved counting the number of messages and number of words contributed by each participant as a means
of determining whether the project members participated in the discussions equally. In addition, we examine whether some groups dominated other groups.

We also used the exchange structure of Francis and Hunston (1992), originally developed by Sinclair and Coulthard (1975) for the analysis of classroom discourse, to analyze the transcripts of the discussions. Exchange structures are sequences of speech acts (agree, inquire, inform, react, etc.) produced when individuals are engaging in conversation. The model was developed for face-to-face conversation, but has been applied to educational CMC by Herring and Nix (1997). The goal of the present analysis is to understand what kind of speech acts takes place in CMC in discussing the multimedia CD. Additionally, we compared the speech act usage of groups within the groups.

Results

What follows are some examples of the results. Although we have many interesting results, we cannot report all of them due to space limitations.

Participation

Overall

Descriptive statistics reveal that 18 participants posted 106 messages during a five-week period. The participants posted more messages in discussion 1 than in discussion 2, although discussion 2 lasted one week longer. The moderator posted four messages prompting the discussions in discussion 1, but two messages in discussion 2. This might have the reason for fewer messages in the second discussion session.

As it can be seen from Figure 1, the average number of messages per individual for discussion 1 and discussion 2 is 3.81 and 2.50, respectively. Interestingly, in discussion 1, the average number of messages per mathematician (5.00 messages) is significantly higher than the average number for the entire population in discussion 1 (3.81 messages). Because the mathematics educators posted only two messages during the first discussion (average = .67 messages), the average number of messages in that discussion session was decreased.

Figure 1: Average number of messages

![Figure 1: Average number of messages](image)

Figure 2 indicates that the average number of messages per day is 2.86 and the average number of words that the participants posted daily is 316.62. These values suggest that the participation rate is relatively high. The participation rate is considerably high for discussion 1 (4.07 messages). In discussion 1, the participants were asked to respond to clear-cut questions. In other words, they were not open-ended; however, in discussion 2, the moderator asked open-ended questions so that the participants could post all their comments and critiques. It seems that open-ended questions might have decreased the rate of
participation in the second discussion although it lasted three weeks.

Figure 2: Rate of participation

In addition, the average message length is 110.52 words, indicating that the participants posted long messages. Since the participants are highly educated people, this finding seems reasonable. Finally, the statistics indicate that the computer-mediated discussion was active. The participants also posted almost equal size of messages both in discussion 1 (109.34) and discussion 2 (112.11). The average values are almost the same for discussion 1 and discussion 2. Previously, it was revealed that the participants posted more messages in discussion 1 than in discussion 2. However, now it is found that although they did not post the same number of messages in the discussions, the size of the messages are similar. This is not surprising because the same individuals posted all the messages.

Group Differences

The data show that 10 females posted 52 messages and 8 males posted 54 messages. In other words, the average number of messages posted by males (6.75 messages) was higher than the average number of messages posted by the females (5.2 messages). It may mean that males expressed themselves more than females. In addition, the average length of messages posted by males was 118.06 which was larger than 102.69 of females. This finding suggests that females presented their ideas briefly, but males wrote more.

Also, there were significant differences among the cultural groups participating in this study. For example, the average message length was 100.25 words for pre-service teachers; however, this value was 126.13 words for mathematicians and 154.69 words for mathematics educators. These findings seem meaningful because pre-service teachers may know less about teaching than mathematicians and mathematics educators.

Speech Acts

Overall

Overall, the participants were engaged in 678 speech acts throughout the online discussions. The speech act analyses indicate that generally the participants are informing each other, sharing their observations, inquiring and commenting on their own statements as they discuss the multimedia case study. These results are consistent with the findings of Herring and Nix (1997) for a distance education course. However, unlike in Herring and Nix's study, the participants use very few directive speech acts, suggesting a relatively polite and egalitarian environment.

Group Differences
It was revealed that females asked more open-ended questions (14) than males (8 questions; inquiry). Possibly females wanted to learn the details of the multimedia case study more than males. Another striking result is that pre-service teachers asked more questions than any other status group (13 open-ended questions out of 22). Although asking questions can be considered as the symbol of power, the group with the least power asked more questions. On-line communication might have resulted in this finding. The pre-service teachers might have felt more comfortable. Thus the traditional roles of teacher-student were not preserved in the computer-mediated environment.

It was revealed that males share their observations (45 times) more than females (31 times), while females asked more open-ended questions. Pre-service teachers shared their observations mostly (47 out 76 times). This may be because as students they regularly prepare assignments including reflections, descriptions and observations.

Conclusions/Implications

The basic goal of this study was to examine how pre-service secondary mathematics teachers, in-service secondary mathematics teachers, mathematicians, and mathematics teacher educators communicated about a multimedia case study through CMC, making use of computer mediated discourse analysis (CMDA). CMDA helps us understand teacher education phenomena better. The analysis reveals empirical evidence of individual and group differences with respect to participation in CMC. Revealing such differences can help teacher educators and instructional designers build online communities in teacher education settings. Participation statistics also provide evidence that helps us to understand power dynamics within the online community. In this study, power structures are potentially always an issue because instructors and students share the same context. Since teachers have more authority than students, in our research we expected to see teacher educators and teachers participate more. We also observed that members of different groups used some speech acts more than others, indicating that participants have diverse intentions.

As an extension of this study, we will analyze the face-to-face discussions of the same multimedia case study by the same people. Therefore, we will be able to compare and contrast both modes of communication. That study will improve our understanding of online professional development of teachers. In particular, we may uncover some strengths and benefits of CMC over face-to-face communication.

The renewal of teacher education through networked learning communities: Evolutionary or revolutionary?

Thérèse Laferrière, Laval University, Canada, tlaf@fse.ulaval.ca
Alain Breuleux, McGill University, Canada, Breuleux@Education.McGill.ca

Abstract: The paper considers the framework within which information and communication technologies (ICTs) integration can support teacher education renewal through collaborative learning. Adopting a socio-constructivist approach and a design-experiment methodology, our research team experimented in different contexts, and presents results pertaining to networked learning communities. The identification of themes and patterns in the activity of these learning communities lead to a discussion of ways of renewing teacher education by integrating ICTs in a way which supports collaborative teaching and learning.

Introduction

For the past seven years, co-authors have integrated information and communication technologies (ICTs) in their teaching and research. Judicious use of ICTs in order to further the understanding of ideas, practices, and concepts as well as pedagogical principles and notions has captured their imagination. With other colleagues, they set in 1995 to design a virtual community of support and communication for pre-service teachers as the first phase of a TeleLearning Professional Development School (TL-PDS). Moved by the vision of interconnected learning communities, each site contributed through an already successful innovation with regard to teacher education.

At the University of British Columbia/Vancouver site, a community of inquiry was an alternative route provided to interested students registered to the post-baccalaureate teacher education program. In Toronto, the CSILE Team was developing the next generation of its computer-supported intentional learning environments. At the McGill University/Montreal site, summer institutes attended by in-service teachers were already focusing on new learning technologies. And at the Laval University/Quebec City site, a network of professional development schools (PDSs), called Le réseau des écoles associées à l'Université Laval was already in place.

Working from their own locus of strength, each site soon began to design new learning practices supported by ICTs for their own communities (pre-service and/or in-service teachers interested in making sense of ICTs for teaching and learning). At first, six design principles revealed to be critically important: ease of access to ICTs, co-constitutionality, participatory design, local grounding, multi-modal social interactions, and diversity. Other design principles apply more directly to the socio-constructivist approach adopted: the classroom as-a-community of learners, active collaborative learning, progressive distributed expertise, collaborative reflective teaching, collaborative knowledge building, and interrelatedness.

[1] This work was done with the support of the TeleLearning Network of Centres of Excellence, Canada.
[2] Brief definitions of these principles are the following: Ease of access: Networked computers and online resources and tools need to be accessible without loosing too much time once basic technical skills are mastered. Co-constitutionality: The development of a socio-technical infrastructure relies on electronic connectivity on the one hand, and on people who value collaborative learning and knowledge on the other; one is not significant without the other. Participatory design: The development of networking capacity involves university-school administrators (partnerships), university- and school-based teacher educators, in-service/pre-service teachers, and K-12 learners. Local grounding: Site-based professional learning communities provide grounding. Multi-modal social interactions: At a local level, learners meet face-to-face, on campus or at the professional development school. Diversity: Learning communities are different in their local champions, circumstances, settings, tools, artefacts, cultures, and languages (in particular English and French).
[3] The socio-constructivist principles applied are briefly defined as follows. The classroom as-a-community of learners: K-12 learners as well as pre- and in-service teachers are learning in networked classrooms designed to become centers of inquiry where people, things, and ideas are valued, and where teaching for understanding is a common goal. Active collaborative learning: The networked classroom fosters active collaborative learning rather than individual learning. Progressive distributed expertise: Teacher knowledge, which is distributed among and far beyond individual participants, may be accessed; virtual collaborative spaces provide opportunities to share resources and expertise to solve complex and ill-structured problems. Collaborative reflective teaching: The design task is that of providing a collaborative learning environment within which problem-setting and problem-solving are carried out in relation to real classroom events.
The latter principles are of a transformational nature, and the driving idea is that knowledge of technology in education is a key driver and a key enabler. This paper tackles the complexity that hides behind the following simple statement: a visible and durable change in teacher education is not an easy task, and is particularly delicate with regards to innovative pedagogical practices by means of technology. Periodical analysis such as the ones by Cuban (2000) demonstrate it. Zhao, Byers, Pugh, & Sheldon (2001) suggested to take the "evolutionary rather than a revolutionary approach to change" with respect to school teachers. We argue that this path needs not only to be taken with school teachers but also to the ones expected to be the providers, namely teacher educators. The networked learning communities our R & D Team has been designing brings evidence to this end.

**Method**

Applying the innovation model developed by Zhao et al. (2001), themes and patterns already identified in the analysis of the design and development of networked learning communities (Laferrière, Breuleux, Erickson, and Iamon, in progress) are reflected upon. Those themes and patterns regard the technical and conceptual appropriation of the technical tools by the learning communities. They emerged from qualitative analysis (design experiment approach, Brown, 1992) of the data accumulated over a sixth-year period, and gathered through participant observers’ notes, interviews, discussion forums, and other artifacts produced by these communities.

**Findings**

The networked learning communities may have been first initiated for pre- or in-service teachers, they came to all include pre-service teachers, in-service teachers, graduate students, and teacher educators. In most instances, school learners were all considered members of the learning communities.

The following themes and patterns were identified as benchmarks of progress regarding the technical and conceptual appropriation of ICTs by the learning communities:

1. *the screen is no longer the screen.* The importance attached to social interaction is rediscovered and the networked computer is no longer perceived by the practicing or future teacher as a tool which isolates its user (pupil or student) but as a tool which supports classroom interaction perhaps beyond the limits of normal timeframes;

2. *technical support is provided by many learners.* In spite of its status or of the status of the individual who is using it, technical support is favorably welcomed by the learner who does not hesitate, in turn, to act in such a way in relation to other learners;

3. *ties, which begin to bind, people, texts and ideas.* These ties transcend time and space within all described communities. Participants were able to become involved in forms of collaborative inquiry by building from available resources and by exchanging their ideas. These opinions were subject to critical review and were considered and qualified by other students and by instructors. According to this perspective, teacher candidates as well as in-service teachers were able to put forth their contribution in relation to the subscribed and developed ideas. This experience had the effect of modifying the pedagogical relationships within the classroom. The experience also created new pedagogical relationships outside of the class. This also allowed for an increase in face to face dialogues between participants;

Collaborative knowledge building: This refers to the design of a rich learning context within which meaning can be negotiated and ways of understanding can emerge and evolve. Student teachers engage in designing and inventing tasks such as the organization of the networked classroom, the development of learning projects, the scaffolding of online group or classroom conversations, and the creation of case studies. Interrelatedness: Knowledge objects, events, actors, artefacts, and authors interconnect in ways that add continuity and integration to student teachers’ experience as they learn to teach in networked classrooms. They add as well to the experience of practitioners working in networked classrooms.
4. the level of understanding of a question or problem of one person becomes an inscription available to someone else for reactivation. The support which must be provided is facilitated by the fact that thought becomes visible in the electronic forum and from the fact that peers contribute; the difficulties experienced by some having recourse, half-way through and in a generalized way, to theoretical perspectives likely to enlighten their reflective practice, become evident in their own eyes, as well as their progress in relation to this undertaking;

5. roles are exercised in a dynamic manner. By inverting the roles of teacher and student in an authentic way (for example, the documents prepared by more advanced student teachers are consulted by the new pre-service teachers in a learning community; the number of readers consulting the work of teacher candidates is widened; teaching notes are written by elementary school learners), participants contribute to the collective knowledge on a given theme or problem;

6. the act of writing is part of the research process. There exists an undeniable potential for immediate feedback. And the continuity of the exercise offers an anchor point for continued reflection. Students who wrote not only for their peers but also for other agents in the field as well as for researchers became initiated into a language used within academic and professional communities. They also positioned themselves by recognizing authority and expertise in the subject matter through the building of community's discourse;

7. the number of readers and authors is increasing. This increase in the number of readers consulting the work of pre-service teachers can make the writings more reflective. That is to say that students' work is not simply a transfer of knowledge to be read by the professor.

These seven themes and patterns capture what participants' in the learning communities have been doing in an increasingly visible manner. The model put forward by Zhao et al. identifies three interactive domains: the innovator, the innovation, and the context. In the case presented, the innovator is a domain extended to all the participants of a specific learning community; the innovation is the learning community, and the context is the faculty of education and partner schools (PDSs).

The innovator' technology proficiency is the first factor identify by Zhao and colleagues that leads to the success of an innovation. Theme 1, the screen is no longer the screen and theme 2, technical support is provided by many learners. They point out that knowledge of the technology and its enabling conditions plays a major role, and this is also true for the learning communities as the above themes evidence. The second factor Zhao et al. stressed is compatibility between teacher pedagogical beliefs and the technology. In the design experiment, the research team defined telelearning as the use of ICTs for learning purposes. This reflected a belief in socio-constructivism and collaborative learning. Therefore, electronic forums became, besides the Web browser and search engines, software applications of choice. Theme 3, ties, which begin to bind, people, texts and ideas, reflects this pedagogical choice. Pre- and in-service teachers as well as teacher educators uncovered together the possibilities of electronic forums for collaborative inquiry. Social awareness is the third and last factor related to the innovator that Zhao et al. identify. They meant the understanding of and ability to negotiate the social aspects of the school culture. In the design experiment, the on-line activity was challenging at times for student teachers that happened to be doing their student practicum in a more traditional classroom (see themes 1, 3 and 5). At other times, it was challenging to school-based or university-based teacher educators who were not ready to make their own thinking visible in the discussion forum (see theme 4). As innovators, participants in the learning communities had to be thoughtful of the values and beliefs of those "of-line" with whom they were pursuing some professional activities.

The three factors that Zhao et al. point to regarding the innovation itself are the following: the project's distance from school culture, the project's distance from available resources, and the project's distance from innovator's current practices. Here again, these three factors bear some relevance in order to describe the learning communities' activity. Distance from school culture was reduced at all universities by the very fact that the learning communities grew out of already existing successful innovations at each site. Distance from available resources has become less and less a difficulty for pre- and in-service teachers. Except in a few cases, this difficulty has now been overcome. As for distance from existing practice, the reality is that, on a daily
basis, old and new pedagogical practices coexist. And each time there is an incoming cohort of new members, they vividly feel the distance from their existing learning or teaching practices. Overall, by reflecting the transformational nature of the activity of the learning communities, the seven themes also reflect the distance of their doings from traditional teacher education.

The last three factors identified by Zhao and her colleagues relate to the context: the human infrastructure, the technological infrastructure and social support. One of the TL-PDS design principles is co-constitutionality, meaning the development of a socio-technical infrastructure relies on electronic connectivity on the one hand, and on people who value collaborative learning and knowledge on the other. Themes 3-7 reflect the social dimension of the infrastructure created, whereas themes 1 and 2 reflect its technological dimension. Social support was provided on campus from the dean’s office, a few close colleagues, and colleagues from other sites also receiving a federal telelearning grant from the Network of Centres of Excellence Program.

Discussion

Throughout the past six years, the three dimensions of the model here applied interacted with one another in an evolutionary manner. Their respective boundaries were redefined a number of times. For instance, at the very beginning, the innovators were the teacher educators/researchers at each of the sites. As partnerships with schools got established, the number of innovators expanded. To become a member in a network-enabled learning community (pre-service or in-service teacher or teacher educator) meant being an innovator among his or her peers or colleagues, and having to be tactful with regard to how to present one’s doings and the doings of the learning community in a professional context where teachers or teacher candidates were less familiar with the use of ICTs. One of the design principles being interrelatedness, continuity and integration efforts have been supported by websites which included the artifacts of more advanced participants and of whole cohorts of pre- or in-service teachers. As a learning community grows along the vision of interconnected learning communities, the network of learning communities becomes a new social context in and of itself, one capable of virtually creating a “critical mass” of a particular innovation. Whereas before the innovation, that is, the learning community, would have been isolated in a given context, a new context emerges out of the synchronous and asynchronous interaction of learning communities.

Zhao and her colleagues studied individual innovators. In the design experiment, teacher educators/researchers took a community approach. Therefore, much interaction within and between the three dimensions has been observable: there are many innovators or participants invited to become more innovative in their learning and teaching; there are learning communities in which the old and the new cohabitate; and there are contexts (schools and faculties of education) whose organizational culture is evolving as it becomes increasingly aware of ICTs’ potential for teaching and learning.

This new ecology may seem to be a progress, but it should not distract innovative teachers and teacher educators from the sustainability and scalability issues now well pointed out in the research literature (Blumenfeld, Fishman, Kracjik, & Marx, 2000). The majority of teachers and teacher educators still lack the technology proficiency (the screen is still a screen) necessary in order to reconcile their views of learning online and learning face-to-face, learning alone and learning together.

Conclusion

Networked learning communities are a framework within which ICT integration to curriculum is most likely to support teacher education renewal through collaborative learning and knowledge building. It is a framework well-aligned on the new theory of learning (Bransford, Brown, & Cocking). Moreover, it is an approach with which we, as teacher educators, came to make sense of ICT in our teaching and learning, and one that is speaking to other teachers interested in the renewal of their teaching as we collectively engage in the knowledge age.

The idea of replacing one or many pre-service teacher education courses by creating networked learning communities, ones also inclusive of beginning teachers and competent teachers and researchers interested in deepening their understanding of driving questions is likely to sound revolutionary to many school-based and university-based teacher educators (Laferrière, Bracewell, Breuleux, Erickson, Lamon, & Owston, 2001). We know, in fact, that for such an idea to grow, a slow evolutionary process is likely to take place.

Effectiveness of Statistical Training with Computer Simulation

Abstract: The effectiveness of computer simulation in statistical training was investigated in two experiments. In the first experiment, subjects learned the Law of Large Numbers either by watching a computer simulation or by reading a textbook chapter. Prior to the training, subjects were presented with either specific or non-specific content-related questions. Post-training test showed that simulation-based training significantly increased the quality of subjects' reasoning on real-world problems. Question specificity had only a marginal effect on the performance. In the second experiment, the effects of simulation- and textbook-based training were measured immediately after the training as well as after a one-week delay. After the one-week period, subjects trained with simulation not only outperformed those trained with textbook on both a knowledge test and a transfer test, they also benefited motivationally. These findings provide empirical evidence in support of the use of advanced computer technology in educational settings.

With the rapid development of information technology, educators now have at their disposal a great variety of technological applications as instructional tools. The area of statistical education is no exception. In recent years, a substantial amount of resources has been invested in the development of computer simulation programs illustrating various statistical concepts and principles. As a result, statistical simulations are now widely available through the Internet and have become an integral part of statistics curricular at various educational levels.

The increasingly important role that computer simulation has played in training demands an equal amount of effort to assess the effectiveness of these programs. Research on the merits of computer simulation in science education has been conducted in a variety of subject domains, including biology, physics and economics, but the results from different studies often lack consistency. The potential of computer simulation in statistical education has also been investigated in a number of studies, again with mixed outcomes. For example, Wackerly and Lang (1996) found that students learned better with computer simulations compared to those using more traditional materials. delMas, Garfield, and Chance (1999) reported using a computer simulation program to illustrate sampling distribution in a classroom setting. They found that the graphical display of the simulation could aid learning but was most effective under certain conditions, such as being paired with a strategy that directed students' attention to certain features in the simulation. Simply going through the simulation process did not necessarily result in conceptual changes. These researchers therefore concluded that computer simulations alone do not guarantee superior learning.

Statistical training has often been considered as being abstract and difficult to understand. As many have observed, too often students develop only a shallow and isolated understanding of important concepts and fail to apply these concepts in their reasoning. In view of current state of practice, there is a great necessity to search for better ways to facilitate the learning process in statistical education. The current study sought to evaluate the effectiveness of a sampling distribution simulation program developed by Lane (1999). Specifically, we expected that the dynamic, graphical presentation of information is more congruent with the essence of the training subject than a traditional textbook-based approach, thus could facilitate students' learning.
and transfer (see Lane and Tang 2000 for a more comprehensive description of the study.)

Experiment 1

Method

The experiment used a 2 x 2 factorial design. The first factor was the content delivery medium used in the training. Subjects learned the concept of sampling distribution and the Law of Large Numbers either by watching a computer simulation demonstration adapted from the Rice Virtual Lab in Statistics (Lane, 1999), or by reading a textbook chapter. The chapter was largely text but included examples, graphics, mathematical formula and a table detailing a hypothetical sampling distribution as well. Prior to the training, subjects read two real-world scenarios that pitted a smaller sample against a larger sample. Each scenario came with questions regarding the sampling outcome as a result of different sample size. The questions were either specific or non-specific. In the specific condition, subjects were asked which sample size would lead to a particular outcome. In the non-specific condition, subjects were simply asked what would happen. Question specificity constituted the second factor of the design. In addition to the above four conditions, a no-treatment group was also employed as control.

One hundred and thirteen Rice University undergraduate students who had no formal statistical training participated in this experiment in exchange for extra credit in a psychology course. Subjects were trained and tested in small groups of 4 to 12 people, and their assignment to experimental conditions was randomly determined. In the experiment, subjects first took a 12-minute paper-and-pencil Wonderlic Personnel Test (as a measure of general cognitive ability). Then the four treatment groups were presented with the two real-world scenarios, and went through a specific training session depending on their condition. Each training session lasted between 25 to 30 minutes. At the end of the training, subjects in all the four treatment groups were given explanations as to how to apply the training to the previous two examples to reach the correct answers. They then took the post-training test. Procedure for the control group was slightly different. Subjects in this condition took the second test without going through the training.

The post-training test was designed to measure how well subjects could transfer the training to novel situations. The test consisted of 12 real-world scenarios embedded in contexts very different from those encountered during the training. Among them, nine problems could be solved by applying the Law the Large Numbers and thus constituted the critical items in data analysis. The remaining three problems served as filler items. Subjects' reasoning on each transfer question was rated on a 3-point scale, where 1 indicates an entirely deterministic response, 2 a poor statistical response, and 3 a good statistical response. Two coders, blind to subjects' condition, each coded the responses from a random sample of 18 (16% of all) booklets separately, and agreed on 83% of the answers. This inter-rater consistency was accepted and one of the two coders then continued to code the rest of responses.

Results

A statistical reasoning score was derived for each subject by averaging across the nine critical transfer problems. The average reasoning score from all the subjects were then analyzed using the Analysis of Covariance (ANCOVA) procedure, with subjects' Wonderlic test scores as the covariate. Figure 1 shows the boxplots of the mean reasoning scores as a function of experimental condition. As can be seen in Fig. 1, both simulation-based training groups scored higher than the two textbook-based groups. The difference was statistically significant, $F(1, 107) = 5.64, p = .019$. Groups that were presented with specific questions prior to the training did slightly better than groups presented with non-specific questions. However, this effect only reached marginal significance, $F(1, 107) = 3.75, p = .055$. The interaction between training medium and question specificity was not significant, $F(1, 107) = 1.94, p = .167$. The boxplots also show that all the treatment groups performed better than the control group. The difference between the control and the average of the four treatment groups was significant, $F(1, 107) = 20.96, p < .0001$. Dunnett's test further showed that three of the four treatment groups significantly outperformed the control group ($p < .05$), with the textbook/non-specific question group being the only exception.
The results from experiment 1 showed that simulation-based training led to improved statistical reasoning on ill-defined everyday problems as compared to a traditional textbook-based approach. However, because the post-training test took place immediately after the training, it remained unclear whether this advantage would last over time. Therefore, a second experiment was designed to address this issue.

Experiment 2

Method

A 2 X 2 factorial design was employed. The first factor was the content delivery medium in the training (simulation-based vs. Textbook-based). The second factor was the timing of post-training test. Half of the subjects in each medium condition were tested immediately after the training, and the other half were tested after a one-week delay. A 5th group took the transfer test without receiving the training and thus served as the control.

Training materials for both simulation- and textbook-based groups were the same as in Experiment 1. Testing materials in the current experiment included two sets of questions. The first was a knowledge test consisting of 10 multiple-choice questions. All the questions as well as their respective alternates were phrased in statistical terms. The second set was a transfer test that consisted of 10 real-world scenarios from the first experiment. Seven of the 10 items are the critical items that required applying the Law of Large Numbers in reasoning. The remaining three were filler items. After the training groups took the post-training test, they filled out a questionnaire measuring their attitudes towards the training. The questionnaire contained 11 items and was centered on subjects' self-evaluation of their test performance as well as their judgment about a particular training method. Subjects' responses were based on 5-point Likert scales.

One hundred and three Rice University undergraduate students with no previous statistical background participated in this experiment. The experimental procedure and coding system for the transfer questions were the same as in Experiment 1.

Results

Subjects' accuracy on the multiple-choice test is shown in Figure 2 as a function of training condition. The data was analyzed using the ANCOVA procedure, with Training Medium (2) and Delay (2) as between-subject factors and Wonderlic scores as the covariate. As can be seen in Fig. 2, subjects trained with simulation were more accurate in this knowledge test than those trained with the textbook. However, the difference between the two medium types did not reach significance, $F(1, 79) = 2.35, p = .130$. Though subjects' performance became slightly less accurate after the one-week delay, the difference, however, was not significant, $F(1, 79) = 0.48, p = .492$. There was also no evidence of interaction between training medium and delay, $F(1, 79) = 0.14, p = .706$. 

![Figure 1. Statistical reasoning score as a function of experimental condition (Small bars on boxplots depict group mean ± one standard error)
Subjects' statistical reasoning score on the transfer test is presented in Figure 3 as a function of experimental condition. A comparison between the training groups and the control group revealed that, overall, training significantly increased the training groups' statistical reasoning on these transfer questions, $F(1, 97) = 7.57, p = .007$. Consistent with the finding of experiment 1, subjects trained with simulation scored higher than those trained with textbook, $F(1, 97) = 3.20, p = .038$ (one-tailed). Subjects' reasoning scores were essentially the same on the immediate and the delayed test. Neither the effect of delay nor the Training Medium by Delay interaction approached significance, $F(1, 97) = .00, p = .994; F(1, 97) = .02, p = .894$, respectively.

Subjects' responses to the survey items showed that their self-perceived effectiveness of a training method did not differ much as a function of experimental condition. However, training medium did have a large impact on subjects' motivation. As shown in Fig. 4, subjects trained with simulation gave significantly higher rating on the motivation scale than those trained with textbook, $F(1, 80) = 22.76, p < .0001$. Although the difference was more evident after the one-week delay, the Training Medium by Delay interaction was not significant, $F(1, 80) = 2.10, p = .151$. The main effect of delay was also not significant, $F(1, 80) = 0.01, p = .916$.

Discussion

The current research provides robust evidence regarding the effectiveness of computer simulation in statistical training. The training content in this study, the Law of Large Numbers, was considered an important yet complicated topic. Bassok and Holyoak (1989) have shown that college students had great difficulty transferring this rule across problem domains. In another study, Nisbett, Fong, Lehman, and Cheng (1988) found that their subjects were able to transfer this principle to new domains immediately following training but not after a two-week delay. In the current study, after going through a 30-minute training session, subjects trained with simulation were more able to identify the key elements of ill-defined everyday problems from a statistical perspective and apply the principle thereafter than subjects trained with a textbook. The benefit of simulation over textbook was manifest immediately after training as well as after a one-week delay. Therefore, the current result suggests that simulation-based training could result in better learning of statistical concepts and further lead to reliable transfer in complex reasoning tasks.

In statistical training, students' motivation often contributes substantially to the learning outcome (Gal & Ginsburg, 1994). Anecdotes had it that students in the classroom are more intrigued by computer simulations than traditional lectures. This idea was put to test in the current study. Although subjects trained with either simulation or textbook rated both training methods as being equally effective, those in the simulation condition consistently gave more favorable opinions when the questions tapped into motivational aspects, such as ease of learning and personal preference. The result thus provides evidence regarding the motivational benefit that students gain from simulation-based training.

The current study emphasized dynamic visual presentation of information in simulation-based training. While visual elaboration is one important characteristic of computer simulation, it is by no means all that simulation has to offer. Many researchers argue that a simulation-based environment is most effective when students are allowed to explore and reach the underlying model on their own. Therefore, user interaction in simulation-based training warrants further research.

On Educating the Future Generation: Rethinking the Role of Teachers in the Technological Era of the New Century

Nan Li
School of Education
Indiana University of Pennsylvania
United States
li_nan1998@yahoo.com

Abstract: This paper discusses the role of teachers from three aspects. First, it posits that we are living at a final stage of the printing-based culture. All teachers must maintain a new worldview that the change is cultural—as what machinery in the Industrial Revolution had transformed our world—it will be changed dramatically by computer technologies. So will be school learning. Second, it proposes that teachers must adapt themselves to meet the new technological environments. Third, teachers need necessary and timely support to sustain their willingness so that the change and readjustment can proceed smoothly.

Decker Walker (1999) explains, “Future generations will value the ability to use information technology as highly as we value the abilities to read and write today” (p. 9). With the advancement of computer technologies into our lives, work, and everywhere today, one of educational debates is no longer whether schools need to use technology, but how and when to use it effectively. In future education, it would become impossible without computers for teachers to offer enriched learning opportunities. When educating children in a technology-oriented environment, teachers must rethink their role.

When looking around us, we must admit that technology is a most remarkable thing that differs our world—yesterday's from today's and today's from tomorrow's. Taking the Internet as an example, we can see how technology has affected the world. As an outgrowth of the Cold War known as ARPANET for military purposes during the 1960s, the Internet navigation was first released to the public in 1991 (Provenzo, Brett, & McCloskey, 1999). However, within a few years, it has spread amazingly wide. Today, more than 60% of American households with children have computers with Internet access (“Know Future,” 2001). A survey by the National Center for Educational Statistics also reported that 95% of US public schools had access to the Internet by 1999.

The computer has become an icon of our times and is endowing our society with a new definition—the technological era or the information age. Let’s think about the Industrial Revolution of the 18th century, which transformed many Western countries from a rural to an industrial economy. Yet, at the core of this revolution was technology such as the steam engine that had functioned centrally. The automobile is another example on how technology has shaped our cities and lives today from those of 100 years ago. Should the way we shop, where we work and live be different had we no automobile today? As Provenzo, Brett, & McCloskey (1999) stated, profound social and cultural changes took place as a result of the introduction of new technologies. We are now living at a final stage of the printing-based culture and the computer technology has affected a crucial change in our culture.

Facing this cultural change, teachers must readjust their role. In a traditional paradigm, teachers serve as the role of the transmissive tool of knowledge (Hunt, 1997). Under most circumstances, when people are comfortable with what they’re used to, the change would be reluctant since people are more likely to use familiar and trusted tools. However, those trusted tools are inadequate for preparing the school children safely into the digital world. As the cross-century ambassadors for better education, teachers must acquire the new ability to use technology to meet children’s needs. In some way, teachers need to take a learner’s role to obtain technology skills for instructional use.

In recent years, the computer use in school has been increasing rapidly. A report from the U.S. Department of Education revealed that there were approximately 8.6 million instructional computers in schools throughout the United States in 1998 and an estimated 4 million dollars was spent on educational technology and the Federal Communications Commission also set up a 2.25 billion dollar annual fund to
assist school libraries with funding for Internet connections. However, the same report also found that mere 20% of teachers felt they were well prepared to utilize technology in their classrooms. This means that the large masses of machines and technological access in fact did not help much to construct quality instruction for teachers in classrooms.

The reasons are many. Yet, the two obvious ones are teachers’ fear and inappropriate institutional support. The computer is undoubtedly a powerful tool that can help achieve many instructional goals. However, the machine is valuable only when human intelligence organizes its use productively and if teachers do not know what to make of the tool, fear it, or misconstrue its use, it will only be used badly. A critical fact is that many middle-aged teachers over forty didn’t learn to use computers while at college and they are now the mainstay in the teaching force. We can understand that it could be a fearful feeling for adults to look a fool and it thus is easy for teachers to feel uncomfortable with the machine, especially when the badly needed support is missing.

In most situations, teachers are willing to learn to use new technologies for their professional and curriculum activities. But a lack of teacher-development program and time dedicated to experimentation can hinder teachers’ technology skills and knowledge (Schrum, 1999). Some ongoing programs, for example, are only intended to provide teachers with a brief exposure of training and practice to incorporate technology into classrooms, which is insufficient. Gaining technology skills differs from learning a new teaching model and it needs time. While urging for teachers to readjust their roles under the impact of the technology change, we must understand that they need necessary institutional support to sustain their willingness so that the readjustment can proceed smoothly.

Providing a staff development program must be based on specific needs. The training program is only effective when it can give teachers opportunities to apply their new skills. It’s not only timesaving but also easy for teachers to accept the new approach at the site when a problem occurs. Among various means to make technology-oriented professional development successful, Schrum (1999) proposes several methods. To make teachers feel comfortable, the researcher suggests that training programs be provided in a classroom setting where teachers know it will work. A cognitive apprenticeship model of teachers helping teachers is also an effective way, in which schools and districts can build up a long-term support relationship by providing trainings such as specific focused workshops followed by time spent observing and working with a colleague educator comfortable using technology.

Under the impact of the cultural change, infusing technology into the curriculum is indispensable. Teachers must recognize the magnitude of the change in order to adapt willingly. It is a trustworthy experience for any major changes to be successful that there must be a focus on the people first and the innovation second. In adapting the change, we also need to understand that institutional support must be closely followed. It is crucial for teachers, especially in the toddler stage, to meet success in their initial forays into the realm of the digital world (Scoulis, 1999). When teachers feel supported, safe, and know where to go for help, their willingness will sustain and the process of the role readjustment can become smooth, the efforts effective, and the outcomes fruitful.

The Role of Intelligent Tutoring Systems in Education: An Overview of AutoTutor

Abstract: Intelligent Tutoring Systems have become more common in education nowadays. AutoTutor is one such system. It uses a world knowledge representation, natural language processing, production scripts and a conversational interface. By assisting students in actively constructing knowledge, AutoTutor shows close to natural didactic and conversational skills. Not only is the system beneficial for both students and teachers, it also helps to test hypotheses in various interdisciplinary fields and generates various new research questions, thus playing an important role in education.

Intelligent Tutoring Systems use intelligent computer-assisted instruction (Graesser et al., in press). They communicate with the learner by keeping a record of what knowledge the learner has and what the system needs to teach. Tutorial strategies applied by the system bridge the gap between the learner's knowledge and the expert knowledge. Over the last few years various systems have been proposed and implemented. One such system is AutoTutor.

AutoTutor assists students in actively constructing knowledge by holding a conversation in natural language. A dialog manager coordinates the conversation that occurs between the system and the student. The manager analyzes the input at a linguistic and a discourse level, in order to determine the right tutoring strategy and responds by using synthesized speech, facial expressions and some rudimentary gestures. At least four components can be distinguished in the system (Graesser et al. 1999).

1. **World knowledge representation**: Understanding natural language requires world knowledge. AutoTutor uses a statistical representation of a large body of world knowledge, called Latent Semantic Analysis. It uses singular value decomposition to reduce a co-occurrence matrix of words (or documents) to a cosine between two vectors. AutoTutor uses LSA to give meaning to a student answer and to match that answer to ideal good and bad answers.

2. **Natural language processing**: Although semantics forms the backbone of language understanding, support is needed from other linguistic information like syntax and pragmatics. AutoTutor uses a dialog management system guiding the student through the exchange and accommodating any student input. Fuzzy production rules and a Dialog Advancer Network form the basis of these conversational strategies. A syntactic parser analyzes the input, translates it in a speech act, in order to predict the structure of AutoTutor's response. In addition discourse markers and dialog history are used to provide the student with a natural conversation. These various components allow for a mixed initiative dialog.

3. **Production scripts**: For its didactic skills AutoTutor uses curriculum scripts, loosely ordered sets of skills, concepts, example problems, and question-answer units. Like most human tutors these scripts follow a macrostructural organization of the tutorial. This allows the tutor to keep track of the topic coverage and follow up on any problems the student might have.
4. **Conversational interface:** Although there is no concluding evidence that a talking head has didactic benefits, there is evidence that students prefer interacting with a human-like tutor instead of text. Since AutoTutor accentuates both conversational skills in addition to didactic skills, it uses a talking head with facial expressions and synthesized speech. Parameters of the facial expressions are generated by fuzzy production rules.

Initially AutoTutor was developed for computer literacy. Evaluations of AutoTutor, using the system as a tutor in a computer literacy course, showed gains in learning and memory compared to control conditions. These results are on par, if not better, than gains in normal human tutoring. Furthermore, evaluations of AutoTutor's conversational smoothness and pedagogical quality of dialog moves also support the claim that AutoTutor is a good simulation of human tutors (Graesser et al., in press).

AutoTutor was designed to be reusable for various knowledge domains. That is, its modular structure allows for domain specific adjustments, without reconstructing the general components of the system. Recently AutoTutor was transferred from the computer literacy to the physics domain. Only two of the modules needed to be changed for the new subject matter: the curriculum script and the LSA space. With the exception of domains that require mathematical precision and formal specification, the system can become an expert tutor in many other tutoring domains within a reasonable amount of time.

We can learn a lot from Intelligent Tutoring Systems like AutoTutor. Testing research hypotheses using a computer model is easier and more reliable than using a human tutor. Various research questions are generated by observing students' conversations with AutoTutor. What kinds of questions are usually asked by students? Can a student's performance been measured by his/her language use? How can we classify various misconceptions and what is the best way to deal with them? Are certain linguistic features used more often in certain fields? To all of these and other questions we have found (or are in the process of finding) answers. These would help the future development of AutoTutor, and education in general.

With a system that shows close to natural didactic and conversational skills, that can be used in a range of domains and that can work at any time at any day for an unlimited period, AutoTutor seems to be the ideal teacher. With the current developments in artificial intelligence, cognitive science and computational linguistics, the question can be raised whether systems like AutoTutor do not pose a potential threat to teachers, tutors and educators. The answer is simple. The current versions of AutoTutor, despite their promising results in evaluations, are far from 'human', and it seems likely that future versions will not fully master a tutor's social skills, pragmatics, gestures and emotions. Nevertheless, when viewed as a prosthesis, AutoTutor can be extremely beneficial. Furthermore, with an increasing demand of literacy and thinking skills at high school and college level, which have hardly improved over the last thirty years (RAND, 2001), additional educational means are welcomed. Intelligent Tutoring Systems like AutoTutor could play exactly this role.

Supporting classroom discourse with technology

Azita Manouchehri
Mathematical Sciences
Central Michigan University
United States
Azita.M@cmich.edu

Abstract: In this work we studied the impact of using NuCalc, a computer algebra software, on the development of a discourse community in a college level mathematics class. We examined: the influence of technology on group interactions; the influence of technology on mathematical investigations of learners; and the influence of technology on teacher's interactions with students. Data points at 4 distinct ways in which the presence of technology positively influenced the learning community we studied. These were: 1) technology as a tool for extending mathematical thinking, (2) Technology as a tool for motivating engagement in group discourse, (3) Technology as a tool for regulating discourse, (4) technology as a tool for refining the culture of classroom.

Introduction

In this research, we examined the relationship between technology enhanced mathematics instruction and group discourse. We analyzed the content and structure of the interactions among a group of prospective secondary mathematics teachers, and whether the presence of technology mediated their mathematical discourse. We addressed three research questions:

What affect does the presence of technology have on the quality of peer interaction?
Do more complex patterns of mathematical discourse arise in the presence of technology?
What influence technology has on the teacher's interactions with students?

Participants and Instruction

The participants were 16 college students enrolled in a senior level mathematics course designed for undergraduate mathematics majors and minors seeking a certification in either middle or secondary teaching. The group composed of 6 female and 10 male students.

The faculty member teaching the class was an experienced mathematician and mathematics educator. Her teaching philosophy matched the goals of reform. The activities used in the current study motivated reasoning, perspective taking, and problem solving. The problems required students to make mathematical generalization using both deductive and inductive reasoning. The use of technology in solving these problems neither reduced the integrity of the mathematics involved, nor led students to immediate answers.

Procedure

Data was collected over a period of 3 weeks. Participants met twice a week. Each class session lasted 75 minutes. During the first two class sessions (phase I data collection) we collected baseline data on the quality of mathematical discussions students had. During the 3rd class period, the instructor introduced the NuCalc software (Pacific Tec 2000). During the second phase of data collection, the last three class sessions, the students discussed specific explorations. The whole group discussions were used as the data source.
Findings

Our results points at 4 distinct ways in which technology influenced the learning community we studied. These are: 1) technology as a tool for extending mathematical thinking, assisting peers in constructing more sophisticated mathematical explanations, (2) Technology as a tool for motivating engagement in group discourse, increasing peer participation and engagement in group inquiry, (3) Technology as a tool for regulating discourse, (4) technology as a tool for refining the culture of classroom shifting the patterns of interactions between the teacher and learners.

**Technology as a tool for extending mathematical thinking:** In this work, we assumed that technology would allow room for group construction of knowledge as individuals interact with each other and with technology to develop a shared understanding of problems, and of their solutions (Cole 1996). Indeed, for the participants in this study convergence on both was facilitated by technology.

**Technology as a tool for engagement in discourse:** In addition to providing students with a cognitive tool for constructing mathematical arguments, technology served as an affective tool for both intensifying and amplifying group discourse. It allowed less reluctant participants enough confidence to enter soci-mathematical interactions in ways that was not possible to them before. In its presence both participation and engagement in problem solving activities and group discourse was increased. This was particularly evident in the significant change we detected in the number of volunteered participation at the two phases of data collection. While during the first phase only 3 students regularly volunteered answers, during the second phase approximately all students were simultaneously involved in sharing and exchange of ideas.

**Technology as a tool for mediating discourse:** Technology helped structure group discourse by organizing and constraining peer interactions. The participants used the available technology to construct a shared conceptual space as they relied on immediate feedback structure of the system to negotiate meanings and to build and share their basic mathematical assumptions. They frequently produced visual displays to reflect their intermediate understanding of problem and of peers' comments and to test each other's assertions. In the process they either confirmed, or adjusted their own understandings as well as their peers'. This was reflected in the significant increase in the number of times they used technology to communicate their thinking, referred to technology based evidence to convince peers, the amount of time they spent on analyzing problems, and the amount of time they spent explaining their responses. These processes led to the construction of more sophisticated mathematical arguments by the group members.

**Technology as a tool for refining the culture of classroom:** In this case study, an obvious impact of the use of technology was increased student commitment to mathematical problem solving, and to knowledge sharing. This led to a natural transition of the locus of control in the classroom. While initially, the instructor was the one who shaped and guided the verbal exchange in class, her presence was not as visible when students used technology to verify statements, and to counter or support arguments. During the sessions that the technology was present she felt little need to encourage participation, the students were initiating more arguments themselves and volunteering explanations to peers. The increase in participation and engagement facilitated the transition of authority from the teacher to students. The shifting relationship was manifested in the decrease in the frequency of the teacher's intervention during their problem solving sessions.

Abstract: This is a report of a study that was conducted to determine if the newly developed planning strategy could be helpful for online course development in Workforce Teacher Education programs at University Council for Workforce and Human Resources Education institutions.

Introduction

In the new educational paradigm, computer and information technologies were the means to change the activities, interaction, and relationship between online educators and students, as well as among students. With proper planning and use, computer and information technologies could empower online educators' creativity and students' responsibility for their own learning. Moreover, the incorporation of computer and information technologies into the educational setting had shown to improve students' abilities to be self-directed learners (Dede, 1997). Computer technology could help students to be more motivated, feel that they exercise control over their learning experiences, and become accountable for their own learning outcomes. Computer technology could serve as a catalyst to transform teaching and learning, and to expand learning productivity and possibilities.

Future education needs effective programs in order to keep up with the new challenges and dynamic evolution of knowledge, computers, and information technologies. Online programs, especially, could be much more affected by these matters. Therefore, a systematic planning approach to properly guide online educators for the development of online courses was needed (Glasgow & Seels, 1998).

Distance learning opportunities that were possible through flexible and dynamic delivery technology had increased the number of students attaining academic degrees. This emerging phenomenon had influenced more university officials to encourage their faculty to convert more traditional courses to online courses or other forms of distance education techniques. Many faculty welcomed the opportunity to use new technologies for delivering their courses, but many of them also resisted this effort for various reasons (Dede, 1997).

In the traditional classroom environment, students and educators had the opportunity to simultaneously and spontaneously interact and communicate face-to-face between and among themselves. However, in online classes those possibilities were limited for various reasons. Class communication and interaction were dependent on the types of technologies used. Also, it was critical to utilize various forms of instruction strategies that were allowed by the new technologies.

Wagner and McCombs proposed three effective guidelines for designing instruction. Those guidelines were: (a) the opportunity for students to operate holistically; (b) students' individual perception and evaluation should develop their behavior; and (c) students' overall development should be a dynamic growth process. These guidelines showed that online learning was suitable to be utilized for improving teaching and learning, especially when students were central to the education processes.

Online educators were faced with challenges of converting traditional classroom activities to online class activities (Simmons, 2000). The ability of the online educators transferring and transforming traditional class activities to online activities without affecting students' concentration, motivation, thought, mastery, and comprehension was critical. Online educators were also expected to deliver the same quality of education as the traditional class in order for online teaching to be accepted as a future main stream of education delivery.
Purpose of the Research

Currently, university faculty are exposed to many forms of online delivery tools such as e-mail, listservs, web pages, chatrooms, threaded discussion, desktop conferencing, digital multimedia, and other. These opportunities might allow faculty to use an online format to deliver their classes. However, there were other reasons faculty delivered classes online. They were encouraged or mandated by the universities or were voluntarily experimenting with the new delivery approach. Some faculty used a complete online format of delivery whereas others incorporated and integrated various forms of delivery technologies. The purpose of this study was to determine if the planning strategy could be helpful for online course development for the faculty in Workforce Teacher Education (WTE) programs at University Council for Workforce and Human Resources Education (UCWHRE) institutions.

Analysis of Data

The following analysis of results was obtained upon completion of the study.
1. Distance education faculty of various backgrounds have the perception that a systematic planning for an online course does not follow the assumption that the sequence of the elements must be ranked in the same order of importance of the elements of the strategy;
2. The key to effective online classes is to have a good planning strategy – properly sequenced, that encompassed several elements that are important to teaching and learning.
3. The faculty of different distance education experiences – number of years teaching and number of distance classes conducted; (a) were equally skilled and capable to systematically plan online classes development; and (b) were aware of the important elements that should be considered for planning of online courses.
4. Most of the faculty that are currently delivering non-computer based distance classes are equipped with the skills and experience of the basic online class delivery tools (e-mail and web-based);
5. Faculty may have little or no difficulty to deliver online classes if proper training is given, online delivery software are user-friendly, and the supports needed are provided;
6. New faculty seems to be more likely to get involved in a new approach of a teaching format when compared to the seasoned distance education faculty
7. Different experiences, skills, and knowledge pertaining to distance education did not influence new and seasoned distance education faculty who utilized various forms of distance delivery tools to have different opinions on the sequence of a planning strategy for online courses;
8. Different experiences, skills, and knowledge dealing with distance education would lead new and seasoned distance education faculty to have different perspectives on which of the planning elements are more important for online course development process.
9. The distance education faculty in this study are aware that: (a) a systematic approach is important in planning and designing their online classes; (b) if this strategy is utilized properly, it should influence online/distance course planning and designing; (c) this planning strategy is important to initiate the effort of converting traditional class and other forms of distance classes into online courses, especially when the faculty showed strong agreement that online delivery will become the future mainstream of education formats; and (d) the strategy is also suitable to be utilized as its’ own planning strategy to transfer the existing traditional course into a complete online/distance course or for integrating traditional and online/distance classes.

Conclusion

Faculty that participated in this study highly agreed that online or distance courses would become one of the mainstream education formats in the future. They also indicated the developed strategy would influence
their planning for online or distance courses. Finally, most of the faculty were found to be familiar with some forms of online delivery tools.

The Effects of Computer Use on Intrinsic Motivation for Continued Study of a Content Area

By Melissa Mohammed
Education Department
Salisbury University
mamohammed@salisbury.edu

Abstract: This pilot study examines how grade 3 and 4 educators may improve motivation though computer usage. By using computer-assisted instruction in a primary subject area, a teacher can encourage students to choose to work in a subject area they previously disliked. The findings of this study are based upon classroom observations conducted during a two-month period.

Students in a mixed 3rd and 4th grade classroom participated in this study. A general measure of motivation indicated that the students preferred a challenging learning environment to other conditions. Furthermore, when the computer was used to present age-appropriate challenge, students were engaged in previously objectionable content areas with few complaints.

Getting the students to recognize that using quality software programs is "fun learning" rather than "fun" or "learning" remains a goal for educators to pursue. Computer usage combines the students' desire for challenge with the their quest for control.

Introduction

What type of technology-based instruction enhances student learning? What type of motivation do educational computer games provide -- intrinsic, extrinsic or both? How much of the content area learning that a child experiences while playing a computer game stays with the child when the session of computer use is over? If researchers can determine how computer use may motivate a child to learn more content area knowledge, another piece of the educational puzzle will be revealed.

The majority of instructional software has typically been of the drill-and-practice variety (Alessi and Trollip, 2001). While these games are efficient at their tasks, they do not seem to encourage higher levels of cognitive processing. There are, however, several programs that have enjoyed both awards from educators and commercial success. Some of these programs contain some drill sections, but all of them go beyond that capability and engage students in high level cognitive processing. The programs examined in this study capture and maintain children's interest (Only the Best, 1999-2000).

Questions about software programs remain. How does software maintain student interest? Is the fun factor the de facto reason for motivation? Should we equate the child's response that a game is fun with the assumption that fun means intrinsically motivating? Or is it possible that "children may be intrinsically motivated to play and win a game, but still be extrinsically motivated to learn school content" (Alessi, personal correspondence)? If we measure intrinsic motivation as the desire to continue studying the same subject matter after playing a game, how much evidence of intrinsic motivation are researchers likely to find?

Literature

Research supporting the positive effects of computer use exist, yet many studies also indicate that the effects are difficult to measure (Kulik and Kulik, 1991). Positive attitude, which may be interpreted as motivation, is one of the most indicated effects of computer use (Kulik and Kulik, 1991). Thus, motivation
may provide a measure for examining effects of computer game usage in education. Commercial computer game makers design primarily for motivation, and they are successful in keeping students interested for the approximately 25 hours that it takes to complete a commercial game. A precedent of designing for motivation has been set by commercial game companies, and positive student attitude toward any type of K-12 computer use shows an inclination that may be exploited. High-quality educational computer games could use the motivation factor as a natural lead-in to academic success, perhaps through the related constructs of student choice and desire for challenge.

In terms of subject area achievement and use of computers, games for teaching the content area of math seem to have the greatest results (Katz and Offrir, 1996; Randel, Morris, Wetzel and Whitehill, 1992). The drill-and-practice necessary for mathematics learning seems to lend itself well to computers, because drill-and-practice takes full advantage of a computer's ability to perform a task repetitively. Other areas have produced promising effects as well, when some aspect of the subject matter can be presented in drill-and-practice form, for example in the example of language arts grammar (Randel et al., 1992).

Educational computer games should meet the instructional design motivation criteria as described by Malone: games should incite curiosity, give challenge, stimulate fantasy and provide user control (Lepper and Malone, 1987; Malone 1980, 1983). Others cite challenge and control as the two most important factors (Hanna, Risden, Czerwinski, and Alexander, 1996).

The instructional design definition provided above lacks a few elements covered in the general area of motivation. This area has been researched from many aspects and includes aspects of motivation measuring such as level, orientation, trait or state. Although this study examines the intrinsic versus extrinsic difference, it is important to acknowledge that extrinsic motivation is not always a poor substitute for intrinsic motivation, particularly when the student has accepted the extrinsic motivation with a sense of "volition" (Ryan and Deci, 2000). The high performance level executed by a student with volitional choice is likely to encourage additional work at the same level (Zimmerman, 1998). In addition, the research may indicate that some other type of motivational factor is at work.

Motivation changes with time while playing games (Westrom and Shaban, 1992). An area related to motivation is interest. Interest also has several varieties, and it can be long term, situational or even shorter (Hidi and Harackiewicz, 2000). Like motivation, interest runs along a time continuum (Hidi and Harackiewicz, 2000).

Choice is another factor in motivation. Generally, choice is found to result in positive affect but with little or no performance impact (Flowerday and Schraw, 2000). It has been hypothesized that performance should be removed from the equation when measuring effects of choice (Hidi and Harackiewicz, 2000). All together, computer-assisted instruction seems to have a history of increasing student motivation overall. This study will examine whether the motivation can be channeled to have a particular result.

Design

The mid-western school where this study took place reflects the heterogeneity of the large university nearby. Its ethnic composition may be attributed to the fact that many of the parents are affiliated with the university in some capacity. While more than 75 percent of the population was Caucasian, the other ethnic groups represented include various African groups, African-American, Chinese, Japanese, Iranian, Korean, and Russian. Ability levels were heterogeneous as well.

One self-contained third and fourth grade classroom was selected for participation in the study. This group is both highly vocal about their opinions and inquisitive in nature. This age level has mastered some basic skills, but could clearly benefit from additional practice of elementary knowledge. This age group is characterized as having good self-esteem, fair reading and writing ability, some logic, and high academic goals (Howe, 1993a and 1993b; Newbill and Clements, 2000). The teacher of this group was supportive of using technology in the classroom, but had moderate experience in technology integration.
Software used was Edmark's Thinkin' Things series, The Learning Company's Reader Rabbit series, and Broderbund's Carmen San Diego series, representing science, reading and math, respectively. These software titles were also chosen because they are slightly less available as local off-the-shelf purchases than the KnowledgeWare's JumpStart series, for example, and they were critically acclaimed by educators (Only the Best, 1999-2000). Motivation may be better measured if the student is not overly familiar with a program, and certain programs such as the Jumpstart series are more likely to be used in student homes. Furthermore, at least one program, the Carmen San Diego series, highly encourages offline uses (Druin and Solomon, 1996). The Learning Company's Cluefinders series was considered as an alternate program.

The researcher was introduced to the classroom as a classroom observer who would visit over a two-month period. First, she randomly assigned students to one of three groups, representing the groups learning with science, reading, and math software. She took pre-experimental measures during the first week. For example, the students were given the Harter Extrinsic-Intrinsic Motivation in the Classroom Scale, a self-report inventory where the scale measures whether students generally feel empowered in the classroom or whether the students attribute their success to external factors. The information from this instrument was compared with student actions during the study. Finally, the researcher offered the students a choice between a science, reading, or math activity on two occasions during that week and the choices were noted. This part of the study took approximately one week.

For the approximately 25 hours each, the children played one instructional game exclusively, effectively becoming an expert at playing that one game. In addition to the two computers available in the room, the researcher added three computers to the classroom, with the software installed on each one. Interview questions after this part of the study revolved around what the student believed he or she had learned about that particular subject.

The week before the last week of the study, students were allowed to choose an instructional activity in one of the three subject areas. Student choices were carefully noted during this time as the student's choice was the dependent variable of this study.

The final week of the study consisted of asking exit interview questions. Finally, the teacher was interviewed for his or her opinions on each student's motivation in the subject matter prior to and after the intervention.

The researcher recorded the answers to interview questions on audio tape and wrote short versions of the students' replies on a paper copy as a backup to the audio-taped discussions. The following items were recorded on a separate sheet for reference: the gender, grade, and age of each subject along with the student's assigned number and real name. She also monitored the subjects' behavior through the use of a tally sheet. The notes on the tally sheet included: the day number of the study, the minutes the student spent using computer game, whether the student played the game alone or with partners, and any particular choices the student made that were relevant.

Information was analyzed in several ways. First, it was noted what choices predominated for both the self-identified intrinsically and extrinsically motivated groups. Then, interview responses and observation comments were reviewed seeking themes among groups of students.

Findings

Some students did not voice a choice of one subject area over another at the beginning. However, mathematics was most often the stated favorite and the chosen activity. Students, in general, said they enjoyed the educational software. The teacher agreed that the students were definitely motivated on days when they used the computer. These findings repeat what previous research has found about high student satisfaction levels and early motivation when using computers (Kulik and Kulik, 1991).

During open-ended interviews, students most often commented that the experience was “fun.” However, only one student referred to the experience as a learning one. A few mentioned the challenge of the programs, sometimes through related phrases such as enjoyed “figuring it out” and “solving problems”.

2125
Page 2065
The predominance of these types of phrases demonstrate how students truly prefer to learn. A number of related positive comments are in table 1.

Table 1. Student comments about the best features of their computer-based learning experience (n=15).

Students want to feel productive. They enjoy the accomplishment which accompanies game playing. Two students expressed the idea that "I’m good at it" and one replied that it was easy to do.

Providing a choice to the students at the end proved interesting but not conclusive. The students expressed the desire to choose, but when faced with a choice most just wanted to experiment. As for the initial questions vis-à-vis motivation toward a certain content area, students tend to restate the favorite subject after the intervention.

Discussion

Looking for ways to measure the computer’s effects on content area learning helps educators meet the need to know when and how to integrate this technology. Using computers in classrooms to encourage interest in otherwise uninteresting tasks may be a use that educators will actually perform.

This pilot study addresses the problems of educational messages "going flat" and the "educational label" being misconstrued (Tyner, 1998). These problems are avoided when learning remains fun. Computers in education can be used for the purpose of sustaining interest and motivation. The challenge is in shifting children’s views to thinking that the computer work is just fun not work that is fun. Schools need to pursue technology use in more carefully considered ways. Those who promote educational technology should design plans which offer more seamless integration to teachers and some choice for students.

A National On-Line Survey of Education Faculties Use of Technology in Perservice Teacher Education Courses

Lillian D. Nunley
Los Angeles County Office of Education
United States
Dyoteamo@aol.com

Abstract: This paper reports the results of a national on-line descriptive survey. Eight hundred and eighteen teacher education faculty members' affiliated with schools, colleges and departments of education (SCDE) from 50 states reported how they used educational technology in preservice teacher education courses. Five research questions were utilized to determine whether there was a relationship between the dependent variables (DV), teacher education faculty members' proficiency skill levels using educational technology in education courses and the independent variables (IV): Technology planning; professional development; redesigning courses for technology integration; assessment and evaluation; and issues related to classroom diversity, equity and equal access of technology. Several low to moderate correlations were found significant at the .05 probability level. Survey respondents reported positive attitudes toward the use of technology and valued it as both a cognitive an instructional media. Technology access, support, time and training were identified as major barriers to technology use.

Introduction

In the 21st century America's economic success will depend on a well-educated population that can contribute to a modern, technologically complex workforce and global economy (CEO Forum on Education and Technology, 2000; Fulton & Pruitt-Mentle and 1998; Gates, 1999). Consequently, as the United States adapts to the needs of the new millennium and the nation seeks to assure educational success for all students, it is imperative that new educational programs, tools, and methods to educate American pupils be continuously identified and implemented. Educational technologies have been identified as effective cognitive and instructional media tools, which numerous scholars, policy makers, educators, parents, and business leaders continue to promote and endorse as potent teaching and learning tools in kindergarten to grade 12 (K-12) and in institutions of higher education (IHE). According to Houghton (1997), Means (1998), Plotnick (1996), due to the rapid changes created by technology, a systematic restructuring of schools [and IHE] based on the needs of an information society is required. Moreover, it is accepted and expected that educators will utilize educational technologies in the classroom to prepare new teachers and students to live and work in the new digital age (Abdal-Haqq, 1995). However, Cuban (1999), Green (1999) and Willis (1997) agree that our current education system continues to prepare students in schools designed to meet the needs of an information-static industrial age. Consequently, installing technology in [k-12] schools and [IHE] has done little to promote the kinds of changes that meet the needs of a 21st-century classroom.

Additionally, Abdal-Haqq (1995), and others have identified several factors, which have conspired to produce the expectation (and in some instances the requirement) that today's K-12 teachers and (SCDE) faculty members' possess among their qualifications the ability to utilize computer-based technologies. These factors include: (a) the need to provide relevant and authentic instruction that reflects contemporary and future social, political, and economic demands on students (Trotter, 1998); (b) the compatibility of certain computer-based technologies with newer, research-based approaches to teaching and learning (Gardner, 1995; Gates, 1999; and Office of Technology Assessment [OTA], 1995); (c) student and parent expectations (Goals 2000); and (d) guidelines and mandates from federal, state, and district government agencies, professional bodies, and American business leaders (American Association of College Teacher Education [AACTE], 1998; Gates, 1999; International Society for Technology in Education Accreditation Committee [ISTE], 1996; National Council for Accreditation of Teacher Education [NCATE], 1998b). Due to the laggard pace (SCDE) have taken in adopting technology, improving their performance in preparing technologically proficient teachers will require expanding technology use among teacher educators.
Houghton (1997) and others, identified several obstacles to infusing technology into teacher education programs: (a) limited availability of equipment, (b) lack of faculty training, (c) no clear expectation that faculty will incorporate technology into academic activities, (d) lack of funds, (e) lack of time to develop faculty in using equipment and software, (f) doubt about the pedagogical validity of using some of the new technologies since the appearance of literature about these tools is relatively recent, (g) lack of technical support, (h) lack of appropriate materials (particularly integrated media materials suitable for teacher education instruction), and (i) the absence of clear programmatic goals for the teacher education program as a whole. According to Schmidt (1995), in order to plan effective educational technology programs for teacher education faculty members’ there exist a need to document current levels of educational technology use among teacher education institutions nationwide. Thus, the purpose of this study was to ascertain how teacher education faculty members’ at SCDE from 50 states used educational technology in preservice teacher education courses to improve teaching and learning in K-12 learning environments.

The Study

The sample population for the study was approximately 818 teacher education faculty members who had electronic mail (e-mail) addresses and who provided instruction to preservice teachers. The respondents were randomly sampled from 50 U.S. states at SCDE affiliated as member or non-member institutions of the AACTE and NCATE, and the AERA. They were asked to complete an on-line survey utilized to collect data. A major part of the Educational Technology Survey’s (ETS) 48 items were based on a 5-point Likert scale. The instrument was designed by the researcher based on a selected review of the literature (Becker, 1995; Good, 1997; Green, 1999; Lan, 1997; Likert, 1932; Moursund & Bielefeldt, 1999; Schmidt, 1995). The survey participants were randomly selected from several lists of Internet-published electronic mail (e-mail) addresses located in professional education directories, SCDE (e-mail) addresses, or affiliated teacher education Internet listservs. The respondents received an e-mail message with information about the study and an Internet URL link address; a website homepage where the survey was located which guaranteed anonymity and invited them to voluntarily complete the survey.

Returned surveys were coded and the data entered into data files using two software applications: (a) Survey Systems™ (Creative Research Software, Inc., 1999), and (b) NCSS 2000 (Hintze, 2000) statistical software. Descriptive statistics were utilized to describe the survey respondents’ general characteristics. Chi-square analysis were performed on nominal and ordinal measures. Correlation coefficients were analyzed using two statistical tests for nominal and ordinal data: (a) Spearman’s Rank Correlation Coefficient and (b) Kruskal Wallis statistical test. These tests were used to determine the relationships between the (DV’s); teacher education faculty members’ technology proficiency skill levels using hardware and software and the following (IV’s): Technology planning and infrastructure components; professional development and faculty technology training; redesigning courses for technology integration; classroom diversity, equity, and equal access of educational technology use; and assessment and evaluation of educational technology use in preservice teacher education courses and during preservice teacher candidates’ field experience and demographic variables.

Findings

Due to the large amount of data collected only the most important findings will be reported. The population for this study was 888 randomly selected teacher education faculty members from schools colleges and departments of education (SCDE) from 50 states. There were 818 usable surveys, which constituted a response rate of 20.0%. An analysis of the respondents’ demographic characteristics revealed that 46.0% of the respondents were male and 54.0% were female. The largest percentage of respondents fell within the age group 46 to 55 years. The largest racial ethnic group was Caucasian/White, which represented 86.4% of all respondents. In reference to teaching credentials offered, 68.7% of the SCDE offered graduate teaching credentials and 84.0% offered undergraduate teaching credentials. In terms of teaching skills, 43.7% reported K-12 experience and 52.7% reported higher education experience. Eighty-one percent held doctoral degrees and 14.9% held master’s degrees. Most teacher education faculty members taught a variety of courses. Approximately 40.7% reported teaching graduate courses, followed
by 39.6% teaching education methods and 30.6% teaching field experience courses. Of the 673 respondents who completed Question 45 of the survey, 93.9% reported home computer ownership.

Nearly 60% of the respondents reported that their SCDE did not have a written technology plan that is updated annually and included national technology standards. Fifty-two percent of the respondents reported that their technology plan did not include a faculty technical assistance team. Sixty-seven percent reported conflicting information about how their education departments address issues related to classroom diversity equity and equal access, and nearly 64% reported that teacher education faculty members did not evaluate the impact of technology use on teaching and learning. Nearly 56% of the respondents reported that their education departments did not conduct faculty training needs assessments annually. Fifty-nine percent of the respondents reported high proficiency skill levels using the following hardware equipment: The microcomputer, CD ROM player, and the modem. Nearly 81% of the respondents reported high proficiency skill levels using the following software applications: word processing and Internet search engines.

Nearly 60% of the respondents reported home computer ownership.

More than half of the respondents reported negative attitudes related to educational technology use and rewards and incentives offered by professional development programs at SCDE nationwide. Sixty-four percent reported that their SCDE professional development programs did not connect tenure and research to technology use. Fifty-one percent reported that their education department offered release time to attend technology related training activities. Fifty-six percent of the respondents reported that they did not believe that education faculty members use educational technology to address multiple learning styles. Fifty-four percent reported that they believed teacher education faculty use educational technology to address the expectations of school districts. Fifty-six percent of the respondents reported that their education departments did not support the use of educational technology by offering state-of-the-art technology training models. Fifty-four percent of the respondents reported that education faculty members use educational technology as a cognitive tool and 75% reported that faculty use technology as an instructional media tool to enhance teaching and learning in the classroom.

Seventy-two percent of the respondents reported that their education department assesses preservice teacher education candidates' use of educational technology during course work. A majority (62%) disagreed that preservice teacher education candidates are required to demonstrate mastery of educational technology use during field experience. Sixty-five percent disagreed that teacher education faculty members monitor preservice teacher education candidates' use of educational technology during field experience. Nearly 63% of the respondents reported that teacher education faculty did not evaluate the impact of educational technology use on teaching and learning. Sixty-seven percent of teacher education faculty members reported that their education department addressed issues related to classroom diversity equity and equal access of educational technology use in preservice teacher education courses. However, on a similar question that was designed to elicit the respondents' attitudes about classroom diversity and equity issues and technology models, which incorporate national technology standards, the results revealed that nearly 60% of teacher education faculty members disagreed with the statement.

The data results revealed that males reported and obtained significantly higher mean scores using educational technology hardware and software, had more positive attitudes than females toward hardware technology use in preservice teacher education courses, and used these technologies at a higher percentage rate in the classroom than female teacher education faculty members. In addition, males obtained significantly higher mean score ranks on all educational technology software items except word processing and desktop publishing. The 30-to-39 age group reported and obtained higher mean scores, had more positive attitudes toward hardware technology use in preservice teacher education courses, and used technology at a higher percentage rate in the classroom than teacher education faculty members from different age groups. The data support a positive correlation between the age group 30 to 39 and high software proficiency levels for the five software items listed. The data appear to indicate that a new younger generation is better prepared to use certain educational technology software and hardware in teacher education courses. The group that obtained the lowest mean score ranks for all 10 software items was the over-56 age group.

The data revealed a strong positive relationship between home computer ownership and high scores for hardware proficiency skill levels and a strong positive relationship between home computer ownership
and software proficiency (skill) levels for nine items. Respondents who reported teaching technology courses obtained higher mean score ranks for all 11 hardware items and higher mean score ranks for 8 of the 10 software items. The second highest mean score ranks were obtained by respondents who reported teaching education foundation courses, and the third highest mean score ranks were obtained by the respondents who reported teaching education methods courses. The lowest mean score ranks for many of the items were obtained by respondents who reported teaching curriculum and other courses. These data appear to indicate a strong positive relationship between types of courses currently teaching and software proficiency (skill) levels for eight items.

Conclusions

Low to moderate correlations was found between several of the IV's and the DV's, significant at the .05 probability level. Survey respondents reported positive attitudes toward the use of technology and valued it as both a cognitive an instructional media. Technology access to equipment, support and training were identified as major barriers to technology use. The results of this study identified the infrastructure, teacher education faculty members' attitudes toward the use of educational technology, training needs, and effective teaching methodologies for technology use in teacher education courses. Guidelines for teacher education programs and school districts can be established using the current research model to provide: (a) skill training and professional development of faculty members' and new teachers; (b) address issues related to classroom diversity, equity, and equal access of technology; (c) provide a theoretical model to redesign teacher education courses and programs and (d) assess and evaluate model technology programs.

Stakeholder Perceptions of the Use and Value of Computers and Technology in an Elementary School Setting: A Case Study of the Vision and Reality of Educational Technology

Pam Petty
Western Kentucky University
Bowling Green, KY USA
pampampetty.com

Abstract: The purpose of this study was to describe the status of classroom computer use at an elementary (K-6) school with a population of 676 students in a rural county in the mid-south. A further purpose of the study included examining and describing the patterns of beliefs or attitudes toward the use of technology in education and the skill levels necessary for use. Teachers, administrators, and parents within one school were observed and surveyed offering qualitative and quantitative data in order to make recommendations regarding the direction of technological development for the school and determining the types of training needed.

Introduction

By examining one school as a case study, it is possible to probe barriers to and facilitators of technology use. To understand the strengths that support effective technology use in education, and learn about the weaknesses that may inhibit the effective use of technology as a learning and teaching tool, one might examine a school’s expenditures on technology, technology use by teachers, and attitudes of parents, teachers, administrators, supervisors of instruction, and technology coordinators regarding technology use. Do teachers feel adequately prepared to integrate technology in the state-mandated curriculums? What effects do teachers’ beliefs regarding the importance of technology have on the way they use technology in the classroom? What similarities or differences appear in expectations relating to technology use in the classroom held by teachers, by administrators, and by parents and how might these similarities or differences effect present or future uses of technology in the classrooms?

Teachers and Technology

Research indicates that teachers must use computers competently in their classrooms, both as vehicles of pedagogically sound instruction and for classroom management. They must have knowledge of hardware and software applications (Hardy 1998; McNamara 1995; Siegel 1995; Walters 1992). However, Rosenthal (1999) sites a survey done by the National Center for Education Statistics (NCES 2000-003) finding that only 20 percent of the nation’s 2.5 million public school teachers feel comfortable using technology in their classrooms. Another recent NCES brief (2000-090) elaborates that 13 percent of all public school teachers with access to computers or the Internet at school feel not at all prepared; 53 percent feel somewhat prepared; 23 percent feel well prepared and 10 percent feel very well prepared. These findings underscore other research (Siegel 1995; Schrum 1999; Strudler & Wetzel 1999) which indicates that even if teachers hold positive attitudes toward technology, the lack of time, access and support needed for teachers to feel competent in using technology in instruction may keep teachers from becoming comfortable with technology in their classrooms.

Poole & Moran (1998) suggest that limited and/or inadequate staff development prevents teachers from utilizing existing technology in their teaching. The authors continue stating, “One-shot workshops, added expense of training, lack of continued support, isolated knowledge, unawareness of school needs, lack of knowledge and support from leadership all contribute to the ineffectiveness of technology staff development”. Studies show that most teachers do not learn to use computers from taking college courses, attending seminars or workshops, or through traditional inservice programs (Galloway 1997). More continuous training (Hardy 1998) in the use of technology in education over the course of seven years may provide teachers with the experience, comfort, and confidence to successfully incorporate technology into instruction.
Braun (1993) underscores the types of training in technology teachers need as he reports conclusions drawn from research done by the International Society for Technology in Education (ISTE), “Teachers need training in the uses of technology in their curricula; time to develop these uses; and support from their administrators in a risk-free environment – and they need these on a continuing, long-term basis”. While many people recognize the need for staff development related to technology, Bailey (1997) states, “Even though there is considerable information about the general characteristics of effective staff-development practices, there have been minimal amounts of information specific to technology staff-development programs”.

Wang (2000) utilizes a model published by Lloyd and Weliver (1989) denoting familiarization, utilization, and integration as three phases that provide a framework for computer training for teachers. The focus of the familiarization phase rests on acquainting teachers with computer equipment and terminologies. The utilization phase of instruction involves teachers using computers as personal production tools. Direct integration of technology into the curriculum occurs in the final phase of training. McNamara & Pedigo (1995) discuss a similar training model that follows three basic levels: awareness level, which provides basic knowledge about computers; development of skills level, actual use of equipment and computer software; and application level, integration of computers into curriculum.

Teachers need models to follow when integrating technology into the curriculum. Sherry, Billig, Tavalin, & Gibson (2000) suggest that teachers need mentors, specialists who help guide their understanding of technology, and on-line resources available to them as they attempt to use technology in curriculum integration. This support structure for teachers provides a level of empowerment to the teachers both as learners and as users of technology.

Thornburg (2000) makes an interesting observation as he notes, “Technology is not the point – learning is”. In the author’s reference to “technological fluency,” he suggests teachers should not stop with students merely knowing how to use computers, but teachers should set examples of how to use computers as tools for learning. Poole and Moran (1998) suggest a staff development model called “Teachers Teaching Teachers Technology” (T-4). The plan works on the premise that a team effort toward technology training can promote effective technology learning by teachers. Teachers obtain release time for working to integrate technology into their curriculum and in developing personal technology skills. A team of “experts” from within the school survey teachers for training needs, develop a training schedule of classes, and serve as instructors in those classes. The teachers trained at the initial classes serve as the next level of “experts” when the training session appears next on the schedule.

By contrast, Saul Rockman, (2000) as quoted in Electronic-School believes that teachers should only learn enough about computers to get their work accomplished. He indicates that students would take the lead in using technology if teachers would move aside and give them permission to do so. The technology gap that exists between students and teachers indicates “… students may know more about how to use the technology than adults” (Watson, 1998). Watson, in her research on the how students use information technologies, goes on to suggest the need for more research into how best to assist teachers in using technology to facilitate student learning. Teachers and Technology: Making the Connection (1995) developed by the U. S. Office of Technology Assessment, indicates everyone benefits from student and teacher collaborations in using technology as “the K-12 students themselves learn the technology and help their teachers find ways to use it” (on-line version). This notion underscores a resent survey (National School Boards Foundations, 2000) indicating that three out of four teenagers use on-line resources via the Internet.

Weiner (2000) indicates that, based on a survey conducted by Market Data Retrieval, funding spent on teacher training in technology constitutes only a minimal amount of the total budget for technology in public schools in the United States. Of the estimated $5.67 billion spent on technology in public schools during the 1999-2000 school year, only 17 percent went to teacher training.

### Training Future Teachers

In reference to encouraging teachers to integrate technology into their classrooms, Dr. Linda Roberts, special advisor on technology to the U. S. Department of Education states, “If you can get teachers to use technology effectively in their own lives, you have won 90 percent of the battle” (Rosenthal, 1999). Rosenthal continues to describe how the National Council for the Accreditation of Teacher Education (NCATE) requires all colleges and universities to train pre-service teachers in how to effectively integrate
technology into their curricula as opposed to only offering separate courses about technology. Brush (1998) concurs with this notion as he calls for integrated technology training throughout the teacher education program. Computing instruction integrated throughout the teacher education program, according to Moursund & Bielefeldt (1999) reigns superior over isolated computer classes. Students who receive computer instruction in an integrated manner more naturally integrate technology into the school curriculum as inservice teachers.

Wang (2000) indicates that preservice teachers placed in practicum settings with teachers who view efforts to integrate technology into the classroom as hindrances to routine work will not appreciate the value of computers in education. While much research exists relating to understanding preservice teacher perceptions of technology (Diegnueller 1992), their perceptions of good teaching practices may reflect an obsolete educational system. In a study of preservice teacher perceptions on changing teacher roles and technology, Carr-Chellman & Dyer (2000) asked preservice teachers to respond to a reading on the future vision of education. Results showed that many respondents preferred traditional teacher roles that reflected the same types of teaching methods as they experienced as students. The researchers credit much of this to the notion of “change” in general, independent of the use of technology in education.

Technology Planning

A 1991 policy statement generated from the Council of Chief State School Officers requires that all states develop and maintain written plans for integrating technology in the education curriculum (Improving Student Performance through Learning Technologies, 1991). Anderson (1996) explains that states develop technology plans of a more general nature than district or local school technology plans. The state plans deal with more non-specific principles, financial support, and issues of district accountability of state funding. District technology plans address the specific needs of a school system and includes an overview of local school technology goals. District plans provide broad outlines of the many aspects of the use of technology in education including administrative concerns, public relations, and other facets of the school system as a whole. Local or building level technology plans focus on curriculum concerns, teachers, and learners. These plans usually include vision statements and set goals for the use of technology to support the curriculum.

Financial, technical, human resources, architectural, and legal aspects serve as major components of technology planning for state, district, and local schools (Anderson 1996). “Although technology planning occurs at multiple ‘levels,’ many principles are identical. Planners need to engage the services, creativity, and assistance of all stakeholders” (Anderson 1996). The magnitude of this planning requires people to establish timelines, delegate responsibilities, and constantly evaluate the plans during the building and implementation phases. Peterson (1989) indicates that school board members and district administrators may not know the steps to take in planning for technology in their school systems.

Data Collection

The first course of action for this study began in January 2000, by initiating two pilot studies: 1) training for parents interested in the use of technology in teaching and learning; and 2) training for teachers interested in increasing their skills in using technology as a teaching and learning tool in their respective classrooms. Every parent in grades Kindergarten through second grade received a letter explaining the purposes for the computer training, when and where the sessions would meet, and what they needed to do to reserve a space in the training sessions. These sessions lasted approximately eight weeks, meeting once weekly from 6:00 p.m. until 8:30 p.m. As demand for hands-on computer time increased, the school library hours were extended from 3:00 p.m. until 9:00 p.m. to accommodate parents who did not have home access to a computer. Parents attending these training sessions completed both pre and post-surveys examining demographic information, technology skill levels and interests, and beliefs regarding the use of various technologies as teaching and learning tools. Field notes from these sessions reflected parent motivations, concerns, visions, and anecdotes relating to experiences their children incurred in the context of using computers in the classroom during the time they attended the participating school.

The second pilot involved training teachers interested in expanding or improving their skills in using technology as a teaching and learning tool. Twelve teachers participated in these training sessions which met two evenings per week for a period of eight weeks. The sessions lasted approximately two and one-
half to three hours each. Teachers brainstormed a variety of topics relating to computer use in the classroom and prioritized the order in which the topics would be offered. Teachers attending these training sessions completed both pre and post-surveys examining demographic information, technology skill levels and interests, and beliefs regarding the use of various technologies as teaching and learning tools. Field notes from these sessions reflected teacher motivations, concerns, visions, and anecdotes relating to experiences with students while using computers in the classroom.

All faculty members, administrators, parents, supervisors of instruction, and technology coordinators associated with the participating school received surveys and consent forms. These surveys were subjected to statistical analysis and were coded based on qualitative responses. A primary goal was to try and discern themes or patterns of beliefs and technology use that might provide useful information for the planning of future technology endeavors at the school.

Results

Perhaps the most significant aspects of this study relate to the comparisons of feedback on issues regarding the use of technology in education from the primary stakeholders at the participating elementary school, i.e., teachers, parents, administrators, supervisors of instruction, and technology coordinators. Much published documentation exists dealing with the benefits and barriers schools encounter in their attempts to integrate technology; however, the extensive body of research reviewed for this study did not explicitly provide findings comparing and contrasting the expectations each group of stakeholders hold for the use of technology in an elementary school setting. This study adds to the literature a discussion of views and beliefs of the stakeholders in one such elementary school and sheds light on how a school might more efficiently and effectively plan for future technology expenditures and integrative programs.

Results of this study indicate the discrepancies in beliefs regarding the use of technology as a teaching and learning tool that exist among the various stakeholders at the participating school. Results also point to areas of common goals regarding present and future technology use. Implications exist for future technology plans, professional development for teachers, and ways to remove barriers to using technology as a teaching and learning tool that presently exist.

Summary

The new millennium brings with it the evolution of technology-supported teaching and learning and also the incredible potential for educators to take advantage of incorporating that technology into their teaching. A review of the literature indicates that our society will continue to rely more and more on technology and future generations must possess the skills to use that technology in the workforce as well as their personal lives. Governmental, private, and business sectors of our society recognize the need for schools to help train students and continue to aid schools financially in their quest for computers and other aspects of technology. Teachers suddenly presented with new and unfamiliar types of technology may or may not readily integrate it into the curriculum as they struggle with inadequate or insufficient staff development. Perhaps Donald Norman (2000) says it best when he states, “Technology is not the answer, but proper technology coupled with informed pedagogy, coupled with teachers who are coaches, guides, and mentors, can lead the way”.

Current literature related to the use of technology in education provides us with information about how traditional teaching models change with the introduction of computers and other technology. These changes affect technology planning for a school or a school system. Teacher training and professional development for teachers in the use of technology compose the subjects of several research projects. To date no consensus exists regarding the most effective model for such training. While the literature provides agreement that integration of technology into the curriculum is paramount, the methods for training teachers to integrate technology and the methods for adopting appropriate pedagogy remain random with a “hit or miss” approach. Colleges and universities face similar challenges in preparing new teachers to readily integrate technology in their teaching.

The literature also indicates that the people responsible for making critical decisions regarding the implementation and use of technology in classrooms make those decisions without the proper information or background knowledge. States and local school districts must make vital and pressing decisions regarding the implementation of technology into classrooms. These decisions must take into account all
the stakeholders affected, i.e., teachers, students, parents, administrators, and the community. Understanding the current status of technology use in a school (or school system) constitutes the first step in making these important decisions (U. S. Department of Education 1998).

Evaluation of Motivation, Interactivity and Learning Styles in Web-Based Instruction and Online courses

M. Ponce Meza & M. Farias-Elinos
Research Coordination
La Salle University
Mexico City

Abstract.
Recently Web-Based Instruction has been adopted for many educational systems in order to support distance education. WBI has become popular in that it overcomes time and space limitation in traditional systems. It is important to provide interactivity and motivation for students besides of assuring understanding and learning. This paper introduces a model used in undergraduate and graduate courses based on web pages and its transition to online courses. Based on the analysis of the students performances, the paper presents the criteria to evaluate the motivation and interactivity and learning styles of the students, comparing it with the results on these aspects developed in courses on these subjects that were not supported by web pages.

I. Introduction
The Internet has affected the traditional education methodology. Especially with the possibility of the World Wide Web (WWW). Using Web-Based Instruction in Undergraduate courses has helped professors to develop new strategies of teaching and learning in their courses. The first stage of this project was developed on the research of finding new ways of using the WWW for teaching specific contents. The second stage was dedicated to the development of specific web pages to support the traditional learning process, and finally, the teaching on line. The last stage, was developed using the experience of the use of web pages in teaching different courses, and evaluating the impact of the web pages in the learning, learning styles, motivation and interactivity showed by the students.

WBI has changed the traditional ways of teaching and learning. In the traditional perspective, teachers and students share the same space at the same time and also, students may work individually or in groups. On the other hand, in WBI, teachers and students may meet asynchronously using communications tools, such as video and sounds at different places. WBI help students to work in a self-driven manner.

Some of the limitations of the WBI is that the lack of face-to-face communications can affect the perceived satisfaction of the students. Then another important concerns in WBI is how teachers can motivate unseen students. There are some specific ways of motivating and develop interactivity in web pages, and online courses. This paper provides an evaluation model that promotes interactivity and motivation for courses based on WBI and detect learning styles. It is objective and based on principles dominating pedagogical philosophy and learning theory.

This paper is organized as follows. In Section II, related works providing motivation and interactivity are presented. In Section III, the model used is introduced. Based on this model the courses are compared for their interactivity and motivation in Section IV. Finally, conclusions and further research issues are discussed in Section V.

II. Related Work
In (2), the authors argue that course design and the teacher’s role might affect student motivation. Based on these arguments, they present three ways to enhance the use of WBI: how to motivate students, course design considerations, and how to motivate instructors.

First, the causes for lack of student motivation include lack of preparedness, lack of funds to purchase electronic resources, initial difficulty in using advanced hardware and software, phobia about technology, lack of background on course, interpersonal difficulty, family illness, etc. The authors suggested the following solutions: get to know the students by providing e-mail addresses: email communications and face-to-face meeting sessions.

Second, as possible course design considerations for providing motivation, the following principles may apply: variation and curiosity, relevance, challenge level. Positive outcomes, positive impression, readable style, and interest. Variation and curiosity refer to providing diversity and making changes in content to stimulate attention and curiosity. Relevance refers to connecting student learning to objectives of the course.

Finally, the authors argued that the motivation problem may also affect teachers, and unmotivated teachers may impact the entire class. In order to motivate the instructors themselves, the following suggestions can be made: more time to redesign the course and develop new strategies to use technology in a meaningful way.

There are three ways of interactions explored in this project: student-course material interaction, student-teacher interaction, and student-student interaction. First, for student-course material interaction, a course should be designed to facilitate self-directed learning, and include many illustrations and guidelines. Second, for student-teacher interaction, teachers need to constantly motivate students. Finally, in order to support student-student interaction, communication tools should be provided.

The model of the web pages and online courses are segmented in the following criteria: a) content, b) graphics, sound, c) authority, which includes the quality of the web page writer, and copyright and trustworthiness of web management organization, d) currency, which refers to whether the web pages’ content is up-to-date or not, e) general appearance, which refers to the attractiveness of the web page, and f) ease of navigation.

Motivation is evaluated by considering the following aspects: a) attention, relevance, confidence and satisfaction. Attention is determined by the interest or curiosity of the students. Thus students are supposed to answer yes on questions like “Does the display provide curiosity?” or “Does the content invoke curiosity?”. Relevance is the applicability of the content to real life or other subjects. Confidence is to describe the students level of understanding of the course material. Finally, satisfaction is to provide the students’ satisfaction after the course, including fairness in grading, positive rewards and psychological impacts.

II. Proposed Model
This proposal tries to develop some objective evaluation criteria that can be useful for WBI designers and teachers. Here the categories to be evaluated are: student-to-course content relationship, student-to teacher relationship, and student-to-student relationship. The evaluation criteria for interactivity include elements inducing student reaction. The evaluation criteria for motivation include elements that stimulate student interest. The elements for interactivity and motivation are somewhat overlapping. The evaluation model may not be an absolute index for WBI products, but it can be used for comparing the relative performance of web pages.
Constructivism emphasizes the learner's intentions, experience, and cognitive strategies. According to constructivism, learners construct different cognitive structures based on their previous knowledge and what they experience in different learning environments. Thus, constructivists are supposed to have learning environments that are as rich and diverse as possible. Constructivists also believe that knowledge does not exist outside the minds of human beings and that what we know of reality is individually and socially constructed based on the learner's previous experience. Also, they believe that learning consists of acquiring viable strategies that meet one's objectives, and learning can be estimated only through observation and dialogue.

The evaluation model for interactive and motivation consists of three relationships: Student-to-course Content, Student-to Teacher, and Student-to Student. Within each relationship, a number of elements that may affect the relationship are identified. Each element is given a score of 1 if it exist and 9 otherwise. Formulas based on the scores given to these elements for all three relationships are derived to evaluate interactivity and motivation.

1. Interactivity
   1) Student-to-course content relationship
      • Providing hyperlinks or directions
      • Providing scrolls
      • Providing multimedia data, graphic, pictures, maps, charts
      • Question/Answer (Trouble Shooting) guide
      • Is there any exercise for the course?
   2. Student-to-teacher relationship
      • Virtual Office Hour
      • Reward (for any achievement such as early submission, etc)
      • Providing contact information for the teacher other than office hour
      • Providing media for communication (Synchronous/Asynchronous): e-mail, chat-room, Internet phone
      • Providing collaboration between students and teacher
   3. Student-to-Student relationship
      • Does the work involve learner-to-learner collaboration
      • Providing media for communication: e-mail, chat-room, Internet phone, bulletin board, feedback
      • Providing contact information among students

2. Motivation
   1) Student-to course content relationship
      • Providing explicit statement of course objectives
      • Providing warm-up exercises
      • Does the web page include a sequence of lessons for students and/or teacher?
      • Providing the background and/or prerequisite courses required for the course
      • Providing multimedia data: graphic, pictures, maps, charts
      • Providing summary and review
      • Does the web page specify updated date?
      • Does each icon have a name that is helpful in guidance?
      • Does the course web page have any references
      • Does the course require students to use their native language?
      • Does the web page provide the time to finish the course (or lesson)?
2) Student-to-teacher relationship
- Providing reward for accomplishment
- Providing collaboration between students and teacher
- Providing teacher's biography (Picture, phone number, e-mail address, etc)
- Referring response time of student input (questions or comments)

3) Student-to-student relationship
- Does the work involve learner-to-learner collaboration?
- Providing media for communication: e-mail, chat-room, Internet phone, bulletin board, feedback
- Does the course require competitions between students in the class?
- Providing each student's picture or biography?
- Providing students with chance to meet each other at least once during the semester?

4) Learning Styles
- Does the work involve learner's learning style preferences?
- Providing media for communication, matches the learning style of the students?
- Does the course adequate the material to the learning style of the students?
- Providing feedback, according with learning style preferences of the students?

For interactivity, the degree of overall interactivity, I, is determined by the following expression. We assume that, the bigger the value I, the higher the achieved interactivity for a specific WBI course. This means that, no matter what educational theory each element comes from, we simply assume that the element, with possible different weight, is helpful for achieving overall interactivity. The value of I can be somewhere between 9 and 1.

Where C1, C2 and C3 are coefficients (or weight value), and SCI (the degree of student-to-course interactivity), STI (the degree of student-to-teacher interactivity) and SSI (the degree of student-to-student interactivity) are determined as follows. We assume that the degree of each type of interactivity has higher value as more elements are provide for the type.

Similarly, for motivation, the degree of overall motivation, M, is determined by the following expression. As in interactivity, it is assumed that, the higher the value of M, the higher the achieved motivation for a WBI course, in turn, this means that, no matter what educational theory each element comes from, we simply assume that the element, with possible different weight, is helpful for achieving overall motivation. Also, the value of M can be somewhere between 0 and 1.

The actual coefficients will be evaluated and analysed to consider the impact of those criteria in the development of the webpages.
Institutionalizing Technology in Schools: Resolving Teacher Concerns

Glenda Rakes, The University of Louisiana, US
Holly Casey, The University of Louisiana, US

Institutionalizing Technology in Schools: Resolving Teacher Concerns

Technology is a fact of life in the twenty-first century. It is an ever-present reality facing people in all walks of life on a daily basis. The need for technology skills in the workplace and in everyday life has brought about new demands on P-12 teachers to prepare today's students to succeed in their life's pursuits. These demands have forced educators to acquire, use, and teach technology skills; in short, to integrate instructional technology into their teaching methodologies as well as into the content areas they teach. Many teachers have been overwhelmed by this change in instructional focus.

The ultimate goal is to move through the change process and integrate technology into teaching and learning to the extent that it becomes "normal" or institutionalized. Research by Fuller (1969) and Hall (1978) have shown that teachers' feelings and concerns have a direct bearing on their behavior. These concerns must be addressed if real change is to be effected.

A question posed by researchers, administrators, and teachers concerns what results P-12 education is receiving as a result of the expenditures for instructional technology acquisitions and staff development (O'Riordan, 1999). With limited funding for technology staff development, it is crucial that training content and methodology meet the specific needs of the P-12 teachers who are being required to change their teaching by integrating instructional technology into their classes. After several years of these attempts, examining the direct responses of teachers' feelings toward this change process should provide some insight into how well these goals are being met.

The teachers in this study responded to the following question: What specific aspects of instructional technology have the greatest positive impact on your classroom teaching?

Procedures

The questionnaire was converted to hypertext markup language (html) and placed on the Internet. Extensive web searches located listservs and newsgroups focusing on P-12 teachers and identified email addresses for school district technology coordinators from all 50 states. The researcher emailed a message to the identified school district's technology coordinator/director, mailing list, and listserv manager, asking them to disseminate the URL for the online instrument to their teachers and members. The responses were emailed back to a specific server, and the data were transferred into a password-protected account.

Methodology

Responses to the open-ended question were coded and categorized using Merriam's (1991) standard qualitative methods. The analysis procedure was designed to identify key words and phrases. The qualitative data from the content analysis of the responses to this open-ended question provides a glimpse into the perceptions that these teachers hold regarding their feelings regarding the use of instructional technology.

Population

The target population for this study was P-12 teachers currently using instructional technology in some form in their classrooms. Five hundred six usable surveys were returned with each of the 50 states represented. Respondents represented PK through twelfth grade teachers with bachelors degree through doctorates with years of teaching experience ranging from less than one year to over 25 years. The respondents represented a wide variety of assignments from self-contained classrooms through specific subject areas including Language Arts, Social Studies, Mathematics, Fine Arts, Physical Education, Special Education, Foreign Language, Computer Science, Business, and Vocational Education.

Analysis

Five hundred six respondents shared their ideas, concerns, and comments regarding the overall impact that instructional technology has had on them as well as their students' response to technology. The responses to the open-ended question were often lengthy. The respondents' comments naturally grouped into reports of (a) increased student motivation, interest and creativity; (b) a sense of personal and professional empowerment, (c) lack of time, training opportunities, technical support, and equipment; and (d) their perceived roles as technology leaders and trainers for peers. Sample comments from respondents will be provided. The range of comments did not reflect any one demographic factor, interest group, or geographic location. The four distinct categories were well defined in the comments as shown in Table 1.
Responses to Open-ended Question

</table>

The largest number of responses (42%) concerned an obvious change in student motivation, interest and creativity. Many of the teachers referred to their students as being more motivated and more engaged in the learning process than prior to the introduction of instructional technology.

The increased creativity and interest described by these respondents were not limited to the students. A Rhode Island respondent added that when they are encouraged to use technology with their assignments the students are more interested and "that makes my job all the more exciting as well." According to one respondent from South Dakota, "Teaching is much more exciting when the students are so enthused [sic] about learning." Responses indicated that instructional technology integration has had an impact on the creativity and interest of teachers as well as their students.

Increased creativity and heightened interest in students was reported from all over the country in every grade level and subject area. Although some of the respondents made reference to specific software applications and P-12 Internet activities, most of their remarks centered on generic learning creativity reflected by the students, not specific activities and products associated with technology products or programs.

Even though respondents were specifically asked to describe positive aspects of teaching and technology, 21% of the respondents reported problems encountered trying to implement technology in their schools and classrooms. Many of the remarks were included with reports of some successes in spite of the teachers' lack of time, training, technology support, and equipment. Of the 108 responses in this area, 42 reports involved problems with technology training provided by the school or district; 29 respondents reported problems with equipment or lack of technology support; 19 teachers focused on lack of time for technology use or preparation; and the remaining 18 responses included complaints about personnel and scheduling matters. This feedback reinforces similar findings from several researchers (Albaugh, 1997; Becker, 1994; Furst-Bowe, 1996; Treagust & Rennie, 1993; Shearman, 1997) all of whom report that a lack of time for training, support, and equipment inversely impact the effective use of instructional technology in schools.

The majority of the responses about training problems concerned the lack of school or district technology training. Over half of the teachers commenting on the quality or lack of district-provided technology training, reported that they had obtained their technology training on their own.

The 29 teachers whose concerns over lack of equipment and technology support covered everything from outdated and broken hardware, to non-existent or non-responsive technology support in their schools and districts. Their remarks chiefly questioned how they could effectively use their training with no equipment for their students to use. Several teachers commented on the lack of fiscal support in their districts and states, and they added their concerns over no funding increases in the foreseeable future. The respondents who expressed their concerns about lack of time to prepare for and to use the technology feared they would lose the skills they developed in their training. Most of the teachers expressed regret that lack of time prevented them from effectively using technology with their students.

There were 58 teachers who reported increasing confidence and their increasing technology leadership roles in their schools and districts as a direct result of their technology training. These responses fell into two areas involving increased comfort and confidence resulting in innovation and integration of technology into individual classes and delivery of training and technology support to other teachers and administrators.

The group of 128 teachers who reported increased sense of personal and professional empowerment also reported the greatest change in their teaching due to technology training. These comments are similar to those
reported by Sheingold and Hadley (1990) as teachers reported that instructional technology enhances their sense of productivity. These respondents described their use of instructional technology with their students and their colleagues. The teachers explained how and to what extent technology training impacted their teaching from increasing technology integration with curriculum delivery to total changes in teaching methodologies.

These teacher comment categories can be compared to the seven Stages of Concern as defined by Hall, George, & Rutherford (1977). These concerns occur in a natural sequence; movement through these stages is developmental. The stages, in order, are 1) awareness, 2) informational, 3) personal, 4) management, 5) consequence, 6) collaboration, and 7) refocusing. The stages are described in Table 2 and compared to the categories of teacher comments derived from teacher comments in this study.

From the perspective of Hall's concerns based theory, institutionalization of an innovation (making it "normal" in the environment) only occurs when most of the individuals within a population have resolved (lowered) their concerns on Stages 1, 2, and 3. In order for any innovation to become an integral part of an organization, strong Informational, Personal, and Management concerns must be resolved (Hall, George, & Rutherford, 1978). The results of this study provide some indication that institutionalization has not yet occurred. "If these early concerns remain intense, then the user is apt to modify the innovation or their use of the innovation, or perhaps discontinue use, in order to reduce the intensity of these concerns" (p. 13).

Many encouraging, positive reports of successful use of technology were reported by teachers across the country. However, even when specifically asked to describe positive aspects of their technology-related experiences, twenty-one percent of the respondents in this study volunteered strong, negative concerns that parallel Hall's (1976) Stage 3 (Management). With frequent focus on the needs of students, teacher concerns and needs are often lost. While care must be taken in generalizing the results from this sample, the results of this study provide some evidence that if technology is to become a normal part of classroom instruction, attention must be given to the persistent,
personal concerns of teachers.
Comparison of Measures of Achievement and Interactive Technology Use in Distance Education

Sherri Restauri
Department of Distance Education
Jacksonville State University
United States
srestaur@jsu.edu

Abstract: This study analyzed measures of achievement for students enrolled in distance education courses via assessment of final course grades. Various uses of interactive technologies in classes taught via Distance Education methods and traditional on-campus methods were also compared in this study. Further analysis of the type of interaction methods used and frequency of utilization was performed to determine effects of these various methods of interaction on the achievement of the distance student. Certain benefits and drawbacks of each of the various interaction methods analyzed in this study were found for both students and instructors. A positive correlation was found between the two criteria used to determine student success in this study in both Distance Education and "traditional" courses. Differences were observed in the use of interactive technologies between Distance Education and "traditional" courses.

Introduction

Providing coursework via the Internet and other technology has become the focus among instructors in both K-12, 2-year, and 4-year schools, colleges, and universities in the last few years, though distance education via such methods as correspondence courses has been around for decades. Various forces, including accreditation agencies, government officials, administrators, and even students and faculty, have challenged the effectiveness of these courses and programs. A range of approaches has been used to determine the effectiveness of these courses and programs. Overall, the most frequent approach is by means of a comparison of the courses taught via Distance Education to the same courses taught "traditionally" (on-campus). Many studies (Souder, 1993) present data in which courses offered through distance education methods have higher student course ratings than traditional, on-campus courses in such areas as achievement on examinations, while other studies (Egan, Sebastian, and Welch, 1991) present cases in which courses taught through distance education methods result in lower student ratings on particular course characteristics, such as class organization. Multiple factors have been analyzed in these comparisons to determine success or failure of the distance education program, including maintenance of funding, faculty development and support, faculty satisfaction, and numerous student variables. There is no question as to whether differences occur; rather, accepting that differences exist between distance education and traditional courses, it is the goal of those individuals participating in distance education to assure that these differences reflect a positive change, rather than a negative.

Student Achievement

Three major variables are typically associated with student achievement, or success in distance education courses (Phipps and Merisotis, 1999). The foremost of these variables is student grades, from which data are normally drawn from the students' final grades in a course. A second variable associated often with student achievement is student attitudes toward the distance education course. Some questions that are often asked of students, based on this variable, are "Was the course presentation successful?" or "Do you feel that you learned useful and applicable material through this method?" and finally, "Could you have learned this material better in a traditional course?" A third variable of student achievement deals with overall student satisfaction toward the course. Generally, these questions are phrased using a Likert scale, or something similar. A question from this variable may be, "On a scale of 1 (worst) to 10 (best), rate this method of education." Unfortunately, it is often left unnoted that many students overall satisfaction, attitudes, and final grades are unobtainable due to "dropping" the course. Also, many students may fail to make any contact or may make only infrequent contact with their instructors in some forms of distance education, and therefore may be given failing grades. Data obtained from situations such as this is not valid because it may be influenced by outside variables such as students' lack of familiarity with technology or outside environmental influences, rather than students' true achievement level.

Interaction
A recent study from the National Education Association (2000) stated that as high as 96% of faculty (n=402) teaching through distance education use some form of interactive technology for one-on-one communication with students, predominantly e-mail. One of the many significant findings from this report stated that “faculty with frequent student interaction...give their distance learning courses higher ratings in meeting the goals NEA has determined are essential to quality education.” Various other types of interactive technology cited include telephone, chat rooms, threaded discussion groups, or face-to-face meetings. Multiple angles of distinction exist within these interactive technologies. One important distinction is between synchronous (real-time, such as chat) and asynchronous (delayed-response, such as email and threaded discussion) communication. Another important facet of these communication strategies is whom the communication is with: this may consist of student-instructor, student-student, or student-material.

Method

An analysis of interactive communication technology usage was performed on 17 online courses (n=6 graduate; n=11 undergraduate) offered during a full college term. Courses were analyzed for usage of three major communication tools available, including e-mail, a synchronous “Virtual Chat” (VC), and an asynchronous threaded “Discussion Board” (DB). Analysis was performed by evaluation of usage data from course platform available via system administrator access to these online courses. Data was also collected from instructors of traditional courses to determine frequency and use of interactive technology.

Further, two unique courses were being offered in multiple formats simultaneously during this term. One course (c1) was being offered both as a traditional on-campus course, and also separately as an online course. The second course (c2) was being offered through three separate formats simultaneously: traditional, online, and telecourse. (The telecourse was taught via videocassettes, distributed to students during an initial class meeting). Data was collected from these courses’ online component, based on the type of interactive technology used, were gathered and compiled into the original 17 courses; further, final course grades for students in these courses were obtained and analyzed for between-group differences.

Data from an online (n=200) and a telecourse (n=11) survey were also collected anonymously and used for further analysis of the results. Students submitted the online survey via the Internet, and all entries were automatically collected into a database for further analysis. Telecourse surveys were completed anonymously in hard copy, and returned by mail to the data analyst. Data was then entered into the online database for compilation and analysis. Questions of interest from the survey for this study include a comparison of the appropriate course type (either online or telecourse) with traditional for “student/instructor interaction” and for “concept acquisition”. Choices for these questions were either “better than traditional courses”, “about the same as traditional courses”, and “worse than traditional courses”. A final question, “What effect did this course have on your contact with your instructor?” was also investigated. Answer choices for this question were either “positive”, “neutral—neither positive nor negative” or “negative”. All surveys were given to students during a time period within the last 3 weeks of class.

Results

Interactive Technology Usage

From the 17 online courses analyzed, 7 (42%) were seen to use DB. Of those using DB, number of topics (forums) created for the course varied from 3-28. Number of student responses (postings) to each forum varied from 1-146, with the average number of postings for each forum was 41. Postings were generally student-student, rather than instructor-student. However, forums must be initially created by instructors, so preliminary questions or postings were always initiated by the instructor. Thereafter, students suffered no restrictions as to the number of postings they were allowed to make per forum. Only 4 of the online courses used VC (24%). Of those courses using VC, the courses consisted of 8, 6, 6, and 5 VC meetings total. Each VC meeting lasted approximately one hour. Of the 17, only 2 courses (12%) used both DB and VC to communicate. VC sessions were generally instructor-led clarification periods in which the students were allowed to request help with specific problems they were encountering in the course. All courses analyzed for this study used e-mail to communicate, and instructors report a high number of e-mail from online students. Instructor-reported usage of interactive technology in traditional classes revealed that the majority of student contact instructors by either face-to-face or telephone, and only a very small percentage use email. A minute number of instructors reported using some form of interactive technology equivalent to email or discussion boards, while none reported using interactive technology equivalent to synchronous chat.
Achievement

Between the two courses offering simultaneous methods, largely varied results were found among courses in relation to students' final course grades. Of the first course, cl, an abnormal grade distribution was found to be present. Grades fell exclusively into either an “A” category or an “F” category in the online component. This data varied slightly in the traditional cl course, yet the majority of grades still fell into the “A” category. Course cl used e-mail and the DB communication function frequently within the online component, and used only email as a mode of interaction in the traditional component.

Course c2 offered a more normal distribution among grades in comparison to cl. Students grades were highest, consecutively, in telecourse, traditional course, and online. Students in the online component had a significantly lower number of “A’s” than their counterparts in either the telecourse or the traditional course. Concurrently, higher class drops or incompletes were found in the online component than in the traditional or the telecourse component. The traditional component of c2 had slightly less than ½ the number of drops or incompletes than did the online component.

**Table 2: Percentage of students' final grades and drops or incompletes in “c2”**

Further data from a survey completed by online students showed that 80% of students rated the course as having either “about the same” or “better” student/instructor interaction than traditional courses. Additionally, “concept acquisition” received 90% response for “about the same” or “better” than traditional courses. One question, “What effect did this online course have on your contact with your instructor?” received 56% response “positive”, 36% “neutral—neither negative nor positive”, and 7% “negative”. Student comments pertinent to these results include:

I appreciate that distance learning is up to me and that my responsibility is to keep up with the course... As always, learning is up to the student, and I did learn!

It was more convenient and I felt that I had better, as well as easier, access to my instructor...

I liked the class, but felt like (professor) could have interacted more with students...

I loved this class. The teacher was wonderful, the students were great, and we all interacted more than I have in any other class. I would gladly do this again.

Comments 1, 2, and 4 were from students who participated in a course using DB, VC, or both. Comment 3 is from a student participating in a course using only e-mail.

Data obtained from students participating in a telecourse revealed that 72% rated their course as “about the same” or “better” than traditional courses on student/instructor interaction. The same percentage, 72%, rated concept acquisition as “about the same” or “better” than traditional courses. For the above question, “What effect did the (telecourse) have on your contact with your instructor?”, 36% of students responded “positive”, 18% “neutral”, and 45% “negative”. One student stated:
Further student comments stated that many of the students did not even watch the videotapes, but studied textbooks only. Students were clearly not engaged with one another or with the instructor at the same level as in traditional courses, or in distance education courses utilizing interactive technologies.

Discussion

Currently, instructors are trained on how to construct courses, focusing mainly on the technical aspects rather than instructional design and communication issues. This trend is beginning to change at the university used in this study, but slowly and with quite a bit of opposition from individuals who, surprisingly, are supporters of distance education. Many instructors hold fears of having control tighten over their teaching methods, and therefore do not appear to be quite so open to new methods of communication. The pattern appears to be this: once instructors try one form of interactive communication aside from email, they quickly notice student responses take on a more positive tone. From this point forward, instructors are more likely to engage in interactive technologies such as threaded discussion boards and synchronous chats. Interaction is clearly a necessity for the majority of students to succeed in distance education courses, so advances must be made to enable and encourage these instructors to take advantage of the interactive technologies present.

Interaction is often the key in many traditional college-level courses that require independent thinking. In distance education, every course requires independent thinking, as evidenced by student comments from the anonymous survey. It is not surprising that the NEA (2000) stated faculty rated their distance learning courses higher and more compliant with quality standards when interactive technology is used. This seems to be an essential element not only for the instructors to keep track of the student’s progress in the course, but for the student to receive feedback, both from his instructor, as well as from his classmates. Discussion board interactivity could be equated to a traditional course’s class discussion. Many times these class discussions serve to clarify concepts for students, or help the instructor focus on topics that students are most interested or having the most trouble with in class. Outside of this typical environment, students continue to demand this feedback and cooperative learning experience. One recent and interesting study focused specifically on the effects of immediacy of response from the instructor in an online course on student’s perceived concept acquisition (Baker, 2001). The results of Baker’s study found a strong positive correlation between the perceptions of instructor immediacy of response to students with affective learning (r=.73, p< .01).

Another finding of the NEA (2000) showed that a very small percentage of distance education courses that were not web-based (online) used chat rooms (15%) or threaded discussion groups (22%), while a much more substantial percentage (62% for both) of web-based courses used chat rooms and threaded discussion groups. This data appears to correlate with the findings of this study, in that the online courses are more likely than other distance education methods to use these methods of interactive technology.

It is interesting to note that four of the seventeen online courses studied in this research used DB for student-instructor and student-student communication, but did not use the VC function. These classes left the VC function enabled, meaning the students were able to browse or “drop in” to the VC room, even though there was no session underway. An archival function present in the course platform for these online courses records each instance of a student entering the chat room, including any comments the students may make. It appears to be significant that courses with students using the DB but not VC function always had students drop-in to the VC rooms, and many times students would leave comments such as “hello, anyone here?” Though these students did not understand how to use the VC rooms, they were clearly open to or curious about these chat rooms. This is perhaps a case where the use of one interactive technology, the discussion board, launched them into looking for other methods of communication, similar to the pattern in which instructors jump from using only one interactive technology to many. Students appeared to go in search of other methods of interaction when they were participating in the DB, whereas those students not participating in DB had virtually no drop-ins into the VC area. Hence, it could be assumed that these students not exposed to a form of interactive communication other than e-mail were less likely to search for other ways to communicate with fellow students and with their instructor. This yields the idea that areas of interactive communication, such as with the VC and DB, should be open or enabled to the students without instructor-mediated conversation, perhaps as a student-student study session.

Also of interest are the grades in the c2 course, in which both the online and traditional components have approximately normal grade distributions. However, no form of interactive technology other than e-mail was used in this course. Students gave lower overall course ratings on c2 than on c1, but appeared to receive grades on a more “normal” scale than in course c1. It is possible that intervening variables such as teaching style, student familiarity with technology used, and many more could have produced these peculiar results. The grades of the c1 course show a
bimodal distribution, with the majority (74%) of students receiving an “A” in the course. This leaves an astounding percentage (26%) of students to receive an “F” in the course. Comparing this “F” grade distribution in the traditional component of this course in which only 7% of students received an “F” grade, a major distinction is observed. Again, intervening variables could be at play, and these results must be taken cautiously. However, the results do indicate that several major between-course, and instructor-dependent factors may be influencing student success and satisfaction in distance education courses.

Conclusions

Student outcomes in distance education courses are the primary concern of most of the advocates and opponents of these non-traditional courses. Faculty, administration, students, and many others hold concern for equitable learning in distance education courses. It is essential to determine what the crucial elements are that must be present for students to obtain an excellent education. The move is underway to go from a number-focused to a more success-focused orientation in most higher education institutions, and soon, the rest will follow. The issues of interaction and student success will clearly continue to be on the forefront of this discovery.

Abstract

This research study examined whether or not integrating technology throughout a sequence of teacher preparation courses was an effective model for ensuring that pre-service teachers graduate with the knowledge and skills needed to integrate technology in their own teaching. The central question addressed in this investigation was: Is there a significant difference between the level of concerns related to technology integration for preservice interns who enrolled in an introduction to technology course and preservice interns who were exposed to technology integrated throughout all of their teacher preparation courses? The results of this study show that preservice teachers still resist the use of technology as a learning tool even after models of technology use are integrated across all of their teacher education courses. However, the results also demonstrate a shift from the preservice teachers focusing on concerns about how technology will impact their role as teachers to concerns about technology’s impact on their students’ learning.

Theoretical Framework

The inclusion of technology into elementary teacher preparation programs has become a necessary and important component in most, if not all, teacher education programs. Traditionally, schools of education have prepared their teacher educators to integrate technology through the use of a single technology course focused on skill development with some discussion about teaching with technology. (Topp, 1996). However, it is unreasonable to expect that novice teachers will have the skills and knowledge necessary to effectively integrate technology in their own classrooms after taking only one course (Jensen, 1992).

For the past ten years the integration of technology into teaching methods courses has been suggested as an effective model for helping teacher education candidates develop a vision of the role of computers in an integrated curriculum (Brownell & Brownell, 1991; Willis, 1997). According to Carroll (2000), it is important for teacher education faculty to model technology proficient instruction in courses where pre-service teachers are acquiring the subject matter expertise they will use in the classroom. With this model in mind, colleges of education are working to develop the technology skills and knowledge of their faculty (Thompson, Hansen, & Reinhart, 1996; Sprague, Kopfman, & de Levante Dorsey, 1998; O’ Bannon, Matthew, & Thomas, 1998; Sprague & White, 2001). Despite these efforts, little research has been done to show that integrating technology into all teacher preparation courses is any more effective than the traditional technology course.

Teacher Preparation Program

During the 1998-99 academic year, a state-supported institution located in a highly diverse urban/suburban region near Washington, DC, redesigned its teacher preparation programs in response to changes in state licensure
requirements. The redesign involved changing from early childhood (PK-grade3) and middle (grades 4-8) education licensure programs to an elementary (PK-6) licensure program. In the original early childhood and middle education programs the course, “Introduction to Educational Technology” was the only course in the programs that focused on technology and was taken at the beginning of the sequence of teaching methods courses. During the development of the elementary program, the program faculty decided to eliminate the Introduction to Educational Technology course and integrate technology throughout all courses.

Students admitted in the 1999-2000 Cohort were the last to go through the early childhood program. These students were required to take the Introduction to Educational Technology course that focused on providing students with technology skills and models for integrating technology in the PreK-3 classroom. However, students entered the course with different levels of technology skills. Those who were proficient with technology often indicated that the course moved too slowly while those who were less experienced with technology felt that the course moved too fast. In addition, for many of the students this was their only experience with technology throughout the program. Therefore, it was necessary to focus on teaching with the technology to encourage these students to use technology for more than drill-and-practice activities.

During the elementary program development effort the faculty expressed the belief that technology should be infused into the program and were committed to modeling the effective use of technology to support teaching and learning. Consequently, a portion of the content from the original Introduction to Educational Technology course was placed in two specific courses, an Introduction to Elementary Curriculum, the first course in the program sequence, and an Integrating Technology into Elementary Curriculum, the last course in the program sequence. Program faculty agreed to integrate technology into content area methods courses that were sequenced between the first and last courses. A faculty member who had expertise in integrating technology in K-12 curriculum (and had been responsible for the technology course that was eliminated) worked to ensure that technology skills needed to complete assignments across all of the teaching methods courses was provided in the first course. In the final course, Integrating Technology into Elementary Curriculum, students were exposed to theoretical frameworks such as, constructivism, integrated curriculum and cooperative learning for integrating technology into a variety of content areas. Students enrolled in 15 credit hours of method courses between these two courses. In these courses, students were exposed to technology appropriate for the specific content area. Students admitted in the 2000-2001 Cohort were the first students to enroll in the new Elementary Education Program.

Instrumentation

During the first week of classes, students in each Cohort were administered the Stages of Concern Questionnaire (SoCQ) (Hall, George, and Rutherford, 1998). This instrument consists of 35 statements related to perceptions about an innovation. The statements were modified to use “technology” instead of “innovation.” Students were then administered the same instrument at the end of their program of study.

The SoCQ is based on a seven stage developmental model: (0) Awareness, (1) Informational, (2) Personal, (3) Management, (4) Consequence, (5) Collaboration, and (6) Refocusing. Respondents rate the degree to which each item reflects their feelings using an 8-point Likert scale that ranges from “Irrelevant” or “Not true of me now” (0) to “Very true of me now” (7). According to the model, as individuals move from unawareness or nonuse of technology into beginning or highly sophisticated use, their concerns shift from being most intense at Stages 0, 1, and 2 to most intense at Stages 3, and ultimately to most intense at Stages 4, 5, and 6.

To score the questionnaire, the statements were collapsed into the seven categories. The responses were converted to percentile scores. Each individual’s highest percentile score was circled. If the highest score appeared twice, it was circled twice. The mean percentile scores for each of the seven stages were computed for each group’s pre and post questionnaire. The results were graphed in order to obtain a profile for each group (Hall, George, Rutherford, 1998).

Results

Forty-two students were enrolled in the 1999 Cohort. Forty students completed the pre-questionnaire and post-questionnaire. The average age of this group was 35 years and there was one male student. In the 2000 Cohort, 48 students completed the pre-questionnaire and 37 students completed the post-questionnaire. The average age of this group was 30 years and there were three male students.
The highest stage of concern on the SoCQ pre-questionnaire for both the 1999 and 2000 Cohorts was Stage 1, Informational. A high score (Very true of me now) on such statements as “I have very limited knowledge about technology” and “I would like to know what the use of technology will require in the immediate future” reflected concerns at the Informational Level. (See Figures 1 and 2 for graphs of the results.) For both groups, the second highest level of concern was Stage 2, Personal. A high score on such statements as “I would like to know how my role will change when I am using technology” reflects concerns at the Personal Level. Responses on all other stages of concern were low. This profile is typical of a nonuser of technology.

On the post-questionnaire for both the 1999 and 2000 Cohorts Stage 2, Personal was equal to Stage 1, Informational. The overall profiles still resembled that of non-users. In this instance, personal concerns (Stage 2) appear to override concerns about learning more about technology (Stage 1). That is, these groups are more concerned about their position and well-being than they are about learning more of a substantive nature about technology (Hall, George, Rutherford, 1998).

The highest stage of concern on the SoCQ post-questionnaire for the 2000 Cohort was Stage 6, Renewal. A high score (Very true of me now) on such statements as “I would like to revise my use of technology” and “I would like to modify our use of technology based on the experiences of our students” reflects concerns at the Renewal Level. When this occurs one can infer that the group has other ideas that they see as having more merit than the use of technology. Any high scores in Stage 6 in a non-user profile should be interpreted as a potential warning that there may be resistance to the use of technology (Hall, George, Rutherford, 1998).

Figure 1: Pre and Post Scores on the SoCQ for the 1999 Cohort
Discussion

Although both posttest profiles are those of a non-user there are some interesting trends accruing in the 2000 Cohort, the group that experienced technology integrated across all of the courses. There is a rise in level of concern in the areas of Consequence and Collaboration. A high score (Very true of me now) on such statements as “I am concerned about how technology affects students” and “I am concerned about evaluating technology’s impact on students” reflect concerns at the Consequence Level. The Collaboration Level contains such statements as “I would like to help other faculty in their use of technology” and “I would like to know what other faculty are doing with technology.” High scores in these two areas show a shift from the preservice teachers focusing on concerns about how technology will impact their role as teachers to concerns about technology’s impact on their students’ learning. They are also showing a willingness to work with colleagues to improve the potential of technology. Such a trend demonstrates that these preservice teachers are beginning to make the shift from technology as a productivity tool to technology as a learning tool. They are starting to see the potential of technology to enhance the learning process. However, more time and opportunity to practice what they are taught in their education courses is needed to enable them to overcome their initial resistance to technology.

Research has shown that shifts from Awareness and Informational concerns to Consequence and Collaboration concerns can occur among inservice teachers who study the potential of technology in a four semester graduate level cohort program (Norton and Sprague, 1996). Inservice teachers have the opportunity to practice and experiment with the activities and models taught in their teacher education courses. They are able to understand which models are effective and which need modification. They see the value of constructivism and student-centered activities because they have the opportunity to try them in their classrooms. For preservice teachers to also have the chance to test these models, teacher education programs must work closely with K-12 schools to ensure preservice teachers have the opportunity to teach with technology in their field experiences (White and Sprague, 2002). Such opportunities could help preservice teachers move past their initial resistance to technology and accept it as a learning tool designed to enhance the learning experience.

Conclusion

On the surface, the results of this study seem to challenge the belief that the integration of technology into teaching methods courses is any more of an effective model for promoting the role of computers in an integrated curriculum than the traditional technology course. However, a closer examination of the data does reveal that preservice teachers who experience technology integrated across all courses do begin to make the shift from concerns
focusing on how technology will impact their role as teachers to concerns about technology’s impact on their students’ learning. Opportunities to practice the models presented in their teacher education courses could enable them to overcome their resistance and embrace technology and its potential to enhance the learning experience. Therefore, teacher education programs must work closely with K-12 schools to ensure preservice teachers have the opportunity to teach with technology during their field experiences.

The Use of Qualitative Methods in Program Evaluation: Elephants can be Elegant

Judy Stahlman, Cleveland State University, US
Kathleen Benghiat, Cleveland State University, US
Stacy Zitek, Cleveland State University, US

Guba in 1978 described the benefits of moving away from the use of quantitative methodology in the field of program evaluation, and replacing this approach with qualitative methods to greatly enhance the information shared with decision-makers. Since that time, many professionals in the field have embraced the use of qualitative methods, however, because these designs personalize the data collection process for the respondents, they present both unique benefits and challenges.

The purpose of this paper session is to present information on the qualitative methods being used to evaluate the Modeling Instruction with Modern Information and Communication technologies Project (MIMIC) that is funded through the federal PT3 grant program and housed in the College of Education at Cleveland State University. The goal of MIMIC is to increase the integration of technology into pre-service teacher preparation courses, thus ultimately enhancing the use of technology by future teachers. Current K-12 teachers, proficient in the use of technology in the classroom, serve as mentors to university faculty and support them in learning new ways to use hardware and software as educational tools. Although there was a need to monitor this project's activities through quantitative methods, each of the MIMIC mentor/mentee teams had an interesting story to tell about their experiences that could only be captured using a qualitative approach.

MIMIC's qualitative data collection system will be described, consisting primarily of monthly logs and personal reflective journals. Presenters will provide an overview of the procedures followed to implement the system and discuss modifications that were made based on insights gained during the first full year of implementation. The benefits of qualitative data collection will be examined as well as the challenges faced in using this type of methodology for program evaluation.

Throughout the presentation and paper, benefits of qualitative data collection will be highlighted through the sharing and description of samples of the rich descriptive data from the MIMIC Project. These samples show the struggles and triumphs of faculty members and their classroom teacher mentors as they search out the most effective educational technologies to teach specific content and then work to integrate those technologies into teacher education courses. As noted, however, benefits did not come without challenges as the MIMIC evaluation team attempted to manage the timely flow of data from a diverse, creative, busy group of individuals. The authors will share how these challenges were met in ways that ultimately enhanced and supported the data collection process, and provided timely formative feedback to the MIMIC staff. Those attending the session will have an opportunity to read "the story of MIMIC" in a handout that shows how qualitative data can indeed provide unique insight into how technology project goals are being met.

Children's Use of the Internet at Home

Yu-mei Wang, University of Guam, US

Perspective
How do school children use the Internet at home? The answer to this question is critical since an increasing number of young children are accessing the Internet on a daily basis. Growing up with the Internet, children nowadays constitute a constant presence in cyberspace. Statistical data show that young children who are on-line are more likely to log on at home than at school. In the year 2000, it was estimated that more than 55 million households owned personal computers. Almost 20 percent of all digital media users were children.

The Internet provides rich information resources and has the potential for transforming children's learning. While the Internet opens new horizons for learning, it, at the same, poses extraordinary challenges to Internet users, especially to young users. The information on the Internet is unfiltered. The absence of information filters, such as editors and peer reviewers, shifts responsibilities of evaluating information to Internet users. In addition, the information on the Internet appears in multimedia formats including graphics, sound, animation, video clips as well as text, which further complicates the user's process of judging the authenticity and credibility of that information.

Presently, there is little research about how children interact with Internet resources. Although the Internet can be a wonderland for children's learning, it can be a messy, confusing, and dangerous ground. It is imperative that we have a better understanding about how young children use the Internet so as to develop effective strategies to guide their exploration in cyberspace. "Without sound research, there is a tendency to react to the headlines and hype of the moment - and that tack may not result in wise school policymaking and parental oversight."

The Study
This study is designed to investigate how sixth graders in a school of the United States used the Internet resources at home; their perceptions about Internet resources and related issues such as parental supervision and guidance they received for their Internet uses; the search strategies they used, and the teachers' role regarding children's Internet use.

Research Instrument
A survey questionnaire was developed and reviewed by a panel of experienced school teachers and experts in the field. The survey questionnaire was then revised based on the panel's comments and suggestions.

Data Collection
The sample population consisted of all the sixth graders in a school in the United States. The survey was administered in late September 2001. All the sixth graders in the school participated in the survey. Altogether 404 surveys were collected, among which, 171 children indicated that they were Internet users and accessed the Internet at home.

Data Analysis
Data was analyzed by using SPSS (Statistics Package for Social Science). The descriptive method was used for preliminary data analysis. Descriptive research is often used to report the characteristics of the studied sample at one point in time. As Gall and Borg (1996) pointed out: "Descriptive studies in education, while simple in design and execution, can yield important knowledge" (p. 376). Frequencies were calculated to generate baseline data on how school children interacted with the Internet resources.

Results
Gender was balanced among the Internet users in the survey with 85 (50%) male children and 86 (50%) female children. Frequency distribution showed that the highest Internet use was to play games (56%), followed by accessing information for school work (47%); downloading materials unrelated to school work (32%); engaging in other activities such as reading for entertainment and doing shopping (29%). Children
reported that they accessed the websites recommended by their family members such as bother, sister and
cousin (45%); friends (44%); parents (43%) and teachers (19%).

Children turned to the Web for resources because it was fun to search for information on the Web (73%).
Their major information search strategy was to use search engines by typing in keywords (68%).
Approximately 56% of children perceived that the information on the Web is most likely accurate while 16%
of the children disagreed and 28% of the children were undecided. These children would use a piece of
information if the web page looked attractive (64%). While 40% of the children indicated that inappropriate
materials (naked pictures, information on how to make bombs, etc.) made them feel curious, 52% of the
children noted that inappropriate materials on the Web bothered them.

While 60% of the children believed that their parents had adequate knowledge to advise them in the use of
the Internet, only 22% of the children reported that their parents frequently supervised their Internet use.
About 33% of the children noted that their parents discussed with them their concerns related to using the
Internet. Children had low confidence in their teachers' knowledge to guide them in the use of the Internet
(35%). Only 11% children reported that their teachers discussed their concerns with them related to Internet
use. Approximately 80% of the children agreed that the Internet provides important resources for learning
and should be integrated into the curriculum.

Implication of the Study
This study generated useful information and provided insights on how young children interact with Internet
resources. Although the highest use of the Internet was to play games, there was a positive indication that
quite a number of these young children were taking advantage of the wonderful resources on the Internet
for their school work. These children supported the integration of the Internet into the curriculum and
understood that the Internet can play a great role in developing their intellectual skills. This positive trend
needs to be supported and encouraged. Teachers and parents can recommend children educational and
age-appropriate resources to maximize the children's learning opportunities on the Internet.

Although these children's understanding of the importance of Internet resources to their education
indicates a level of sophistication for their age, they were naive in their judgment of the quality of Internet
resources. A large number of these children perceived that the information on the Web was most likely
accurate. These children indicated that they would accept a piece of information if the website looked
attractive, thus confusing visually appealing web pages with the quality of the content. It is a great
challenge for schools and parents to educate young Internet users to become critical readers and to acquire
skills on how to evaluate Internet resources.

The most troubling finding of this study was the low parental and teacher involvement in supervising and
guiding the children's Internet use. Although the majority of children trusted that their parents had
adequate knowledge to provide guidance, most parents never or rarely supervised their on-line children.
Parents have a major role to play in protecting their children from the potential exposure to inappropriate
materials on the Internet. Inappropriate materials on the Internet can be harmful for young children.
Parents can surf together with their children, model the appropriate use of the Internet, discuss with their children
the responsible use of the Internet, or consider installing filtering programs to help sift through information.

Schools need to share its role in guiding children's Internet use. This study found that teachers played a
disappointingly limited role in this regard in the eyes of children. It might be that teachers themselves did
not have adequate knowledge about the Internet. Schools should offer workshops to teachers to train them
to become effective Internet users. In addition, schools should organize workshops for parents to help them
develop strategies to guide their children's use of the Internet. More importantly, schools need to educate
children to become their own guardians in the use of the Internet.
Technology Resistance and Barriers: “Baby Steps” to Online Courses

Abstract: A simple, step-by-step approach to overcoming barriers to online course development and technology use in education is outlined. The “Baby Steps” approach is effective dealing with several of the barriers to technology use.

Introduction

Administrators in university educational settings must face and deal with faculty resistance to information technology usage in the teaching profession. Faculty reasons or explanations for resistance toward technology usage in classroom teaching or online course development are considered valid issues or criticisms: much time is required upgrading classes with technology, technology equipment is not always available or reliable; some course content is not always suited for newer technologies, etc. However, many of the reasons for not using informational technologies have their root in emotional and/or psychological habits. This paper will address some of the barriers that prevent faculty from incorporating technology into the classroom. By making use the structure of Blackboard, an online course management software system, a systemic approach to dealing with individuals will learn how to use technology in the classroom and online course development.

Many people have difficulties using new technologies. For some the stress of using new technologies and computers, specifically, has caused apprehension and fear. This fear of technology has been termed, “technophobia”. In investigations of technophobia, Weil and Rosen (1987) found three techno-types: (1) Eager Adopters, (2) Hesitant “Prove its” and (3) Resisters. This article will focus on the resisters/technophobics. Resisters/technophobics avoid technology, want nothing to do with it, and may fear any machine or gadget they touch. As a result of this behavior, they feel embarrassed, intimidated, or shamed due to their lack of knowledge. The natural and expected reaction to fear is to avoid the feared stimulus, in this case technology, and avoidance will reduce fear in the immediate time frame but increase the fear in the long run. The more they resist and avoid technology, the more fearful and anxious they become towards technology. This avoidance method becomes a vicious technology-fear cycle. The fear of technology or technophobia is one barrier that leads to resistance toward using technology in the classroom.

Another factor that leads to resistance to technological use is the human tendency to view the unknown as “of one piece.” We have termed this tendency “monolithia”, an etymological fraternal twin of “monolithic,” which means, “consisting of a single stone.” The English language gets this word through French and Latin from Greek. The dictionary definition of “monolithic” that best fits the usage for this paper is
“constitutes a massive undifferentiated and often rigid whole.” Many times university faculty have a tendency to view online courses and educational technology as monolithic. Faculty perceive technology and its use as a single, insurmountable task rather than a step by step, or piece by piece, learning process. Fear is heightened, and resistance to technology is accentuated.

Faculty members being required to use technology in the classroom and seeing technology as monolithic may exhibit procrastination as well as technophobia. Procrastination or task avoidance involves putting some task off until later. Procrastination is usually interwoven with the need to be perfect, also known as perfectionism, which further prohibits the learning and use of technology. Individuals put tasks off until such time that they can do them perfectly. The psychological dynamic in operation is often anxiety or fear. For example, if the task is completed, they may be evaluated on the task. The individual will be forced to realistically find out how well they did in the task. This process is difficult for some people to handle. So we may avoid tasks outright or strive to be so perfect that it is put off or worked on until in our minds it is perfect. Naturally, this often results in the task never being completed. Fritz Perls (1992) termed this anxiety “stage fright.” An actor does not know after performing whether the audience’s response will lead to applause or rotten tomatoes being thrown at the actor.

Technophobia, monolithia, and procrastination are all related to habits of mind and emotion. Monolithia is a thinking problem, whereas technophobia and procrastination involve the emotion of fear. The fourth and fifth barriers to using technology in the classroom are low motivation and reactance. Psychological reactance is defined as the tendency to oppose any action or suggestion on the part of another that would restrict our behavioral freedom. Or put more colloquially, “no one likes being told what to do.” Humans exhibit varying levels of reactance. Low motivation and reactance are less related to emotion and more related to individual behavioral patterns. When dealing with faculty exhibiting low motivation and reactance to technology it may be more difficult to change these behavioral patterns. Low motivation is evident when an individual does not have enough mental or physical energy and/or drive to complete a task. In the case of an individual who has both mental and physical energy and/or drive to complete a task and does not do so, this is commonly referred to as “laziness”. Reactance tendency is very common among individuals; however some individuals exhibit a stronger reactance tendency than others. An important realization about these five barriers is that very rarely do they occur in isolation; usually some combination of the barriers occurs.

Understanding basic psychological principles can help faculty overcome the barriers that may be preventing them from using technology in the classroom. Joseph Wolpe (1958) postulated that anxiety or fear could not be present in a person at the same time as relaxation and serenity. Fear is the autonomic nervous system arousal that is a preparation for fighting or fleeing – the “fight or flight” response. This notion that fear and relaxation cannot occur simultaneously Wolpe termed “reciprocal inhibition”. In effect, fear inhibits relaxation and vice versa. This is hardly a surprise. But out of this idea he developed a clinical technique for reducing fear, which he called “systematic desensitization”. The individual, whose fears brought them for help, constructs a “fear hierarchy”, with the help of therapist, which consists of images or stimuli that are graded in terms of the fear they evoke. Generally, the hierarchy consists of items that gradually lead to, and are in some sense related to, the most feared of the items down to least feared item. The individual is asked to imagine the least fearful of the hierarchy until they feel fear, then begin a relaxation exercise until the fear is gone. By the process of working up the fear hierarchy the individual finds that they can relax even while thinking of the most feared of the hierarchical items. A later development related to systematic desensitization is “in vivo desensitization,” in which a person learns to relax in the presence of the fear producing stimuli rather than using images of feared stimuli. Through these techniques fear of technology can be reduced, and individuals can start to learn to use technology without the experience of fear.

In addition, a technique similar to systematic desensitization can be very effective helping people better manage their time. Alan Lakein (1989), the well-known time management specialist, writes that people can use the “Swiss cheese” technique when working on a task. This approach involves working on small pieces of a task or project (baby steps) until the whole is completed.

To help individuals resolve the barriers that prevent them from mastering and using technology in the classroom and/or putting classes online, we have devised an approach we term “Baby Steps”, which is a step-by-step method using Blackboard. Blackboard is an online course management system that is widely used and available commercially. We could just as well use WebCT or another software package. Blackboard is the system in use on our campus. The step-by-step hierarchy found below includes putting course syllabi online, links to websites relevant to the course, e-mail usage for class members, build tests online, online grade book, using the
discussion board, and using the virtual classroom. The hierarchy of tasks moves from the simple and quick to the more complicated and time consuming. Blackboard’s software application is a simple but potentially very powerful method for teaching and desensitizing faculty to technology use. In addition, Blackboard illustrates many other technological learning tools for working in different areas of computer technology. This learning experience can result in reducing or resolving barriers concerning computer technology.

The step-by-step approach addresses each of the barriers that we have identified as important in educational settings. It can reduce anxiety regarding technology use, help people get past seeing technology use as monolithic, reduce resistance in poorly motivated or reactant individuals, and reduce procrastination because so little is asked at any point.

Hierarchy

First the faculty member must logon to Blackboard then click on “control panel.” The tasks in each step below are accessed from this page.

1. Put the course syllabus online.

This step requires only 3 clicks and the completion of 5 fields if the syllabus is on a disc. There is a browse action required, but this is relatively painless.

2. Add links to interesting websites related to course content.

This step is slightly more time consuming than Step One. It requires that a faculty member know of interesting and pertinent sites and that the URL of that site be typed or copied into a field on a Blackboard form.

3. Email the class members using the email function.

Maybe this one ought to be Number 2, it is so simple. The faculty member clicks on the link, Send E-mail, on the Control Panel then types the mail message. Then clicks Send and OK. This feature of Blackboard is very handy for informing students about a change in class schedule and is one of the most immediately rewarding features of the software package.

4. Post assignments.

This task is virtually identical to putting the syllabus up.

5. Customize the course page’s buttons.

This is definitely not for beginners. Various colors and patterns are chosen to heighten the attractiveness of each course’s site.

6. Put up the course calendar.

This perhaps requires more work than any step but building tests, but students having a clear understanding of what is required and when it is required reward the effort.

7. Build tests online.

This is getting to the tricky and only bright faculty should attempt this task without supervision. The up side is that tests given online are auto-graded and recorded in the gradebook.

8. Use the online gradebook.
This task would by necessity be completed after an assessment was built and given, and it requires a lot of work, but that work is rewarded by relieving the faculty member of the laborious task of entering grades by hand (and averaging them by hand).

9. Use the discussion board.

This feature is used to have an online discussion, not in real-time

10. Use the virtual classroom.

This is the tough part. This feature is basically a chat room in which the faculty leads a discussion. The Room also has a whiteboard of sorts on which students and faculty can draw. 95% of traditional students today know how to do this. And faculty probably can learn.

Procedure

Faculty members complete the first few steps at faculty meetings held in a computer lab. There they can receive the help they may need from more adept colleagues. People tend to be less afraid in a group, as well. Each step is rewarded with praise and thanks. The praise and thanks, consequences of putting items online, serve as reward for the behaviors of the faculty. The positive natural consequences of using the technology take effect nearly immediately by reduced work load on faculty and improved coordination of educational activities.

The Science Section of SITE 2002 offers a variety of presentations in several formats including full papers, short papers, an interactive session, a workshop, a demonstration, and video presentation.

Among full papers presented, hear results from Tiffany Koszalka's study investigating the relationships among the use of different types of resources during instructional experiences in middle school science and career interests. Tom Frizzell will provide information about using the scanning electron microscope to augment content and pedagogy preparation of preservice teachers. Umesh Thakkar also utilizes scientific instrumentation technology to facilitate learning. Hear how teachers and teacher educators are integrating Bugscope into their lessons. Another paper, describing a collaboration among university faculty, local teachers, and students, describes the Riverlink project and its use of data collection and analysis to facilitate science learning.

Short papers include a description of a course, "Our Physical World: Science for Elementary Teachers" by Charles Hartshorne from the University of Florida, and how is uses technology-enhanced learning environments to support science instruction to elementary teachers. Also hear Marietta Langlois describe a program through which inservice teachers can get professional development that combines mathematics and science content with inquiry based pedagogy.

Come to an interactive session to see how Bill MacIntyre uses Starry Night, a computer planetarium program. He will demonstrate how 2 or 3 students can work co-operatively on a single computer to achieve mastery of the spatial aspects of astronomy.

In Lisa Bienvenue's workshop, you will learn to use several freely available web-based science and mathematics visualization and modeling tools to help you teach Biology, Earth Science, Mathematics, Chemistry, and Environmental Science.

From Patricia Donohue's session, you will take home our easy step-by-step guide called Natureshift Exploration Model. You will learn how to apply the NS Exploration Model to your classroom, to build learning experiences that will help your students pick an individual path to their own learning.

See A Gathering of BUGS- Bringing Up Girls in Science. Mark Mortensen will present a videotape showing how his 4th and 5th grade girls learn science in an after-school program at the University of North Texas.

_Linda Easley Roach teaches science methods to senior preservice teachers at Northwestern State University in Louisiana. She is also the University Contact Person for all Alternate Paths to Certification for NSU._

Incorporating Technology in Early Childhood Science Activities

Michael Joseph Bell, West Chester University, US

Science activities for young children should focus on the world around them. Life and earth science, properties of objects, physical science and biological science should be highlighted, for young children to understand scientific concepts in terms of their daily lives. Incorporating technology in early childhood science requires teachers to (1) integrate technology through methods that complement science curricula and uphold the principles of developmental and authentic early education, (2) use materials and equipment that augment and support young children's perceptions of their world for the purposes of gaining accurate information, and (3) support child-centered methods of organizing information and understandings.

This paper will focus on inquiry-based methods of incorporating technology into early childhood science activities. Considerations for developmentally appropriate and authentic science experiences for young children will be discussed, as well as the effective use of technology to broaden each child's skill development in gathering and organizing information about their world. Early childhood educators should view their role in science activities from the perspectives of facilitator with the goal of expanding young children's skill development through child-centered science activities that promote autonomy, independent decision-making, and scientific curiosity.
Introduction

This paper presents the design and evaluation of the MUST multimedia-case ‘Color & Light’. This case has been developed within the framework of the MUST-project (Multimedia in Science & Technology). The MUST-project is a joint venture on behalf of three Teacher Education Colleges, the National Institute for Curriculum Development and the University of Twente in the Netherlands. The MUST-team aims at developing and researching multimedia-cases and support tools for the professional development of preservice-teachers in Dutch elementary science education (Van den Berg, Jansen, & Blijleven, 2000).

Cases, Case-based Instruction and Multimedia-cases

A case is a realistic description of subsequent activities carried out by professionals. Multimedia applications add the power of computer technology to approaches of case-based instruction, because multimedia can stimulate more than one sense at a time and in doing so, may get and hold more attention (Jonassen & Reeves, 1996, p. 703).

Design of the MUST Multimedia-case ‘Color & Light’

‘Color & Light’ is developed on the basis of an ‘evolutionary prototyping’ approach. This approach combines input from theory and practice through the cyclic process of analysis, design, development and formative evaluation of prototypes (Smith, 1991). The structure (see Figure 1) of the first MUST-case ‘Liquids in Testtubes’ is used as a framework for the development of each MUST-case. The subsequent components of each case were designed on the basis of curriculum deliberate processes in the MUST-team. Formative evaluations are an integral of the MUST design approach (developmental research: Van den Akker, 1999).

Figure 1: Design structure of a MUST-multimedia-case

The interface of ‘Color and Light’

The interface-structure of every MUST-case is the same. Each page can be divided into two main parts, namely: (1) the navigation-part, which contains buttons (hyperlinks) for the navigation through the case and (2) the main-part, wherein the information to be studied is presented. The navigation part has also another function. Its color and background-illustration ‘tells’ the user what the subject matter of the involved multimedia-case is about. The navigation-part of ‘Color & Light’ consists of a colorful bar with an image of a rainbow, representing the topics ‘color’ and ‘light’. Next, the different components of a MUST are presented.

Video

The core-component of a MUST-case consists of non-scripted edited videos of an elementary science lessons, representing both a realistic and relevant context for preservice-teachers. The clips are edited in a way, that provides the opportunity to analyze the presented lesson(s) critically (cf. Merseth, 1996). The video-page of ‘Color & Light’ consists of three videos. In the first video this series of lessons is introduced by means of an narrative about two children buying new clothes and a class discussion about this narrative. This lesson is an
example of how a teacher can activate pupils' concepts (about 'color' and 'light'). The second and third lesson are hands-on experiments with different colors of paint and felt-tipped pens. Aim of these two lessons is to give pupils the opportunity to check and if necessary adjust their concepts about 'color' and 'light' phenomena.

Location

The location-page of a MUST case gives the student background information about the school, the class and the video-teacher. Aim of this component is to give students the opportunity to interpret and judge the teacher's actions and to compare the 'video-school' with their own student-teaching schools. The class-section consists of background information about the pupils. This section starts with a clickable photo of the class. By clicking on one of the pupils, the user gets detailed information about the selected pupil (e.g. who is this pupil, what does this pupil think of: the school, the series of 'color' and 'light' lessons and science in general). The clas-section contains also scans of the assignments, pupils carried out during the hands-on experiments. Preservice-teachers can view these assignments to check what the pupils learned from the series of lessons.

Comments

This component includes comments on the video-lessons by the video-teacher, experts and preservice-teachers. Aim of these comments is to let students experience that certain lessons, in this case a lesson about 'Color & Light, can be considered from different perspectives. These different perspectives add, according to Shulman (1992 p.12), complexity and richness to a case that gloss rather than simplify or trivialize a case.

Subject matter

The subject matter-page is meant for preservice-teachers, who are uncertain about their own subject matter knowledge. This page offer preservice-teachers the possibility to refresh or increase their subject matter knowledge. In the 'Color & Light' production, the subject matter is presented by means of small animations and simulations of mixing colors', 'refraction of light' and the working of a prism. A major advantage of using animations and simulations is that they let students experience 'color' and 'light' phenomena in an active way.

Other Hyperlinks

On the curriculum-page, the user can find information about how the case is related to the content areas for elementary science and to the national standards in the Netherlands. The 'learning theoretical background' page consists of information about different ways to open pupil's concepts about 'color' and 'light'. Aim of this component is to make students aware, that there are more ways to open pupil's concepts, than the method presented in the video-lessons. A brief justification of the rationale and the decisions made during the design and development of the multimedia-case are presented on the justification-page of the cd-rom (For a more elaborate description of the design of a MUST multimedia-case, see Van den Berg & Visscher-Voerman, 2000).

Formative evaluations of the MUST Multimedia-case 'Color & Light'

In the forthcoming months, several formative evaluations will be conducted. First, the "technical usability" is investigated by means of expert appraisal and a test with preservice-teachers. More important, are two try-outs in which the effectiveness of the case is subject of study. The first try-out is focused on the actual learning processes of preservice teachers working with the case. The second try-out aims at gaining insight in the transfer effect of the cases and therefore concentrates on the realtionship between the case and student teaching.

Abstract: National and international assessments of K-12 science literacy indicate that most U.S. students have inadequate knowledge of science, and statewide exams from Kentucky confirm this trend for the Commonwealth. This disturbing trend has precipitated the design of a series of four inquiry-based science courses geared toward K-8 pre-service teachers. These courses are unique compared to other general education science courses at EKU in several respects: (1) they are designed using Kentucky Department of Education’s guidelines for Standards-Based Units of Study; (2) they use inquiry-based learning following Newton’s Rules of Reasoning in Philosophy; (3) they use collaborative teams to create a group learning environment; (4) they introduce technology as an integral tool to enhance science learning; and (5) pedagogy issues are integral to the course structure. Analysis of student content knowledge and attitude toward science demonstrates that these courses increase student learning in science and improve student attitude about teaching science.

Introduction

Results from the Third International Mathematics and Science Study (TIMSS) administered in 1996 (NCES, 1999) and 1999 (Martin et. al., 2000) demonstrate that U.S. students continue to perform poorly in science knowledge and skills compared to their counterparts in other developed nations. This trend is mirrored in science performance data from Kentucky, which shows that only 5% of elementary students in 1999-2000 were considered proficient in science, while only 1% of middle school students obtained science proficiency during the same academic year (Kentucky Department of Education (KDE), 2000). Results from the 2000 National Assessment of Educational Progress indicate that a statistical correlation exists between science performance and science teacher preparation (NCES, 2002). Preliminary statistical analysis of K-12 student performance in Kentucky shows a similar correlation between the science course requirements for K-12 teacher education programs and performance of students taught by these teacher education graduates. One solution to this problem is to ensure that teacher education programs include science requirements that demonstrate best teaching practices in the sciences and that contain the core content that will be taught in the K-12 classroom. Current teacher education programs at Eastern Kentucky University (EKU) and elsewhere in Kentucky are quite
successful at preparing secondary education teachers for the science classroom (KDE, 2000), but requirements in
the elementary and middle school teacher education programs at EKU have been more fragmented and
contain few credit hours (maximum of 12 credit hours for elementary teacher education without science
emphasis) of science content.

An analysis of current science courses offered in the elementary and middle school teacher education
programs at EKU demonstrates that no possible combination of 9-12 credit hours of science courses available to
education majors will meet all the science content standards required in the K-8 curriculum. Additionally, these
courses often enroll 50+ students per section. Under these circumstances, professors are often unable or
unwilling to use current best practices in teaching science. For example, few science professors use inquiry-
based learning or allow students to work in groups to solve problems. In many cases the classroom’s physical
layout does not allow students to move desks, so they are not able to easily form into comfortable working
groups within the confines of the classroom. Additionally, the science courses either use technology that is
sufficiently expensive that it will not be available in the K-8 classroom or they use little technology outside the
realm of laboratory equipment. Therefore, current science requirements in the K-8 teacher education programs
at Eastern Kentucky University ensure that most future teachers will not be able to meet the content standards
nor the technology standards required for quality teaching in the science classroom. With funding from the U.S.
Department of Education’s PT³ program, science and education professors at Eastern Kentucky University have
designed a series of technology-infused courses that, taken as a package, will ensure that future teachers are
exposed to the content and technology standards required for quality teaching in the science classroom. The
design process for Earth Science for Teachers will be used to demonstrate the unique qualities of this type of
science course and to show the impacts of inquiry-based science courses on teacher content knowledge.

Standards-Based Design

Traditional general education science courses are unsuited to the preparation of good science teachers
due to incomplete coverage of K-12 core content in these courses. A survey of science courses and faculty at
EKU indicates two reasons for this incomplete coverage: disconnectedness between the objectives of the
course/instructor and needs of the pre-service teacher, and unawareness of core content by science content
faculty. Of the 23 introductory science courses (100 or 200 level) available to pre-service teachers, 13 of these
courses serve as an introductory course toward a major in the discipline or as service courses for other major
disciplines. Therefore, the courses are designed to address a particular subset of disciplinary content with the
assumption that students will take further courses in the discipline, but pre-service K-8 teachers are not required
to take additional courses in the discipline and often do not have adequate flexibility in their schedules to allow
for free electives in the sciences. On the other hand, upper level general education courses and introductory
general education courses not linked to majors are specifically designed for non-majors, and therefore are not
restricted by any content requirements. As a result, these courses are often designed to showcase topics of
interest to the instructor with little regard for the needs of pre-service teachers. This subset of courses could be
revised to meet the needs of K-8 pre-service teachers, but a survey of science faculty determined that 80% of
EKU faculty in the science departments were unaware that specific core content concepts to be taught in the
classroom are mandated, and many of those who were aware of the core content standards were only able to
demonstrate a nebulous understanding of the core content standards (e.g., students need to know about rocks).

The science courses for teachers created during this project were designed using Kentucky Department
of Education guidelines for development of a unit of study (1998). Kentucky’s learning goals and academic
expectations (KDE, 1995) and core content for assessment (KDE, 1999) relevant to science were identified and
partitioned among the four science courses to ensure that all concepts and skills/processes required for K-8
science teachers would be addressed in the package of four courses. Each design team identified essential
questions based on the core content on which to focus the learning in the course. The essential questions then
guided the design of activities and investigations needed to answer each essential question.

The goal of using standards-based teaching in the courses is to ensure greater quality of science content
knowledge in K-8 teachers. To determine the impact of standards-based teaching on the content knowledge of
pre-service teachers, the 4th, 8th, and 12th grade TIMSS exam was administered online (www.getsmarter.org) to
students in Earth Science for Teachers at the beginning and end of the semester. Each exam is a mixture of six
broad science topics: biology, chemistry, earth science, physics, measurement, and scientific inquiry. Students
did not receive the exact same set of questions during the pre-testing and post-testing phase, but there is a
common and consistent test bank for each grade level. At each testing phase, the following data were collected:
the score of each student, the number of times that each question was answered, and the number of correct and
incorrect responses to each question. Questions were sorted based on grade level, science content, and whether
the content was covered during the Earth Science for Teachers course. Data were statistically analyzed using
the Student’s t-test for normally distributed data and the Signed Rank test for non-normally distributed data.
The null hypothesis was that there was no change in the proportion of correct responses before and after the
course. The alternative hypothesis was that the proportion of correct student responses increased after taking
the course. The statistical analyses indicate that there is insufficient evidence that students showed
improvement in test performance on material based on grade level or subject matter. The exception is that,
using a 90% confidence level, students did show improvement in biology (p = 0.0117) and earth science (p =
0.0977) when all grade levels are analyzed together. It was determined, however, that an improvement in
student test performance occurred after taking the course on questions assessing material covered during the
Earth Science for Teachers course (p = 0.0149), but there was no improvement on test questions whose content
was not covered in the course (p = 0.2085). In other words, students learned science core content covered in
Earth Science for Teachers by taking the standards-based course.

The most obvious benefit of designing a course based on the core content standards is to improve the
students’ content knowledge and skills on topics they will be required to teach in the K-8 classroom. However,
this method of design also allows the course to address pedagogical issues in the science. The standards-based
design encourages the development of inquiry-based activities rather than lecture-driven instruction, encourages
collaborative learning environments in the classroom, and encourages interdisciplinary connections as
appropriate (KDE, 1998, p. 3).

Inquiry-Based, Collaborative Learning

The content and teaching methods of science faculty in higher education serve as the focal point upon
which pre-service teachers base their beliefs, attitudes and behaviors towards teaching science (Tosun, 2000).
After completing college-level science courses, pre-service teachers overwhelmingly have negative feelings
towards science courses, using words/phrases such as “meaningless”, “impossible”, and “boring” to describe the
courses they completed. Koballa and Crawley (1985) determined that pre-service teachers who dislike science
ultimately avoid teaching science, which merely serves to continue the cycle of science phobia. This is partially
related to students’ self-efficacy. Tosun’s study indicated that “a lack of confidence due to low achievement in
science courses was evident” (2000, p. 376). Traditional science courses use lecture as the primary teaching
method, and science is presented as a series of facts and truths transferred in an authoritarian manner. Students
are passive learners and do not become an active part of the scientific discovery process. A course that allows
students to enter the learning cycle at the discovery stage and encourages repeated success in the classroom
makes a student more confident of his/her own teaching skills (Tosun, 2000). The inquiry-based courses are
designed for students to work collaboratively in groups throughout the semester, which encourages students to
learn from their peers. Students are also active learners who gain confidence in the process of scientific
investigation and in themselves as investigators by using Newton’s Rules of Reasoning in Philosophy (Motte &
Cajori, 1962, p. 398). Students who completed Physics for Teachers show an improvement in attitude and
confidence about teaching science as determined through pre- and post-testing of attitudes. Additionally,
student comments on course evaluations indicate that students find the inquiry-based learning non-threatening
and relevant to their courses. Finally, students commented that they were able to use many learning styles that
helped them to understand the material better. Overall, students feel that they know more science, find science
more enjoyable, and feel more confident about teaching science after taking the inquiry-based courses.

Technology Integration

Recent results from the 2002 National Assessment of Education Progress indicate that student
performance is improved with the use of technology in the classroom (NCES, 2002). Technology is an integral
part of the scientific process, but due to large class size, lack of laboratory time/facilities, and the focus on
lecture-driven teaching methods, many pre-service teachers are not exposed to technology integrated into
science courses until their science methods course. However, Cronin-Jones and Shaw (1992) demonstrated that
beliefs about science teaching held by pre-service teachers were not significantly impacted by their experiences
in a science methods course. Therefore, technology integration into science content courses is crucial to preparing pre-service teachers who are capable of using technology appropriately in the K-8 classroom and who understand the importance of technology to scientific investigation and learning. In cases where technology already exists in a science course, it is often used primarily for classroom management, or the technology is significantly advanced compared to that found in the K-8 science classroom. To ensure that pre-service teachers use technology as an integral part of learning and to demonstrate technology available to K-8 teachers, a technology integration plan was developed for the courses in parallel with the content design. This plan requires the designer to identify objectives for the learning activity and to identify how the technology used will help to meet that objective. The technology is used to help answer the essential questions, and is therefore presented as a crucial and integral part of the learning process. Students who completed Earth Science for Teachers during Intersession 2001 indicated on a student survey that they enjoyed the exposure to the software programs during the course (5 out of 12 respondents), and encouraged more technology integration into the course (4 out of 12 respondents).

Pedagogy in Content Courses

Science content knowledge is crucial to the effectiveness of science teaching in the K-8 classroom (NCES, 2002). However, proficient knowledge of science content is not sufficient to ensure that K-8 students will receive a quality science education. Madison County, Kentucky, employs a high number of EKU graduates who successfully completed science courses in their college curriculum, but state assessment scores in science for this county are significantly lower than other subject areas. A survey was sent to all elementary teachers in Madison County requesting feedback regarding potential reasons for the low science scores. In 10 of the 16 responses (62.5%), current in-service teachers replied that science was not being taught effectively (or not being taught at all) because teachers were uncomfortable with the design and implementation of inquiry-based science teaching at this level. For example, one respondent indicates that pre-service teachers “need instruction and materials that will be used and implemented within an elementary classroom, not to be doing excessive papers and reviews”. Others indicate that pre-service science instruction “is not focused on classroom instruction techniques or appropriate lesson plan preparation”.

The course requirements and structure in the inquiry-based courses rely heavily on the development, use and adaptation of lesson plans from a variety of grade levels. Additionally, student surveys administered at the end of the semester indicate that students find it helpful that the instructors model appropriate activities with appropriate equipment, and that students have opportunities to develop lesson plans for use in their classroom. For example, one student indicated that “the class is an excellent model, and I plan to use everything we did in class in my own classroom”. Subsets of these courses have been offered to in-service teachers, and the feedback from in-service teachers, who are most capable of determining the usefulness of the pedagogy presented in the course, was positive. Student surveys were administered in the Earth Science for Teachers course on the last day of class. In-service teachers were asked to answer the following question: “Overall, how would you rate the value of this class?” On a scale of 1-9, with one being significantly below average and 9 being significantly above average, the course received 8.2 ± 0.8. An open response question asked students to “describe any teaching methods which helped you understand the course content”. Two-thirds of the students (sample size = 12) indicated that the multiple hands-on, inquiry-based activities were most helpful, and one-third of the students also indicated group discussion of questions was helpful. One student responded, “I already knew the content, but I like the inquiry approach. More teachers will teach this way if they are taught this way.” Another student indicates “I think that what I have gained most from this class is the ‘how to’ teach these concepts to my students. I have always struggled with finding the appropriate labs to teach/reinforce concepts, and this class has given me lots of good ideas along with another approach to teaching science.” This evidence suggests that these inquiry-based science courses provide significant support for pedagogical needs of in-service and pre-service teachers.

Conclusion

Quality preparation of future science teachers is the key to improving science education in the K-8 classroom. However, traditional, lecture-based science courses have not been effective at improving content
knowledge, improving teacher attitude about science and its importance in the curriculum, infusing technology into the curriculum to enhance learning, nor modeling best pedagogical practices. Preliminary results from research on the design and implementation of standards-based, inquiry-driven courses indicates that the implementation of these courses increased student content knowledge, improved student attitude, integrated technology into the classroom in a relevant and appropriate manner, and provided materials and models for teaching inquiry-based science in the classroom that students found useful and appropriate. Student surveys and statistical analysis of content knowledge assessment support the hypothesis that using inquiry-based, technology-infused science courses to teach pre-service teachers improves student attitude and competence regarding science teaching.

Acknowledgments

The authors would like to thank Ms. Lynne Brosius and Ms. Jo Blanset for their help with the statistical analysis required for this paper. Thanks also goes to Mr. Jesse Ward for administered the surveys to Madison County, Kentucky elementary school teachers. The design of two of the courses presented herein, Earth Science for Teachers and Chemistry for Teachers, was funded through a Preparing Tomorrow’s Teachers to Use Technology (PT3) implementation grant from the U.S. Department of Education.
Learning Virtually – by Design

Patricia J. Donohue
Dakota Science Center
Natureshift Linking Learning to Life Project

From this session, take home our easy step-by-step guide for using online technology to engage your students' interest in learning and thinking constructively. The Natureshift (NS) "Exploration Model" makes students think and we are also proving it because students are showing us that it's true. From this session, you will take home our easy step-by-step guide for applying the NS Exploration Model to your classroom, building learning experiences that will help your students pick an individual path to their own learning. Apply this simple technique in your classroom and you will have two guarantees as a result: 1. Students will be engaged and 2. Students will process for you what they learned. You even get a little extra - your students will apply new technology creatively and appropriately in their thinking.

After five years and $5 million building our Exploration Model and testing it with teachers as well as informal educators, our project is beginning to find evidence of learning. We suspect the learning we see in students might prove to be long-term, but that cannot be known until long-term studies assess what we achieved. Nevertheless, we know student thought processes are engaged. We know students show evidence not only of content acquisition but also of higher order thinking. A NS Exploration Project is by nature summative and forces the application of higher order thinking by design. A project engages students because its challenge is authentic to their lives. Learners of any age will pursue their own curiosity about genuine concerns in their world. The result is that a student project will reveal the full extent of what has been learned. The project is constructed from the building blocks of knowledge acquired through the Exploration journey. Because it requires the use of new technologies, students can now teach others what they know and what they have learned more engagingly and more thoroughly. S.A. Barab, et al. in their recent publication "Constructing Virtual Worlds: Tracing the Historical Development of Learner Practices" (Cognition and Instruction, Nov. 2001) confirm the power of local resources and collaborative learning on student constructed knowledge using virtual technologies (pp 47-90).

What is this model and what does it do? It will engage your students' interest. It will guide him or her along a path of self-inquiry in search of new knowledge. Half of that path will take the student on a Web Quest after research information. The other half of that path requires students to quest after this new knowledge in the world around them, at home, at school, in the community. When the student has completed an Exploration, he or she constructs meaning from what was studied, applies it in a self-designed project, and teaches others what was learned. Along this learning path students are given opportunity to employ technology to their tasks. They learn by actively doing. They succeed by having fun. They investigate their lives by satisfying their natural curiosity. You will find it hard yourself to have as much fun again playing with a learning model in your classroom.
On-line Microscopes & Inquiry-based Science Instruction: Improving Technology in Teacher Education

Abstract: The purpose of this paper is to present a project in which on-line access to a scanning electron microscope (SEM) is used to enhance the science and technology content and pedagogy preparation of preservice teachers. By integrating an on-line SEM into teacher education courses, new teachers emerge from our teacher education program with advanced technological and pedagogical skills to effectively integrate technology into science curricula.

In this paper, we will discuss the incorporation of inquiry-based scanning electron microscope (SEM) activities in three teacher education courses: a science teaching methods course and two instructional technology courses. The use of the on-line SEM and the inquiry-based instructional approaches used in this project are consistent with the National Educational Technology Standards and Science Education Standards. Moreover, this project demonstrates the complexity and benefits of coupling technology and content to significantly enhance science teacher preparation.

At Iowa State University, the integration of the SEM into the education courses occurs at the sophomore, junior and senior levels. At the sophomore level, preservice teachers are first exposed to the SEM in the course Introduction to Instructional Technology. A requirement for all education majors, this course is designed to develop students’ basic skills with information technology and to introduce pedagogical considerations in the use of technology in learning. Students learn about the SEM in a large lecture and engage in hands-on activities in the small laboratory setting. Finally, the students explore instructional strategies essential for implementing web-based lessons.

At the junior level, education students who choose to minor in educational computing (approximately 12% of education majors) receive a more in-depth experience with the SEM in the course Using Computers in the Classroom. The sole purpose of this course is to develop students’ ability to design and implement technology-based learning environments for K-12 students. In this course, the preservice teachers develop proficiency in using the on-line SEM and design and implement science lessons that effectively incorporate the SEM. In addition, students in this course critique the on-line SEM interface and provide feedback to the developers to refine the webpage.

In the semester prior to student teaching, all elementary education majors (N = 1,000) enroll in the senior level course entitled The Teaching of Science. The purpose of this course is to prepare future teachers to teach science to children in grades K-6. In this course, emphasis is placed on developmental implications, teaching processes, and discovery/inquiry approaches to science instruction. Students in this course develop a working knowledge of the on-line SEM and explore its potential to support K-12 students’ science learning. In addition, some of the pre-service teachers have extended their knowledge of the SEM and served as mentors to the inservice teachers wanting to incorporate the SEM in the classroom. In this manner, these students develop proficiency in the operation of the on-line SEM, assist in-service teachers in designing lessons into which SEM activities are appropriate, and experience the classroom use of the on-line SEM with K-12 students.
In each course where the SEM was incorporated, the complexity of technology integration was experienced. To varying degrees contingent on the course and preservice teachers' developmental levels, technology integration beyond teaching about the SEM, was difficult for the students to conceptualize. Although they viewed the SEM as a valuable educational tool, the preservice teachers had difficulty identifying and developing ways to integrate the SEM into the curriculum. In addition, many preservice teachers possessed misconceptions about the capabilities of the SEM. The students often related the SEM to past experiences with light microscopes. As a result, the curriculum integration ideas they developed for the SEM were inappropriate. There were also specific access concerns related to the technology when using the SEM via the internet and in the classroom.

Using the SEM in teacher preparation courses had a number of experiential and pedagogical benefits. The SEM provided an opportunity for future science teachers to use real-world science tools that they can realistically use in their future classrooms. Via the on-line SEM, the preservice teachers engaged in real-world scientific inquiry with experts in the field. Most important, the use of the SEM in the teacher preparation courses created learning environments where preservice teachers were empowered to think critically about science content and authentically engage in the scientific process.

While this project has achieved its goal of enhancing the science and technology content and pedagogy preparation of preservice teachers, it has also generated more questions than it has answered. Integration of the SEM into teacher education courses has provided a vehicle by which we can better understand scientific inquiry-based technology use and it's implications for K-12 classrooms. Further research in this area will be necessary to determine how best to utilize the SEM technology into teacher education courses in order to improve K-12 science education.
Recent research data provide evidence of a strong focus on the development and fostering of Math and English skills at the elementary level. Unfortunately, other areas of study have not received necessary attention (Goodstein, 2001). At the University of Florida, the School of Teaching and Learning teamed with the College of Liberal Arts and Sciences to address this situation. With the assistance of a PT3 grant, we have designed a course entitled Our Physical World: Science for Elementary Teachers. The course discusses basic physical science for elementary teachers, emphasizing applications from everyday life. The scope of the course is similar to many college-level science courses. However, while most courses focus solely on the acquisition of science content knowledge, Our Physical World also focuses on the acquisition of pedagogical content knowledge in science (Duggan-Haas, Enfield, & Ashman, 2000). Topics addressed in the course begin with the scientific method and span the entire spectrum of the physical sciences, even discussing Einstein and relativity. The purpose of this course is twofold. First, the course provides tomorrow’s teachers with appropriate science content knowledge. Second, the course models appropriate methods of integrating meaningful science learning into the elementary classroom.

In order to attain these goals, Our Physical World was designed and created as a web-based learning environment. There were three major reasons for creating this environment. The first reason was accessibility of the information. While initially intended for students of the course, we thought that the information presented, both in the course and on the website, might be useful to other elementary teachers. The second reason was adaptability. With a web-based learning environment, activities and information can easily be updated and modified. The final reason was ease of communication. On the website, individuals will be able to suggest activities that they have found useful, and provide feedback to the creators of the website.

There are four major components to the website: a course information area, a relational database, a search mechanism, and an administrative area. The first component of the course is the “Course Information”. This area contains important information for students enrolled in Our Physical World. Items such as scheduled events, syllabus information, readings, assignments, and experiments are listed here.

A second major component of the course is the relational database. Upon entering the learning environment, teachers are provided with various activities designed to promote meaningful science learning. This database is part of the course website, but potentially could be accessed by elementary teachers elsewhere. Eventually, the database might be expanded to cover other science areas, such as the biological and chemical sciences. The premise of the database is that elementary teachers can search for activities by choosing various criteria. The search criteria include the following: topic, grade level, keyword, activity type, amount of materials necessary, and Sunshine State Standards (Brogan, 1995). Any, or all, of the search criteria may be used when searching for various activities. The search areas of topic, grade level, and keyword, while general, are useful in narrowing down any search for activities. Activity types will include simulations, laboratory experiments, web-quests, tutorial, classroom demonstrations, and others. One of the more interesting areas of search criteria is the “amount of materials necessary”. Upon leaving elementary education programs, students go to different schools, with each of the schools possessing different resources. The “amount of materials necessary” field is broken down into four levels,
addressing the varying level of resources. These levels are low, medium, high, and computer based. While each of these levels is relative, simply examining a few of the activities for each of the levels would make the criteria for each very clear.

A third component is the search mechanism. This search option was added, after the initial conception of the database, in order to assist Florida teachers relate science instruction to the appropriate standards. This tool allows students to search content by the Sunshine State Standards. Sunshine State Standards as a search criterion will obviously be of most utility to Florida teachers.

The final element of the website is an administrative area. In this area, administrators are able to add, delete, or modify any of the activities or search criteria. Also, there is an area for individuals using the site to suggest activities by completing information about the suggested activity on a form. These activities are then reviewed by the main site administrator, and, based on quality, either added or not.

With further development we hope that this database will prove to be a valuable science instruction resource for teachers everywhere. While only students registered for the course will be able to view the modeling of various activities, it is the opinion of the creators that the resource alone would be extremely useful. As mentioned previously, the database may eventually stand on its own, outside of Our Physical World, and may be expanded to contain other areas of the sciences, and possibly videos of the course activities being modeled. With these additions, the goal of improving the instruction of all sciences at the elementary level may be attained.

Relationships between the use of web resources and student interests in science: Support for technology integration decision-making

Tiffany A. Koszalka
Instructional Design, Development and Evaluation
Syracuse University
United States
takoszal@syr.edu

Abstract: This study was designed to investigate the relationships among the use of web resources during middle school science and student science career interests. The results indicated that there were significant predictive relationships between the regular use of web resources and science career interest. Findings suggested that regular use of web resources predicted science career interest scores differently for boys and girls. The regular use of web resources was not predictive of boys' career interests, only predictive of girls' interests in science careers. The use of web resources also had a mediating effect on other characteristics that are generally associated with developing interests in science. Understanding these relationships can help strengthen the processes of designing science education and support decision-making related to securing educational resources that may inspire students to pursue science.

Introduction

The U.S. invests millions of dollars each year on developing and securing new technology-based resources to inspire students to pursue science. To assure these investments are meeting the goals of the educational system it is important to understand the relationships among the types of resources used during science and levels of student interest in science. However, identifying the relationships among resources and interest requires consideration of the complex and multi-leveled environment of the classroom. This study investigated questions about these relationships. Is regularly using web resources during science predictive of middle school students' interest in science? Is the predictive nature of using web resources the same for boys and girls? Is the use of web resources related to differences in science predisposition factors among students?

Career Interest Development

Career development research generally has focused on identifying relationship among family factors such as parents' education and career (Helwig, 1998) and specific school-based career interventions (Hill, et al., 1990) thought to affect children's formation of career aspirations and their eventual participation in adult careers. Gallagher's (1994) work demonstrated that instructional experiences in middle school were predictive of persistence in the study of science in later years. However, no research could be found that investigated the relationships among use of specific educational resources and student science career interests. Interest, an acquired attention or enthusiasm for a particular field, is a learned characteristic and has been shown to be the key factor in making career choices (Hill, et al., 1990; Neimeyer & Metzler, 1987; Vondracek, Lerner, & Schulenberg, 1986; Super, 1984). Emergent interests in a career domain leads to intentions or goals for further activity exposure, which increases the likelihood of subsequent task selection and practice (Lent, Brown, & Hackett, 1994; Flum & Blustein, 2000). Career interest development begins in pre-adolescence, before the fifth grade, when patterns of career aspirations have a tendency to reflect development of the individual's sense of industry (Erikson, 1963; Havighurst, 1964) and interests in line with those careers held by family members or based on direct suggestions from parents or significant family members (Helwig, 1998; Trice, 1992). When children enter into the early stages of adolescence and begin to explore relationships and activities outside the family, including experiences in formal education, they often begin to develop career interests independent of family members. In addition to formal and informal learning experiences, much research has shown that adolescents' development of science career interests is also related to several predisposition factors including the adolescent's 1) perceptions of science – can I see myself as a scientist, 2) perceptions of friends' and teachers' interests in science – are my peers and mentors interested in science, 3) participation in science activities at home.
Factors that may affect career interest development

As the Internet becomes more commonly used in classrooms, opportunities to further explore career activities, tools, and people are more available. Recent studies have found that when web resources were introduced into the classroom students interacted in more complex tasks, developed greater technical skills, and used more outside information (Hardin & Ziebarth, 1995; Owston, 1997; Rice, McBride, & John, 1998) than before the Internet was available. Thus, web resources provided vast and easily accessible information and human resources that promoted exploration of and interaction with additional information resources. Adolescent may be able to develop more informed self-perceptions of working within a specific career while interacting with web resources, e.g., participating in exploration and feedback processes. These perceptions may in turn influence science career interest (Blustein et al., 1994). Another factor found to be important in career interest development was gender. Often family experiences (Hanson, 2000) and perceptions of career-related opportunities (Roeser, Eccles, & Sameroff, 2000) strongly influence girls' career choices. Providing rich environments that include web resources, could influence girls choices because science is perceived as a more traditionally 'male' career (Hanson, 2000; Andre, Whigham & Hendrickson, 1999), and thus girls' interests will be more contextually influenced by exposing them to the vastness of science careers and those female role models who excel in science careers. Girls also tend to be more oriented towards social relationships (Swanson, 1997; Gurian, 2001) and may thus be particularly swayed by human contact and collaborative activities generally associated with the collaborative use of web resources in school settings. Since girls tend to work together more collaboratively when using technology and use computers more for learning activities where boys were found to use computers alone and for purposes of gaming, web resources may have more influence on shaping girls career interests (Swanson, 1997).

The Study

A one-time cross-sectional observational method was used to collect data from more than 600 middle school students and their teachers in a diverse group of 23 science classrooms from in three states (Koszalka, 1999). All classrooms were required to have school access to web resources, although there was no requirement that teachers had to use these resources. The middle school students who participated were intact groups from the science classrooms taught by the participating teachers. The dependent variable was Science Career Interest. The science career interest measurement scale was continuous with possible scores ranging from 0 to 36. The higher the score, the more interest the student has in pursuing science-related careers. The student-level independent variable measures were predisposition factors: 1) perception of science, 2) perception of others' interest in science, 3) parental and home factors, 4) interest in science-related activities outside of school, 5) computer technology use in the home, and 6) gender. Teachers were asked to provide information on classroom-level factors, e.g., the types of resources used regularly in the classroom.

Science Career Interest was measured by administering the Investigative (science) career interest summary scale of the Self-Directed Search Career Explorer (SDS), a career-counseling tool for middle school children. As in previous career interest exploratory analyses (Borget & Gilroy, 1994), only the scales for science careers were used so that a relative measure of interest in science careers could be obtained for each participating student. To classify the classroom into resources use types, the teachers were asked to respond to six questions regarding the use of different types of resources during science activities. Responses provided an indication of resource use patterns and were used to classify classrooms into a one of four resources use types.

The career instruments were administered to middle school students at the beginning of a science class at the end of the school year. At the same time, teachers completed the teacher survey, collected the completed surveys

Page 2118
and informed consent forms, and sent them to the researchers. Descriptive data were computed using SPSS version 8.0 for Windows. Hierarchical linear models (HLM) were used to examine the associations among classroom-level factors, student-level predisposition factors, and science career interest using two-level hierarchical linear models. This analysis could assess how science career interest differed depending upon classroom variables and on the individual characteristics they brought to the situation, i.e., predisposition factors and gender.

Findings

A total of 677 surveys, from 23 teachers in 9 schools were administered and returned. Fifty-eight surveys were either returned without signed parental consent forms or with incomplete data and were removed from the sample. The remaining 619 surveys were used in the data analysis that included 51% girls (n=304) and 49% boys (n=297). Eighteen students in the sample did not identify their gender. Mean scores were calculated for all boys' and girl's interest in science careers in general and for groups of boys and girls who exhibited each characteristic associated with different levels of predisposition to pursue science. The HLM analyses demonstrated that use of web resources overall was not predictive of boy's science career interests (t = 2.077, p < .061). Girls' science career interest was predicted by the regular use of web resources (t = 4.323, p < .000). (See Tab. 1)

Table 1: Student-Level Effects for Boys and Girls

The relationships among science career interests and predisposition factors were different in classrooms where web resources were and were not used regularly. As boys' (t = 6.664, p < .000) and girls' (t = 5.202, p < .000) perception of science increased, so did their interest in science careers. For both boys and girls a significant interaction was found between their perception of science and classroom use of the web. The interaction slopes indicated that there were stronger relationships between perceptions of science and science career interest for both boys (t = 2.911, p < .009) and girls (t = 2.849, p < .010) when web resources were used in the classroom than when web resources were not used. Perceptions of others' interest in science was positively related to boys' science career interest (t = 2.624, p < .017). The interaction between perceptions of others' interest in science and use of web resources in science class in boys resulted in a significant negative relationship (t = -2.298, p < 0.020). The level of interest in science-related outside activities was not significantly related to science career interest for girls (t = 0.743, p < .466) on its own. However, the interaction between interest in science-related outside activities and use of web resources in science class for girls resulted in a significant
positive relationship ($t = 4.700, p < 0.000$). Home technology use and parent/home support to pursue science did not have a predictive relationship for science career interest in either boys or girls, nor were the strengths of their relationships different in the students who used web resources, hence they were dropped from the model.

**Discussion**

Developing interest in specific career domains, such as science, is a consequence of many learning interactions with the people, information, and objects of the practice (Lave and Wenger, 1991). Conceptually, previous research provided indications that working with science practitioners and exploring science information was important to the development of interests in science careers (Vondracek, 1993; Helwig, 1998; Hill et al., 1990). The use of web resources during science can provide adolescents with opportunities for exploring science by providing access to additional social and supportive information. Thus, the significant relationships found support a conceptual hypothesis that increasing the richness of the types of information through web resources during science was related to higher levels of science career interest. In addition, this study provided some interesting findings related to the relationship among the use of web resources and girls interests in science careers. The findings suggested that the use of web resources might have acted as an influencing agent supporting girls developing interests in science because they potentially exposed them to rich examples of science in practice. They may also have provided motivational and interactive experiences as well as another venue for social interaction and learning through collaborative activities with fellow students.

The results of this study also suggested that the relationships between science career interest and predisposition factors were different in classrooms where students regularly used web resources and classrooms where students did not use web resources. For example, all boys' interests in science were predicted based on their perceptions of other’s interests in science. If their friends ‘liked’ science, they were much more likely to ‘like’ science themselves. When comparing students in classrooms that used web resources and those who did not, the relationship was different. Perceptions of others’ interests was not as strong a predictor potentially indicating that sources on information available on the web became more important in informing interest than perceptions of others in the adolescent’s life. Thus, factors such as the use of web resources in classrooms may play a significant mediating role in shaping a student’s interests in science careers.

Understanding relationships between the use of web resources and students’ science career interests can provide a basis for developing and securing resources that have been empirically shown to be related to higher interest in science careers. If these results hold up in replication studies, there are implications that may support academic decision-making and policy. Given a goal of inspiring students to pursue science careers, policy makers may find this type of research supportive of decisions to allocate financial commitments for enhancing computer equipment, facilitating curriculum development that brings science learning and science communities together, providing teachers with the time and training to integrate web resources into their teaching. These findings shed new light on understanding the complex relationships between the use of resources in the classroom and multiple factors that affect the development of science career interest. Without an understanding of the relationships between the use of resources in the classroom and student science career interest there is a risk that large investments in educational resources will go unmatched in student outcomes. The results of this study demonstrated that the regular use of web resources in middle school science classrooms were predictive of girls’ interests, but not boys’ interests in science careers. The use of web resources also seemed to have a mediating effect on the relationship among predisposition factors to pursue science and science career interest. Understanding such relationships can inform decision- and policy-making in regard to providing access to, and support of, web technology use in the classroom.

The Regents Scholars Program - Creating a Statewide Collaboration to Enhance Mathematics and Science Education

Marietta Langlois, Ph.D.
Coordinator, Regents Scholars Program
Wright State University
marietta.langlois@wright.edu

Sheryl Hansen
Director, Professional Development
Ohio Learning Network
shansen@oln.org

Abstract: The Regents Scholars Program is a unique and distinguished academic experience for in-service teachers. This statewide program draws upon the expertise of university faculty across Ohio to offer professional development that combines mathematics or science content with inquiry-based pedagogy. Teachers will have the opportunity to work with Arts & Science and Education faculty at 13 participating universities in a combination of distance and face-to-face learning experiences. The implementation plan for this project emphasizes faculty development, course development and establishing a collaborative degree structure. The Regents Scholars Program anticipates enrolling students in the fall of 2003.

Introduction

The Regents Scholars Program is a unique and distinguished academic experience for in-service teachers. This statewide program draws upon the expertise of university faculty across Ohio to offer professional development that combines mathematics or science content with inquiry-based pedagogy. Teachers will have the opportunity to work with Arts & Science and Education faculty at 13 participating universities in a combination of distance and face-to-face learning experiences. After completing 35 semester hours and a capstone project, teachers earn a Master’s degree in mathematics or science education. The Regents Scholars Program anticipates enrolling students in the fall of 2003.

Two key features of the Regents Scholars Program are quality and the use of technology. By collaborating and sharing resources, participating universities will be able to offer their “best” to create a truly unique educational experience of distinct faculty, coursework and learning experiences. Technology permits the program to extend beyond one campus. E-mail, interactive television and the Internet also allows for learners to interact with counterparts from across the state and to collaborate with college faculty.
Program Development

The implementation plan for this project emphasizes faculty development, course development and establishing a collaborative degree structure. Faculty development strategies include listservs, a web site and online and face-to-face training sessions. Listservs and the web site are used to share information such as useful web sites, training opportunities and meeting minutes. Funds were also allotted for faculty to enroll in web-based mathematics and science education classes as well as course design and facilitation classes.

Course development strategies include faculty stipends, online course standards and establishing a Regents Scholars Content Excellence Seal for courses that meet the standards. Because of the unique challenges created by inquiry-based pedagogy, few online mathematics and science education courses existed in Ohio. Thus, faculty were offered a $3,000 incentive to put an existing course online. Course guidelines were also developed to reflect the National Research Council, National Council of Teachers of Mathematics and Ohio Academic Content Standards. Lastly, to capitalize on existing, outstanding learning opportunities, the Regents Scholars Content Excellence Seal was developed. Courses that are awarded the seal are eligible electives in a student’s program of study.

The collaborative degree structure emphasizes home institutions, cohorts, cross registration and face-to-face summer institutes. Students will be assigned to home institutions. The home institution serves as the university of record and enrolls the student, keeps the transcript and awards the degree. Cohorts will also be initiated at the face-to-face summer institutes and maintained through a Regents Scholars Program web site that promotes reflection, collaboration and support.

Participating Universities

Universities participating in the program include Bowling Green State University, Cleveland State University, Kent State University, Miami University, Ohio University, Shawnee State University, The Ohio State University, University of Akron, University of Cincinnati, University of Dayton, The University of Toledo, Wright State University and Youngstown State University. Sponsoring organizations include Ohio Board of Regents, Ohio Learning Network, Ohio Department of Education and Ohio Resource Center.

Abstract: This paper shares the results of an action research project in a science teacher education classroom. The setting is a laptop university and students have access to Inspiration software as well as networking software (ICU) that allows instructors/students for "real time" viewing of individual student group concept mapping exercises.

Most instructors aspire to creating classroom settings that promote higher-order thinking. A considerable amount of work has been done around the creation of so-called constructivist learning environments (Greening, 1998). As an example, problem-based learning has gained popularity not only because problem solving is practised but because the learning is contextualised. Gagne (1985) posits that problem solving elicits two types of learning namely: the learning of a specific “higher-order rule” that allows the student to address similar problems and secondly a set of general problem solving skills or “cognitive strategies”. According to Gagne (1985) “cognitive strategies are a special type of intellectual skills used by the learner to regulate the various stages of information processing”. Young (1997) links these information processes and cognitive strategies, see (Table 1).

Table 1: Cognitive Strategies Associated With Information Processes

The Power of Graphic Organisers

Of particular relevance to my own action research is the encoding process. Teachers have effectively used webs as graphic organizers in the process of determining student’s prior knowledge. Semantic networking (Fisher, 1990; Jonassen, 1996; Jonassen, Peck & Wilson; 1999) resembles webbing except that all the links between ideas are labelled with a relational phrase. The concept map, as defined by Novak and Gowin (1984) has emerged as a most powerful graphic organizer. In the strictest definition, the concept map extends the semantic networking labelling and has the additional feature of representing concepts in a hierarchical distribution.

Though a variety of webs and maps have been around for some time, it is only in the last decade that software has been developed specifically to create these graphic organisers. Some examples include: SemNet®, Learning Tool®, TextVision®, CMap® and most recently Inspiration®.

A MindTool Approach

With these pieces of software it becomes very easy to map out ideas. Whereas hand-drawing maps in the past could be relatively time-consuming, these facile software approaches open the door to extend the learning through software-enabled constructivist exercises. Computer–generated graphic organisers represent a class of applications that Jonassen (1996) would refer to as “mindtools”. “A Mindtool is a way of using a computer application program to engage learners in constructive, higher-order, critical thinking about the subjects they are studying” (Jonassen, 1996, p.iv).

A concept mapping program for instance may be used in three distinctly different teacher–student exercises: (1) the teacher may have students construct a concept map at the onset of a unit in an effort to access prior knowledge; (2) a teacher may engage students in preparing a pre and post concept map (reference) for a unit of study and (3) a teacher may work with the students in an ongoing exercise that gradually builds the map as the unit content emerges.
Action Research in Science Education

For some time I have posed my teacher interns with the task of preparing a concept map for curriculum units they are likely to encounter in their public school teaching. Acadia University has been a laptop institution (Hemming & MacKinnon, 1998) since 1996. This year as part of the network software accessible to all students and professors, Inspiration and ICU became available. Inspiration is a most popular mapping tool (www.inspiration.com) while ICU is a “home-grown” networking tool (a take-off on ICQ). ICU allows the instructor to link with any obliging student on the network and access (and control) their screen. With a classroom digital projector and laptop docking station, this has allowed for an interesting Mindtool approach.

In three independent science education classes of approximately thirty students I led the following exercise. After a short tutorial on Inspiration in the second class meeting, I asked students to construct a concept map of the content we had analysed thus far. On a weekly basis, students would work in groups to update and modify their concept maps. Because I could access their screens at any time and in turn project their screen for the entire class to observe, it became a unique opportunity to unpack their thinking around the hierarchy of concepts and corresponding relational links. In essence as a class we were able to “negotiate the concept map” in real time.

The Impact of Negotiative Concept Mapping

In ten (one-hour) open-ended qualitative interviews following the completion of the course, there were several emergent themes.

Students found the negotiative concept mapping (NCM) to be a great means of reviewing the work from past meetings. Students suggested that the interactive nature of constructing the NCM in real time allowed them to better understand the nuances and complexities of relationships between concepts. In several instances students alluded to defending their choice of conceptual hierarchy and how it helped them to build confidence in the content. Unanimous reference was made to the quality of discussion that NCM promoted in class. At the close of the course students were asked to submit an essay that summarised their growth in the course. Students were astounded at the practical utility of having constructed a concept of the entire course and found this to be invaluable in assimilating their learning in the course. They repeatedly made reference to the ability to see how all aspects of the course were linked from beginning to end and the inherent “sense-making” that this imparted.

All indications are that this “mindtool” approach utilising Inspiration and ICU, shows great promise for classroom instruction. The facile communication allows the professor and teacher intern to interact in a constructive setting in a way that was never before possible.

Using the Spreadsheets to Enhance the Learning of Science at Foundation Year Chemistry.

Stimela Simon Mathabatha
Department of Chemistry
University of the North Foundation (UNIFY)
South Africa
e-mail: setimelam@unin.unorth.ac.za

Abstract
At heart, real understanding in science is essentially qualitative yet is often expressed in mathematical relations. Most advanced science students therefore spend a great deal of time and effort doing calculations. These calculations pose two kinds of demands namely: • some of the mathematical models involved are complex and/or • there is a need for repetitive analysis of large amounts of data and both of these can serve to focus students' attention on mechanical mathematics at the expense of their understanding of the underlying scientific principles. These difficulties reduce the level of cognitive ‘chunking’. This is a serious hindrance to students' learning and the need is for a tool or tools that can be used to raise the level of chunking so that pupils can focus on the underlying scientific concepts. Ideally such a system would be capable of being used by both pupils to model simple systems in which they can express their understanding of the science involved and by their teachers to construct more complex models for the pupils to explore. This paper examines a variety of ways in which one tool, a spreadsheet, has been used to promote learning in an important concept area, that of chemical equilibrium at a University Foundation Year (UNIFY) chemistry and its implications to classroom practice for teacher educators.

Introduction
Spreadsheets have a number of attributes, which make them suitable for use as a computational tool in the school science classroom and laboratory. For example, they can be used in either of two complementary modes. In the first, students use the tool to express their own ideas, usually by testing a variety of models (of their own construction) using fixed data, while in the second, students explore models which express the thinking of others, usually by feeding variable data into a fixed model. The latter category commonly involves exploring the accepted scientific models although it also encompasses students exploring expressions of each other's ideas. The differences between these modes of use are similar to the expressive/exploratory distinction described by Brosnan (1989). Schibeci (1989) provide further useful discussions of these ways of using spreadsheets models in science learning environment.

The nature of students’ difficulties with equilibrium
Chemical equilibrium is a core chemical concept, an understanding of which is essential for most qualitative and quantitative work in chemistry and thus its study forms a central part of advanced chemistry courses. These courses tend to stress the quantitative aspects of the topic - fulfilling the necessity of teaching students to use the appropriate equations. Studying equilibrium therefore involves both difficult and/or repetitive calculations. In their different ways these provide barriers to conceptual understanding. The topic thus provides a good focus for exploring the different kinds of barriers both these types of arithmetical demand pose to conceptual understanding (Stevens, 1991).

Participants and Context
The participants in this study were UNIFY students at the university of the North, South Africa. Sixty (60) potential student participants were selected from 150 UNIFY students according to their willingness to participate in the research. The sixty students were chosen to achieve a balance of gender, science ability and socio economic background. The participants' background is such that they have been exposed to
inadequate teaching, lack of laboratory and computer facilities, little attention to skills and lack of exposure. All these resulted in rote learning by the students, lack of interest / negative attitude and very little or no understanding. The UNIFY intervention provides the students an opportunity to access Computer Assisted Learning (CAL). This initiative is on its developmental stage as there is no proper CAL programme in place. As a way of introducing CAL, the spreadsheets have been used in the chemistry lessons to enhance their learning of some chemical concepts, especially that of equilibrium. A questionnaire was used to find out the students’ initial conceptions about equilibrium. A set of spreadsheet activities were designed and undertaken with the students in a computer lab during chemistry lessons. Some interviews were conducted during this sessions.

Addressing the Students’ Difficulties

One of the main problems that UNIFY students have in coming to a full understanding of chemical equilibrium is that of the ratio of equilibrium concentrations. Students often believe that at equilibrium the composition of the reacting species is equal to, or at least in the ratio of, the balanced chemical equation for the reaction, e.g. that for the reaction, 2HI(g) ⇌ H₂(g) + I₂(g). One solution to this problem is for a teacher to enter data sets of equilibrium concentrations on a worksheet and allow the pupils to write their own equilibrium law expressions and see the consequences. Knowing the balanced chemical equations the students are free to try any analytic relation they choose on one data set until they find one or ones that give constant values. The other problems students have that can be addressed using the spreadsheets are; the effect of changing concentrations, pressure and temperature on equilibrium.

Implications for Teacher Educators

The use of spreadsheets demand more time from the educator to design adequate integrated teaching and learning materials for the students. It helped in the improvement of the classroom teaching and assessment, as it demanded the design of effective alternative assessment tools. It also motivated the students and enhanced their creative and critical thinking skills. The participants’ overall performance in chemistry significantly improved compared to those who learned through traditional methods.

Conclusion

The examples briefly described above cover a range of conceptual, arithmetic and programming difficulties and are intended to illustrate some of the variety of ways spreadsheets can be used to address the variety of mathematical problems faced by students of science. The key point is that the computational tool is being used to allow students to see the quantitative consequences of differing qualitative conceptions. The apparently paradoxical conclusion of this is that a computational tool’s most important attribute may be the help it gives in changing qualitative understandings. For the purpose of validation of the instruments, the study will be undertaken again next year with large samples of students from similar programmes.

Anchoring Instruction in a Web-based Adventure Game: How does it work?

Leslie M. Miller, Janette Moreno, Donna Smith, Janice Mayes
Rice University
Center for Technology in Teaching and Learning
United States
lmm@rice.edu

Abstract: How does one capture best practice from the paradigms of situated learning and anchored instruction and combine that with the powerfully engaging multimedia gaming environments that are popular with adolescents? Is it possible to design a game with substantive science content that is intrinsically motivating for middle school students? These types of questions were the driving force behind the creation of a web adventure series, THE RECONSTRUCTORS™.

The web site (http://reconstructors.rice.edu) is part of a project funded by the National Institute on Drug Abuse. The content focus of this effort is the history and biological impact of a class of drugs known as opioids. The benefits and challenges of using this type of approach for teaching sophisticated science concepts to middle school students is described in this paper.

Pedagogical Foundations

The Internet's unique capabilities offer a certain seductive aspect that engages people of all ages. Not all of the Internet's applications could be said to have high educational value. Yet, from our own research on adolescents' media habits and preference, we find that “playing games” is high on the priority list of how they use computers (Miller, Schweingruber & Brandenburg, 2001). On the educational side of the equation, however, the Internet provides support for new instructional approaches, such as cooperative learning with other learners at a distance, demonstrations, online references, powerful simulations, tips, tutorials, and wizards (Carliner, 1998). Our efforts are directed toward blending the excitement of games with compelling science content to “create interesting, realistic contexts that encourage the active construction of knowledge by learners” (CTGV, 1993, p. 52). The work of John Bransford and the Cognition & Technology Group at Vanderbilt (CTGV) pioneered the way for exploiting the power of technology to achieve serious instructional goals. In their interactive videodisc program, Jasper Woodbury Problem Solving Series, mathematical concepts were emphasized (CTGV, 1990).

The pedagogical strategies of situated learning (Brown, Collins and Duguid, 1989) or anchored instruction (CTVG, 1993) can provide the prerequisite framework on which to build multimedia environments that have significant learning outcomes. The task of blending best practice in education with the bells and whistles of multimedia is challenging. Perhaps that is why it is more common to find multimedia, particularly on the web that is rich in technique, but shallow in content. The use of technology for technology's sake rather than wrapping technology around tried and true learning principles is a common pitfall.

Much of what is available on the web is a compendium of information with little structure or scaffolds on which students might build their own knowledge. Some observers have charged that this has led to 'lazy' learning models, “where the student is simply confronted with a vast resource and left unguided” (Weller, 2000, p.9). This type of exploratory learning can sometimes have an effect opposite from that which was intended. It can cause disorientation, difficulty in navigating from point to point, and cognitive overload (Wild et al., 1994). To overcome these challenges, several researchers have proposed the use of narrative
as a means of providing structure to multimedia materials (Laurillard, 1998; Laurillard et al., 2000; Plowman, 1998). The use of narrative in combination with multimedia has several advantages:

- It sets a context or situates a problem that is to be solved.
- It grounds the use of text, graphics, animation, voice/music and interactivity with a certain mood or theme.
- It allows the layering of learning objectives so that an array of objectives as described by Bloom’s Taxonomy (Bloom, 1956) can be woven into the story or problem.
- It exploits theories of constructivism that suggest narrative is a powerful instructional tool (Bruner, 1996).

Interactive Multimedia Options

The term “interactive multimedia” can mean a wide range of things. One of the first tasks of an instructional designer is to determine who is the audience and what will best reach them. The delivery options range from producing multimedia CD-ROMs or DVDs to interactive web sites that offer animation, video, and audio by a variety of authoring tools. After consideration of multiple alternatives, the decision to use the web with Macromedia’s Flash for the delivery of The Reconstructors™ was made. The reasons behind this choice were several:

- It eliminates the distribution issues associated with CD-ROMs and DVDs. If one wants to attract an audience in the school, home or other public Internet access environments, then web delivery has a ubiquity that far surpasses the distribution of a disc. The ability to have the site linked from other sites cannot be underestimated;
- Macromedia Flash allows for the expansion of screen size unlike other authoring tools that have a fixed window in which to view the production;
- Flash allows for relatively small files sizes that can be downloaded in segments to address the needs of those with slow bandwidth connections;
- All of the elements of sound, animation, and interactivity that engage learners can be incorporated with Flash; and
- The most significant advantage of Macromedia Flash files is the rapidity with which changes can be made to the site. Based upon feedback from users collected via e-mail, problems can be remedied, or suggestions for improvements can be made almost immediately.

The disadvantages that militate against the use of this authoring and distribution strategy are mainly related to the reliability of schools’ connectivity and the use of firewalls that prevent student access. In these instances, we have provided the web site on a CD-ROM for classrooms and this has worked effectively. Another minor disadvantage is the necessity to download the Flash plug-in by those who are not operating with a relatively recent browser.

Weaving Narrative with Learning Objectives

Given that an authoring tool and distribution strategy were determined, the process of moving from learning objectives to final product is non-trivial. Several basic questions had to be addressed:

- What methods, techniques and structuring devices should be used to support students in understanding the science content and demonstrating their knowledge of it?
- What type of narrative is of interest to middle school students?
- What type of story setting and characters should be created that would best match the instructional goals?
What motivational aids should be included?
How should the science concepts be presented?

A first obvious step is to articulate what conceptual targets you want encompassed within the adventure game. In our particular endeavor, once we had delineated all the fundamental, as well as the sophisticated neuroscience concepts that were germane to understanding opioids, it became clear that this would have to be an adventure game unfolding in “episodes” or learning chunks. Chunking the concepts also provided an obvious way to support the learner with scaffolds. The interactivity allows one to check at each point whether the learner has acquired the concepts and/or provide feedback. In a gaming environment, these checkpoints, when passed allow the player to “move to the next level.” This provides the motivation and captivation typical of adventure games, but adds the educational dimension by focusing on substantive content.

Figure 1. The Reconstructors™ logo features three of the main characters

Adventure games also typically take place in a distinctive story environment or “computer world.” In these worlds, the player navigates by clicking or by “picking up “ or manipulating objects. Games like Myst, have pioneered this genre. Middle school teachers allowed us time with their students to survey them and follow up with focus groups. The results of surveying over 500 students on their preferences are reported elsewhere (Miller, 2000). We presented our ideas for a setting, a story, and rough sketches of characters to a smaller number of students in focus groups. Through this dialogue the following computer world and corresponding “problem-solving” scenario emerged with the attention to building a narrative that could draw the player through the set of episodes (Figure 2).

THE PROBLEM

It is the year 2252, ten years after the Great Plague that ran through earth’s population killing millions and causing the collapse of civilization. Now the earth has entered a new Dark Age, a time when much of the knowledge from the past has been lost.

You are a member of an elite group known as THE RECONSTRUCTORS and you help the People by recovering lost medical knowledge. Your skills are urgently needed because pain-relieving drugs are almost non-existent now. Stories and documents refer to powerful pain-relieving medicine from the past.

Your mission is to reconstruct the knowledge and uncover this medicinal mystery.
All depends on you!

Figure 2. The Reconstructors™ Adventure Mission Statement

A student enters a futuristic world in which he or she assumes the role of a “Reconstructor” charged with re-discovering medical knowledge from the past. The five episodes – Plaguing Problem, Ancient Alarm, Analgesic Anxiety, Mystery of Morpheus, and Alpha and Omega – carry the concepts and narrative forward. Over the course of the episodes, players “solve the problem” while learning about concepts such as neurotransmission, the neurobiology and history underlying drug addiction, pain management, and analgesia.

The actual design process moved to a flow chart of the narrative with interactivity and learning objectives denoted to ensure that the narrative both incorporated the agreed upon concepts and had sufficient interactivity to engage the learner. The creation of storyboards depicting each screen followed. It was this
final step that was then turned over to the Flash programmer. An example of a segment of a storyboard follows (See Figure 3).

<table>
<thead>
<tr>
<th>15.</th>
<th>To whoever finds this record, my time is running out. The plague is killing me, and I don't want my data on the nervous system and what each part does to be lost. This system is the key to making smart robots and so much more. Without it, we would not be able to think and move or feel pleasure and pain.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Interactivity:</strong> Button Advance</td>
<td></td>
</tr>
</tbody>
</table>

| 16. | **Parts of the Nervous System:** Brain Spinal Cord Peripheral Nerves Neurons |
| **Interactivity:** At the top of the screen is the title: Parts of the Nervous System. Underneath this are the 4 parts that are hotlinks. Each time the player clicks on a part of the nervous system, that part lights up in the nervous system diagram (on the left hand side of the screen) and information about it appears on the right hand side of the screen. When the player clicks on neurons it hotlinks to Fred's Nerve2 Neuron sequence. |
| **Interactivity:** Button advance |

| 17. | Neurons: link to Fred's Nerve to Neuron Sequence. |
| **Interactivity:** Button advance |

Figure 3. Storyboard Segment from "Mystery of Morpheus"

The comments received from end-users suggest that the web site has drawn the attention of students of all ages to investigate topics that may not normally be tremendous attention grabbers. Yet, crafted within the game environment and built around solid educational strategies, the site has proven efficacious in both gaining screen time and teaching difficult topics. Another paper presents the results of pre and posttest field test results with middle school students. Significant gains were made in specific knowledge concepts for students of all socio-economic status groups and for both genders. (Miller, Schweingruber, Oliver, Mayes and Smith, 2002).

Summary

Bruner's (1996) advocacy of narrative as an effective pedagogical approach in science education coupled with the "problem-solving" characteristics of CTVG early work in multimedia were used to produce a web adventure series with substantive science content within an engaging computer world. This process and the decision points helped to generate an adventure series that has been commended by several
educational organizations. To our initial question, can the power of the game environment be harnessed for educational ends; the answer is a definite yes.

The instructional design steps were:

- Determine scope and specific science concepts.
- Devise "problem" or adventure through dialogue with students.
- Create flowchart of web adventure.
- Produce screen-by-screen storyboard.
- Obtain teacher input.
- Program the resulting product.
- Evaluate outcomes.

The success of the initial series has spawned the creation of a second series, MedMyst, which explores the topic of infectious diseases. (See http://medmyst.rice.edu.) The same procedures described in this paper were employed. Again targeted at middle school students, this web adventure may also find its way into classrooms across the world via the Internet.

Math and Science Education using Spreadsheets and Modeling.

Simon Mochon  
Department of Mathematical Education  
Center for Research and Advanced Studies, Mexico  
smochona@conacyt.mx

Abstract: In this article we present examples of a series of spreadsheets designed to support teaching math and science at the junior and high school levels. Each spreadsheet has an accompanying worksheet which guides the student in the exploration of the topic contained in the spreadsheet. These materials were born as an extension to two parallel projects. One, has the aim of teaching math with technologies. The other, has the purpose of using mathematical based explanations to support the teaching of the sciences (chemistry, biology and physics). To illustrate the whole package of activities, we will also include part of a worksheet corresponding to one of the spreadsheets presented.

Modeling as a learning strategy and Spreadsheet Modeling

There are two different objectives in the classroom connected to the modeling process. One is to learn to construct mathematical models. The other is to take advantage of this activity to learn some of the topics in the science or math curriculum.

A book that gives a wide view of different attempts to use modeling software in education is the one edited by Harvey Mellar and others (Mellar et al, 1994). The theme of this book is well summarized in the first paragraph of the Introduction, “Modeling and Education” by Harvey Mellar and Joan Bliss:

“This book is about modeling in education. It is about providing children with computer tools to enable them to create their own worlds, to express their own representations of their world, and also to explore other people’s representations. It is about learning with artificial worlds.”

According to these authors, the purpose of modeling in education is to create “artificial worlds” as images of real phenomena to allow the students to reason and learn with them. This group distinguishes between two different types of learning activities associated with modeling, “exploratory” and “expressive”. Exploratory activities are ones in which learners explore models provided by someone else, for example a teacher. Expressive activities are ones which learners construct models according to their own ideas.

Our own experience has shown that modeling in the classroom is really a combination of both kinds, since, to begin with, the computer tool already restricts the way a students can design the model. Actually, for the learning to be effective, it is recommended to let the student express their own views but with some guidance through worksheets.

In our early research (Sutherland et al, 1996), we introduced the spreadsheet as an innovation into students’ science classroom (physics, chemistry and biology). We designed worksheets which presented the students a particular scientific situation and guided the students to construct the spreadsheet and analyze the results. In the elaboration of the worksheets we follow a didactic approach known by some authors (diSessa, 1993) as “bottom to top”. We started the worksheets with very specific cases and gradually move into a more general analysis of the phenomenon.

Due to its structure, the spreadsheet facilitates the modeling process. But probably one of the most important features of constructing a model on a spreadsheet, is that the labeling of parameters, columns and graphs, allows the user to maintain links with the situation being modeled.

When working in mathematical modeling or in problem solving activities, we move back and forth between the abstract mathematical representation and the physical world. The spreadsheets provide what we can call an “intermediate state”. This, in a way, is a link between the abstract and concrete worlds. This artificial world has characteristics of both worlds, so there is no need to go back and forth between them during the analysis and we can stay most of the time in this “in between state”.

For the last six years, the Ministry of Education of Mexico has being sponsoring, a national program to teach math and science with technologies at the secondary level (Mochon, 2000 and 2001). Parallel to this educational project, there is an ongoing research project that has as its main purpose to investigate the impact of this technological implementation in students’ learning, teaching practices and curricular transformation.
Teaching math with spreadsheets

A deeper conceptual understanding of math requires the coordination of several representations like the symbolic, the graphic and the numeric and their connection to real contexts to provide meaning. This can be accomplished using the spreadsheet as a tool with its several representations and embedding the topics (as much as possible) in real situations (mathematical modeling approach). The materials presented in this section have these characteristics.

For example, the following spreadsheet shows an exploratory activity on the topic of quadratic equations (the graphs moves according to the values of the constants in the equations which can be changed by controls).

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>y = 0.5x^2 - 3.5x + 1</td>
<td>x</td>
<td>y</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>x = 3.5</td>
<td>y = -5.18</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notice that there are two different forms of the quadratic equation, one in red and one in yellow. The use of this spreadsheet is assisted by the following two worksheets.

**Activity**

**Exploring graphically quadratic functions (1).**

*(uses Excel file “QuadraticExplor”)*

In this activity you will explore graphically quadratic functions in two of their standard algebraic forms, finding the effect of each coefficient.

**Getting acquainted with the spreadsheet:** Open the spreadsheet “QuadraticExplor.”

On the left side of the screen you will see two quadratic equations (one in red and one in yellow) written in different forms. Each of the three constants in them has a control so you can change the equations as you wish. Do this and observe how the graphs on the right move accordingly.

Below each equation you can find represented a point satisfying that equation. You can change their x value with the controls associated with them. Do this and observe how the corresponding point moves along the graph.

**Project #1:**

Investigate the family of parabolas:

\[ y = x^2 + c \]

Describe the family: __________________________

What does the constant c represents? ____________...
Project #2:
Investigate the family of parabolas:
\[ y = a \, x^2 \]
Describe the family: ____________________ ...
What is the difference between the parabolas with "a" positive and negative? ____________________ ...

Project #3:
Investigate the family of parabolas:
\[ y = (x + r)^2 \]
Is there a change of shape or only a change in position? ____________________ ...
Describe the family: ____________________ ...
What exactly does the value of \( r \) represent? ____________________ ...

Project #4:
For the second equation, given in the form: \( y = a \, (x + r)^2 + s \), find out the effect on the graph when each of its constants is changed.

Project #5:
For the first equation, given in the form: \( y = a \, x^2 + bx + c \), find out the effect on the graph when each of its coefficients is changed.

Exploring graphically quadratic functions (2).
(uses Excel file "QuadraticExplor")

In this activity you will explore graphically quadratic functions considering the three cases that might occur related to their zeros and showing the equivalence between two of their standard algebraic forms.

Getting acquainted with the spreadsheet: Open the spreadsheet "QuadraticExplor" (see previous activity)

Project #6:
Write the first equation on the screen as: \( y = x^2 - 6 \, x + 5 \)
Using its graphical representation, find the location of the zeros of the above function: \( x = \) ___ and \( x = \) ___
Change the equation to: \( y = x^2 - 6 \, x + 8 \). Now the zeros are: \( x = \) ___ and \( x = \) ___
Change the equation to: \( y = x^2 - 6 \, x + 9 \). Now the only zero is: \( x = \) ___
Finally change the equation to: \( y = x^2 - 6 \, x + 10 \). What happened with the zeros of this function? ___ ...
Analyze now the family of parabolas: \( y = x^2 + 4 \, x + c \) to find out for what values of \( c \) there are two zeros, one zero or no zeros. State your findings here: ____________________ ...
Give some general conclusions about the zeros of quadratic functions: ____________________ ...

Project #7:
Write the first equation on the screen as:
\[ y = 2x^2 + 4 \, x + 1 \]
Change now the constants of the second equation until you make its graph coincide with the first one. Write below the equation you found:
\[ y = \] ____________________
Verify algebraically below that these two equations are equivalent.
Now write the second equation as:
\[ y = (x - 3)^2 - 2 \]
Change now the constants of the first equation until you make its graph coincide with the second one. Write below the equation you found:
\[ y = \] ____________________
Verify algebraically below that these two equations are equivalent.

The spreadsheets developed in this fashion cover a wide range of topics within the subjects of arithmetic, algebra, geometry, probability and statistics and higher math like calculus and differential equations. Their main objective is to use the graphical representation as a center piece since visualization helps the student better understand the math concepts.
To give one more example of these exploratory activities in mathematics, the following spreadsheet contains the graphic representation of the binomial and normal distributions. Each of these distributions has two parameters that can be changed with controls, seeing the effect immediately in the graphs. This graphical representation is very useful to compare the two distributions and determine in what circumstances the normal distribution can be a "good" approximation of the binomial distribution.
Teaching science with spreadsheets

We can predict natural phenomena because it follows some ordered behavior. Behind this order, we find a few principles that can be formulated mathematically. A deeper understanding of science requires the use of these principles as mental tools.

Thus, the materials presented in this section are based on the idea that the students can achieve a better understanding of some scientific phenomena if they are imbedded in proper mathematical formulations that will give them a more precise structure and the possibility of quantification. The activities in here have the aim of complementing the normal presentation of subjects done by the science teachers in their classrooms.

The applications of this spreadsheet are almost endless and depend on the particular objective of the teacher (some worksheets are already developed to use with this spreadsheet). The next spreadsheet shows the electronic structure of atoms. In the right side of it, the element can be chosen with a control (the elements can be ordered by atomic number or by groups). The program gives all the information about the number of electrons in each orbital. In the right side of the screen appears a model of the atoms with each of the electrons represented in a color corresponding to the level it belongs. Again, the visual image is very helpful (each electron moves randomly around its orbit when pressing the F9 key).

Finally, the last spreadsheet shown below is a simulation of the system spring-mass. The user can fix the values of the mass, the spring constant and the damping constant. Also, he can decide on the initial position and
velocity of the mass. With the control associated with the time, the simulation can be moved forward and the graphs will show the position and velocity of the spring (the spring on the right moves up and down accordingly).

Conclusions

As we could see from the examples given in this article, the spreadsheet is a very versatile tool to design all kind of exploratory activities in math and science. It has the important characteristic that we can combine together the numerical and graphical representations of the situation being presented. In addition, the controls in it give a dynamic component which is very effective for visualization purposes (obviously, this feature can not be shown in the static pictures presented in this paper).

An added extra feature of the spreadsheet is that through all the labels in tables and graphs, the spreadsheet keeps a close contact with the phenomenon being modeled or the problem being solved. This is very important when the spreadsheet is used for educational purposes.

Another crucial idea hidden in the modeling of the spreadsheet is that recursive relationships are the main mode to express formulas in it. This suggests that we should bring into the classrooms of math and science, more consistently, this type of recursive math.

A Gathering of BUGS

Mark Mortensen, PhD
Dept. of Technology and Cognition, University of North Texas, markmort@unt.edu

Abstract: The purpose of this video will be the presentation of first year, after-school activities of participants in the Bringing Up Girls in Science (BUGS) grant project. The video will observe the 4th & 5th grade participants in the science lab, interview the participants and interview the lab instructors.
Abstract: The purpose of this study was to determine mathematics and science teachers' initial perceptions of change prior to their participation in a year-long professional development program that emphasized integration of the math and science utilizing graphing calculators. The results indicate that as a group, the teachers (1) exhibited high information stage concerns and collaboration stage concerns; and (2) are more aware of the graphing calculator and its potential than previous groups. Mathematics teachers were more familiar with utilizing graphing calculators while science teachers were more familiar with utilizing computers. Mathematics teachers reported higher technological proficiency, but their stage concerns were not statistically different from the science teachers.

Mathematics and science educators include the use of technology as a common goal in their most recently developed standards. The National Council of Teachers of Mathematics Principles and Standards for School Mathematics (NCTM, 2000) suggests a framework for the types of technology-based activities and content that should be taught. Similarly, the National Research Council's National Science Education Standards include suggestions for science education reform in technology-based content and professional development (NRC, 1996). Further, both documents point toward significant increase in the integration of math and science. Reading between-the-lines, technology is encouraged as a tool that can facilitate such integration.

Graphing calculators show promise for integrating mathematics and science. There is a growing body of recent research into the use of graphing calculators in the teaching of algebra (Beckman, Senk, & Thompson, 1999; Dunham & Dick, 1994; Embse & Yoder, 1998; Milou, 1999); in both chemistry and physics (Adie, 1998; Roser & McCluskey, 1999; Taylor, 1995); and even the integration mathematics and science (Tharp et al.).

The State of Texas has developed the Texas Knowledge and Skills (TEKS) (http://www.tea.state.tx.us/teks/). The TEKS clearly extend the national reform documents by specifically indicating the use of graphing calculators in algebra:

Students use a variety of representations (concrete, numerical, algorithmic, graphical), tools, and technology, including, but not limited to, powerful and accessible hand-held calculators and computers with graphing capabilities and model mathematical situations to solve meaningful problems (§111.32. Algebra I (One Credit) #5).

Beyond the explicit statement that graphing calculators be used in the teaching and learning of mathematics, the new Texas Assessment of Knowledge and Skills (TAKS) (http://www.tea.state.tx.us/student.assessment/taks/index.html) requires the use of graphing calculators on the state-mandated tests at the ninth, tenth, and eleventh grades for math and at the eleventh grade for science.
Theoretical Framework

The implementation of technology will require change in the classroom. One model that has been utilized to inform the decision-making process when innovations are introduced is the Concerns-Based Adoption Model (CBAM). CBAM states that successful implementation of an innovation is a process not an event (Hall & Hord, 1987; Fullan, 1991; Friel & Gann, 1993), developmental in nature (Hall & Hord, 1987), and a highly personal experience for each teacher (Hall & Hord, 1987). Hall, George & Rutherford (1986) define concerns as the feelings, thoughts, and reactions that individuals have about an innovation or a new program that touches their lives. To measure these concerns, Hall, Wallace & Dossett (1973) developed the Stages of Concern Questionnaire (SoCQ). Initial research on the instrument construction verified the existence of seven stages in the concerns process: awareness, informational, personal, management, collaboration, and refocusing, with internal reliability for individual scales ranging from $r=0.64$ to $r=0.83$ (Hall, George & Rutherford, 1986).

Participants

The participants in this study are high school math and science teachers from a single large urban school district in Texas participating in a year-long professional development program that is ultimately aimed at improving math and science achievement. Within the professional development program, the teachers are divided into two sub-groups. The two subgroups are Algebra I (ALG I) with Integrated Physics and Chemistry (IPC) and Algebra II (ALG II) with Chemistry I (CHEM). The teachers are paired because the vast majority of students who are enrolled in ALG I will also be enrolled in IPC and because there is significant overlap in the knowledge and skills that are taught in each course. There is less overlap with students for the ALG II and CHEM group, but curricular overlap is strong enough to warrant the pairing. The teachers are recruited through their building principal and science department chairs and must participate as pairs, one from math and one from science.

The focus of the professional development is on increased communication and collaboration between math and science teachers within the district and specifically in individual schools, with a heavy emphasis on technology. Graphing calculators (TI-83s), Calculator-Based Laboratories (CBLs), and Calculator-Based Rangers (CBRs) with multiple probes were provided to all teachers at the beginning of the program to be used in all subsequent workshops. Each teacher will ultimately receive a minimum of 125 hours of professional development that culminates in a two-week summer institute. Upon the completion of the 125 hours, each teacher will receive a set of ten calculators, CBLs, and CBRs, an overhead panel for display purposes, and up to four additional probes for use in their classrooms.

Methods

Research questions

1. Are there significant differences between the holistic stage concerns profiles for mathematics and science teachers?
2. Are there significant differences between the stage score profiles for mathematics and science teachers?
3. Do the demographic profiles differ for mathematics and science teachers?

Data was collected from a total of forty-three secondary mathematics and science teachers during their respective introductory sessions in September 2001. There were 21 science teachers and 22 mathematics teachers.
All participants were administered the Stages of Concern Questionnaire (SoCQ) on the first day of the in-service. The SoCQ is a thirty-five item Likert-scale instrument that contains seven levels of responses. The responses range from 0 = irrelevant to me, 1 = not true to me now, to 7 = very true to me now. A demographic survey also was administered at this time. The survey collected two types of information: background and technology-using history. Background information collected included gender, years teaching, highest degree earned and age. Technology-using information collected included self-rating of the ability to integrate graphing calculators and computers in the classroom, in-service training received, and number of years integrating a graphing calculator and computer in the classroom.

Mean stage scores and total concerns score were calculated for mathematics and science teachers. To determine overall concerns levels, two analyses were performed. First, mean stage scores were converted to percentile ranks based on the norms presented by Hall, George & Rutherford (1986). Second, a peak stage score analysis was calculated for each group. Peak stage scores are defined as the stage at which an individual has his or her highest percentile rank score on the seven concern stages (Hall, George & Rutherford, 1986). Finally, analyses of variance (ANOVAs) were performed on mean stage scores and total concerns score to determine subgroup differences. Since there are seven stages of concern, the significant p-level for mean stage score ANOVAs was p=0.007 (p=0.05/7). Total score ANOVAs used a significant p-level of p=0.05.

Results

Mathematics teachers had the highest percentile concerns at the awareness and information stages and their lowest percentile concerns at the management and consequence stages (Awareness=81, Information=80, Personal=76, Management=47, Consequence=48, Collaboration=68, and Refocusing=42). Science teachers had the highest percentile concerns at the information stage and their lowest percentile concerns at the management and refocusing stages (Awareness=84, Information=91, Personal=85, Management=56, Consequence=63, Collaboration=80, and Refocusing=57). Overall, the percentile scores demonstrate that both groups are very aware of graphing calculators and their uses and want to learn more about how this technology impacts their classroom. The profile also demonstrates that the groups were users of the technology in the classroom but still desiring information on how to best integrate the technology to impact student achievement.

No significant differences (p<0.007) were found between the two groups of teachers. Thus, while percentile scores varied slightly as to highest and lowest percentile concerns, all participants entered the in-service with similar expectations.

Demographic analysis found that (1) participants were predominantly female (>60% for each group), (2) most chemistry teachers had a masters degree or higher while most mathematics teachers had only a bachelor's degree, (3) years of teaching experience was related to course taught (more years taught the higher the level class), (4) most mathematics teachers had never integrated computers in instruction while most science teachers had integrated computers in their instruction, (5) almost all mathematics teachers had integrated graphing calculators in the classroom while science teachers had used graphing calculators in instruction, and (6) science teachers self-rated themselves as novice users of graphing calculator and intermediate (almost experts) at using computers in the classroom while mathematics teacher considered themselves novices at integrating computers in the classroom and intermediate (almost experts) at using graphing calculators in the classroom.

Summary

Both groups entered this in-service very aware of the technology being discussed in the in-service and wanting to learn more about applications of the technology in the classroom (high information stage concerns). Needs focused primarily in the areas of how will this curricular change impact me and my teaching (high personal stage concerns) and how can I work with others to help bring about this curricular transition (collaboration stage). This early awareness of graphing calculators and interest in the integration
process is atypical for those entering previous math, science, and technology professional development programs (Chamblee, 1996; Chamblee & Slough (in press); Slough 1998). This warrants further investigation.

Demographical data present distinctly different groups. This fact agrees with current research in this area (Chamblee, 1996; Chamblee & Slough (in press); Slough 1998). Science teachers were more familiar with integrating computer applications in the classroom while mathematics teachers were more familiar with integrating graphing technology in the classroom. This finding is consistent with emphases in both disciplines. Also, math teachers rated their technical proficiency high with regard to the graphing calculator and the science teachers rated themselves as novices. Yet, there was no statistically significant difference between the groups mean stage concerns. At first, this may appear to be problematic with regard to either the self-reporting or the CBAM model. When, in fact, mere technological proficiency does not make one immune to the same stages of concern. This warrants further investigation.

Similar research questions were utilized to analyze the differences between the ALG I, ALG II, IPC, and CHEM teachers who participated in the professional development program. Due to the limited space, the results are discussed in a separate paper (Chamblee and Slough (in press B)).

Integrating Remote Scientific Instrumentation in the Curriculum to Support Inquiry: Case Studies in K-12 and Teacher Education

Umesh Thakkar, Glenn A. Fried, Benjamin A. Grosser, Scott J. Robinson, Daniel E. Weber
University of Illinois at Urbana-Champaign
Urbana, IL 61801

Marquette University
Milwaukee, WI 53233

Judy A. Lee
Blocker Middle School
Texas City, TX 77590

Abstract: This short paper describes our ongoing plans to gain in-depth understanding of how teachers and teacher educators are integrating remote scientific instrumentation technology to facilitate inquiry in classrooms by participating in the Bugscope project.

Introduction

As K-12 schools and colleges of education respond to efforts to reform science, mathematics, and technology education, changes are occurring in learning, teaching, and research activities in classrooms (e.g., National Commission on Mathematics and Science Teaching, 2000). Bugscope is an example of such changes. Bugscope allows students, teachers, and teacher educators to study insects and other arthropods through remote access and control of an environmental scanning electron microscope (ESEM). The ESEM is an advanced electron microscope that allows high resolution examination of specimens in their natural states; for example, wet, oily, dirty, non-conductive samples. To participate, teachers and teacher educators submit an online application. Included in their application is a brief proposal where they describe specific classroom plans to use Bugscope. Classrooms mail in insect specimens in advance, and these are prepared and inserted into the microscope. Then, using a World Wide Web (web) browser from their classroom computers, students, teachers, and teacher educators remotely operate the microscope to examine their specimens. Each classroom has opportunities to participate in Bugscope any number of times, and there is no cost for classrooms to participate. A goal of Bugscope is to provide sustainable remote microscope access to K-12 and teacher education classrooms nationwide at a rate of 50 classrooms per year.

Background

Although remote instrumentation is today an exotic and expensive technology, it is becoming part of daily practice in science. This suggests two things (Bruce et al., 1997). First, students, teachers, and teacher educators need to learn more about it because this kind access and control is becoming an integral part of doing science. Second, it is likely to become much more commonplace and less costly in future. The particular instruments and scientific domains may differ, but understanding of the principles underlying this mode of learning through projects like Bugscope is generalizable. Despite the importance of remote instrumentation, few projects have used it for K-12 and teacher education instruction. Two examples are mentioned here. One project is Chickscope, which allowed students and teachers from ten classrooms ranging from kindergarten to high school, including an after-school science club and a home school, to study the 2-day chicken embryo development using a remotely controlled magnetic resonance imaging instrument. Another project is MicroObservatory, which allows high school students and teachers to control a network of five automated telescopes over the Internet. However, such projects are not applicable across K-12 and in
teacher education classrooms. Also, rarely do such projects allow sustainable, real-time remote access and control capabilities to classrooms across the nation, as does Bugscope.

Challenges of Inquiry-based Learning and Teaching

Recent reports concur that inquiry-based projects successfully facilitate learning. One report has suggested that inquiry-based instruction “allows students to engage in practices of scientists and to construct their own scientific knowledge through investigation rather than memorization” (Linn et al., 2000, p. 2). Another has called for an emphasis on inquiry in teaching and learning across K-12 (National Research Council, 2000). Such reports highlight importance of improving teacher preparation programs through use of information technology. However, getting teachers and teacher educators interested and familiar with inquiry and providing support for them, can be challenging (Thakkar et al., 2001).

Since March 1999, more than 60 classroom sessions in more than 25 US states have participated in the Bugscope project. A report documented that Bugscope serves the purpose of stimulating an interest in the scientific research enterprise among students and teachers across the nation (Thakkar et al., 2000). Yet additional challenges remain. For instance, how does Bugscope contribute to the growth of teachers and teacher educators in understanding the possibilities of remote scientific instrumentation for learning, teaching, and research? How does remote scientific instrumentation technology support student, teacher, and teacher educator collaborations and expand participation in science (especially for underrepresented groups). In general, how do we build a community for inquiry learning?

In order to address such challenges, we are collaborating with Bugscope participants, such as Korb and Lee (co-authors), to develop case studies across K-12 and teacher education classrooms. We plan to use a variety of data (such as classroom proposals, teacher surveys, image acquisitions, session logs, and electronic communications). For instance, Korb wrote in the proposal to use Bugscope in her secondary and elementary science methods course: “I am interested in modeling the use of technology to these future educators. ... I also feel that having some control over the process of inquiry and discovery when using the Internet is extremely valuable for young students to construct their own knowledge. ... How exciting to be able to choose a specimen, send it to be processed for EM imaging and then explore particular driving questions. ... I will use the process and the final images to show preservice teachers how to further investigate insect and animal life cycles, anatomy, animal diversity and contribution to ecosystems.”

These collaborations will help to provide a deeper understanding of the impact of remote scientific instrumentation in learning and teaching. Additionally, it will provide an understanding of how this technology is shaped by different classrooms in different ways.

References

Abstract

Digital cameras, spreadsheets, and selected websites enable teachers of elementary and middle school students to "take only pictures, leave only footprints" as they tackle the problem of measuring and identifying trees. In the task described in this paper, teachers experience the integration of the national science, mathematics, and technology standards. They develop a unit of measurement, then measure indirectly, using informal notions of similar triangles. They hone observation and classification skills using an online dichotomous key.

An important focus of our work in teacher education is the authentic use of technology in learning the content and processes of science and mathematics. Tasks that support elementary and middle school preservice and inservice teachers in their development of content and pedagogical knowledge while making appropriate use of technology are not readily available. A team of five individuals—two science educators, a mathematics educator, a graduate student, and a public school classroom teacher—collaborated to develop a task entitled "Measuring and Identifying Trees with the Help of Technology." This task is available at http://msed.byu.edu/pt3/tree.html. We believe it contributes to the following goals for the use of technology in teacher education.

1. Supporting teachers as they learn important science and mathematics concepts and processes (e.g., observation and classification skills; development of a consistent unit of measurement; and use of ratio, proportion, and similar triangles in indirect measurement).

2. Modeling the authentic use of technology in a learning task. For us, authentic use of technology means that the task is much richer for the learner than it would be without the use of technology.

This task is organized as follows:

1. Establish the need for learning to measure the height of a tree or another tall object through indirect measurement.

2. Develop the concept of pace as a nonstandard unit of measurement; then, using a spreadsheet and finding the mean for paces of individuals within the group, develop the length of a consistent pace for that group.
3. Applying informally the concepts of ratio, proportion, and similar triangles, measure the height of a tree using a stick as a side of the triangle and the length of a consistent pace as the measure of length.

4. Observe characteristics of the tree in addition to its height (bark, leaves, twigs, seedpods, coloration, etc.); gather data through field notes and use of the digital camera (no collection of artifacts permissible except through virtual means).

5. Using field notes and photographs, consult a dichotomous key on the Internet to determine the possible identity of the tree. The following websites should prove helpful:

   http://www.cnr.vt.edu/dendro/dendrology/syllabus/key/key1.htm — This site helps you identify trees using the characteristics of leaves.

   http://www.cnr.vt.edu/dendro/dendrology/syllabus/twigkey/key1.htm — This site helps you identify trees using the characteristics of twigs.

   http://www.enature.com/guides/select_trees.asp — This site will help you identify a tree by leaf type or other attributes, or you can enter a tree name for information about the tree.

   http://www.noble.org/imagegallery/woodies.html — This site provides images and information on selected trees and shrubs.

Ideally, the first stages of this task should occur in an outdoor environment, especially the measurement of the heights of trees. In the absence of trees with foliage, however, the experience of measuring trees can be replicated through the projection of photographs of selected trees on overhead screens around the room.

Acknowledgements

Thanks to Dave Dimond, Clinical Faculty Associate, Brigham Young University/Public School Partnership, and to Leigh Smith, Instructor, Department of Teacher Education, Brigham Young University, for their collaboration on this project.
Though recognized as a legitimate and positive aspect of teaching and learning, simulations are being more widely used by authors for the 2001 SITE annual than in previous years. However, the wide variation in defining “simulation” in education has continued to contribute to the small number of studies in this area. The range in availability of hardware, courseware, and software in international locations where some of these investigations were done certainly has contributed to the variation in sophistication of data treatment. Additionally, though the global economy and international testing have moved countries closer in terms of educational goals, differences in educational philosophies have certainly contributed to the issues addressed and undertaken by this year’s contributors.

With only nine submissions, the variety of definition is again seen as a strength of this technology driven teaching strategy. The way educators have chosen to define and then implement technology in the classrooms of their districts and countries is as varied as the geographic locations of the schools. Regardless of the complexity or simplicity of the technology available or the cognitive entry level of the personnel proposed for using the innovation, readers can certainly find a situation or discipline that mirrors their own. Reports of technology use for teacher-preparation as well as use with the P-12 students also increase variation.

Papers submitted range from virtual classrooms in qualitative physics to reflective teaching and critical thinking simulations. Perhaps papers dealing with lesson planning and how simulations can serve as safe-havens for “practice” of skills learning in the pre-service teacher preparation classroom either individually or in groups show the technology version of “practice makes perfect.” Specific studies of how technology can be used to increase the “liveliness” in classrooms for today’s technology savvy students may say it best through the use of video, audio and animation.

Simulations have the ability to advance the experiential knowledge of the students using them regardless of age, stage, or location. For this, the studies promoting the use of technology in simulation should be commended.
3-D VIRTUAL CLASSROOM TECHNOLOGY

Kimberly Arseneau Miller
Department of Reading, Special Education, and Instructional Technology
Towson University
USA

Angela Glod
Department of Reading, Special Education, and Instructional Technology
Towson University
USA

Abstract: Travel to another country? Perform experiments without expense? All of this is now possible for the average student who has access to a computer in a virtual classroom. The implications for virtual 3-D technology in an online or traditional classroom are practically limitless. Online instructors consistently struggle with the task of creating a sense of community among students who often feel isolated or removed due to the lack of face-to-face interaction. Traditional classroom instructors often struggle with the task of creating real-life learning situations due to financial or distance barriers. Activeworlds is a software company that has developed 3-D technology that makes it possible for educators to create the virtual classroom that they desire. This presentation will be an overview of the 3-D virtual classroom as an emerging component of online and computer-assisted learning. Both an online class lesson and a real classroom activity using virtual 3-D technology will be demonstrated.

Simulated Lesson Design Studios

Willis Copeland, University of California, Santa Barbara, US

Teacher education programs have traditionally found it difficult to provide their credential students with the opportunity to practice complex skills such as lesson planning in ways that offer both detailed and constructive feedback and sufficient opportunity for student reflective response to practice. That is, it is easy to communicate to students the mechanics of lesson planning but much more difficult to engage students in repeated opportunities to plan lessons under conditions that allow them to examine closely the products of their planning with the benefit of focused feedback.

Preparing Credential Students to be Lesson Planners

The PT3 Program at UC Santa Barbara is working to develop an approach to provide our credential students with opportunities to practice, in controlled settings and with appropriate feedback, the designing of learning experiences (lessons and units) that make appropriate use of technology. We are designing what we call “Simulated Lesson Design Studios” into which our students could “enter” as individuals or as small working teams. Each SLDS will be specific to a grade level and content area and will contain the necessary tools and resources to allow our credential students to create a lesson or unit for a specified classroom of pupils. Each SLDS is contained on a CD-ROM and features a user interface built on the metaphor of a workshop with workbenches, tools and drawers of materials. “Tools”, located on various “workbenches” in the SLDS, are used to create such things as learning objectives, assessments, needed materials lists, and lesson delivery sequences and to assemble these components into a printable “lesson/unit plan” file. Other “workbenches” contain electronic tools useful, for example, in creating computer-generated graphics and multimedia components.

Resources, found in “materials drawers” in the SLDS include background for the teacher concerning the lesson’s content, a list of California Content Standards, a selection of available print materials for pupils that might be pertinent to the lesson, potentially helpful websites, computer applications that might be appropriate for pupils, videotape resources that might be used in the lesson, technology resources that are available in the school and thus could be planned for in the lesson, background information on pupils in the class for which the experience is being designed and even samples of activities that have been designed by other teachers and that might be incorporated into the complete lessons/units that the students are designing. Credential students would have to decide which tools and resources to use, and in what order. It would never be appropriate to use them all. There would not be “one best” way to proceed and different students working in the same workshop would very likely create discernibly different products.

We are in the process of creating a number of these Simulated Lesson Design Studios. Our students will then be assigned, outside of class time, to enter an SLDS and create learning experiences that make creative and appropriate uses of technology. Meeting in class sessions after such creative work is finished, the students’ products can be presented, examined and compared. Because all students will have had access to the same tools and resources and will have designed for the same class of pupils, differences in the resulting products can be compared and, as is typical of all good design studio work, individual students’ creative thinking and understanding of possibilities can be expanded.

Our development work has now turned to disciplined inquiry focused on both the process by which students engage in the task of lesson design, review and reflection and the results of engaging in this process in terms of students’ planning ability.

Interactive Session

We propose to offer an interactive session at SITE 2002 in which attendees can 1) work with sample Simulated Lesson Design Studios as would credential students, 2) hear about the results of our observational studies of credential students at work in SLDS’s, and 3) engage in a discussion of various pedagogical strategies that might be used with credential students and the possible advantages and disadvantages of these approaches. Attendees will be invited to explore questions such as the following: Would SLDS’s be better used by individuals or by small working groups of credential students? What might be the expected characteristics of lesson plans that these students might produce from within a SLDS? How could students’ reflection on and learning from an experience in an SLDS be best facilitated? At what stage in a credential student’s professional development would work in SLDS’s be most appropriate? How many separate sessions in an SLDS be necessary for real learning? How would a university faculty member most appropriately evaluate a credential student’s work in an SLDS?
Most college students have grown up with television and video games either as an enrichment of their lives or as a babysitter. After having been exposed to a myriad of visual stimulation experiences throughout the years, many students are dependent upon seeing, or interacting when involved in various learning opportunities.

Teacher education courses are particularly fertile ground for visual experiential opportunities in the field of practice. The synthesis of theory and experiences through presentations employing not only words, but videos or other images illustrating concepts has the potential to hold the students' interest as well as stimulate energy.

I will describe in this paper how to use a computer presentation program to increase the liveliness of learning experiences through video, audio, and animations. Group process, a major component of teacher education will be the focus of the video.

A digitalized video vignette portraying a situation in which both the teacher and the students in the classroom try to draw the non-responsive student into a discussion will be used as the demonstration. The teachers in training will be asked to share their interpretations of the class's interaction on the video, and their comments will be categorized and prioritized in a manner that will help them both understand and be a part of the process. Encouragement of critical thinking, along with sharing ideas with their peers in the class, increases the possibilities for both extension of knowledge and experiential learning. Seeing how others draw conclusions in vivo is, in itself, a valuable group experience.

The slide show is set up in the following manner:
1. A short verbal description (approximately 3 slides) of the goals of the slide presentation. This includes animations and photos.
2. A slide with 40 seconds of digitalized video with a vignette illustrating the behavior of a student reluctant to participate in class and the response of the class to her.
3. A succession of slides that stimulate the discussion process by introducing various questions to encourage students' synthesis of the situation. Suggestions provided by students re: teacher and student intervention will be displayed on the slides, prioritized and integrated into the broader learning goals of the course.

In my experience, using presentation programs that illustrate specific points through videos or photos along with encouraging students to become part of the presentation process is most effective in increasing student interest, sharing ideas as a class, and integrating theory and practice.

To avoid the pitfalls of irrelevance or lack of participation of students, the points illustrated should be clear and concise. The video or other media must illustrate the class or student problem well and provide opportunities for creativity in interpretation and critical thinking. The instructor, of course, should be experienced and well prepared, and the students must be equipped to participate through reading or other assignments or experiences pertaining to the material to be demonstrated.

Although problems taping and digitizing material may prove a barrier in some institutions, creative solutions are often available through University Television, cable TV stations that are required to do public service, or "home made" video vignettes subsequently digitized through campus media services. It may not be as slick as some day time soaps, but live action examples coupled with student participation and problem solving has the potential to combine theory and practice in an interesting and energizing manner.
Abstract: This demonstration presents online simulations built with Macromedia Flash 5.0. The simulations provide interactive interface for undergraduate students to change variables of an online chemistry lab to test theories and phenomena that are not easy to observe or accomplish precisely in real world lab environment. The simulations seek to provide students with conceptual understanding of scientific phenomena. Another advantage of using the simulations is that the online accessibility of the simulations breaks the limit of different platforms in different computer operation systems. Therefore, students can access the simulations with browsers in whatever system they are using.

Introduction

When learning scientific theories, students may lack experience in the phenomena that scientific theories seek to explain. Traditional lectures and textbooks typically present abstract symbolic representations of scientific concepts or principles without providing sufficient experience with the phenomena associated with the scientific concept and principles. In addition, some of the phenomena that scientific theories seek to explain are difficult for students to experience. According to Paivio’s (1971, 1986) dual coding theory, information encoded in both visual and verbal formats is better remembered than information which is encoded in only one of these two formats. Today’s computer technology can provide dynamic graphics, visuals, and simulation experiences. They can help students relate abstract contents such as mass, velocity, and acceleration to real experiences. Animated visuals can also provide explicit demonstrations that are not easy to be observed simply by naked eyes.

Tools for development

Macromedia Flash 5.0 is a powerful tool in building web-based animations and interactive simulations. Using web-based simulations in learning breaks the limits of time, locations, and computer platforms. Students can explore the content with internet-ready computers without the restrictions of time, locations, and operation systems. The small file size of the Flash simulations also reduces the time for downloading. The program provides features for building graphics and making simple animations. With the feature that allow developers to program for the characters in the simulation, it gives space for developers to manipulate their creativity.

Content of The Simulations

This proposed demonstration includes two projects. One is a series of web-based simulations of Newtonian mechanics. Users can test their knowledge of Newton’s laws of motion by changing any of the variables such as friction, mass, and the direction of gravity. This series of simulations seek to help students explore the context that is not easy for them to experience in their daily life. By exploring the motion in the simulated contexts that allow students to change the magnitude and direction of friction, gravity, and the mass of an object, students’ alternative conception could be changed by the simulations. Therefore, they can build their scientific understanding of Newton’s laws of motion. The other is a series of on-line chemistry lab simulations used in the introductory chemistry courses for the APL (Active Learning Package) project at Iowa State University. The chemistry simulations are used to provide college students a chance to
experience lab situations by changing the variables such as volume of solutions, mass of compounds, and molarity of solutions on the interface of the web pages. The accompanied animations of microscopic level chemical reactions are aimed to make chemical phenomena explicit and to help improve student understanding.

**Objectives**

My objectives of building the above simulations is to develop a package to further investigate the effect of using computer simulations and also to help students learn science. While demonstrating the simulations, I would like to share with educators and instructional designers how to effectively use web-based simulations in instruction. I also expect to receive feedback from people who are interested in using simulations and animations in education. With insightful feedback, I will be able to modify existing projects and develop future projects for further research with deeper considerations.

A Qualitative Examination of Student Responses to Test Questions After Simulation Software Use

Kimberly Nyles-Roque
College of Education
Iowa State University
United States
roque@iastate.edu

Abstract: In this study, student explanations for their answer choices on a Physics post-test dealing with motion were examined. During the qualitative examination of the data two trends emerged. First, students often fail to identify all forces involved in a problem. Second, students often fail to comprehend that multiple forces may act simultaneously.

Introduction

It is frequently observed that learning to apply Newton's 1st Law is a difficult task for beginning Physics students (Mahoney, 1994; Wanderee, Mintzes, & Novak, 1994). Andre and others (Andre, Hasselhuhn, Kreiter, Baldwin, Leo, Miller, Mroch, Duschen, Werner, & Akpan, 2000) have conducted two studies to examine the use of simulation software in addressing this learning gap. The first study used a more exploratory version of the software. It was found in this study that males who used the simulation software before reading the text benefit more from its use than did females (Andre, et al. 2000). The second study used a more directive piece of software and evidence was obtained that indicated that both males and females benefited from its use. Qualitative data was gathered during the first study in the form of student explanations of their choice of answer on the post-test. The present study examines the qualitative data set not previously analyzed during the first study.

This study was conducted to extend previous research concerning the use of physics simulation software to teach Newton's 1st Law of Motion to beginning physics students (Andre, et al, 2000). As part of Andre et al's first study, students were asked to explain their answers to conceptual questions dealing with motion. This study explores the nature of the reasoning and conceptions of motion displayed in student explanations of their answers. Specifically, the nature of errors in conception or reasoning were explored

The Study

The design of this study was primarily qualitative in nature. In the original 1993 study students were asked to explain their answer selection on a 46 question, multiple-choice Physics test. These explanations were entered into a spreadsheet program and then coded using the following categories: Correct Response, Explained Answer, Diagram Used, Formula Stated, and Use of Newton's 1st Law. It was possible for a single answer to be coded in multiple categories.

Research questions examined during the initial qualitative evaluation were as follows.

1. Did students express the application of Newton's 1st Law in their explanations?
2. If so, did they apply this law correctly?
3. If Newton's 1st Law was not applied correctly to the problem what mistakes did the students make?

It should be noted at this point that the qualitative results are somewhat limited in scope due to several factors. First, the qualitative examination of the data was not conducted until some eight years after the initial study took place. This made it impossible to triangulate results by interviewing subjects for clarification. Second, many students did not provide explanations of their answer selection for every test question or did not
provide explanations that indicated in any manner their thought processes. Third, no information was available to the researcher that indicated the student’s previous Physics experience. Fourth, as in any qualitative analysis the science/teaching/software design background of the researcher did guide the direction of the research questions being examined.

Discussion

Two significant trends emerged when examining the explanations of students who answered questions incorrectly. First, these students frequently failed to identify all of the forces involved in the problem. Second, many students misinterpreted Newton’s 1st Law in such a manner that they believed one force stops as soon as another starts. The concept of multiple forces at work simultaneously was not attained. It should be noted that the use of multiple forces was not required by every question on the posttest; consequently, these two trends were not observed in every question.

The first trend is perhaps the most significant as it indicates that an average of 56% of students who incorrectly answered a test question, failed to identify all the forces involved in the problem. The following two student quotes were in response to a problem that involved a bullet being fired at a target. At the exact moment the bullet is fired the target is dropped. Students are asked if the bullet will hit the target.

- ... the power and speed of the bullet will travel mostly straight while the target falls
- The target is lowered and the bullet will still be going straight

In these examples the students have failed to identify the force of gravity as it is applied to the bullet. Both the bullet and the target will fall at the same rate, so the bullet will hit the target.

The tendency of students to fail to recognize multiple forces at work simultaneously can be illustrated by the examination of their responses to a problem that involves a ball being kicked off the edge of a cliff. Students are asked to describe the path that the ball will take as it falls. The following are three quotes from students that typify this error.

- It must travel out a little before gravity takes it over
- The ball goes straight for awhile from the force then gravity overcomes and pulls it down
- After its inertia is gone it will fall. Thus the straight line and then the angled fall

In these examples students fail to realize that gravity is affecting the ball simultaneously to the kick. Although this trend was only present in an average of 41% of incorrectly answered questions, the trend remains significant in teaching.

Implications

The strength of the trends that emerged from this study indicates weaknesses in both the simulation software used and the instructional setting of the software use. Although students are acquiring a sense of Newton’s 1st Law they are not developing the ancillary skills necessary to consistently apply it correctly. The concepts of identifying forces and simultaneous forces need to be more explicitly addressed either in the software or during classroom instruction.

Integrating Virtual Reality (VR) into Classroom Curriculum

Kenny Ott
Adult and Career Education
Valdosta State University
United States
kott@valdosta.edu

Abstract: This paper discusses the potential use of Virtual Reality (VR) integration into classroom curriculum. Utilizing VR has been difficult for many educators because of resource and financial limitations. Although VR has been in existence for many years, recent technological advances have impacted its practicality and usability in the classroom environment. This paper provides an overview of VR and specifically how VR can be integrated into classroom curriculum. In addition, several Internet sites located on the World Wide Web are discussed that show the potential of VR integration. Virtual reality can be an exciting addition into educational curriculum.

Introduction

The term Virtual Reality can be defined in many ways. VR can be identified as a completely immersive environment or a simple three-dimensional (3-D) animated object. The development cost may start at hundred’s of dollars and reach into the million’s. Dunning (1998) identified that the cost can vary from very expensive computer-assisted virtual environments (CAVEs) to VR technology that are viewed inexpensively on a personal computer. CAVE products were originally developed by the military and other governmental agencies to provide realistic training. The cost and resource requirements for CAVE products have the potential to easily reach into the hundred’s of thousand’s or even million’s of dollars. In addition, the video gaming industry has been creating CAVEs and immersive VR environments that provide realistic environments. Development of the games produced by this industry is very expensive. Thousands and thousands of dollars are sometimes spent to produce the simple graphics required for some of these virtual scenes.

VR in Classroom Curriculum

Unfortunately, developers of classroom curriculum have found it difficult to create immersive educational environments due to production cost limitations (Dunning, 1998). Advancements in VR techniques have rapidly developed over the last few years. Recent technological advancements have made it affordable and practical to implement new technologies in the classroom (Rodriguez, 2001). New software packages have lessened the cost limitation and increased the usability.

Briggs (1996) identified that VR has several applications in the educational environment. He defined VR as a computer-generated, 3-D simulation in which a student can interact and have the feel of immersion in another environment. Using VR students are able to see distant galaxies or explore complexities of the anatomy. History students can explore ancient historical sites and take a virtual tour of a present day site that would be too expensive and time consuming to visit. English students could take a virtual tour of an ancient Shakespearean playhouse. The possibilities are truly endless.

By experiencing a virtual environment, the experience may be more engaging than simply reading a text or sitting in a classroom listening to an instructor. Students can learn by experiencing an immersive environment that has already been built or discovered. A student may be able to experience something in a virtual environment before dealing with a real life situation (Dunning, 1998).

Winn and Jackson (1999) developed several propositions about VR in educational environments. Some of these propositions are: (1) Virtual Environments (VEs) are less expensive than costly simulators, (2) VEs can be safer than some real-world environments, (3) VEs allow quasi-natural interaction with environments or objects, (4) VEs provide environments where students can learn, (5) VEs are very useful
when they simulate concepts that are normally not assessable to the senses, (6) when changes in 3-D perspectives increase learning VEs are very effective, (7) VEs support constructivist concepts (8) participants in VEs actually experience a sense of presence, (9) VEs allows for situating education in a real world context, and (10) collaboration in VEs are an available option. The above propositions are important when considering integrating VR into classroom curriculum.

**Immersive Imaging Technologies in VR**

One form of VR is the interactive photographic process, sometimes termed “immersive imaging”. It is photographic immersive imaging technology that allows the student the opportunity to manipulate photorealistic images. These developments are beneficial because they articulate three-dimensional photographic imagery instead of three-dimensional computer generated imagery. These images allow students to view and manipulate environments or objects from many viewpoints. The VR images can be viewed in a linear and non-linear manner (Trelease, Nieder, Dorup, & Hansen, 2000). By manipulating the image, with the cursor, one may rotate on object and pan in or out, up and down or left to right. Two types of immersive imaging are panorama and object movies (Comer, 1999).

Taking multiple photographs of an object develops object movies. These overlapping photographs of the object are blended together and process using a software package. By moving the cursor a student can manipulate an object and examine it from several different angles. A panoramic movie allows the student to view an environment from 360 degrees horizontally and 180 degrees vertically.

The equipment needed to develop object and panoramic movies can be relatively minimal and inexpensive. Almost any camera can be used to accomplish the photographs. One may use an inexpensive disposable single use camera or a very expensive digital still camera. A tripod with a leveling device, for a panoramic movie a panoramic head is very beneficial. A major item in VR development is of course the software package for gathering, blending, stitching, compressing, and exporting the object or panoramic movie. For object movies a backdrop should be used, such as a piece of black material to provide consistent background color. In addition, a turntable will be used to place an object on to take the pictures. The object will be rotated and photographed from different angles to develop the image. This would be accomplished by rotating the object 12 times every 30 degrees to obtain a 360-degree image. There are numerous companies that have developed expensive turntables, but a turntable such as a Lazy Susan will accomplish the task.

**Authoring Tools in VR**

Several new software packages are presently available to develop VR. Some of the more popular programs are: Picture Works Technology (Spin Panorama, Spin PhotoObject and VRTour); Live Picture’s Reality Studio (Photo Vista and Object Modeler); Enroute Imaging’s QuickStitch 360; and QuickTime VR (QTVR) Worx (Panoworx, ObjectWorx, and SceneWorx). QTVR Worx is a comprehensive software package developed for photorealistic visualization of environments or objects. QTVR, developed by Apple, was one of the first authoring VR tools on the market for use on a personal computer. And has developed a compete package that includes everything needed to integrate QTVR into classroom curriculum.

QTVR Worx has been in existence for several years but has recently developed an educators’ special edition that includes the VR Worx 2.0 and the VR Toolbox QTVR Curriculum. This edition is specifically designed for educators. This unified set of programs and curriculum includes student handbooks and a teacher’s manual. A workbook, included in the package, describes everything a classroom teacher needs to know to integrate virtual reality into the classroom curriculum.

**Examples of Immersive Imaging**

Several examples of panoramas and object VR movies can be examined on the World Wide Web. The QuickTime VR gallery provided several unique examples of VR movies (www.qtvr.com). An interesting site that simply shows how VR could be used to explore a facility is at the Harvard University http://www.news.harvard.edu/tour/main.html. The site has approximately 75 QTVR movies and takes the visitor on a virtual tour of the Harvard campus. Students can examine a wide variety of anatomy resources at Wright State University (www.anatomy.wright.edu/QTVR/QTVR_menu) to get a full grasp on basic
anatomy. Architecture students can tour a building or house to fully understand constructional considerations and to develop a comprehensive understand of the interior makeup of a structure (http://www.qtvr.com/qtvrshock/index2_2.html). In addition to these sites there are numerous web sites that can be accessed to enhance the tradition classroom curriculum.

Conclusion

Virtual reality, if used in an appropriate manner, can be a wonderful element to add to the traditional classroom curriculum. It is no longer an expensive technology tool that is monopolized by governmental, corporate, or business agencies. VR is a practical tool that can be integrated into education. VR in educational environments is, for the most part, still in its infancy. In the foreseeable future resource limitations, financial constraints, and apprehension about using VR should decrease and educators will eventual use VR on a larger scale. VR integration can be an exciting new addition to the classroom curriculum.

Comparing Simulation-based Lesson Planning in Experienced and Preservice Teachers

Harold R. Strang
Curry School of Education
University of Virginia
United States of America
hrs9j@virginia.edu

Abstract: First, the four major features of the most recent LP II lesson-planning simulation are described. Next, major variables obtained during participation are defined. Finally, initial findings derived from data generated by collaborating clusters of preservice and inservice cohorts are discussed. The results suggest that, across cohorts, variables cluster to produce a single factor defined by the complexity of participant navigational movement during lesson planning. Furthermore, experienced teachers achieved significantly higher scores on this factor than did their inexperienced counterparts. Regarding planning outcomes, the increased open-ended nature of the simulation experience appears to have yielded results best defined by the interaction among a variety of qualitative variables rather than by unitary values of specific qualitative variables.

Introduction

Over the past several years, an ongoing research project in preservice and inservice teacher education at the Curry School has focused on developing and testing the educational efficacy of software-based lesson-planning simulations (Strang & Clark, 2001; Strang, 2000; Howard & Strang, 2000). The purpose of the current study is to compare the decision-making processes and planning outcomes of experienced and preservice teachers as they complete the most recent LP II simulation. This tool allows participants to create lessons for motivated and unmotivated software-defined students. The results obtained from this study will not only contribute to lesson-planning pedagogy, but when provided to future participants during simulation debriefings, will stimulate personal involvement in group discussions and ultimately help the participants to improve their lesson-planning decision-making skills. After describing the LP II simulation’s interactive features and the empirical measures derived from its use, this paper will describe a preliminary study designed to assess the simulation-generated lesson-planning patterns for motivated and unmotivated students exhibited by preservice and experienced teachers representing two levels of teaching.

The LP II Simulation

Interactive Features

Using common keyboard and mouse functions, from 10 to 30 participants, seated in front of PCs in a computer lab, typically engage in the lesson-planning simulation alone or cooperatively in small clusters. As described by Strang and Clark (2001), the LP II simulation experience involves a decision-making sequence defined by the following four-phases.

1. A grade level is selected and the genders of hypothetical high- and low-motivation students are determined.
2. A three-step sequence is completed that defines the content of the simulated lesson. This sequence includes defining the lesson subject (language arts, social sciences, mathematics, or science), selecting a subject area from three appropriate Standard of Learning (SOL) goals (Virginia Department of Education, 1999), and finally, selecting one of three specific lesson goals related to the selected SOL.
3. A series of decisions is made that defines the nature of the lesson activity for each of the two hypothetical students. This major planning phase involves deciding for each student the number of distinct
activities, and, then within each activity, what the student will do, with whom the student will work, what learning aids will be used, what level of thinking will be encouraged, and how long this activity will last. Throughout this phase, decisions may be communicated via options defined by the software or via options authored by the participants themselves. Also, during this phase, participants may include an explanatory note accompanying any recorded lesson-activity decision.

4. The lesson’s instructional effectiveness is evaluated for the hypothetical students during the final phase. Any combination of seven software-defined and two participant-defined evaluation options can be used to define how each of the two hypothetical students’ lesson-related learning is to be evaluated. This phase also includes the preceding phase’s note-taking option.

Navigation within the simulation is extremely flexible. After the high- and low-motivation students are defined, participants can quickly access previously completed phase screens to review and/or edit decisions and then quickly return to the current screen. Navigation within each of the phases also provides maximum flexibility.

Empirical Measures

Two types of variables are generated by participant keyboard and mouse activity during the lesson planning.

1. Process variables. Measures in this category focus on how participants plan the lessons for each of the two students. Specific variables include the length of time devoted to planning the lesson, the number of decision reviews and changes, the frequency of creative participant authoring, and, the frequency and length of participant note taking.

2. Outcome variables. Measures in this category focus on the results of participant planning for each of the two students. Specific variables include the length of student lessons, the number of lesson activities, the opportunity for independent student work, the cognitive demands placed on the student, the technology support integrated into the lesson, and the number of different forms of evaluation employed at the end of the lesson.

The Current Study

Samples of preservice and inservice teachers representing two grade level categories (grades 1-5 and grades 6-12) were drawn from students enrolled in both on-grounds and off-grounds teacher-education courses offered by Curry faculty members. All participants completed the simulation in collaborating clusters of from two to four teachers who, just prior to participating, had self-selectively formed clusters based on teaching level and teaching discipline. The cluster count for preservice and inservice teachers was 54 and 23, respectively.

The goal of the current study was to explore how the preservice and inservice teachers at each of the grade level spans planned lessons for their motivated and unmotivated pupils. A two-step analysis plan was implemented. First, two principal components factor analyses with varimax rotations were performed to ascertain the degree to which the six process and six outcome variables constituted mathematically as well as conceptually distinct factors for motivated and for unmotivated students. Next, a second level of analysis was performed to ascertain the influence of teaching experience, teaching level, and student motivation level on the mathematically defined factor scores. To achieve this outcome, factor scores were submitted to the appropriate number of 2(teaching experience) X 2(grade level category) X 2(pupil motivation level) ANOVAs.

Results

Mathematical Factor Validation

Neither of the two principal components factor analyses yielded viable two-factor solutions. Inspection of both numerical factor loadings and graphical scree plots suggested single-factor solutions. Factor structure
replication across the high-motivation and low-motivation data was assessed via the coefficient of congruence statistic (Gorsuch, 1974, pp. 253-254). The resulting coefficient of 0.924 further attested to the validity of the one-factor interpretation. Table 1 displays the factor loadings for the six process and six outcome variables for motivated and for unmotivated students, respectively.

Table 1: Factor Loadings for the Six Process and the Six Outcome Variables

An inspection of the loadings revealed that the single factor was primarily defined by complexity of participants' navigational movements during their lesson planning. The most prominent variable was participant completion time, a measure that embraced the reviewing of previous decisions, the changing of previous decisions, the authoring of personal options, and the inclusion of personal notes variables. Interestingly, the results of the navigational complexity seemed also to yield student lessons that were longer and more likely to include more activities.

ANOVA Results

The results of the split-plot ANOVA applied to the factor scores yielded one significant main effect and no significant interaction effects. Experienced teachers scored significantly higher on the navigational complexity factor ($F(1,73) = 6.75, p = .011$). Neither the teaching level main effect ($F(1,73) = .204, p = .653$) nor the pupil motivation level main effect ($F(1,73) = .200, p = .656$) approached significance.

Conclusions and Implications

Two important observations can be drawn from the findings of the present study. First and most clearly, the quantitative variables generated during participants' completion of the simulation collectively define a dimension anchored on one end by fast, linear planning movements, and on the other end, by slow, nonlinear planning movement. Furthermore, the ANOVA results suggest that teaching expertise is a major definer of a participant's movement pattern. It appears that with their rich collective histories of professional classroom instruction, experienced teachers, in collaborating clusters, were able to use the simulation's movement and authoring freedom to create more complex and perhaps more integrated and more individualized lessons for their simulated students than were their preservice counterparts. Of course, support for the later two planning outcome assumptions requires validation via a qualitative analysis of the records of individual participant clusters. To further support the necessity for such analyses, let's briefly review the second important observation linked to the findings.
No meaningful outcome factor emerged from either of the factor analyses. A comparison of the key attributes of the current simulation and its predecessors may help to explain why a clear lesson-planning outcome factor structure, found in earlier simulation results (e.g., Strang, 1998), did not appear in the current LPII simulation findings. The present simulation was deliberately constructed to offer participants more opportunities both to navigate option screens freely and to do more than point and click when they made planning decisions within these screens. It is apparent that the increased freedom offered in the LPII has yielded a powerful quantitatively defined navigation factor. But variability attributable to an increased number of lesson-planning options, coupled with the opportunity to circumvent preprogrammed options with personally authored alternatives, has yielded lesson-planning outcomes that are highly individualized yet fail to fit clear factor structures. Of course further qualitative analyses of the current data and both quantitative and qualitative analyses of future participant datasets must be performed both to validate the current results and to define more completely the importance of the navigation and outcome variables.

A confirmation of the current findings will result in several practical changes in the LPII simulation’s use in teacher training, particularly relating to the content and procedures that define the group-debriefing sessions that follow the creation of the lesson plans. Content shifts may include changing the Compare Profile. This printout, which presently allows participants to compare quantitatively their individual (or cluster) navigation and planning decisions with group averages, may be redesigned to present solely quantitative information on navigation patterns. Two additional post-training feedback instruments may be employed to provide participants the opportunity to compare their individual (or cluster) planning decisions with those of classmates or mentors (e.g., experienced teachers). The Event Record presents a decision-by-decision printout with an accompanying timeline, and the Lesson Plan printout creates an integrated picture of content, activity, and evaluation decisions with accompanying self-authored options and notes.

Procedurally, the debriefing session may be reframed to focus on the sharing of planning decisions via group discussions or one-on-one dialogue exchanges. Such a debriefing restructuring redirects the activity’s focus from an information-providing session to one that promotes dialogue exchange tied to personal planning commitments. Finally, with its emphasis on exploration and discovery and de-emphasis on specific pedagogical absolutes, the restructured debriefing will offer more universal appeal as a dialogue tool in teacher education methods courses.

Abstract: Nurturing reflective teaching and improving critical-thinking instruction are achievable only when teachers-in-training are provided with opportunities to build professional knowledge and practice reflective teaching skills. The CSTGCTS computer simulation was developed to provide such opportunities. A pretest -posttest control group design was defined by four preservice teacher groups and two treatments. The findings suggest that the employed treatments contributed to reflective teaching and helped enhance professional knowledge and teacher behaviors on the part of preservice teachers during the teaching of critical thinking.

Introduction

Many recent studies have addressed the importance of nurturing reflective teaching in teacher education (Rodriguez & Sjostrom, 1998; Abell, et al., 1998). Recently, the principal author developed the Computer Simulation for Teaching General Critical Thinking Skills (CS-TGCTS) program, a software tool designed not only to cultivate reflective teaching in participants, but also to bring about improvements in their effectiveness in the teaching of critical thinking.

Definitions of reflective teaching suggest that performance with regard to professional knowledge and teacher behaviors are two indices for understanding a preservice teacher's degree of reflective thought in his or her teaching practices (Abell, et al., 1998). Two types of knowledge and three categories of teacher behaviors were identified and incorporated in the CSTGCTS program. Knowledge was divided into content knowledge and pedagogical content knowledge of critical thinking while teacher behaviors were classified into those that contribute to enhancing students' prior knowledge, their critical-thinking dispositions, and thirdly, their critical-thinking skills. Moreover, since increasing self-awareness and provoking mindful learning are crucial for breeding reflective teaching (Collier, 1998), interventions designed to improve these two mechanisms were central in the CSTGCTS program. With the focus on nurturing reflective teaching, this study tested the following hypothesis: Providing immediate feedback concerning teacher behaviors as well as literature related to professional knowledge would increase self-awareness of teacher behaviors and increase mindful learning in professional knowledge, which in turn, would provoke reflection in teaching practices, and, further, result in improved teacher behaviors.

Method and Results

Participants were 50 male and 99 female preservice teachers enrolled in a two-year teacher program at National Sun Yat-sen University, Taiwan. The interactive experience was achieved via the CS-TGCTS's two serial simulations, each of which takes about two hours to complete. The software also provided records of professional knowledge and teacher behaviors that denote critical thinking. Professional knowledge was measured by the Questionnaire of Professional Knowledge for Critical-thinking Instruction (Yeh, 1999), whereas teacher behaviors were measured by teachers' actual usage of 12 teacher behaviors in the CS-TGCTS program.

The study employed a pretest-posttest control group design. Participants were randomly assigned to one of the three experimental groups or to a control group. Two treatments were employed. Treatment I included five text files of research-based literature concerning professional knowledge for teaching critical thinking; Treatment II included a bar chart which indicated the usage rate of twelve teaching behaviors during the first simulation. The treatments were administered at the completion of the first simulation. Group A (the control group) received neither of the treatments; Group B received only Treatment I; Group C received only Treatment II; and Group D received both treatments.

The first MANCOVA yielded a significant group effect for professional knowledge, Wilks’ Λ = .88, p
The ANCOVA results also indicated a significant group effect for content knowledge, \( F(3, 143) = 4.10, p < .01 \), but not for pedagogical content knowledge, \( F(3, 143) = .38, \) ns. Comparisons of the least-square means revealed that participants in Group B and Group D, who received the treatment of professional knowledge, acquired more content knowledge than did the control group, \( p < .05 \).

The second MANCOVA yielded a significant group effect on teacher behaviors, Wilks’ \( \lambda = .82, p < .001 \). Follow-up ANCOVAs, similarly, showed significant group effects for all aspects of teacher behaviors, \( p < .01 \). Comparisons of the least-square means revealed that Group D outperformed the other groups on teaching behaviors for increasing prior knowledge \( (p < .05) \); Group C and Group D outperformed the control group, and Group D outperformed Group B on teacher behaviors for enhancing critical-thinking dispositions \( (p < .05) \); Group C and Group D outperformed the control group on teacher behaviors for improving critical-thinking skills \( (p < .01) \). Moreover, based on the total mean scores on the posttest, Group D outperformed the other groups, \( p < .001 \). The mean scores for the four groups were 48.77, 53.59, 56.50, and 60.99, respectively. Group D, which received both types of treatments, achieved the greatest improvement in teacher behaviors among the four groups.

Discussion and Conclusions

The hypothesis proposed in this study was fully supported. More specifically, the data confirm that preservice teachers who received interventions for increasing self-awareness and mindful learning benefited the most from the computer-simulated training: their teacher behaviors improved significantly, and they outperformed their counterparts in the control group on all teacher behavior measures. These findings also support earlier conclusions that appropriate feedback increases self-awareness (Yeh, 1999); mindfulness and self-awareness contribute to nurturing reflective practice (Titone et al., 1998); and reflective teaching requires background knowledge (Rodriguez & Sjostrom, 1998).

The data also show that computer-simulated training leads to greater improvements in preservice teachers’ content knowledge than pedagogical content knowledge. The insignificant improvement in pedagogical content knowledge most likely reflects the fact that this type of knowledge addresses a much broader scope of understanding than simple content knowledge—a scope that involves teachers’ responses to students with differing needs in a specific domain. An alternative explanation is that the CS-TGCTS’s instructional components focus more on the acquisition of content knowledge than on pedagogical content knowledge.

In conclusion, nurturing reflective teaching is crucial to successful teacher education. The ultimate goal of emphasizing reflective teaching is to help the preservice teachers gain a deeper understanding of their teaching practices so that they can improve them. The findings provide evidence that the CS-TGCTS simulation is an effective tool for improving preservice teachers’ reflective teaching in critical-thinking instruction. Finally, the simulation’s educational benefits are strongly related to its capacity to improve professional knowledge coupled with its capability to provide an analytical yet supportive environment for practicing teaching skills.

Technology Portfolios in Pre-Service Social Studies Teacher Education

Marsha Alibrandi

A state-mandated technology portfolio required for initial licensure has changed the lives of Social Studies Methods Educators. North Carolinian Social Studies professors meet the challenge in various ways. This case study investigates the types of adaptations made to accommodate the new requirement. As digital archives, lesson plans, webquests, geographic and Census information become available through Internet sources, how are today’s initially-licensed teachers being prepared to meet challenges of integrating technology across the social studies?

Since 1999, the North Carolina Department of Public Instruction has required a Technology portfolio for initial teacher licensure. For students earning a license as part of an undergraduate degree, this means that during the ‘professional semester,’ or the semester of the student teaching practicum, the student must design, implement and field test digital portfolio products developed within the Methods class.

Professor A:
In a one-semester combination of Methods and student teaching, how, when and where are the appropriate practice and tools integrated into the pre service course? Over a three year period, refinements to a computer lab component have resulted in the development of more streamlined lessons, tools and products. The dilemma a teacher educator faces is, "What gets left out of the Social Studies Methods curriculum?"

One successful practice has been to add a computer lab component to the Methods class. Meeting on Fridays afternoons from 3:30 to 5:30, the computer lab component is amazingly well attended. Research on prior skills of the students revealed that many have never used the Internet to search for lesson plans or student activities, most had never designed or mounted a website, a few had used some of the functions of PowerPoint, and none had heard of WebQuests.

Discrete lessons are sequenced and presented weekly during the Friday labs. The first four weeks introduce new skills; one each week. Students have collaborated in co-designing the lab components. The four components are:

1) Boolean searches for finding Social Studies lesson plans, student activities, simulations, role plays, web quests, maps, digital archives and other useful Internet resources. Students are generally unaccustomed to using Boolean search strategies prior to this introduction.

2) The WebQuest on WebQuests at the Filamentality website. Students are assigned to develop a WebQuest using a self-guided worksheet developed by a prior student.

3) Power Point: Features and functions of Power Point are introduced in the first hour, and a 6 slide product is required by the end of the second hour in which images are imported, sound and slide effects are demonstrated.
4) Web site development. With a former student lab assistant, a one hour step by step tutorial was developed to assist student to design a website with additional pages and links and images.

Subsequent Fridays (of which there are only four and students often stay after class to work on their products), additional effects, enhancements and techniques are added, but primarily this is lab time for the design and development of the products. The website component is now available on the web at: http://www.ncsu.edu/ced/clt/workshops

Students indicated in reflections on their prior knowledge that their skills were generally undeveloped. For example, several were learning for the first time that multiple windows could be open and in use, many had never imported an image, and most had never used the sound or slide effects in PowerPoint. None of the undergraduate students had ever developed a web page. Note that these students began matriculating in 1998.

Professor B:

In a Middle School Social Studies class, the introduction and co-construction of a virtual field trip was designed to develop curriculum-appropriate products in line with the middle school Social Studies curriculum which introduces the major world regions of the Americas (grade 5); The Eastern Hemisphere: Europe and the former Soviet Republics (grade 6); Africa, Asia and the Pacific Realm (grade 7) and North Carolina and the World (grade 8).

With assistance from Instructional Technology specialists who join the Methods class to co-construct virtual field trips with pre service middle school teacher candidates. Over a semester-long double methods course (Social Studies and Language Arts), the students spend one and one half hours per week preparing their technology portfolio products. Instruction in Hyperstudio and DreamWeaver prepare the candidates for the virtual field trip products they are assigned to create are to enhance the curriculum they will teach in their student teaching practicum sites in the following semester.

In each of these settings, the curriculum is the driving force behind what products the students will develop. Several of the middles school products are mounted at the www.ncsu.edu/clt website. In the high school Methods class, students mount WebQuests at the Filamentality site or in university web space, mount their webpages either at the university or at their practicum site schools, and several developed activities for high school students that require the development of PowerPoint presentations.

From shared constructivist theoretical perspectives, the integration of technology and computer skill development is grounded in the target curriculum. To demonstrate best practice and ‘seamless’ technology integration, computer lab components are collaborative endeavors that use student skills as the basis of cooperative learning.
North Carolina's Sixth Graders Go to Russia:
A Global Education/Curriculum Integration Project that Redefines the
Virtual Field Trip and Makes Social Studies Education in a Technology
Enabled Environment Meaningful and Exciting

<mailto:pruinnc@aol.com>

Abstract: This project traces the three year development of preservice teachers’ global technology
projects from the after-the-fact journaling accounts of a research trip to Russia to a year long
research study about Russia involving hundreds of sixth grade students, their teachers, a university
research team and preservice teacher education students. Sixth grade students and their teachers
involved in the final year of the project used a curriculum integration teaching and learning approach
to study Russia. The students’ ability to recall discrete facts and engage in reflective thinking as well
as both teachers’ and students’ attitudes about learning using this approach were measured.

This paper discusses the preliminary results of a project that examines the effectiveness of using the
curriculum integration approach for teaching and learning in a technology enabled environment. The overall
project that used Russia as its focus began in 1997 with a professor’s research trip to Russia to study Russian
education, specifically teaching and learning approaches used in middle grades. The project evolved from a single
professor researching to preservice teacher student involvement. Students accompanied the professor to Russia,
taught classes and observed in Russian schools, pre K-college. While in Russia, the college students journaled back
information via the Internet about the country, culture and education. Colleagues and middle school students
following the trip in the United States were fascinated by the accounts, but were disappointed that they were unable
to ask questions of the travelers. In an effort to satisfy the demand for home-bound students and teachers to play an
interactive role in the research in Russia, the most recent version of the research trip was built to maximize
involvement by sixth grade classes.

The 2002 Great Adventure to Russia Project (www.ncsu.edu/chass/extension/russia-nc6) was developed as
an experience that used a curriculum integration approach to teaching and learning in a technology enabled
environment. Researchers sought to determine if, by using the curriculum integration approach to teach early
adolescents about Russia, students were able to both recall discrete facts and practice reflective thinking. Attitudes
about learning and teaching were also examined.

In September of 2001, the project enrolled forty sixth grade classes interested in studying Russia. It took
the classes through the months of preparation for an actual trip to Russia in February. Students were part of the
home-based research team and took the trip virtually.

Briefly: In the fall and winter middle school classes received Internet Postcards From Russia, met the NC
State traveling student research team on line, and logged on to offer suggestions about what to pack to survive sub-zero
weather and what gifts to bring to host families. In late November, sixth graders posted 500 questions for the
team to research while in Russia. Three hundred questions were selected to be answered. One half of the questions
would be answered by team members interviewing Russian students and parents and the remaining 150 questions
could be answered through general knowledge of the professor researcher. To coincide with the trip, teachers would teach a unit about Russia that was prepared using a technology enhanced curriculum integration format driven by the students’ research questions. While on the trip to Russia, the traveling research team would send home daily reports, pictures and interviews conducted with Russian school children. The home-based sixth grade teams researched Russia and supplemented what they learned with information from the field, sent back via the web. Students completed their study of Russia by sharing their research projects. This activity enabled all of the students to know the information gathered about the classes’ questions. The final stage of the project provides for teachers and students from around the state to come together to report their project findings at a Global Connections Conference at NC State University in May.

As of late December we have discovered the following:

Postcards From Russia have generated a great deal of excitement in the classrooms. Reports from teachers tell of students racing to computers to pull up the most recent card in order to answer the mystery question included in each card. Children beg for research time to discover the questions’ answers and learn more about Russia. Because few of the children had little knowledge of Russia before the project, we have determined that the information on each postcard has elevated the level of learning for all of the students. This is evident in the complexity of the 500 questions that we have received. Many of the questions are sophisticated and indicate a deeper level of knowledge about Russia. We believe this to be an example of Vygotsky’s (Vygotsky, 78) scaffolding principle. Students’ level of knowledge can be raised if new information is introduced incrementally.

High interest in social studies has been generated through the game board homepage, the postcards, the mystery game, Teachers Talk pages, etc.

By submitting research questions, students report they have felt empowered to be able to direct their own study of Russia.

Teachers are heartened that university researchers are examining how students learn best. They have reported back that interest and support of their classroom efforts is empowering.

Teachers are willing to incorporate technology into their classroom, especially if it can be accomplished seamlessly and in support of the overall lesson.

Interest in a topic can be gradually built through high interest touchstones.

As of this writing, teachers have yet to teach the unit, but students are already doing informal research on their questions. This indicates that once excited about a topic, early adolescents want to continue their learning. They are eager to add their input to the learning process, as evidenced by the 500 questions. If they seek to answer their own questions they are that much more motivated to research.

This ambitious project researches teaching philosophy and approach, examines how we believe students learn best, and shows the scope of what can be taught in a technology rich environment. It emphasizes the need to imagine and act on the possibilities teachers have if they dare to develop and dream in a technology enabled environment.

THE ETHICAL, CULTURAL AND SOCIETAL ISSUES OF TECHNOLOGY IMPLEMENTATION: THE ROLE OF THE SOCIAL STUDIES

Michael J. Berson, Ph.D.
Department of Secondary Education
University of South Florida
U.S.A.
berson@tempest.coedu.usf.edu

Abstract: This paper describes the integration of social, ethical, legal and human issues surrounding technology into social studies instruction. The cornerstone of this work is the promotion of participatory citizenship by evolving a culture of caring online. The emphasis of this work is on the dissemination of constructive solutions and a plan of action for the social studies, which fosters protective and productive online learning experiences for children and youth.

The Internet provides an extraordinary tool for enriching teaching and learning in the social studies; yet, safe and productive participation in cyberspace necessitates the ability to make informed decisions and apply online critical thinking skills. Internet safety encompasses those initiatives which mediate the online experiences that are disadvantageous to a child's physical, cognitive, and socio-emotional functioning. The recognition of threats to children in cyberspace is an important first step in developing constructive solutions and a plan of action which fosters protective and productive learning experiences. Through the social studies, the opportunity to foster the social and emotional skills of young people in cyberspace can be integrated into civic education with an exploration of the ethical, cultural and societal issues related to technology implementation. Social studies citizenship concepts are integrally linked to the ISTE National Education Technology Standards for Teachers and Students which promote cybersafety. This paper will describe an overview of a project to engage social studies educators and students in an exploration of critical social issues and public problems in cyberspace.

Pedagogical and Research Aims of Project

The Internet serves as a powerful medium for education, entertainment, information retrieval, and communication; however, cyberspace also may transform the nature of social interactions among youth. Whether these changes are beneficial or problematic may depend on the influence of parents, teachers, and peers whose guidance may assist students in making informed decisions and allow them to demonstrate an ability to apply online critical thinking skills and productive social participation. Issues of accountability, responsibility, tolerance, and respect--topics which are often addressed in the social studies curriculum--are critical to counter exposure to hate, violence, misinformation, consumer exploitation, and sexual predators in cyberspace.

In the social studies, exploration of the ethical, cultural and societal issues related to technology implementation is an extension of participatory citizenship with a focus on engaging educators and students in a dialogue about emerging social implications of technology. Thematic strands in the social studies which address participatory citizenship include: Power, Authority and Governance; Global Connections; and Civic Ideals and Practices. As teachers become interested in developing curriculum and experiences for their students, educators often recognize that they need to broaden their own knowledge and understanding as well. Social Studies teachers can bring these perspectives into the classroom by accessing online materials and promoting cyber-interactions, which can be useful resources for making connections within the classroom and fostering informed and active participation in the global community.

Identifying linkages between civic action in the social studies and national technology standards provides a basis for emphasizing Internet safety in the social studies classroom. ISTE has recognized that reliance on technological
resources and expansive communication networks must be accompanied by greater attention to and awareness of the repercussions to peoples and nations. They have developed National Educational Technology Standards (NETS) for teachers and students which promote responsible and safe use of technology resources.

Program Goals and Objectives

This initiative models active participation in a multidisciplinary, community-oriented intervention effort which engages educators and students in a dialogue about critical social issues and public problems. The cornerstone of this work is the creation of safety for vulnerable children and the advancement of advocacy efforts by parents, schools, and communities to evolve a culture of caring online. In the context of the social studies curriculum, students and educators can explore the social, ethical, legal and human issues surrounding technology.

This project focuses on disseminating constructive solutions and a plan of action for the social studies, which fosters protective and productive online learning experiences for children and youth. The overall goal is to disseminate information in the social studies to promote technology learning experiences which are protected and optimize students' skills in participatory citizenship and global connectivity via cyberspace. Moreover, this project explores challenges and potential solutions for mobilizing and coordinating the transfer of technology safety innovations across instructional settings.

Objectives

The outcomes of this research include a clarification of policies and practices that may contribute to safety for children online. The objectives of the project are:

- To discuss teachable moments in the social studies curriculum that foster safe practices online and facilitate the application of critical thinking skills for responsible decision making
- To clarify future directions in technology applications which necessitate awareness and education on cyberethics within social studies classrooms
- To inform preservice teachers about Internet safety issues and instructional applications which promote social studies citizenship skill development as a nontechnical approach to protecting children in cyberspace
- To promote critical and active users of digital information who consider the authority, bias, and currency of the available information
- To identify barriers to educators' effective integration of online safety practices

Collegiality in Project Development

The ability of schools and universities to overcome many pressing challenges, including the pressures of curriculum standards and intensified assessment requirements, ultimately rests with schools shedding their identity as isolated institutions. As we seek new perspectives and insights, it is critical that we anticipate the school of the 21st century in which interdisciplinary and interprofessional collaboration is an established mechanism for meeting the needs of students. This is a key component of the Internet safety action plan which has been developed. Ultimately, this exchange may create the potential for educators to access their untapped resources and discover the richness of their strengths for advancing powerful teaching and learning while preparing children and youth for safe online experiences.

This project conceptualizes schools and universities as prosocial support systems for children and families in which educators are active participants in multidisciplinary, community-oriented intervention efforts. The project builds on a University of South Florida (USF) community-wide initiative which focuses on Internet safety for children in the Tampa Bay area. The Advisory Committee for the USF project includes collaboration among an interdisciplinary group of professionals from K-12 schools, law enforcement, mental health agencies, public libraries, child protection agencies, child abuse organizations, Internet safety advocacy organizations, and university researchers in education, children's mental health, and trauma. This initiative also draws on evolving knowledge through collaboration with researchers throughout the nation and around the world who are similarly dedicated to fostering safe practices online in conjunction with teachers and caregivers.
Pedagogical Ethnotechnography: A Study of the impact of Information Technology as a pedagogical tool on the attitudes of Preservice Social Studies Middle School Teachers

Prince Hycy Bull, North Carolina State University, US

In February 2000, the United States Department of Education realizing that there was a critical need to integrate technology in teacher education programs and teaching, issued this challenge to all higher educational institutions to integrate technology as a pedagogical tool.

**Purpose of study**
- The purpose of this research is to study the impact of information technology as a pedagogical tool:
  - On the attitudes, self-efficacy and practices of preservice middle school social studies teachers toward technology information;
  - To analyze how effectively information technology is integrated and modeled in the course;
  - To identify factors that enhanced their practices in using information technology.

**Theoretical framework**
Two theoretical frameworks guide this study: social cognitive theory and constructivist learning theory. The social cognitive theory states that behavior, cognition and environment co-exist in a reciprocal relationship and thereby influence each other. Self-efficacy is a central theme of social cognitive theory. It states that a person's belief in performing a behavior or a task can lead to the successful completion of the task (Bandura, 1986).

The second theoretical framework guiding this research is constructivism. Constructivist theory states that students' experiences, collaboration and self-construction of knowledge is relevant to instruction. According to the National Council for Education Statistics (NCES, 2000), report on teachers' use of technology, for each classroom instructional activity, teachers who reported feeling well prepared or very well prepared were more likely than teachers who reported feeling unprepared to assign students to use various technologies.

**Teacher Education Programs and Information Technology**
According to Gunter, Gunter and Wiens (1998), instructors need to strive to light a fire and motivate preservice teachers to understand the influence educational technology can have in their lives and classrooms. In a 1998 survey of 416 Colleges of Education, the International Society for Technology in Education (ISTE, 1999) concluded that teacher-preparation programs were not giving preservice teachers the needed training to integrate technology into their teaching. Green (1999) reiterated the view that there was enough evidence to suggest that one of the greatest challenges for college and university faculty was integrating technology into their instruction.

**Social Studies and Information Technology**
The teaching of social studies is no exception to the limited use of information technology in instruction. It was this limited use of information technology in social studies that led Martorella (1997) to assert that, "technology is a sleeping giant in the social studies curriculum" (p.511). If technology is a "sleeping giant," then, who is going to wake the sleeping giant and how effective will the giant be upon waking? This researcher argues that part of the answer to the first question can be found in the curriculum of teacher education programs and the answer to the second half of the question depends on how effectively technology-trained preservice teachers integrate technology on becoming In-service teachers.

According to White (1999), the integration of technology in social studies provides opportunities to empower students and teachers and facilitates a constructivist approach. The traditional approach to social studies has been teacher centered with lecturing, reading texts, and taking tests. The transformative constructivist approach, as defined by the National Council for the Social Studies (1994), stressed the importance of technology integration at all levels of social studies education by focusing on teacher education programs as a starting point.

**Preservice Social Studies Teachers and Information Technology**
According to the research on effective social studies teaching, White (1999) stated that effective teaching and learning takes place when preservice social studies methods courses use the transformative approach. According to White, the transformative approach reflected the constructivist approach to teaching and learning, which included modeling and applying, reflecting, collaboration (Vannatta and Beyerbach, 2000), and developing an interactive community of learners (White, 1999; NCSS, 1994).

The goal of every teacher education program and every methods course in social studies is to integrate technology within the curriculum rather than teach it in isolation (Mason et al. 2001). According to Halpin (1999), the integration of technology across the teacher education curriculum provides preservice teachers with an explanatory and discovery oriented environment enhancing their abilities to use different computer applications for instructional purpose. Halpin states that the use of technology facilitates a problem-solving environment, a tenet of constructivist theory, with the goal to motivate students to seek information and solve problems. Keiper, Harwood and Larson (2000) state that integration of technology-enabled teaching and learning enhances social studies instruction in K-12 classrooms and makes lessons exciting for the teacher and the students. According to Partee (1996), the integration of electronic communication in teacher education programs not only provided an alternate environment but also extended the boundaries of the traditional classroom. Electronic communication through email (Hall, 1993) and Newsgroups (Lempert, 1995) provided alternate communication for classroom participation and peer support during student teaching.
Research Questions

Research questions and hypotheses will be used to understand the impact of technology information as a pedagogical tool on the attitudes, self-efficacy and practices of preservice middle school social studies teachers.

1. How effectively is technology integrated in the middle school social studies methods course?
   - What is the effect of using electronic forum as a pedagogical tool on the attitudes of preservice teachers towards information technology?
   - What is the effect of using synchronous e-chat as a pedagogical tool on the attitudes of preservice teachers towards information technology?
   - What is the effect of using asynchronous email/listserv as a pedagogical tool on the attitudes of preservice teachers towards information technology?
   - What is the effect of using the Internet as a pedagogical tool on the attitudes of preservice teachers towards information technology?

2. What are the pretest and posttest attitudes of preservice middle school social studies teachers toward technology information (Electronic mail, WWW, Multimedia, Teacher productivity and student productivity) in the social studies methods course?

Methodology

Participants

1. Participants are 10 middle school social studies preservice teachers currently enrolled in a social studies methods course at a large research based southeastern university. Participants were purposefully selected for this study. WebCT is used in this research as the web-based pedagogical medium guiding information technology integration in the course. WebCT is a web-based flexible, integrated pedagogical tool designed to foster inquiry, encourage discourse and inspire collaboration between instructor and students, and students and students.

Pedagogical ethnotechnography

This research employs the use of a “pedagogical ethnotechnography” method of research developed by this researcher. This researcher defines a “pedagogical ethnotechnography” method as a study of technology as a pedagogical tool as experienced by stakeholders—students, teachers, or school administrators—within an educational realm with an empirical analytic paradigm, within a defined boundary set by the empirical analytic paradigm. Pedagogical ethnotechnography utilizes both qualitative and quantitative methods.

Qualitative Analysis of Data

1. The qualitative data is collected through forum, email, and e-chat databases, classroom observations and group interviews. The qualitative data will be coded and analyzed using Glaser’s (1978) constant comparative methods. Although the constant comparative method is presented as a series of steps, the process when practically applied is non-linear, goes on all at once and the analysis keeps doubling back to more data collection and coding, (Brogdan and Bilken, 1998).

Quantitative Analysis of Data

The Independent variable is the use of information technology through WebCT to positively influence student’s attitude towards information technology as a pedagogical tool. The dependent variable is students’ attitude scores of Teachers’ attitudes Towards information-Technology Scale (TAT). A t-test of independent samples will be conducted for the five part index — Electronic mail, WWW, Multimedia, Teacher productivity and student productivity - means (pre and post test) at the alpha level equal to .05 to test for a significant attitude towards information technology as a pedagogical tool. According to Knezek and Christensen (1998), the internal consistency reliability estimates for the five scales on the TAT - Electronic mail, WWW, Multimedia, Teacher productivity and student productivity - range from .93 to .96.

Preliminary findings

Initial review of data show that there is some positive attitude by preservice teachers toward information technology as a pedagogical tool, especially in the teaching of middle school social studies:

- Overall, students feel that technology can enhance lessons but there are inherent dangers in using technology in instruction, such as supervision of students.
- Students also recognized that use of technology as a pedagogical tool is a collaborative effort in which teachers and students learn from each other.
- Students are also concerned about the effects of the “digital divide” on student’s learning outcome outside of the school.

The initial findings from the qualitative analysis seem to be leading to positive preservice teachers attitudes toward technology information as a pedagogical tool.

Abstract: This presentation will explore the use of genealogy software in developing social studies lessons to address NCSS and state content standards using students' natural curiosity about individuals, families, and ancestors. Genealogy software programs and lessons incorporating this type of software will be discussed. In a project as part of two graduate technology classes, inservice teachers collaborated to develop lessons based on national and state content standards designed around the use of a genealogy software program.

Introduction

Social studies and technology seem made for each other. Almost any software package or application can be integrated into the instruction of social studies concepts. Some authors have questioned the value of technology use in instruction in general and social studies instruction in particular (Shaver, 1999). Shaver (1999) points out that often the effects of the technology as the medium are confused with the effects of the content and the methodology of instruction. On the other hand, Schwartz and Beichner (1999) maintain that although the social studies classroom may, at first glance, appear to be the same as it was 20 years ago, technology has had a positive effect in many social studies classrooms. They also assert that the inclusion of computers in the teaching of social studies is mandated for several reasons: (a) computers are one of the most powerful influences in society today; (b) good teaching today looks like good teaching of the past, but today's technology makes good teaching more accessible; (c) today's social scientists rely heavily on computers, requiring that students be exposed to these methods used by social scientists; and (d) the Internet makes possible global connections and interactions that can have a profound effect on students.

The National Council of the Social Studies (NCSS) offers as one of its ten themes "Science, Technology, and Society" which addresses the concept that modern life would be impossible without technology (Roblyer & Edwards, 2000). To understand the effect of technology on society, one must understand and use the technology itself.

Social studies instruction provides opportunities to use a variety of software. Software which allows teachers to develop lessons that promote open-ended learning environments can be invaluable in the social studies classroom. Open-ended learning environments such as problem-based learning (Morrison, Lowther, & DeMeule, 1999) and mindtool learning activities (Jonassen, 2000) can be utilized in lesson development using software that is designed for non-education uses. Family Tree Maker, a genealogy package, is one such program.
Delving into family history has great allure for learners of all ages. Genealogy has been used successfully to understand cultural backgrounds (Simon & Simon, 1978), to develop skills in the use of library resources (Southwick, 1985), to promote family awareness and intergenerational communication (Allen, 1987), and as a motivational tool for middle grade students (Fielder, 1985). The marriage of genealogy and technology, through genealogy software and the Internet, appears to be the next logical step in the exploration of this beguiling topic.

Goodlad (1984) found that the range of instructional practices used by classroom teachers is narrow: “They lectured, monitored seatwork, and engaged in activities requiring only rote learning” (p. 298). Few instructional activities required or encouraged active learning, and the most often observed instructional group is the whole class (Goodlad, 1983). Factors that contribute to this limited repertoire of teaching strategies, as suggested by Goodlad (1984), include the following reasons. First, society does not pressure schools to change these instructional practices, since they reflect the conventional wisdom about how classrooms should be conducted. Second, these are the ways in which teachers themselves were taught from their days in elementary school through college. Third, preservice teacher education programs are of insufficient depth to successfully counter the conventional wisdom about teaching and classroom learning.

Present teacher education programs are in a position to counter the conventional wisdom about teaching and classroom learning. By engaging preservice and inservice teachers in in-depth research and development of problem-based learning activities, teacher education programs are better able to impact the quality of instruction in K-12 classrooms. The activities discussed in this paper were designed to provide for teachers the kinds of learning experiences that will ultimately benefit their own students.

Genealogy Software

Genealogy software is abundantly available, ranging from simple database type programs that are available as freeware or shareware to complex multimedia programs costing over $100. Genealogy freeware is readily available as free downloads on the Internet while some of the more expensive commercial versions have downloadable trial copies. The software is available for the PC or the Macintosh platforms with several outstanding programs available for both. Lists of genealogy freeware can be found at http://www.gensearcher.com

The Internet supplies a plethora of websites that provide information and assistance in genealogical research. Many of the genealogy programs have websites that provide access to major genealogical resources such as war pension lists, U. S. Census records, and Social Security death index. Several outstanding genealogy packages include the basic genealogy software, CD-ROM databases of information, and Internet websites with access to genealogical resources.

Several websites (i.e., www.familychronicle.com/software.html) provide reviews of various genealogy packages; one site (www.mumford.ab.ca/reportcard/) provides a report card that compares15 of the packages on 12 items. The report card is based on scorecards of each of the items for each package. These reviews and comparisons assist the teacher in selecting the most appropriate genealogy software for lesson development.

Broderbund's Family Tree Maker was selected for use in the lesson development activities for several reasons (a) the level of experience required to use the features of the program is considered intermediate which would make the learning curve manageable, while providing access to a program with powerful features; (b) its excellent website (www.familytreemaker.com) provides powerful support for activity development; and (c) its multimedia capabilities allow the inclusion of photos and sound.

The Project

One way of understanding the uses of technology in today's society is to experience its impact in project-based learning. The use of genealogy software combines the use of a dedicated database program with the power of the Internet and the storage capabilities of CD-ROM. Two of the ten NCSS themes address the individual and individual development and identity. Genealogy software provides an excellent vehicle for developing some very important and powerful concepts about the individual.

Students in two graduate technology courses were taught the use of Broderbund's Family Tree Maker and then were required to develop lessons utilizing the software. Students worked collaboratively on these
lessons. These inservice teachers taught various grade levels from elementary to secondary; the content areas of the secondary teachers included all subjects. Therefore, the collaborative groups were encouraged to create interdisciplinary connections in the lessons they developed and to address all related content standards. Although the lessons included various subject areas, the preponderance of lessons dealt with social studies issues as the major focus of instruction.

Social Studies Content Standards

According to Parker and Jarolimek (1997), social studies content standards should serve as a framework for K-12 social studies program design, serve as a guide for curriculum decisions by providing performance expectations for all students, and provide examples to guide teachers in lesson development. Louisiana and many other states require that classroom teachers connect instructional objectives and activities to benchmarks that represent student performance expectations. The use of genealogy software in the K-12 setting lends itself naturally to the accomplishment of the following historical thinking benchmarks and foundation skills that were developed by the Louisiana Content Standards Task Force.

Louisiana History Content Standard

(www.doe.state.la.us/DOE/assessment/standards/SOCIAL.pdf)

Standard: Students develop a sense of historical time and historical perspective as they study the history of their community, state, nation, and world.

Historical Thinking Skills (K-4)

- Demonstrating an understanding of the concepts of time and chronology
- Recognizing that people in different times and places view the world differently
- Identifying and using primary and secondary historical sources to learn about the past

Historical Thinking Skills (5-8)

- Describing chronological relationships and patterns
- Demonstrating historical perspective through the political, social, and economic context in which an event or idea occurred
- Analyzing the impact that specific individuals, ideas, events, and decisions had on the course of history
- Analyzing historical data using primary and secondary sources
- Identifying issues and problems from the past and evaluating alternative courses of action
- Conducting research in efforts to answer historical questions

Historical Thinking Skills (9-12)

- Applying key concepts, such as chronology and conflict, to explain and analyze patterns of historical change and continuity
- Explaining and analyzing events, ideas, and issues within a historical context
- Interpreting and evaluating the historical evidence presented in primary and secondary sources
- Utilizing knowledge of facts and concepts drawn from history and methods of historical
- Inquiry to analyze historical and contemporary issues
- Conducting research in efforts to analyze historical questions and issues
- Analyzing cause-effect relationships

Louisiana Foundation Skills
The following foundation skills apply to all students at all grade levels in all disciplines.

- Communication
- Problem Solving
- Resource Access and Utilization
- Linking and Generating Knowledge
- Citizenship

The Lessons

All lessons were designed to incorporate the Louisiana History Standard and its accompanying benchmarks that focused on the Historical Thinking Skills for grades K-12 as described above. Included within the latter were benchmarks relating to the historical impact of specific individuals or events, analyses of primary and secondary sources, and research endeavors based on historical questions. Many of the lessons addressed additional social studies benchmarks related to geography and civics standards. Other subject area standards enhanced the lessons by providing interdisciplinary connections.

Lesson plan topics were grouped into three broad categories: family relationships and genetic traits, family histories of famous Americans, and family histories of participants in famous events. Some plans were designed with novice genealogists in mind and were based on family group records and pedigree charts. Other plans provided experiences for more advanced learners and incorporated timelines of important events and graphic organizers. All participants designed a rubric for evaluation. Technology performance indicators included the use of logical thinking programs, writing and graphic tools, and the use of digital cameras and web tools.

Learning activities were tied directly to the state standards and benchmarks. For example, a lesson based on the family history of President John F. Kennedy was developed. The state content standard was History: Time, Continuity, and Change. Students develop a sense of historical time and historical perspective as they study the history of their community, state, nation, and world. The benchmark was Describing chronological relationships and patterns, and the learning activity, using Family Tree Maker, provided opportunities for students to create a Kennedy Family Group Record and a Kennedy Pedigree Chart. A later activity based on the Group Record and Pedigree Chart included the creation of a timeline of Kennedy family events, using illustrations, magazine articles, or Internet photographs.

Conclusion

The instructional use of genealogy and technology can lead to a richer, deeper teaching and learning experience for those involved in social studies education. Teachers should use software like Family Tree Maker, a program not originally designed for educational purposes, to create problem-based learning experiences for K-12 students. This type of teaching can address some of the criticism of narrow, teacher driven instruction through the motivating nature of both the topic and the medium. In this way, someday the comment “teachers teach as they were taught” will have positive implications.

Using Web-Enhanced Problem-Based Learning in Teacher Education

Susan Gibson
Faculty of Education
Department of Elementary Education
University of Alberta
Canada
susan.e.gibson@ualberta.ca

Abstract: Integrating computer technologies into preservice teacher education programs is critical if future teachers are to become effective users of these technologies in their own teaching. However, preservice teachers need to be challenged to rethink traditional instruction when considering how best to use these technologies. One possibility for integrating computer technologies into teacher education courses in a non-traditional way is through a constructivist, problem-based learning approach. This paper is a report of one instructor's experiences with this approach through the use of a virtual field trip to an elementary school in a social studies curriculum and instruction course. Students were interviewed and surveyed about their course experiences with the virtual field trip. Findings indicated that students constructed a better understanding about the teaching of social studies as well as gaining more confidence and competence with the integration of computers into their teaching as a result of their course experiences.

Introduction

Most teachers graduate from teacher education institutions with limited knowledge of the ways technology can be used in their professional practice (Wetzel & Chisholm, 1996). Few preservice teachers have any instruction in actually using technology in the classroom (Vagle, 1995), and yet, being able to effectively apply technology is high on the list of what beginning teachers should know and be able to do in today’s classroom (Kortecamp & Croninger, 1995). Integrating technology in teacher education programs is a necessity in order that preservice teachers are able to see the importance of developing and using computer-based lessons in their own teaching (Wiburg, 1991). “Preservice teachers need to perceive computers as integral parts of the instructional strategies and professional activities of teachers and become committed to their use” (Woodrow, 1993, p. 373). However, merely exposing students to technology is not sufficient. They need computer experiences that help them to rethink traditional instruction rather than simply using computers as an add-on to that instruction (Barron & Goldman, 1994; Heterick, 1996).

One possibility for integrating computer technologies into teacher education courses in a non-traditional way is through a constructivist, problem-based learning approach. According to Cameron White (1995), "A constructivist process orientation to teacher education is essential if we are to encourage students to develop problem solving and critical thinking skills and to apply, analyze, synthesize and evaluate knowledge, skills and attitudes" (p. 290). Computers can be effective vehicles for introducing problems for student investigation because they "allow students to experience a shared context in which they engage in sustained thinking about complex problems and engage in interpretive learning experiences" (Barron & Goldman, 1994, p. 84). A key characteristic of problem-based learning is that the learning should be situated in the examination of authentic, real-life problems of relevance to the learner (Duffy & Cunningham, 1996). Using the computer in this way provides authentic examples and problems of education from real classrooms, thereby heightening students' appreciation of the realities of teaching practice (Downs & Rakestraw, 1997).
In this paper, I describe a constructivist, problem-based learning approach that I have developed for use in an undergraduate teacher education course. The course is delivered by means of a web enhanced, interactive, virtual field trip to a local elementary school.

Description of the Virtual Field Trip Experiences

Using WebCT, I designed a web-based virtual field trip to an elementary school as a learning tool for an undergraduate social studies curriculum and instruction course offered as part of a teacher education program at a large university. My goals for the course were both to expose my students to ideas for integrating technology into their teaching and to assist them in clarifying their roles and responsibilities as social studies teachers.

The virtual field trip is organized around five key problems about teaching social studies from actual classroom practice. These key problems are:

- Why is social studies taught in elementary schools?
- How do you choose content and plan for instruction in social studies?
- What resources are available to support your teaching of social studies?
- What approaches to social studies teaching would best help you to meet your goals? and,
- How do you assess children in order to enhance their learning in social studies?

My students use a variety of multimedia experiences provided through the virtual field trip to assist them in the investigation of these five problems. Through the virtual field trip, they are given the opportunity to look at each problem from a number of perspectives, including teachers, children, peers, the curriculum and social studies experts. Students can listen to interviews with teachers, children and other student teachers in which they talk about social studies; view videoclips of social studies classrooms "in action"; examine lesson plans, curriculum guides, samples of children's work and other school-related artifacts; hear from social studies experts across the country; and, interact online with each other and myself using the WebCT conferencing tool. As a way of authenticating the virtual field trip experiences, students can also take a virtual tour of the school building, listen to a welcome message from the principal, view samples of teachers' weekly timetables and examine the school handbook.

Two weeks of this 13-week course are spent examining each one of the five key problems specifically. Students have one face-to-face seminar and one class in the computer lab each week. During the lab sessions, students work independently selecting, collecting and synthesizing the information presented on the virtual field trip. After examining each problem using the virtual field trip, we share their experiences and discuss their ideas in small group and large group sessions during the weekly face-to-face seminar. At the end of the two-week period, students write a reflective synthesis paper in which they discuss their learning about the specific problem under investigation based on their web and seminar experiences. We then move to the next problem and repeat the pattern until we have completed all five of the problems.

A major assignment for the course offers interested students the opportunity to design their own learner-centred, computer-based project for a specific grade and social studies topic from the elementary school curriculum guide. A variety of formats are possible including: Hyperstudio multimedia projects, web quests, web activity pages, virtual field trips, and Internet treasure hunts, among others. Since the majority of my students have limited computer skills, they are encouraged to work in pairs or small groups to capitalize on each other's computer experience. A lab assistant offers further help and extra lab time is booked outside of class time to allow students to practice newly acquired skills. Weblinks to tool training sites are provided on the virtual field trip site as well for students to learn how to use the tools on their own. As a culminating activity, students share these computer projects in presentations to the class.

Student Feedback on the Virtual Field Trip

A research assistant was hired in the Fall of 2000 to administer an entering and exiting questionnaire to the class (n=22) and to interview self-selected students several times throughout the 13 weeks of the course in order to ascertain what students felt they were learning from the virtual field trip. Student feedback from the initial and summative questionnaires and the interviews suggested that my
course goals were achieved and that the web-based experiences were important to achieving those goals. Generally, students liked that the virtual field trip provided exposure to a novel, constructivist-based approach to teaching and learning. The problem-based approach set within a "real" school context gave students a meaningful, authentic and relevant learning experience. The multiple perspectives were appreciated as they helped students to gain insights about teaching and children as well as allowing them to pick up teaching, resource and organizational ideas. In this way, students were offered an opportunity to link the theories they were hearing about in their university courses to the statements made by the children, teachers and experts in the field.

As well, students liked the hands-on learning that the virtual field trip offered. Requiring them to be actively involved on a regular basis with the computer as a component of the course experience resulted in a general decrease in technology anxiety and an increase in their confidence with the computers. Students were also better able to envision how to apply and integrate technology in their teaching and were motivated to develop technology-based projects for use in their future classrooms.

Based on the findings, I feel that I have been able to assist my students in developing new models of teaching and learning using computer technologies. I feel confident that I am addressing the concern expressed in the research literature regarding preservice teachers not learning enough in their courses about how to integrate technology into the various subject areas (Rose & Winterfeldt, 1998; Vagle, 1995).

Concluding Remarks

Interactive multimedia based on problem-based learning principles may be one of the combinations that will contribute to the next wave of improvements in the proportion of future teachers learning with technology. This article has presented one such possibility for helping preservice teachers to "rethink" traditional instruction by immersing them in a constructivist, problem based learning environment with the assistance of computer technologies.

Social Studies and Technology: Teachers' Perceptions of Effective Integration

Tina Heafner
Department of Curriculum and Instruction
University of North Carolina at Greensboro
United States
tlheafne@uncg.edu

Abstract: Billions of dollars are being poured into technology with the hope that innovative use of technology will improve our schools. With the growing expenditures on technology in education, a pertinent issue arises: How is technology being used to enhance the curriculum? Effective uses of technology vary among disciplines. Thus this study focused on secondary social studies instruction. This study sought to examine secondary social studies teachers' perceptions of effective integration of technology.

Introduction

Schools are moving at different paces at integrating technology. Technological resources within schools can be placed on a continuum, with the opposing points being the technology-rich and the technology-poor. Where schools fall on this continuum depends on how they value technology (Maushak, 1999). Concern about the social consequences of technology have driven some to suggest de-emphasizing technology in education, while others have argued that effective instruction, particularly in social studies education, must include a range of computer technology skills (Martorella, 1997). Even within the technology-rich schools, there are varying degrees of integration of technology into the curriculum. Varying beliefs about the effectiveness of technology has contributed to the inconsistency in implementing technology.

Effective uses of technology vary among disciplines. Successfully integrating technology in social studies classrooms is a vital issue facing social studies educators (White, 2001), especially with the inconsistencies that exist in technology use. In many social studies classrooms, technology is viewed as an extra resource and is not integrated as an essential component of the curriculum. As Berson (1996) has noted, social studies educators have been reluctant to integrate computers into their curriculum and instruction. Limited research exists on the effective integration of technology in social studies classrooms (Mason, Berson, Diem, Hicks, Lee, & Dralle, 2000). Thus the question arises: What is the effective integration of technology in social studies classrooms?

Literature establishes parameters for effective integration as instruction that motivates, provides variety, promotes meaningful learning, and facilitates interactive learning (White, 1997). Effective integration of technology allows for students to take a more active role in their learning and allows them to connect with worlds and cultures that historically would have been impossible. White (2001) argues that effective utilization of technology not only empowers students, but it is a means for transforming the curriculum to one that facilitates the development of students who can think for themselves and participate as responsible citizens in an ever changing world. The effective integration of technology "redefines what classrooms are, how kids learn, and what constitutes a learning community" (Sullivan, 1994, p. 5). Mason et al. (2000) recognize the lack of empirical research in technology integration in the social studies. They also call for continued research to expand technology use within the social studies curriculum.

The Study

The purpose of this study was to examine how secondary social studies teachers in North Carolina define effective technology integration. Using a survey design, descriptive data was collected to identify teachers' beliefs about technology integration in secondary social studies classes. A multistage sampling procedure was used to identify the sample. The target population of the study is all secondary social studies teachers in North Carolina. The questionnaire was designed to identify the importance of existing beliefs about technology. The guiding research question for the study is: How do secondary social studies teachers define effective integration of technology in social studies?

Findings

Effective integration of technology in social studies classrooms is defined by the development of respondents' responses in a pilot study. Patterns that emerged identify teachers' perceptions of effective integration of technology. First, the effective integration of technology extends learning beyond what could be done without technology. Technology increases teachers' resources and options as they plan to help students gather, organize, manipulate, and think about new information. Technology provides resources that are relevant, current, and engaging. A teacher remarked, "Activities using technology should be designed that cannot be done the 'old-fashioned' way."

Effective integration of technology in social studies enhances the curriculum. Effective integration of technology enhances learning by offering access to resources that are not accessible in a traditional classroom setting. Teachers have access to useful and innovative teaching materials and valuable primary sources through the Internet. A teacher commented, "Technology should enhance the existing curriculum, not be an add-on." The ideas established in the NCSS: Social Studies Curriculum Guidelines state that social studies teaching should draw from a broad range of content sources and use varied learning resources and activities (NCSS
Many teachers identified the use of technology to supplement their instruction and instructional resources. A teacher stated, “The effective integration of technology utilizes a multitude of computer programs to supplement text and teacher instruction.”

Next, the effective integration of technology promotes communication among students, teachers, and the global community. One teacher described his/her classroom’s partnership with another classroom in Eastern Europe via email as a method for effective technology integration. Effective integration of technology offers students and teachers the opportunity to become interconnected with the local, national, and global communities. Email and discussion boards allow students and teachers to communicate with the students and teachers around the world. Many teachers reported the increased communication with their students due to the use of email.

The effective integration of technology changes the classroom environment. Instruction shifts from a teacher-directed approach to a more student-centered classroom. Technology as a tool does not change basic learning processes, but instead it transforms how these processes are developed. Teachers can more easily prepare lessons; consequently, their focus shifts to explaining information instead of conveying information. One teacher remarked, “I use technology every day to prepare for my classes. I believe it helps to have access to up-to-date information at the click of a button. I use Microsoft Word and Excel to create worksheets and charts for my students to complete, as well as the Internet to contact them about missing homework assignments. I also use PowerPoint presentations to make the information a little more exciting than simply having to take notes from the overhead, where there is little color or animation. Also, my students prefer to take notes from something that is legible (typing), rather than trying to decipher my handwriting.” Another teacher responded, “To effectively use technology, students should be actively engaged in data collection or manipulation, not just random surfing.”

Lastly, the effective integration of technology promotes skills, knowledge, and participation of students as good citizens in a democratic society, which are the goals of the National Council on the Social Studies (NCSS). One teacher commented, “Technology provides a variety of instructional strategies to take advantage of different learning styles. The frequency of use allows students to develop technological skills and enhance inductive learning.” Another teacher commented, “The effective integration of technology means that students will be able to use technology in all facets of instruction. For example, they can use the Internet to conduct research, Microsoft Word to type a research paper, use PowerPoint to create a presentation, include a spreadsheet or graph in the PowerPoint presentation.”

Conclusions

Social studies is often perceived as a boring subject. The common methodology for teaching this “boring subject” is the transmission of facts through direct instruction. This is reflective of a curriculum that was designed decades ago. White (2001) suggests that many social studies classrooms reflect little meaningful instruction. White (1997) asserts that effective integration of technology can provide opportunities to make social studies education empowering and transformative. To promote technology use in secondary social studies, teachers need to conceptualize what it means to effectively integrate technology.

John Lee, Georgia State University, US

Many social studies educators have argued that preparing students for the responsibility of the office of citizen, in terms of developing the knowledge, skills and dispositions necessary for informed deliberation, active decision making and civic participation, is in fact the perfect place to let students learn to critically explore their world through the use of such interactive technologies as the Internet. A key assumption of this proposed use of technology is that having access to up-to-date knowledge resources, archives, and experts via information technology can improve teaching and learning within the social studies.

However, in spite of its promise and potential, the literature suggests that very little development, and implementation of technology has taken place within social studies preservice and inservice classrooms. The danger of such a situation continuing, Fontana warns, may well be that, others who know nothing of the discipline will shape these important networking tools without the needs of the social studies in mind. If social studies educators fail to be at the forefront of technology, they risk having parents and policy makers conclude that the social studies are not relevant in the information age.

However as Means and Olsen note, efforts to introduce technology into schools as a whole have struggled because they were founded upon the "wrong model of teaching with technology." The problem they contend was that "product developers believed in their content knowledge, pedagogical techniques, and in the power of technology to transmit knowledge to students" instead of providing the types of technologies that support "students and teachers in obtaining, organizing, manipulating and displaying information." With this in mind, the question that must be addressed by social studies educators in the information age is how can we prepare social studies teachers to best implement current and emerging technologies within our classrooms? The process of answering such an important question, we believe, must begin with the development of a clearly defined theoretical foundation designed to inform our understanding of why and how the incorporation of technologies can move us toward the National Council for Social Studies' (NCSS) vision of powerful social studies teaching and learning. It is disconcerting that despite support for integrating technology; the application of technology within the realm of social studies is theoretically underdeveloped. Even the most recent research that has advocated the use of a constructivist theoretical perspective to undergird the use of technology in the social studies classroom has not fully developed a clear framework of principles that support the integration of technology into the social studies. The purpose of this paper is to provide such a practical constructivist framework of principles, along with specific examples of how the application of technology, and in particular the Internet, can be used as a developmental tool to facilitate inquiry, perspective taking, deliberation, and knowledge construction in the education of young citizens.

The paper will argue that if technology is to have a powerful impact on the teaching and learning of social studies then "the ways that we use technologies in schools should change, from their traditional roles of technology-as-teacher to technology-as-partner in the learning process." The key to achieving powerful teaching and learning in social studies, therefore, is not technology itself, but rather how technology is used as a tool to encourage the doing of social studies in the pursuit of citizenship. Such efforts must be grounded in theory; otherwise, the results will be little more than a collection of disparate individual efforts that do little to truly advance social studies programs toward the NCSS's vision of powerful teaching and learning.

The challenge in preparing social studies teachers to use technology must begin with identifying why and how technology can be used to facilitate the creation of meaningful and disciplined knowledge within each student, and not to serve as a substitute for knowledge creation or for traditional classroom "teacher talk." The theoretical foundation for the integration of technology into the social studies emphasizes that the proper role for technology in the social studies is that of "technology-as-partner." Grounding one's actions within and through such a theoretical framework, we contend, is a vital first, and much needed step in the process of developing and preparing social studies teachers who know why and
how to use technology to transform their classrooms into a model based on authentic student inquiry and experiences.

Engaging in scholarly dialogue: CITE Journal and the social studies

Abstract: This paper focuses on dynamics that are unique to electronic publishing. The content of this paper is drawn from the authors' experience editing the social studies section of Contemporary Issues in Technology and Teacher Education (CITE) Journal. In this paper, the authors' will discuss the unique characteristics of the electronic publishing milieu with special attention to how these characteristics are incorporated within the editorial philosophy of the social studies section of the CITE Journal.

Introduction

Contemporary Issues in Technology and Teacher Education (CITE) Journal is an electronic publication focusing on theory, current issues, and current practices relating to technology and education. The journal is divided into numerous sections including social studies. The social studies section of CITE Journal is endorsed by the National Council of Social Studies College and University Faculty Assembly. The journal includes sound, animated images, and simulation, as well as immediate dialog about articles concerning current theoretical issues. CITE Journal accepts submissions relating to current issues in social studies and technology education, conceptual or theoretical uses of technology in social studies as well as significant policy and practice issues. Readers of articles may also write critiques/commentaries and submit them for publication. These publications are treated as articles and refereed in the same way as all other articles.

As a scholarly publication CITE Journal reflects 3 unique electronic publishing dynamics. These dynamics include the interplay of unique characteristics relating to the journal’s electronic or multimodal nature, the iterative character of the scholarly debate that occurs in the journal, and the potential for a new type of critical reading of scholarly papers. This paper is focused on these distinct dynamics.

CITE Journal’s electronic or multimodal nature

Electronic publication opens the door to a wide variety of presentation techniques. Authors writing in electronic or multimodal mediums are no longer tied to linear narrative. In disciplines such as history and literature non-linear narrative is prompting a reconsideration of issues relating to the intent and authority of the reader and the author. Digital non-linear presentation provides students with a means to explore alternative representations of their findings. Non-linear hypertext narratives can be used to connect arguments to evidence and they give readers a greater deal of autonomy (Rosenzweig, 1999). Some radical thinkers see hypertext as freeing mechanism that may displace traditional narrative (Landow, 1995). Others suggest that hypertext is oversold and not substantially different than other forms of non-linear text.
What is beyond debate is the technical capacity of hypertext, which enables writers to construct connective meaning in ways that are not possible in traditional narrative (Dobrin, 1994). CITE Journal encourages non-linear narrative texts and facilitates the development of these texts.

Articles in electronic publications can incorporate a wide variety of media including still images, audio, and video. In addition, software specific simulations and demonstrations may be used to enhance the rhetorical value of a piece or to communicate a practical dimension that might otherwise be absent in a print journal. CITE Journal is providing social studies researchers opportunities to develop a wide range of alternative presentation formats.

An example of an alternative presentation can be found in a CITE Journal article on Geographic Information Systems by Alibrandi and Palmer-Moloney (2001). In this article, Alibrandi and Palmer-Moloney use links and images to engage the reader with a wide range of possible web-based experiences. Readers are encouraged to read (via links) the literature that informed the authors' findings. Readers are also able to experience a variety of GIS related web-based resources. As readers use these resources concurrent with reading the article, they can generate a type of authenticity that is very difficult in traditional print media.

Readers might also experience an author's actual research data or foundational work. Another article in CITE Journal by Sherman and Hicks (2001) invites readers to view virtual reality files from a course taught by the authors. The potential for engaging the work underlying an authors' published findings is a groundbreaking step in publishing. CITE Journal is dedicated to continuing to provide readers with access to the raw data used by researchers.

The common way to refer to the experiences resulting from reading multimodal online articles is to use the much overused term "interactive." The Journal of Interactive Media in Education defines interactive as referring "both to interaction through the media with other people (e.g. teacher-student, student-teacher, researcher-teacher), and to interaction with the materials embedded in the media (e.g. control of a simulation or educational game)" - (see the Journal of Interactive Media in Education at http://www-jime.open.ac.uk/). CITE Journal promotes interaction in both senses of the above definition. As previously described, readers are encouraged to experience various forms of media. In addition, readers are encouraged to interact with other scholars. The primary vehicle for this personal interaction is the commentary feature in the journal. This feature generates a form of scholarly debate that is almost impossible in traditional print media.

The iterative nature of the scholarly debate on CITE Journal

Scholarly discourse should be continuous, vibrant, and iterative. Often the nature of these debates is severely limited by the publishing environments in which debates takes place. Responses and rejoinders to published journal articles are important and often quite vibrant, but the restrictive characteristics of print journals sometimes limit the reader's ability to access the full debate. Often responses and rejoinders are published in latter editions and the reader may not have all of these pieces available. Electronically published journals can offer the reader the opportunity to easily immerse themselves within ongoing academic conversations. In addition, the dialogue can be presented in a dynamic fashion as additional responses are published.

One of the most important features of CITE Journal is the commentary. Editors and readers are invited to write commentaries for published and soon to be published works. These commentaries are organized on the CITE Journal web site in a thread. As new commentaries are written the thread reflects the changes.

There are numerous issues in social studies that may be relevant for such scholarly discourse. The question of how technology fits in with the democratic mission of social studies is a prime example of how discourse in a web-based environment might be enlivened. The active interplay of ideas is essential for a democratic society and CITE Journal encourages this type of active engagement. The Web allows for a level of flexibility that is better suited for the multiple voices that must be heard in order for the dialogue to be democratic. In addition, the focus of control over the discourse can shift from the authors and editors to the reader.
Critical reading and CITE Journal

Critical theorist claim that objectivity, truth, and other fixed and permanent means for analyzing text (and philosophically life in general) are flawed. An exhausting variety of theories have been proposed as corrections for the "flaws" of objectivity. Although CITE Journal is not a publication that actively explores critical theory, it does serve as an outlet for the expression of certain critical theories. In a broad sense, CITE Journal is critical because it is in hypertext and it is multimodal and the articles in the journal are given meaning when they are read. This form of "reading" hints at the "writerly" potential of web-based publishing. The term "writerly" is attributed to Roland Barthes who conceptualized of "writerly" text as a form of text that is situated in the present and is real only when experienced. The multiple meanings that emerge from reading experiences are in a sense exaggerated in hypertext by the presence of choices about how to proceed through a text. Readers can follow links within and outside the CITE Journal web site. They can access simulation, video, and audio, which may accompany the text. They might also take the text out of its presentation context (using a save or cut and paste technique) and redesign the text to better suit their needs.

Beyond the technological characteristics that allow for critical reading, CITE Journal editors actively seek topics that might generate critical analysis. In addition, readers are invited to participate in dialogue spinning off an original publication. Since there are no restrictions on publication quantity, multiple voices can be heard without the stifling influence of publication costs.

Conclusion

CITE Journal is focused on the proposition that scholarly publication in a web-based environment can encourage a type of interaction that is impossible in traditional print format. By connecting readers to resources outside the actual publication and encouraging other scholars to engage in electronic scholarly dialogue, CITE Journal is operating in a new landscape. This new landscape can serve to free readers from the constraints of linear text and can provide new media outlets for authors seeking to express their findings in contexts that reflect their research. In addition, CITE Journal is promoting new type of critical reading that places the reader at an advantage. Readers can access the author's research to confirm or disconfirm findings and to follow-up or expand upon the author's findings. Most importantly, a dynamic scholarly dialogue that is not possible is traditional print can be facilitated on the Web. By publishing in CITE Journal social studies scholars can expand on the existing paradigms of publishing and research and open new doors for future understandings and interpretations.

Use of digital historical resources in a large urban school system

John K. Lee

hicks@vt.edu

Abstract This paper will report on the results of comprehensive survey administered in a large urban/suburban school district in the southeastern United States. The findings presented in this paper will illuminate the extent to which teachers are using digital historical resources and the ways in which they are using them. This study involved a survey of 73 high school social studies teachers in a large southern urban/suburban school district. The survey instrument included four dimensions, a demographic section, a section surveying teachers' general belief about social studies and his or her use of non-web based primary historical sources, a section inquiring about teachers' comfort with technology, and a section on the specific uses of digital historical resources. The findings of this survey support the contention that digital history has the potential to alter the general study of history, but there are several obstacles to this change.

Introduction Throughout human history technological innovations have interacted with academics. The emergence of modern science in the 16th century was in part a consequence of the development of print technology and the newfound ability to publish and disseminate scientific findings. The rapid expansion of science led to the invention of new technologies, which in turn have made possible academic work in a variety of academic areas. Today it is Internet technology that is most dramatically affecting academia. The academic study of history with its reliance on information is particularly susceptible to change. With the advent of the Web, historians and students now have access to materials in places and at times that were previously unimaginable.

As teachers and students begin to use historical resources, social studies and history instruction will change. This article is a report on the results of a comprehensive survey administered in a large urban/suburban school district in the southeastern United States. The findings presented in this article will illuminate the extent to which teachers are using digital historical resources and the ways in which they are using them. Before presenting these findings three ideas related to the phenomena of digital history must be explored, 1) What is digital history? 2) How does digital historical research differ from traditional historical research? and 3) What are the pedagogical implications of digital history?

What is digital history?

Digital history is the study of the past using a variety of electronically reproduced primary source texts, images, and artifacts as well as the constructed historical narratives, accounts, or presentations that result from digital historical inquiry. Digital historical resources are typically maintained on the World Wide Web. The availability of the materials on the Web is the most important distinguishing characteristic of digital historical resources. By using online historical sources teachers and students can avoid the complexities of access that are associated with visiting a physical archive.

Beyond the enabling fact that digital historical resources are “available,” these materials also facilitate the construction of new types of scholarship and narratives. In the digital genre of history, students have the same access as historians. Interpretations compete on the same ground. As the numbers of students making interpretations increases and as students’ various interpretations begin to vie for attention and respect, students will begin to adapt to a view of past that is tentative and process oriented. These changes have enormous implications for social studies teachers. Teachers will no longer be able to present history prima facia. Instead, using digital historical resources students will negotiate the stories of the past through their own inquiry and investigation.
How do digital historical resources differ from primary source documents?

Despite the similarities, digital historical resources are different from non-digital materials in at least four ways: 1) digital historical sources are more accessible, 2) they are easier to manipulate, 3) they are searchable, and 4) the flexibility of the web allows for a dynamic organizational strategy. Digital historical resources are clearly more accessible than non-digital primary source documents and artifacts. The ease of publication on the Web has lowered economic barriers to creating historical archives. This economic reality has resulted in the production of numerous very high quality collections. Although a comprehensive list of digital historical collections is not yet available, one of the best lists can be found at http://www.historymatters.gmu.edu/. In addition to increased availability, the structural differences between digital historical and non-digital resources (easier to manipulate, searchable, and flexibly organized) represent a major improvement over “physical” resources. Teachers and students can search digital historical collections to find information using rational and teachable techniques. The Web allows for the organization of individual documents and collections in logical and easy to use formats. As is the case with narratives, students who are constructing digital collections can arranged collections in a non-linear fashion that might reflect some of the idiosyncratic characteristic of the documents.

The unique characteristics of the Web, particularly its hypertextuality, also encourage alternative narrative forms. The nonlinear shape of the Web can serve as a lever to encourage students to deal with the multiple sequences, voices, outcomes and implications of historical narrative (Ayers, 1999). As students write historical narratives in hypertext they will have the ability, through the construction of links, to exercise a greater sense of control over the narrative and particularly the structure of arguments within the narrative.

How has digital history affected college and k-12 history and social studies education?

The Web did not simply appear and change social studies overnight. In fact, to the contrary, the almost euphoric expectations that accompanied the introduction and development of Web were for the most part unmet. The pronouncements of a technology revolution that echoed through the decade of the 1990s and followed us into this new century were in hindsight shallow and rhetorical. In the discipline of history there is reason to believe that most teachers actual practice was relatively unaffected by the technological revolution of the 1990s. In a wide-ranging series of reports based on a national survey of over 4,000 teachers Becker (2000) found that fewer than 20% of social studies teachers use computer technology. In a study of 54 elementary pre-service social studies education students Sunal, Smith, Sunal, and Britt (1998) found a low likelihood that teachers could plan to use the Internet to facilitate an inquiry lesson.

The most active use of digital historical resources to date has been in colleges and universities. For examples of hypertext scholarship online see Hypertext Scholarship in American Studies http://ehmm.gmu.edu/aq/. Examples of students’ digital historical scholarship can be found at the Virginia Center for Digital History http://jefferson.village.virginia.edu/vshadow2/projects/projects.html. The use of digital historical resources in colleges may well be a consequence of the hands-on historical activity that is associated with college level history. The shear number of resources available online is certainly adequate for facilitating serious historical inquiry and research. Numerous college history professors are making use of the Virginia Center for Digital History’s Valley of the Shadow to facilitate their students’ primary document based historical research. Galgano (1999) reported on his use of the site in an undergraduate history methods course in which students analyzed newspaper articles, letters, and diaries and completed exercises on historical bias, document verification, and statistical analysis. Umbach at Cornell University has also used the collection to facilitate students’ analysis of documents and to construct of online hypertext narratives. See Umbach’s students’ work at http://instruct1.cit.cornell.edu/courses/hist100.06/. Using digital historical resources also offers historical methodological advantages over traditional historical resources. Kelly (2000) found that college history students engaged in a higher level of recursiveness (returning to the same document) when they used digital historical resources as opposed to print resources. The author also found that students were better able to relate documents and make connections when using digital historical resources.

The literature on the use of digital historical resources in k-12 social studies and history instruction is very limited. It focuses primarily on descriptive reports of classroom practice using history-related resources on the World Wide Web. Most of these reviews were very positive and almost utopian in orientation. Most often the authors claimed that the Internet offered “promise” or “potential” unmatched in educational history. Despite the lack of depth evidenced in these descriptive reports, some researchers made efforts to substantiate the pedagogical worthiness of digital historical resources. Wilson and Marsh (1995) reported that the use of the computers and, specifically, the Internet could better engage students and “stimulate an interest in the written word as students search for documents in remote libraries.” Rehmel (1998) described a teachers’ experience
with online historical inquiry that was plagued by poorly operating hardware and uninterested peers. Rehmel concluded that using technology does not excuse teachers from maintaining student interest and focus in inquiry. Warren found that student generated web-based primary source collections are an invaluable means of injecting authenticity into high school history classrooms.

Method

A four part 84 question survey was sent to 110 high school social studies teachers in a single school system in a southeastern state. 77 surveys were returned. Of these 73 completed surveys were included in the analysis (representing a 66% of the survey population). The survey instrument included several questions concerning the participants' background. Another set of questions related to participants' teaching style, including questions about participants' philosophy of teaching history and their use of primary sources. Additional questions focused on participants' comfort level using various types of technology such as email, word processors, spreadsheets, and multimedia. A final set of questions concerned participants' use of digital historical resources including the types of resources used, the frequency of use, and pedagogical reasons for use. In reporting the results, descriptive statistical analysis was used.

Results

Characteristics of the school system

At the time of this study, the school system had 10 high schools and over 65,000 K-12 students. It was the fourth largest system in the state. The social studies curriculum in the system included high courses in U.S. history, world history, economics, and civics/government. In addition, students could take elective courses in area historical studies (e.g. Russian history), psychology, sociology, or current issues. The 2000 United States Census showed that the county's population was roughly half white and half black, with the northern area of the county distinctly white and the central and southern areas of the county distinctly black. A substantial number of the blacks living in the county attended a different school system in a city within the county. Forty-eight percent of the county's K-12 students were white, 39% were black, 5% were Hispanic, and 5% were Asian. The school system, like the county, had very distinct racial lines. Four high schools in the southern half of the county had 77% of all the blacks students in the county and 89% of all the students in these four schools were black. Respondents indicated that just over half of the schools (53%) were predominantly white, while 28% were predominantly black and 19% multiracial. Twenty eight percent of the respondents indicated that they worked in urban schools. Half of the participants indicated that his or her school was varied in terms of socio-economic status.

Characteristics of the teachers

Answers on section 1 of the survey provided a profile of the teachers who completed the survey. Teachers from grades 9-12 teaching in all mainstream social studies content areas were represented in the survey. Most of the teachers surveyed taught more than one grade level and all 4 grades were well represented in sample (28% taught 9th, 38% taught 10th, 46% taught 11th, 35% taught 12th). There was a wide range of courses taught. Sixty-two of the 73 participants (86%) taught history (either United States or world) and 12 of those teachers taught both courses. The other commonly taught courses were civics/government (25) economics (18), and geography (10). Participants taught an average of 13 years. Forty-four participants (60%) had a master's degree and 7 (10%) had doctorates. Half the teachers were male and half female and there was a normally distribution of teachers in terms of age age.

Reasons for teaching history

The first question in part 2 of the survey asked teachers to indicate the importance of several statements concerning why his or her students learn history. Participants believed that learning about the connections between the past and the present was the most important reason for learning history, acquiring knowledge of basic facts was second most important and developing skills of historical inquiry was third. Making historical generalizations and understanding the place of America in world history were considered to be somewhat less important. Developing a sense of time was thought by the participants to be the least important reason for teaching history.

The uses of historical sources in social studies

Participants were asked the extent to which they used primary sources in their class. All 73 respondents (100%) indicated that they used primary sources. When asked about the frequency of this use 30
respondents (42%) said they used primary sources more than once a week, 19 respondents (26%) said they used primary sources once a week, and 23 respondents (32%) said they used primary sources a few times a year. Participants were also asked if they used primary historical materials that were from specific resources. Almost all the teachers indicated that they used historical primary sources from the textbook (95%). A very large majority of teachers used primary historical sources from the Internet (86%). Smaller percentages of teachers used primary sources materials from resource packs (46%) and book based collections (65%). Teachers used primary source texts and images with equal frequency, but were less likely to use historical video and audio recordings.

In addition to being asked about the frequency of primary source material usages, participants were also asked about the reasons for using these materials. Participants’ responses indicated that providing students with a context for developing their historical thinking skills, providing students with a sense of the experiences and conditions of the period being studied, and providing students an understanding of the essential facts, concepts, and generalizations that underlie historical knowledge were most important. Providing students with an opportunity to question historical truths and engage in historical interpretation or revisionism were considered to be less important. Test preparation was by far the least important reason for using primary source materials.

Participants were also asked how important certain historical activities were for using primary source materials with their students. Using primary sources to learn about individuals and events was listed as most important. Detecting bias, distortion, and propaganda was second most important. Skills that are normally associated with the work of historians such as determining the context and credibility or authenticity of the sources were less important for teachers.

Comfort with technology

Participants were asked about their comfort with using certain technologies. The responses suggested that teachers were not comfortable using all forms of technology. Respondents were very comfortable using word processors, email, and the web. They were much less comfortable teaching students how to use these technologies.

The uses of digital historical resources in social studies

When asked, “have you ever accessed historical primary sources from the Internet for use in your classroom,” 65 out of 73 (89%) of the respondents said yes. The use of digital historical resources was limited by participants’ inability to find time to conduct searches on the Web and participants lack of access. Teachers most often made copies of the materials from the Web and brought them into class. Far fewer actually used computers in the classroom. When asked what needed to change in their school or classroom in order to increase the likelihood that they would use primary sources from the Web, teachers suggested the most important change would be to increase the number of computers. The second most important change would be to have more time in the curriculum to study historical documents. Following these two were fewer standards, training on using primary sources from the Internet, and training on historical methods for using primary sources.

On the last section of the survey participants were asked to agree or disagree to a series of questions about using web-based or digital historical resources. Participants strongly agreed that the Web provides access to previously unattainable resources. Participants also agreed that the Web was a valuable tool for comparing sources from the same period. To a lesser degree they believed that Web access has changed the way they teach. Participants disagreed with the statement that using primary sources on the Web makes no difference in how they teach. They agree with the idea that online primary historical sources give students a richer sense of historical experiences and conditions. Finally, participants tended to agree with the notion that teaching with web-based historical materials was different that teaching with traditional historical materials.

Conclusion

The findings in this study support the anecdotal evidence that suggests digital historical resources are being used in high school social studies classes. Eighty nine percent of respondents in this survey indicated that they used digital historical resources. Although there were limits on this use (time and computer access were the most important limits), the teachers in this survey seemed to recognize that digital historical resources were unique and valuable. The availability of previously unavailable resources was considered to be the most important attribute of the Web. This finding suggested that development of digital historical resource should be a high priority. Participants thought that using digital historical sources was (or would) change the way they
taught. This finding suggested that digital historical resources possess some unique characteristics. Additional research should be conduct to uncover the differences between digital and non-digital resources.

Participants' general preference for having students make connections between the past and the present was an indication that teachers were interested developing real world functionality in the classrooms. Participants were willing to use web-based historical materials to help their students make these connections. Given the participants' responses concerning the importance of using primary source materials (both digital and non-digital), one could expect these materials to occupy a central position in the classroom. To some degree this was true, but a majority of the teachers were still reluctant to use primary historical sources more than one time a week. This was most likely a product of participants' belief that using primary historical resources does not help in test preparation. In a pedagogical atmosphere that rewards students' who posses “test-ready” factual understanding, teachers' unwillingness to regularly use primary source materials to conduct authentic historical inquiry is not surprising. Until the current practice of testing low-level historical knowledge is abandoned primary source materials will not be used frequently enough to meet the goal of helping students make connections between the past and present.

Participants were specifically asked about their use of digital historical sources. The literature suggested that there was a distinction in usage between digital and non-digital resources. Participants confirmed this finding when they indicated that their teaching style changed when using digital historical resources. They also recognized that certain conditions (including more time and resources) must change before effective use of digital materials can be achieved. This finding suggested that teachers must be provided more time to prepare their pedagogical knowledge of digital historical resources and that more computers should be placed at teachers and students disposal.

Abstract: This paper explores the dynamic changes that occurred in teaching and learning when ED 478: Issues in Alaska Native Education, a traditional content course, was redesigned to become a technology-rich environment with support from a PT3 grant. The impact of technology was addressed from the point of view of the instructors and the students. Findings indicated that technology positively impacts the quality of student writing and creates an atmosphere where higher level discussion can occur in class. Many challenges still exist. Recommendations for the future included working with instructors to provide additional knowledge; allotting adequate lead time to review and revise course; collaborating with others in PTEP program on course sequence, scheduling, and continuity.

Introduction

The University of Alaska Anchorage School of Education along with partner school districts and businesses have participated in a Partnership for Teacher Enhancement grant during the last three years, working to redesign the teacher education program. A one-year, post graduate, intensive, internship model, Post Baccalaureate Teacher Education Program (PTEP) was developed. Our PT3 grant actively supported the integration of technology throughout the PTEP, including the development of an Essential Technology Skills Assessment (ETSA) and the redesign of ED 478 to be a technology rich course.

The PTEP was designed as a technology integrated program with no stand-alone technology class. Prior to the first cohort, the UAA PT3 grant supported the development of an Essential Technology Skills Assessment (ETSA) to assess student technology knowledge and skills and to ensure students had basic skills needed to be successful in technology rich classes. The ETSA was based on the ISTE National Educational Technology Standards (NETS) for Teachers.

Completion of courses in Alaska Studies and multicultural education/cross cultural communication are required for initial certification in Alaska. ED 478: Issues in Alaska Native Education meets the requirement for Alaska Studies. The course was delivered to the first cohort in a traditional fashion and sandwiched into an already full course of studies. Technology infusion into the program was not totally successful during the first year. Changes were made to the program structure, course sequence, and to how technology was infused.

ED 478: Issues in Alaska Native Education was moved to the summer session to focus on cultural issues from the beginning of the program and was to be redesigned to become a technology rich class. It became the initial course for the year-long cohort group. The course provided historical context for issues teachers in Alaska will face, as well as, a model for use of powerful and relevant technological tools. It was team taught by Paul Ongtooguk, a content specialist, and Ann McCoy, a technology specialist.

The instructors' backgrounds complimented the redesign of this course. Paul Ongtooguk is a senior research associate at the Institute of Social and Economic Research at the University of Alaska Anchorage. He is a project director for the Native Studies Curriculum Development. He taught high school
history and social studies in rural Alaska and currently teaches ED 478. Ann McCoy is an assistant professor in the Elementary Education Program and director of the Alaska PT3 grant. She came to Alaska to teach elementary school in rural Alaska. She has developed and taught education technology courses, foundation, and methods courses at the university level. Pablo Cantu, technology coordinator for the Yupiit School District, teaches in Chevak, Alaska and provided technology assistance during the course.

Ongtooguk and McCoy met several times to prepare for changes to the class. The meetings were not structured nor were the instructors compensated for course redesign. They discussed alternatives and changes to course assignments to integrate technology. The ETSA provided the basis for the technology skills. The instructors were not aware of the impact that would occur when the two courses were merged.

Students (n=28) in the second cohort began the program in June, 2001 in ED 478: Issues in Alaska Native Education. The redesigned, technology rich course was team taught by a content specialist and a technology specialist with assistance from a rural educator. ED 478 required students to use a website to access readings about traditional Alaska Native education and other topics that affect Alaska Natives. Students read and responded to the readings using Blackboard, an online course management software. Students developed collaborative projects that utilized a variety of technology skills. Content structure included at least nine readings and responses, video, web research, guest speakers and class discussion.

Technological skills emphasized in ED 478 included: pre-assessment of technology skills, Internet tools; search strategies, site evaluation, information literacy; simple web page and bookmarks; basic word processing; simple spreadsheets and graphs; using databases; graphics, movie basics; and computer operations and troubleshooting. Additional skills were added to the second summer session class.

Students had limited access to technology during the first two weeks of the class. Access to the computer lab was limited because it was being used by another class in the afternoon. Access to technology became more available at the beginning of the third week of class. As part of the Alaska PT3 grant, iBook computers were distributed to all students for their use during the year. Technology support was provided in the School of Education computer lab by lab aides, the rural educator, and the technology instructor.

It was a challenge to integrate two very different classes in an unfriendly scheduling format. Class met four days a week for three weeks (12 sessions) in June from 9:00 AM to 12:30 PM. During the first week course content was featured and technology was limited to introduction to Blackboard, email, and Internet strategies. During the second week, technological skills were emphasized and content was given more limited time. Video was used to illustrate traditional skills and also introduced as a technology. The final week was content heavy with most technology support provided after class hours. When it became evident that students would be unable to complete the collaborative web site project, they were given an additional week to work on it.

Findings

In typical classes, the instructor and students spend class time checking to see what was learned from reading and discovering other perspectives. In-class time was a precious commodity in this compressed class. Blackboard allowed instructors and students to make much better use of class time. This was Ongtooguk’s initial experience using Blackboard to support instruction. Students learned about each other when they posted what they had learned from their reading on Blackboard and read postings by other students. Class time was spent on challenging each others perspectives and learning from those different perspectives. This took the discussion to a higher level. The instructor could ask probing questions like: “Is that important?” “How do you know?” The cooperation and collaboration that occurred in this class was a good model for prospective teachers. Our goal was to encourage them to not be solo teachers. Cooperation and collaboration is rarely modeled by instructors in the university but we did. The following posting from the Blackboard Discussion Board illustrates student communication.

Think Different Thread Posting to Blackboard by T: “The study of history sure does come from a lot of different angles. The old constructs like social Darwinism get blown out of the water for their racism and moral content and I wonder if there are other constructs to replace them with, ones that facilitate our understanding but without so much moral and cultural overlay. I am constantly being reminded to “think different” and that’s a good place to start. I want that to underlie how I go about my teaching career. I think a lot of what has been discussed in class is relevant well beyond the confines of AK Natives issues. It makes my desire to teach more keen and the responsibilities that come with it seem greater. Two things that I put together was the progression of ANCSA and the People of Kauwerak. After a Disaster, it was
Ekeuknick and his Power of Imagination that leads his people to adapt and survive. He “took pride in all that he was doing because he saw each man was necessary for the living of the whole” In the same way, the AFN used the power of their collective imagination after a heap of disasters to adapt and survive in the modern world. ANCSA is their legacy.”

Response to T from K: “It didn’t occur to me to see the parallels with Kauwerak. You are absolutely right. As we’ve seen throughout this class once again the culture of Native Alaskans teaches respect for the ways of the past while adapting to the changing world around them.”

All readings were posted online on the Alaskool web site (Ongtooguk, 2001). The level of class was much higher than if the readings had not been readily available. However, the development time for a comprehensive web site was enormous and included addressing issues of: securing copyright permission, time to post readings to web site, and other development matters. Many expenses associated with the development of a web site were funded for the Alaskool web site with a prior grant. This gave us a no-cost head start developing the course because the resources were already available.

The use of technology helped make the quality of student writing much stronger. Writing was not done only for instructor but as part of a shared experience. In many cases, written responses to reading more thoughtful than those from students in previous classes who responded only to the. Ongtooguk found when a student’s response surprised him, he could easily refer to earlier responses to gain perspective.

Students spent a lot of time in their responses on native/non-native issues in education. Non-native issues were not the same as native issues. These issues can be tricky to deal with and potentially explosive in the classroom. Students saw model of respect for different opinions and participated in working together in a constructive way. The modeling of discussion of important but difficult issues in classroom provides good lessons for potential teachers. The usual model is to teach to the boring by having students confined to safe topics. Our model allowed students to engage in tough issues in safe boundaries. Student reflections indirectly showed positive response to being challenged. The following threaded discussion shows how students dealt with sensitive issues.

Issues Thread Posting to Blackboard by S: “One of the things that shocked me most was realizing that the purpose of school was to make natives less native, Assimilation, and this is still how school works for the most part. Oh my goodness, what a horrible revelation. The entire purpose is cultural genocide. It still exists, we still teach it!!! It made me clearly see why to many school seems worthless. Why one would not want to attend. Now there is a goal, to attempt to change this. To no longer teach things we are not aware of. Along with this I really find one of the most important things I am learning is that content without context means nothing. That motivation is everything. To this same thread was the last few moments of class today, the classroom should be a good, safe place to disagree. How true, classrooms are where we should teach people how to disagree in a good way. It is not important to always win someone over, but to clarify your own position. Without knowing all sides of an issue how can we make anything but uninformed choices? I have a lot to think about.”

“Today, helped me understand the ANCSA paper, where and how things happened. Federal Indian Law and working within the established system is brilliant. The Native Land Claim is following the law! Why is this not out there in public knowledge? I understand the emotion behind the issue and the passion of all involved, but this must get out there, to all!”

Response to S from R: “Consider this though: To an educated Bostonian being Native meant that you were part of a culture which in the long course of human history had not managed to learn to write, do mathematics, discover the true nature of God, plant gardens and farms, build tall buildings, organize orchestras, build ships, travel around the world, invent the wheel, the plow, sails, smelting, glass, or paper. Native were superstitious and pagan, they lived in homes with dirt floors, they often starved to death. Wouldn't any caring Bostonian want to make a Native less Native, for his own good? And once that attitude was formed, when would it logically change? At what point would you expect our hypothetical Bostonian say, "They are far enough along, we should let them run their own lives?""

Response to S from C: “I, too, have a problem with assimilation. How can we have this huge melting pot without assimilating? And how can we maintain our wonderful diversity if we do? The more diverse we are, the more ideas, approaches, ways of thinking, and variability we have to adapt to changing environments. We need to keep all that we can. But today we are losing this diversity at an increasing rate. An article in the Daily News today stated that we are losing one language every 2 weeks! It is just too easy to accept the default (English) and not worry about our native tongues or cultures and just assimilate. I have a renewed interest now in relearning my first language!”
The class provided a demonstration of the promise of technology. Students learned of the usefulness of tools in content classes. Blackboard was used as an organizing tool. Students were able to log on to Blackboard and click a link to the Alaskool web site or the ETSA web site; links to additional web resources; an outline of class activities and readings with links. A powerful part of technology (Blackboard and email) was the ability to capture and record class interactions including tracking changes of ideas and development of issues. The course was much more documented than a traditional course.

The use of technology can be labor intensive. Ongtooguk went into class thinking he would respond to each student. The time needed to monitor and respond to discussion was very consuming. He never had time to walk away during the entire time, as opposed to a traditional class where once the in-class time is over, you are finished until the next class. There were 580 postings to the Blackboard Discussion area to 12 forums. Eight forums were used to post responses (n=459) to class readings. The remaining four forums were used for more general purposes. One was used to introduce students to Blackboard and to other members of the class. Others were available for general questions and for students to post resources they wanted to share. The final forum allowed students to post anonymously to provide suggestions for changes to the class. Table 1 illustrates the response patterns to the readings.

Blackboard allowed the instructor to spend more time than the three weeks indicated in the class schedule by responding to students either on Blackboard or with email. Students posted their responses to readings prior to the next class session. Many students posted at 1:00-2:00 AM or 6:00 AM prior to start of class at 9:00 AM. Ongtooguk found he had to read the last set of responses at 7:00 AM or as time went on 6:30 AM. Instructors could be overwhelmed by the amount of discourse on the discussion board.

The college wasn’t ready for technology. The logistical problems for use of technology were enormous. Many students did not have access to technology and when they finally did, many were not familiar with the laptops. The challenges of technology are illustrated in the following posting.

Overwhelmed? Thread Posting to Blackboard by E: “I can relate. I could barely understand what the assignment was today, let alone imagine how my contribution to our group site will have quality and content. Being unable to do homework outside of computer lab hours is also a major handicap for me and a handful of other students. I don't understand some of this tech language and the quick explanations in more tech language aren't always helpful. At one point today I was so far off of where the group was I just kind of glazed over and didn't even try to ask for help. Most Alaska native kids have probably spent a significant portion of their education feeling like I did today, only far more so. This may be just as important a lesson for me as how to make a web site.”

Response to E from J: “Hear Hear. I’m with ya.”

Response to E from instructor: “The sense of being lost - significant point of shared experience with many students. I am glad you brought this up as something important to recall as a teacher.”
Conclusions and Recommendations

Students were given the opportunity to provide suggestions and recommendations for changes to the class. They offered many of the same ideas that the instructors had identified.

Review Thread (anonymous) Posting to Blackboard by A1: “I wanted to take a moment to say a few words about this class. I enjoyed it tremendously. It was thought provoking and mind blowing to some core issues I struggle with. I loved that Blackboard gave us such a wonderful opportunity to see what everyone was thinking about the articles and issues. I think it is a powerful tool to use in any class.”

“My biggest concern and problem throughout the course has been the computer issue. I was one of the few who did not own a computer. I feel I was at a huge disadvantage, I repeat huge disadvantage, as all the readings and all the responses were via computer. I loved the computer part, but for me not having one meant reading and responding to articles and to other students was very difficult. To those who have computers, this may not seem a huge deal, but imagine taking away your car and then asking you to commute [30 miles] everyday, it would be more than inconvenient. I was told I would be given a computer for the year, so didn’t purchase one, next time computers should be handed out in the beginning.”

“That said, again I love the technology aspect of the class. All the amazing tools we are learning to use are going to enhance our teaching so much. I am thrilled to be learning it! And can’t wait to set up my own classroom web page!”

“Finally, please make the class longer next year. There were many issues and topics I wanted to turn into discussions but with the shortness of time I always hesitated to bring them up. I have learned a lot and learned there is still so much to learn...”

Response to A1 from A2: “I think that the tech portion of this class should start the week before our content classes start, meeting at least three times, for maybe an hour an one half per class. ... We should be up to speed before we ever get into class. We have enough to do once we start. I understand that the previous class may still need their computers, but we could certainly use the lab to get started. Then the tech class should be a separate class that runs before or after Paul’s class for an hour. ...”

“Technology had a positive impact on teaching and learning. It was evident the university needed to address access to technology issues. Because this is the beginning course of a year long cohort program, we would like to work collaboratively with others in the PTEP program to: continue the dialogue with students later in the year; make recommendations for the next cohort; and look at where the other parts of technology fit into the program. Students and instructors all felt that three weeks did not provide adequate time to adequately address the content and technology. A recommendation emerged that students learn some technology skills early before beginning the content. Perhaps some of the technology skills could be moved to the foundations and methods classes.”

Before we teach the class again, we need more lead time to reconstruct the class. Instructors should be compensated to redesign the course. We learned that adding technology creates many unexpected changes that must be considered. Having the knowledge gained from the first session will help to develop a reading list ahead of time and review and possibly revise the ETSA model. Developing rules for engagement on the discussion board, including how and when instructors respond, should be a priority. At the conclusion of the class, provide time in class to summarize what we were trying to model.

Abstract: This paper describes the design and development of an interactive, educational web site for teaching and learning about American history. History teaching at both the high school and college levels persists in using traditional teaching methods, usually using teacher-directed approaches. Our goal is to develop new forms of history education that draw upon online resources and transform history teaching into a more student-centered, interactive experience.

Over the past eighteen months, the University of Houston College of Education and Department of History in collaboration with the Gilder Lehrman Institute of American History in New York and the Chicago Historical Society, has been developing an extensive array of historical resources for social studies and history teachers and students at the primary and secondary levels. Featured in the February 15, 2001 Wall Street Journal, the site is located at http://www.gliah.org. It contains over 1,500 active pages, including a comprehensive online U.S. history textbook; a searchable database containing the transcripts of over 600 primary source documents; glossaries, timelines, bibliographies, annotated hyperlinks, and essays on such topics as the treatment of American history in film and the history of aspects of private life.

The faculty participants—a historian who regularly teaches the large U.S. history survey class, a specialist in instructional technology; and a specialist in teacher education and social studies curriculum development—bring complementary talents to this project. These three faculty members work with graduate students and K-12 teachers to ensure that the materials designed will be pedagogically sound, meet state and national standards, and are motivating and interesting to students.

To help teachers meet state and national standards concerning content, pedagogy, and technology integration, the site contains classroom activities and handouts; lesson plans; and electronic lectures. It also serves as a portal to carefully evaluated historical resources on the World Wide Web including historical games, images, maps, music, newspaper articles, and speeches.

Our Website seeks to take advantage of the Web's communication, interactive, and search capabilities. An "ask the historian" feature, for example, allows students and teachers to pose questions to professional historians. Flash movies illustrate important themes in American history.
Instructional Design Model Used

The Reflective, Recursive, Design and Development model or the R2D2 model (Willis, 1995) contributed significantly to the process of design and development of this Web site. The R2D2 model is a non-linear instructional design model that promotes recursive, developmental planning, reflection, and collaboration among experts and participants. The R2D2 model is based on a facilitation model in which objectives emerge as the project is developed and are not “set in stone” during the design phase. A rather vague goal is accepted as the project begins, and the goals are negotiated and become clearer and more detailed as the actual development of the project occurs. There is also an increased emphasis on learning in meaningful, constructivist contexts.

A key component of the R2D2 model is that different parts of the development can occur simultaneously and can inform and change the design of another part. In addition, a collaborative, cross-functional team, rather than individuals working in isolation, drives the development of the project. Different project members often have interchangeable roles as opposed to the more traditional roles of instructional designer, programmer, and graphic artist, and contribute to emerging decisions, solutions and alternatives. These roles and activities often emerge as the project progresses and not from detailed flow charts and storyboards although there is a structure that guides the process. This structure gives this model its name – reflection and recursion.

Reflection provides opportunities for the development team and stakeholders to think about and reflect on both the decisions that have been made and also future decisions. The idea of reflective practice stresses the need to think about and revise ideas, plans, concepts and procedures based on “observation and analysis of what is happening in the practice environment” (Schon, 1991). As the project takes shape, feedback and other types of formative evaluation contribute significantly to the development process. This reflection by both the team members and other stakeholders is also a recursive process and occurs throughout the project. This model is an example of a participatory process since it provides the opportunity for all team members, stakeholders and prospective users to have a significant role in decision-making process.

This constructivist approach offers a significant improvement over more linear, sequential instructional design processes where individual team members may create various phases independently from one another. In addition, goals that are flexible and dynamic encourage opportunities for more interaction, creativity, and motivation among team members.

Many types of formative evaluation inform the recursive process throughout the project. Some assessments may be based on responses by content and design experts, while other feedback may be based on actual use by the target audience.

Initial Goals of the Project

In developing our site, we were guided by several goals:

Goal 1: To give students more meaningful, active learning opportunities through project-based activities using primary sources.

The Website gives students the opportunity to work with archival resources from the Gilder Lehrman Collection, on deposit in the Pierpont Morgan Library in New York, as well as selected materials from the Chicago Historical Society, items which were previously accessible only to scholars. It also contains extensive activities designed to promote active learning, including exploration guides that introduce students to working on particular historical topics; quizzes to test student knowledge; resources that link the past with current events and assignments involving maps, original documents, and statistical information.

Goal 2. To give University of Houston students the opportunity to participate in designing and developing online exhibitions and instructional materials for primary and secondary students and teachers.
Creating the site has been a collaborative process in which faculty members and students have had the opportunity to work closely together, combining their skills, knowledge, and energy. This process has been mutually beneficial. Students who had sophisticated computer skills have learned a great deal about history and research methods. Faculty members, in turn, have learned a great deal about the kinds of active learning strategies that work most effectively with today's students.

**Goal 3. To carefully assess how online history resources can be most effectively incorporated into K-12 classrooms.**

Many teachers do not know how to effectively incorporate Internet resources and primary source documents into their teaching. In social studies, technology is often used as an add-on, available when the "real work" is finished, or as a reward for good behavior. This project has sought to develop a database of activities that will allow instructors at the introductory college and secondary levels to incorporate these resources in their courses; to train prospective teachers to use technology effectively in their history classes; and to test these activities in an actual U.S. history survey class classroom.

**Focal Points of the Instructional Design Process**

The principles of the R2D2 instructional design model, reflection, recursion, and participation, take place over the entire design and development process and provide three focal points: Definition, Design and Development, and Dissemination.

For this project, the Definition focal point provided a basic understanding of the users of the web site, in this case teachers and their students in grades 5 through college level and anyone interested in American history. The goals of the site were discussed collaboratively and were vaguely defined. These goals, as described above, became clearer and more detailed as the development progressed.

The Design and Development focal points are ongoing and involve all team members and an increasing sample of potential users. The design began with a vague plan sketched out and prototypes of the Web pages were created. Menus and navigation elements were developed as participants used the materials and more content was created. Feedback was solicited from both end users and content experts as the Development focal point continued. The process is very flexible and is driven by feedback and usability testing.

The Dissemination focal point is ongoing as well. The Web site came online in May, 2001, and content continues to be added. At the beginning of 2002, there was an average of 2,500 users a day on the Web site.

**Unique Features of the Gilder Lehrman Institute of American History Web Site**

[Image of the Gilder Lehrman Institute of American History Web Site]

http://www.gliah.uh.edu
Dynamic Database

Our site, which complies with the latest standards for accessibility under the Americans with Disabilities Act, has a dynamic, database-driven design. Documents, texts, hyperlinks, and images have been placed in a searchable, relational database, and Web pages are generated dynamically using Cold Fusion. This approach eliminates the redundancy that plagues many web sites; allows the designers to change a single record and affect the entire web site; and gives all pages the same look and feel. More importantly, it allows users to request the information that they want, rather than simply presenting the material in a rigid, predigested format. The website's Verity search engine allows users to conduct a keyword search of all text.

CLASSROOM MATERIALS:

Handouts and fact sheets:
- Toward Revolution
- Impact of the Revolution

Maps:
- (1783) The United States of North America with the British and Spanish territories according to the treaty.
- More maps on the Revolutionary Era

Images:
- Spirit of '76. Copy of a painting by Archibald M. Willard, 1876.
- Molly Pitcher at the Battle of Monmouth. Copy of engraving by J.C. Armistage after Alonzo Chapel.

Quizzes: Test your knowledge by taking our Revolutionary War quizzes.
- Quiz 1
- Quiz 2

Interactive Materials

Materials have been designed to increase user interactivity with both primary source materials and with content experts. The site's Ask the HyperHistorian feature has been well received and provides users an opportunity to ask an historian a question about an event, a person, or an issue in American history.

Content Materials

The Web site contains an entire American history textbook and over 300 annotated primary source materials. The site also serves as a portal for access to the history profession's major institutions such as historical archives, journals, societies, and institutes. A comprehensive guide to historical museums on the World Wide Web as well as living history museums and presidential libraries is also provided. Other resources include annotated links to audio resources such as speeches and book discussions by historians. Links to visual resources such as maps and historical images are included as well.

Welcome to the HyperHistorian

What is a HyperHistorian?

If you have questions as you browse the materials on this Web site, you may visit a question to the HyperHistorian. The current HyperHistorian is Francis Baxter, John and Rebecca Moores Professor of History at the University of Houston. Think of the HyperHistorian as an expert at your fingertips who can assist you in finding the answers to just about any question you have related to materials found on this site.

You can also browse the Question Archive and look at selected questions and replies.

Ask the HyperHistorian a Question

Unlike the "This Day in History" features that one finds in daily newspapers, our Day by Day in History provides images of the past and links to valuable online resources. In addition, users can choose to display only certain categories of events such as abolition and the American revolution.
Flash Movies

A Time Machine created in Flash tests users' knowledge of historical events and dates.

Our Flash movies provide an audio and visual overview of key themes in American history.

Primary Source Materials

Move your mouse slowly over the text of the letter. The translation will appear in these two areas.

Among this site's distinctive features are online exhibits on African American life at the turn of the century illustrated with an early form of photography known as cyanotypes and a java-script program which automatically transcribes an 18th century letter.

Summary

Learning American history not only requires students to master content, but also to learn how to think four-dimensionally - that is to understand that our society's values and institutions are the product of an ongoing process of change. Students should not passively absorb historical materials but they need to learn how to conduct research, how to evaluate and interpret original sources, including visual and auditory sources, and to understand how seemingly disconnected events of the past interrelate. By providing teachers and students with comprehensive historical resources, including research guides, primary documents, and original interpretations, we seek to transform history into a much more active, engaged process of learning through doing. By participating in this project, students

Even more important to us as the Web site itself is the process by which this site has been created. Students have been actively engaged in both designing and developing this site, experimenting with new ways of presenting and displaying information, and devising ways to transform history learning into a more active process.

Making the Dismal Science Relevant with Projects and Handheld Computers

John Mergendoller, Buck Institute for Education, US
Jason Ravitz, Buck Institute for Education, US

One-half of the states require high school students to complete an economics course before graduating. For most students, this encounter with the dismal science is a frustrating one. Economics is a complex and difficult subject, and students often struggle to make sense of its abstract concepts and laws which seem irrelevant to their lives.

One way to make economic concepts more meaningful to students is to use it to analyze the world they live in. We have developed an example unit that focuses on the fundamental economic concept of "demand," and employs handheld computers to aid students as they interview their peers to determine the actual demand for certain foods and concert tickets. Once the interviews are over, the handhelds are used to graph the results and transfer the data to desktop computers for further calculations and analysis.

This session will describe the project and demonstrate software program developed for the handheld. Attendees that have handhelds will be "beamed" the program so they can try it out by collecting demand data from others in the session (or elsewhere). They will be free to use it in their classes when they return to their schools.

The Buck Institute for Education is working with teachers to integrate handheld computers into the classroom instructional process. The session will end with a discussion of the ways handhelds can be used by teachers and students and the distribution of relevant text resources and www links.
Integration of Technology in Elementary Social Studies Teacher Education: Adapting a Curricular Model

Jeff Passe, University of NC-Charlotte, US
Tracy Rock, University of NC-Charlotte, US

Tanner and Tanner (1995) present a model of Curricular Sources and Influences to explain the development of the K-12 school curriculum. A graphic representation of their model shows the school curriculum in the center of a circle. Around the circumference of the circle are political influences, social influences, economic influences, and technological influences. These four types of influences affect each other as they help determine the decisions made by school boards, administrators, teachers, parents, and students. Specific examples of the four influences are governmental agencies, publishers and testing companies, professional educational organizations, and colleges and universities.

The Tanner and Tanner model (1995) appears to effectively describe curriculum development at the K-12 level, but may also be useful in understanding curricular changes at the university level. This study focuses on a series of curricular changes in a single course, Elementary Social Studies Methods, over a ten-year period. While there were many adaptations and adjustments in the course, this study will only examine attempts to integrate technology education into the course. The Tanner and Tanner (1995) model will guide the discussion.

Significant Stages of Curricular Change in Technology

1. Get Ready! In the earliest stage, the professor was the instigator of the curricular change. He wanted to alert the preservice teachers of forthcoming developments in technology (e.g., greater accessibility of the Internet) that would influence their elementary social studies classrooms. The nature of the change was limited to discussion because neither the university nor the students had access to the technology.

2. Look at This! When the federal government began to provide grants to universities for technology, the teacher education program used the funds to create a technology classroom. With this innovation, the professor (on his own volition) began to demonstrate some of the social studies applications of advanced technology (e.g., software to create time-lines.) Because the students still did not have access to the technology at home or school, there was no application.

3. Get Your Feet Wet! As an incentive to promote its new technology goals, an additional phase of state funding was offered to teacher education programs. The faculty leaders in technology used the funding too create computer labs in the College of Education. Now it was possible for students to access the technology even if they did not have the necessary hardware at home. The professor decided to require students to conduct Internet searches for social studies resources and use email to share their findings.

4. The State Steps In! The State Department of Public Instruction, concerned about reports of slow integration of technology in K-12 programs, began to require each teacher education program to demonstrate how it meets the state technology goals. In response, the teacher education professors met to assign competencies to each course. The social studies methods course expanded its technology integration with additional assignments and instruction.

5. Take Your Work Home with You! The personal computer revolution finally reached the point when, because of dropping prices and growing popularity, nearly every preservice teacher owned or had easy access to a computer. The professor began to encourage on-line submission of assignments by offering test point bonuses as an incentive. Most students were drawn to the incentive and subsequently developed considerable technological comfort and skill.

6. Get Organized! The computer revolution turned into a financial windfall for many companies. Several successful individuals and corporations invested their profits into foundations to promote technology education. Through this outside funding, professional organizations hopped on the bandwagon to create new organizations, conferences, and journals. In the field of social studies education, a group of young faculty developed a project to expand technology integration in their field. The professor of the methods course became involved in this project, and received further stimulation and training in technology. These experiences were translated into new components of the methods course, such as GSI and listserves.
7. Here Comes the Test! Dissatisfaction with the progress of technology integration in K-12 programs led the state to develop a testing program to force students to meet the competencies. After a series of invalid and unreliable assessments, student anxiety reached its peak when they learned that failure on the state test would delay their teacher certification. The testing program was then replaced by a plan to have each university develop its own assessment. The faculty responded by creating a simple form for students to demonstrate the technology competencies. They were required to meet 18 of the 24 competencies to graduate. In response, students in the methods course eagerly sought the technology education that was offered by the professor.

8. Report Card Time! The Department of Public Instruction began to survey teacher education graduates concerning the quality of their preservice experiences. The results of these surveys, combined with various test results, were incorporated into a “report card” that would be shared with the public. The university did not do as well on the first few reports as it would have liked. Technology was the main weakness. Interview data indicated that many recent graduates did not understand the competencies or felt that they received inadequate instruction. Further analysis revealed that many students took shortcuts in meeting the competencies, or sought out part-time faculty to sign off on their forms without providing evidence. In response, various administrators pushed for a new technology course that would be required for all preservice teachers. Because the proposed course would be taught separately, and not be integrated with the rest of the program, several members of the elementary education faculty, many of whom were strong believers in curriculum integration, were resistant.

In order to forestall the creation of a stand-alone technology component, the professors who taught the curriculum course and the social studies methods course devised a plan to integrate all of the technology competencies into their courses. Their proposal attempted to reduce the students’ confusion, maintain control over assessment, and enhance the instruction in technology. Social studies methods became the primary course for technology integration.

Application of the Tanner and Tanner (1995) Model

The preceding saga fits the Curriculum Influences model, even though Tanner and Tanner (1995) designed it for explaining K-12 curricula. The curriculum of the social studies methods course appears to have been transformed by economic, political, social, and technological influences. The economic stimulus of state funding was an immediate influence on the use of technology in the course through the creation of technology classrooms and labs. After its initial economic impact, the political maneuvers of the State Department of Public Instruction, through its development of technology goals, testing programs, and report cards, became a major influence on the nature of the preservice curriculum. Social factors, such as the popularity of computers and the Internet, along with the university’s public relations concerns, also played a role in shaping the curriculum. Professional organizations also played a significant role in the expectations and activities of the course. Of course, the role of technological influences cannot be underemphasized.

Implications

Integrating technology into the social studies methods course was not simply a function of adapting the technology for student learning. Professors must be cognizant of the social, political, and economic influences that advance or retard the process.

While economic and technological changes were helpful in transforming the course to the professor’s goals, those influences may not continue to be positive. The downturn in the economy, particularly in the technology sector, may lead to a slowdown in student access to and interest in technology.

The political influences on education have been rapidly increasing over the past several decades. Recently, the power of the state has been expanding further into the domain of the university. Any curricular changes in teacher education must be planned with an eye toward the state’s expected role. This may be the most crucial aspect of technology integration. Curriculum developers may not be well versed in governmental matters, and may have to change the ways they prepare for reform.
Real™ History: Using Multimedia Software to Introduce Historic Events and Promote Constructivist Principles in Secondary Social Studies Classrooms

Beverly B. Ray, Ph. D.
Idaho State University

Abstract: Real Media Slideshow™ Basic software can be used to promote hands-on, peer-to-peer learning and collaboration in a variety of secondary social studies classroom settings. Teachers and secondary students can use the software to create powerful multimedia presentations that illustrate key instructional concepts and themes. This paper will outline the steps involved in researching, storyboarding, and constructing a presentation that illustrates an historic event in the Real Slideshow™ Basic multimedia format.

Introduction
Motivating students to learn about history can be a difficult task for many teachers. Real Networks™ Slideshow Basic is a dynamic freeware application that social studies teachers can use to motivate and inspire their students by allowing them to experiment with multimedia design in ways that are both creative and constructivist in nature. Creating animations in Real Slideshow™ Basic involves students in their own learning, even as the process creates a powerful learning environment for students. Animations such as those created in Slideshow™ Basic are "highly effective tool[s] for illustrating a concept" or historic events (Roblyer & Edwards, 2000). The research and design process promotes critical thinking, problem solving, and cooperative group interaction. Students are able to construct their own understanding of an event as they research, plan, and create the presentation.

Literature Review
Teachers who use multimedia programs, such as Real Slideshow™ Basic, recognize that students have different learning styles, that all students can learn, and that all students can have expertise. Multimedia is a "fluid" environment that requires the student to make decisions and evaluate the process continuously (Roblyer & Edward, 2000). This environment forces students to use higher order thinking skills (Marchionini, 1988). Students who may not find other learning activities motivating, may find working on multimedia projects engaging (McCarthy, 1989). Working together in small teams on Real Slideshow™ Basic presentations can also promote cooperative interaction, thus increasing learning, improving social skills, and promoting problem-solving behaviors (Cooper, et. al; Johnson & Johnson, 1989/1990; Slavin, 1980).

Planning the Project
Step One: Review Real Slideshow™ Basic Presentations
Before beginning the project students should review a variety of Real Slideshow™ Basic presentations (see Figure 1). In particular students should focus on the amount of scripting, the type of images, and the amount of audio contained in various Real Slideshow™ Basic presentations. Teachers can download or link to Real Networks™ Slideshow™ presentations at Real Networks Web site.

Step Two: Research the Topic
A major component of the process involves researching topics, locating resources, and analyzing resources to determine their appropriateness to this multimedia format. Using Internet sites such as the National Archives or the Library of Congress (see Figure 2), students should carefully select a few powerful images that relate to one key event or theme. Working with three to five carefully selected images and one audio file is recommended for beginners.
Step Three: Storyboarding the Project
Students can use sticky notes, storyboard sheets, or concept mapping software to assist them in storyboarding their entire presentation before they ever begin working in Real Slideshow™ Basic. Ideally, students should develop their presentation frame by frame. Determinations about the sequencing of images and the inclusion of text should be made at this point. Students might want to end the presentation with a final screen that displays one or two hyperlinks to sites that further illustrate the contents of the presentation.

Step Four: Working in Real Networks Slideshow™ Basic
Real Networks™ offers basic advanced tutorials online to assist users learning how to create Slideshow presentations (see Figure 1). Peer tutoring and the team aspect of group work will allow more technologically literate students to assist their peers in developing the presentations. When assigning students to groups for this project, teachers may want to assure that at least one team member has computer experience with various multimedia software. While Real Slideshow™ Basic is an easy to use program that even novices can use effectively, it is a good idea to have a basic set of directions available for students to refer to while working at the computer (see Figure 3).

Step Five: Publishing the Presentation
Once the graphics and audio files are inserted into Slideshow, the file should be saved to disk. The file can also be published to the Internet if viewing by a wider audience is desired. However, if copyright protected files are used, permissions should be obtained before publishing to the Web. Playing the file either from disk or online will require a media player, such as the free version available from Real Networks.

Step Six: Using Slideshow™ presentations in the classroom
The teacher should assist students in creating questions that lead to discovery. For each presentation, students should prepare a list of questions for the entire class that spiral from the basic to the complex (Teachers Curriculum Institute, 1998). The slideshow is the primary source around which student inquiry occurs.

Conclusions
Having students construct a multimedia presentation in Real Networks Slideshow™ Basic takes little more time than constructing a presentation in Microsoft PowerPoint™ or Hyperstudio™. But the benefits are just as great for students. Not only do students get experience in using multimedia software that is a popular standard on the Internet, but they also gain cognitive benefits from constructing their own knowledge of the historic events. This kind of project is more meaningful because it challenges students to research, plan, and create an original presentation. During the process, they exercise critical thinking skills while constructing their own understanding of historical events.
Creation of an interactive slideshow challenges students to conduct historical research, make choices about the quality of media files included in the presentation, and learn how to plan, design, construct, and publish a multimedia presentation. Creating a Real Slideshow™ Basic presentation also allows students to reflect on the project by discussing what went well, what needs to be improved or revised, and what else can be done with the Slideshow™ Basic software.

newmanj@mail.ecu.edu

Abstract: This is the story of how a slave born in 1838 is leading students and faculty at East Carolina University into the technologically-advanced 21st century. Allen Parker was a former slave from northeastern North Carolina who published a narrative of his life in 1895. Pursuing his story has led professors and graduate students in 2001 to integrate technology into their classes in History and Teacher Education as a natural part of the learning process. The Allen Parker Slave Narrative website is a doorway to his world, just as his narrative has been an opening to the world of 21st-century technology.

Introduction

As the Internet evolves, there is a growing realization that new technologies can help teachers move beyond traditional instructional strategies to more dynamic methods that reach a multitude of learning styles (Fraser, 1999; Clark & Cunningham, 1999). When approaching new technologies, teachers tend first to duplicate familiar, traditional forms of instruction. As they gain experience and their comfort level increases, they can move beyond traditional forms to use new technologies in creative ways (Fraser, 1999).

One effect of computer-enhanced instruction can be a revision of the traditional role of the teacher from authoritative expert to supportive guide. The teacher becomes a co-explorer with students (Kandies & Stern, 1999). In this student-centered learning environment, the student assumes more responsibility for constructing his or her own knowledge (Kandies & Stern, 1999). In addition, technology allows new forms of communication that change interaction patterns between students and teacher and encourage the development of a community of learners (Kandies & Stern, 1999). The possibility of communicating easily outside class meetings bridges the time lapse between in-class interaction which can extend, in some cases, up to a week. Such a transformation occurred with the Allen Parker project, which involved professors, teachers and students from two university courses in different disciplines.

This is the story of how a slave born in 1838 is leading students and faculty at East Carolina University into the technologically-advanced 21st century. Our project began with a traditional History course on slave narratives in American History. The class project was to research the accuracy and context of a narrative published in 1895 by Allen Parker, a former slave from northeastern North Carolina. Technology in the form of a website, a class listserv, email, digital cameras, and streaming video created a class synergy that transformed individual research efforts into a rich, collaborative historical discourse and allowed the class to move beyond expected results. Students in the History class published their research as an interactive, educational website that, in turn, enhanced learning and teaching of History for teacher education students seeking to teach social studies from multiple perspectives.
The next step in the Allen Parker project was to make the information available for teachers and students of all ages in Eastern North Carolina. A casual conversation between a student from the History class and a professor from teacher education generated the next phase of the project—collaboration between History and Social Studies students.

One of the goals of the advanced social studies class was that teacher education students use technology to transform their teaching. The professor modeled for them how classes can be student-centered and how they can require students to co-construct their knowledge through the use of technology. Students researched social studies information on the web and integrated that information into their teaching. Students were also encouraged to use historical information from the context of their communities in eastern North Carolina. They exposed their own students to the Parker narrative and used it to generate lesson plans that were placed on the web as a resource for other teachers.

Parker’s story served as a launching pad not just for learning historical information from new perspectives, but also for showing the professor and students how new technology can provide new ways of interacting and learning. The transformative process began at the university level with professors and students whose learning experience was altered by technology. Through teacher education classes, it extended to elementary students in classrooms in eastern North Carolina.

**Allen Parker**

Allen Parker was born on a plantation in Chowan County, North Carolina, in 1838. Like thousands of his African-American contemporaries from eastern North Carolina, Allen Parker escaped from slavery to Union-occupied territory. After serving in the Union Navy, he migrated to the Northeast eventually settling in Worcester, Massachusetts. There he spent the last decades of his life selling popcorn and homemade candy for a living and watching his four children die in their youth from diseases no longer a threat today. He later joined the Worcester chapter of the Grand Army of the Republic, a fraternal organization for Union veterans, and made an extended trip to London in 1905. His obituaries in 1906 describe Allen Parker as “one of the best known colored men in Massachusetts.” Although he never learned to read or write, in 1895 Parker published a short narrative of his life as a slave in Chowan County.

**Allen Parker Leads Historians to Technology**

Dr. David Cecelski, Distinguished Whichard Professor in the Humanities at East Carolina University during 2000-2001, discovered a rare copy of the Allen Parker narrative in a library in the Midwest. He designed a seminar course in which the students would focus on slave narratives from Eastern North Carolina, and would do a joint research project on the Allen Parker narrative to verify its details and place it within a historical context. Joyce Joines Newman, Instructional Technology Consultant for the College of Arts and Science at East Carolina University, was a non-traditional student in the class. She provided technical support to faculty and students as the Allen Parker project led them to incorporate more complex technology into their instructional strategies.

From the beginning, students themselves introduced technology into the History course through the establishment of a class listserv by one student and the creation of a web site for the Allen Parker slave narrative by another. This was done with consent of Dr. Cecelski who lacked technological experience himself but was receptive to the idea because of his student-centered teaching style. In the class were several non-traditional students who were extremely self-motivated. These factors allowed technology to become an integral part of the research and documentation process itself.

Technology altered class dynamics by facilitating a sense of unity and shared purpose among class members whose project was to verify the factual information in the Parker narrative and gain insight into its social and historical context. To do that, individual students accepted responsibility for researching different aspects of the Allen Parker story, using traditional research methods including spending hours alone reading dusty archived materials. Since each student was researching a unique but important area, each had to be successful and productive for the research to be complete. Each person had strengths within
the project, and their weaknesses were ameliorated by the strengths of others. Class members also acted as peer reviewers. When there was a conflict of information or a difference of opinion about accuracy or interpretation, class discussion and consensus resolved the issue.

Communication through the listserv reinforced the learner-centered, proactive format of the course. Messages were channeled through the campus email system, which let students communicate their findings as they occurred, and allowed them to receive immediate compliments, encouragement and feedback, generating a class synergy that kept them moving forward in their project. This maintained the emotional momentum of the class between once-a-week meetings, defined a sense of purpose among class members, and created a stronger sense of group identity than occurs in many courses. Class field trips to Chowan County and the Peter Parker Plantation also strengthened group bonds and provided an opportunity for the use of additional technological tools. Members of the class made digital videotapes and still photographs which they posted on the website as streaming video and linked images.

At the end of the semester, as the class finished their research, Dr. Cecelski edited their annotations and they were posted on the Allen Parker web site in pop-up windows accessed through hyperlinks. These annotations provide supporting evidence, explanations and references for the narrative. It helped that Allen Parker turned out to be a remarkable subject for research and that serendipity frequented the project. Not only did the students locate the plantation where he was born, but it is still a working farm owned by descendants of the family who received the original grant from Lord Granville in the early 1700s. When they looked for Parker's pension records in the National Archives, they found not just a few pages of information. Instead, questions about his Naval service and the legality of his marriage had generated 177 pages, including depositions from family, neighbors, and doctors that provide an unexpected physical and personal portrait of Parker.

It was an exciting time as the students watched their bare bones research assume a fleshed-out form. The web site was developed as an educational resource providing social and historical context for the narrative--timelines, maps, images and original documents. There are links to websites with related images and information. Content derived from course lectures and readings, primary and secondary sources in libraries and archives, oral interviews, web research, interlibrary loan, field trips, contacts with community members, email, telephone conversations, and collaboration with faculty at ECU and other universities.

Perhaps the most interesting aspect of the Parker project in terms of using technology is that the technology reinforced the format of the class, which was a collaborative effort requiring the cooperation and active participation of each member of the group. While many courses that involve research require each student to work independently and competitively, this project relied on the sharing of information and the subordination of personal ego to the group's goals. The fact that individual contributions are not identified on the web site underlines the interdependence and collaboration among all class members. The web site presented research results as a complete and seamless visual product, which enhanced the sense of accomplishment by the group as a whole.

Allan Parker Links Teachers With History and Technology

Allen Parker's influence on students and faculty continued through collaboration with Dr. Joy Stapleton of the Elementary and Middle Grades Education Program and graduate students in her course on Teaching Social Studies in the Elementary School. Members of the class included full-time graduate students and teachers from elementary schools in the surrounding area. As part of a midterm exam each student developed curriculum-compliant educational activities based on information in the Allen Parker slave narrative. Posted on the Parker web site, each project includes an overview, standards, materials, children's literature, activities and references, making the site a collaborative, interdisciplinary effort and a resource for public school teachers throughout the state.

The course was designed to challenge teachers to become familiar with the supplemental social studies information that is available on the web and to encourage them to integrate the information and the use of technology into their lesson plans. Most of the students were aware of lesson plans on the web, but were
not aware of the array of information that they could use to supplement lessons. The course utilized online
modules, email communication, and extensive reliance on web technology including research activities and
online course materials (in Blackboard courseware).

During the class, the web shifted from being just a resource tool for teachers to being a supplemental
instructional tool for their students. The professor modeled good web sites and then sent students out on the
Web looking for similar sites that could enhance instruction for their grade level. Students found that the
web could serve not only as a source of information to enhance their lesson plans, but that there are many
web sites designed as educational tools to be used by children themselves. For example, web sites that
could complement the Allen Parker narrative ranged from sites tracing the Underground Railroad with
concrete images of houses along the route to sites with simulations that involved decision-making and
higher-order thinking skills. In addition to using the web as a resource, teachers published information on
the web for others to use.

The Allen Parker project moved to a new phase with the addition of lesson plans developed for elementary
school teachers. The addition of these plans made the Parker web site a more robust tool for teachers in
eastern North Carolina. Teachers can now use the web site to integrate primary sources into their
classrooms as well as to teach the potentially controversial topic of slavery and race relations.

True to the learner-centered nature of the project, students and faculty from the two courses came together
at the end of the semester to learn from each other's experiences with the Allen Parker narrative. Educators
questioned historians about community resources and research strategies. Historians asked about such rich
historical information could be presented to young children in meaningful and creative ways. This event
was recorded in 35 mm photos that were scanned and posted on the website.

Final Thoughts and Comments

The Allen Parker Slave Narrative Site is an example of how technology can transform teaching at all levels.
The creation and use of the project web site changed courses for students of many ages. It was used as a
vehicle to move to more technologically-enhanced forms of research and communication. There are
numerous web resources for teachers who are interested in using computer-assisted instruction. For
example, there are sites with electronic text collections, primary history documents from around the world,
transcripts and audio for key historical speeches, documents pertaining to slavery, African-American
history pages, digital images of African-American life, or excerpts from other slave narratives. The same is
true for other ethnic communities as well as for other Social Studies topics.

We encourage teacher-educators to model computer-assisted instruction for their students through the use
of web sites, communication, course software, multimedia, and digital imagery. Teachers tend to teach the
way they are taught, so that such modeling will eventually result in a far-reaching transformation of the
teaching and learning process, affecting not only university students but also the children they teach.
Technology-based instruction has become more important as we prepare students to be competitive in this
age of information. The Allen Parker Slave Narrative website is a doorway to his world in the past, but it
has also served as an opening to the world of 21st-century technology.

Acknowledgements

The following people were indispensable to the Allen Parker project and the authors of this paper would like to express gratitude to them for their invaluable contributions: Dr. David S. Cecelski, members of the Fall 2000 History 3005/5005 The Slave Narrative in American History course, members of the Spring 2001 ELEM 6406 Teaching Social Studies in the Elementary School class, citizens and researchers of Chowan County and Worcester, Massachusetts, Professor Maury York and the staff of the North Carolina Collection at ECU's Joyner Library, and the Department of History and the College of Arts and Sciences at ECU for funding research.
Using Digital Image Editing to Step Back in Time

Scott M Waring, University of Virginia, US
Tommy Fallace, University of Virginia, US

This session is geared towards Kindergarten through university level educators who are interested in integrating technology into instruction. The presenters will share their experiences with instructing elementary pre-service teachers from the Curry School of Education at the University of Virginia to use Adobe Photoshop in effective ways when teaching to elementary social studies standards. This group of pre-service teachers collaborated with fourth grade teachers in a local school to develop curriculum materials to teach the Virginia history Standards of Learning. Using Adobe Photoshop, the pre-service teachers superimposed digital images of fourth grade students taken with a digital camera into historical artifacts. The virtual history lessons were taught using the digital images of the fourth grade students as writing prompts to excite the students about the content.

With this workshop, the presenters propose to introduce Adobe Photoshop as a means of inserting digital images of people into digital copies of historical artifacts to make teaching history standards more meaningful. The participants will learn how to use digital cameras to capture digital images of themselves and make them ready for use in an image editor. They will then explore Library of Congress' American Memory photograph archive and learn how to efficiently use Alta Vista for image searching of historical images on the Internet. Once the participants have digital images of themselves and a historical photograph, painting, or image, they will learn the basics of image editing to superimpose their picture onto the historical item in Adobe Photoshop.
A Model of Professional Development for History Teachers:
Technology Supported Discourse to Support Action Research on
Technology Supported Discourse

Elizabeth Wellman, Ed.D.
Director of Technology Projects, California History-Social Science Project
University of California at Los Angeles
ewellman@ucla.edu

Jana Flores
Executive Director, California History-Social Science Project
University of California at Los Angeles
jsflores@ucla.edu

Abstract: In a professional development program conducted by the California History-
Social Science Project, K-12 teachers' explore using discourse as a tool in their classroom.
They are introduced to a model for discourse use, specifically on-line discourse, and develop
supports for their students use of it. They then go back to the classroom and, using an action
research model, implement the use of discourse with their supports. They report back to the
group using an online environment. This online environment itself acts as their support and
incorporates many of the same discourse tools and supports they are using with their students.

Introduction/Background

The California History-Social Science Project (CH-SSP), is a legislatively-mandated professional development
program, one of nine California Subject Matter Projects, administered out of the University of California, Office
of the President. The Executive Offices are based at UCLA, and oversee seventeen local sites across California.
The CH-SSP is committed to improving the teaching and learning of history-social science for all students
through: strengthening disciplinary content knowledge as outlined in the California History-Social Science
Content Standards; promoting the study and teaching of history-social science from a multi-cultural
perspective; fostering historical inquiry through the interpretation primary sources, exploring cause and effect,
creating historical narratives, and considering the nature of change; enhancing instructional strategies to
promote accessibility to the discipline; promoting collaboration across grade levels; enhancing teachers' use of
technology as an integral part of the instructional process; and developing teacher leadership.

The CH-SSP Teacher Researcher Initiative Project (TRIP) engages teachers in action research on the use of
technology-based discourse tools to support historical thinking and understanding. This project has grown out
of a teacher professional development project in 1999 and 2000 which encouraged the exploration of the use of
technology in K-12 classrooms through the development of lesson plans. At the end of those two years we felt
that, although the lesson plans were exemplary, the teachers were not approaching the use of technology from a
perspective of the potential for fundamental instructional methodological change in their classrooms. As we
examined our approach, we decided that the focus on lesson plans, a standard product of teacher professional
development programs, was deterring from the teachers focusing on some of the fundamental instructional
issues we were trying to engage them in. In 2001, we switched to an action research model, one that we posited
would result in more reflection and experimentation. As a result of this paradigm shift, in January and August
2001, thirty-four teachers from across California conducted research in grade 3-12 classrooms with diverse
student populations. Participation by the teachers varied, as about 20% were unable to finish their research.
The rest finished their research and wrote papers. Of these papers, 60% focused on discourse and about 40%
focused on the use of multimedia in the classroom. Of those that focused on discourse, their results for students were also varied, however, there were across the board significant gains in student motivation, student participation and significant gains made by low performing and ESL students. This project has been modified in response to feedback from the teachers and will be repeated in January, 2002 to include thirty new teachers and twelve repeating teachers.

**Purpose/Theoretical Perspective**

The primary purpose of the professional development is to engage and support teachers to investigate instructional methods that support students’ development of historical thinking and understanding, and to investigate using technology to support the instructional methodology in ways that could not be done without technology.

Fundamental to how we approach the professional development is our approach to history. We approach history as a discipline as opposed to a subject (Stearn, 1993). Discourse in the History/Social Science classroom supports students in externalizing thinking and in creating cultural supports for thinking (Bain, 1998). For teachers, this requires that they provide social assistance (scaffolding) to the learners to support the necessary competencies through which the historical thinking and understanding can emerge and be internalized (Vygotsky, 1978). Technology based tools can provide this assistance (Salomon, 1988). We model this approach with the professional development. We approach the teaching of history as a discipline. We engage in discourse with cultural supports to externalize the teachers’ thinking. Action research provides for inquiry through reflection, it brings the unconscious to a conscious level (Schon, 1996). The teachers’ understandings can emerge and be internalized. Technology tools are used to support this.

Discourse and action research are therefore, central to this professional development approach. We see discourse as a creative process in which a shared understanding is created (Bohm, 1996). To engage in discourse is to engage in both the discipline of history and education. It is reflective and iterative in nature. It involves social assistance and the use of tools. Scaffolding is provided by the professional developers (facilitators). Tools are non-electronic (small group discussion, writing) and electronic (email, bulletin boards, chat, threaded discussion, electronic annotation).

Action research is also a process. It is a way to engage with classroom teaching and bring more of it to a conscious level (Hopkins & Antes, 1990). It is reflective and iterative in nature. Reflection encourages the challenging of ones existing theories and preconceived views of teaching (Kettle & Sellars, 1996). Action research involves social assistance and the use of tools. As with discourse, scaffolding is provided by facilitators (coaches) and tools are both non-electronic and electronic.

As elements of both of these processes we engage in reflection, collaboration and inquiry.

**Technology Supported Discourse and Action Research**

We see our professional development model as a system of people, practices, and technologies. The human activities are served by the technology (Nardi & O'Day, 1998). It’s parts consist of facilitators, teachers and students; the practices of discourse and action research, in the disciplines of history and education; and the supporting technologies.

Teachers participate in online pre-institute discourse activities, then spend three days at UCLA starting the research process (see below). Back in the classroom, they implement their action research. Finally, they write up their results for dissemination. In total, this is a five to six month commitment.

The action research process consists of six overlapping stages.
First, they question their assumptions about the disciplines. Through online discourse before the institute and in person discourse during the institute, the hidden assumptions that we all have are brought to the surface.

Second, they pose a problem (research question). They will discuss these with the other teachers and give other teachers feedback on their problems.

Three, as each teacher focuses on one problem, one aspect of their teaching, the plan for the solution should emerge (research plan) and worked out collaboratively.

Four, they will implement the action research plan in their classroom.

Five, both qualitative and quantitative data will be gathered by all teachers, analyzed and shared with peers to assure the highest level of reliability and validity possible.

Six, the process and the results of the action research are documented, peer reviewed and disseminated.

The first three stages of this process are the most difficult for the teachers and are the point where substantive scaffolding needs to be provided by the facilitators for the teachers. Primarily, scaffolding needs to be provided in the area of online discourse and in the conceptualization of the action research. In 2001, the scaffolding involved working in small groups and having consistent electronic contact with other group members and with facilitators using a variety of electronic tools including chats, email, and threaded discussion. These small groups worked independently. The outcomes of the groups varied tremendously, with the single most telling factor being the provision of scaffolding by the facilitator. This year, to provide a more uniform experience for the teachers, we have decided to have all of the participants work in one electronic environment. There is flexibility in this environment to break into groups, yet, still remain communicating with the larger group. Blackboard.com is the environment that we will be using. This environment allows us to engage in online discourse with the teachers to model the use of online discourse. In this environment, the teachers will engage in the same kind of discourse – discipline-based and related to activities – that their students will be engaging in. Scaffolding of various kinds will be provided by the facilitators. This will include providing supporting materials; developing both directed questioning and providing for open ended discussion of the research; providing prompts on thinking about the issues; and notification when responses are posted. This year, the scaffolds that are used and their success in assisting teachers to engage in both research and discourse, will be a research focus for the project.

Technology Supported Discourse in the Classroom

The focus of all of the action research plans is on some aspect of the use of technology supported discourse. Although in their research process the teachers may identify many problems, they are asked to focus on those which involve discourse as a solution. Their use of discourse as a solution uses technology as a tool. For the teacher, this expands their discourse tools in the classroom. How the technology is used for discourse, under what circumstances, with what scaffolding tools, and with which students is what each teacher explores individually.

The creation of teacher generated supports, or scaffolding tools, for technology supported discourse was an area that many teachers struggled with. For most of them, this meant developing supports of a type that they had never developed before. A wide variety of tools were used, from specific to general, sometimes without the teacher understanding that they were using them. For a databased discussion group, one middle school teacher used very explicit pull down menus with prompts for the students and reminders of what they should be thinking about when they are participating in on line discourse. These prompts were both discipline based and writing based. The disciplined based prompts supported the students in thinking like a historian. For instance, they remind the student to seek corroborating evidence for their conclusions. The writing based tools supports addressed how the students should be crafting their answers and what depth of answer was expected of them at various times. For a different form of online discourse – chat rooms - a high school teacher provided a different form of support. In this case, he provided real time scaffolding in an environment where the students were conducting a historical discussion. These prompts consisted of crafting the discussion, helping students stay on task, providing questions to help them expand, clarify, question one another, predict and engage in historical thinking and understanding. This form of online communication also seemed to require more scaffolding for appropriate responses and to keep the students from diverging from the focus of the chat. These teachers and
others expressed in their papers the need they had to better develop these teacher generated support tools and to have more support in this activity. In response to this, the use of appropriate scaffolding in different online media, for different students, for different purposes is another major research focus of the 2002 work.

Preliminary Results

There are two areas of results. The first is the results from the professional development, the second is the results of the action research.

In 2001, twenty of twenty-six teachers submitted final papers, a much higher percentage than anticipated. Eight teachers will be submitting papers in December. The positive indicators for the professional development included:

- renewed enthusiasm for participating in discourse activities in their classroom,
- a deeper understanding of the nature of discourse activities,
- a change in the way they approach thinking about activities in their classroom,
- a change in the way teachers perceive their students, particularly low performing students,
- more perceived and actual choice of instructional methods and instructional tools.
- A greater understanding of the role of scaffolding supports in their classroom and a greater ability to develop and implement them to support online discourse.

For a number of teachers, they felt this experience completely changed the way they thought about their approach to teaching history. Most teachers felt some positive change in their thinking about historical thinking and understanding in their classroom.

There were a number of difficulties with the professional development. They included:

- The level of discourse between teachers was not as high as we had hoped.
- A number of teachers were very focused on multimedia for classroom use. These teachers tended not to explore the discourse issues.
- Inconsistent facilitator support across groups.
- Last minute technical difficulties with the planned online environment.

We believe that the environment, and the occasional lack thereof, was primarily responsibility for these results. Our belief is that the changes we discussed above will addressed these difficulties we have had.

The preliminary positive results of the action research, across teachers, were:

- Motivation to participate in technology-based discourse activities was much higher than to participate in non-technology discourse activities. There was nearly 100% participation.
- Non-technology discourse activities were positively affected, both in the level and amount of participation.
- Low-performing and English as a Second Language students showed the greatest gains in participation, understanding and their ability to express their ideas.
- A significant percentage of students used historical thinking and understanding.
- Misconceptions were diagnosed and mediated much early than in the traditional classroom.

In particular, we found the results with low-performing and ESL students to be unanticipated and very exciting. As a result, we are making this an additional research focus for the project in the year 2002.

There were a number of difficulties with implementing the action research, including:

- lack of principal and school support,
- lack of appropriate technology,
- lack of technical support at the school,
- competing demands on classroom time,
- competing demands on lab time.
These are difficult to address as they are out of the control of both the classroom teacher and the professional developers. We will be communicating more closely with the principals this coming year, to try to develop more support within the school environment for the teachers engaging in this research.

Results from eight more teachers are expected in December 2001. Thirty more teachers will be participating in January 2002. Their work is expected in May 2002.

**Conclusion**

Discourse is an important methodology both in professional development and in History/Social Science classrooms (Schon, 1983, Vygotsky, 1978). The traditional forms of discourse used in the classroom, in-class discussion, small group discussion primarily, most facilitators and teachers find limited. By engaging in professional development which uses action research and technology supported discourse, teachers themselves become immersed in an iterative, reflective environment which encourages the externalization of their thinking. It also immerses them in the ‘doing’ of their discipline. This gives the teacher a solid experiential and methodological foundation on which to develop and expand, using cultural supports and technology as a tool, the forms of discourse being used in their own classrooms. This approach can open the teaching of history from a subject which teachers teach and students take; to a discipline, where technology supported discourse leads to historical thinking and understanding as core student processes.

History Education Online:  
A Critical Analysis through Focus Groups

Cameron White, University of Houston, US  
Tony Talbert, University of Houston, US

Introduction

Meaningful, integrative, value-based, challenging and active teaching and learning are vital for effective online discussion. Powerful online teaching and learning suggests establishing a framework focusing on content, connectivity, and community (Brown, 1999). More specifically, this framework necessitates setting a positive learning environment, establishing a learning community, building in powerful pedagogy, establishing rights and responsibilities, using open-ended discussion and activities, and focusing on discussion organization and management. Vital needs for all involved that will also be discussed include establishing ongoing support and follow-up, social context for learning, communication, toleration, and intrinsic motivation (White and Weight, 2000). Essential components for effective online courses, appropriate netiquette, and the role of the facilitator will also be investigated.

Successfully integrating technology in social studies classrooms is a vital issue facing social studies educators. Unfortunately and all too often, problems occur when social studies teachers are presented the new technology, expected to implement it, then left to battle alone with their own issues regarding effective integration. Nevertheless, technology skills are now essential for social studies teachers and students and technology provides innovative potential for meaningful teaching and learning.

Online teaching and learning is relatively new in teacher education and especially in our schools. Only in the last few years has there been even minimal research and literature regarding issues, trends and effective teaching and learning online. There is even less research in the merging of online courses and social studies education. Perhaps a key issue is ensuring effective learning in an online environment. Jonassen states that there are four paramount attributes of constructivism that facilitate an effective learning environment including: (1) providing opportunities to foster personal construction of knowledge; (2) setting an appropriate context for learning; (3) facilitating collaboration amongst learners; and (4) facilitating learning and collaboration through conversation (1995).

Issues dealing with learning via technology (online teaching and learning) suggest developing a constant awareness regarding dialog, discussion, and discourse as we hope to establish collaborative learning communities. Research suggests that online teaching and learning can encourage otherwise silent students to participate, can promote the ideal of serious dialog regarding comments, can facilitate discussion on issues and themes that are unlikely to be approached effectively in classrooms, and can facilitate the development of collaborative learning community (Weisser, 1997; Parkyn, 1999; Swartz and Hatcher, 1996). Parkyn (1999) suggests specific pragmatic details vital for effective online learning including detailed instructions and expectations, monitoring, etiquette, and equal involvement of all (including the instructor).

Within a social studies framework, an online teaching and learning must focus on knowledge, skills, and attitudes related to social education. It must also address the components of powerful social studies teaching and learning including approaches that are meaningful, integrative, value-based, challenging, and active. The ultimate goal might be the transformation of social education to a student-centered, problem-based, critical analysis focus (White, 1999). History education at both the college and secondary school levels persists in using traditional teaching methods, usually using teacher-directed approaches. The goal of this project is to develop new forms of history education that draw upon online resources and transform history teaching into a more student-centered, interactive experience. The objective is to give students more meaningful, active learning opportunities through project-based activities and the ability to integrate new technologies into their coursework.

Technology-based curriculum and instruction offer a way to help students develop the skills characteristic of history as a discipline: the ability to conduct research, to analyze primary sources, to weigh evidence, and develop coherent
interpretations. New technologies offer a cost-effective way to give students access to primary sources and to create multimedia projects.

For the past year, professors at the University of Houston in both history and education have collaborated to develop a comprehensive collection of online history resources drawing upon original scholarship and the documents and images in the largest private collection of American history documents, the Gilder Lehrman Collection, on deposit at the Pierpont Morgan Library in New York. Featured in the February 15, 2001 Wall Street Journal, the site is located at http://www.gliah.org. It contains over 1,500 active pages, including a comprehensive online U.S. history textbook; a searchable database containing the transcripts of over 600 primary source documents; glossaries, timelines, bibliographies, annotated hyperlinks, and essays on such topics as the treatment of American history in film and the history of aspects of private life.

The site, which complies with the latest standards for accessibility under the Americans with Disabilities Act, has a dynamic, database-driven design. Documents, texts, hyperlinks, and images have been placed in a searchable, relational database. Among this site's distinctive features are online exhibits on early African American life illustrated with an early form of photography known as cyanotypes and a java-script program which automatically transcribes an 18th century letter.

The lacking element in this site has been pedagogical. Many teachers do not know how to effectively incorporate Internet resources and primary source documents into their teaching. In social studies, technology is often used as an add-on, available when the “real work” is finished, or as a reward for good behavior. These occurrences are due in part to the assumption by administrators and teachers that the training needed to implement technology effectively is too extensive and too technological or, on the other end of the spectrum, that the training can be done with one long and usually unproductive in-service session quickly forgotten as the year progresses. A false over-reliability or even blind acceptance of technology in schools also causes these issues.

Many well established teachers ask why they should use technology in social studies when there are successful methods already being used within their classroom? The issues presented in this paper focus on making social studies a more powerful and meaningful experience through technology integration in hopes of meeting students learning goals and meeting the needs of facilitating a critical and active citizenry. What society demands our children be able to do when they leave the educational system is much different from what it was as few as ten years ago. They must be proficient in using technology and understand the implications of its use in the future as well as how it has effected us in the past. Social studies teachers must modify the old style of teaching to fit the new way of learning. Social studies is not just about covering content; it is about analyzing content and developing social skills and attitudes, all with a critical thinking and problem solving focus.

Technology also has the ability to make learning exciting and worthwhile, allowing students to interact with the computer as well as other students while observing and acquiring the most current information on places they would otherwise never experience. We, as educators sometimes fall into a trap of anesthetizing the students...[There's] not enough stimulus (Sizer, 1992). Implementing technology can wake up those sleeping students as well as promote a motivation to learn independently. We focus too much on extrinsic motivation to ensure learning; perhaps technology integration can facilitate a movement toward more intrinsic motivation. This should be the goal of every social studies teacher and can be developed and fostered quite effortlessly in a technological classroom.

The role of technology in social studies teaching and learning can be much more meaningful and powerful. If we are truly interested in promoting a social studies that goes beyond traditional transmission to a more transformative knowledge, skills, and attitude development that facilitates an informed and active citizenry, then technology must play a more central role. Many of the excuses that pervade successful social studies technology application including content coverage, time, availability, training, and traditional praxis should be addressed. There really is no excuse if we keep in mind the ultimate goals of social studies education.

This project attempts to provide the connection between the wealth of documents and resources at the Gilder Lehrman site and actually using them in a classroom.

Many well-established teachers ask why they should use technology in history courses when there are successful methods already being used within their classroom? The suggestion is not to change the instructional methods that work, but making history a more powerful and meaningful experience and meet the changing needs of society and
future leaders. What society demands our children be able to do when they leave the educational system is much
different from what it was as few as ten years ago. They must be proficient in using technology and understand the
implications of its use in the future as well as how it has affected us in the past. History teachers must modify the
old style of teaching to fit the new way of learning. History education is not just about covering content; it is about
analyzing content and developing social skills and attitudes.

The Project

One of this project's major objectives is to ensure that instructors at the secondary and college levels are able to
meet state and national standards concerning content, pedagogy, and technology integration, including Texas
Essential Knowledge and Skills; Texas Technology Applications for Teachers, and the National History Standards.
Program curricula has been designed that support these standards and base student assessment on these standards
through a variety of means such as online quizzes, rubrics, and student-centered projects.

This project has three primary goals: (1) To develop a database of activities that will allow instructors at the
introductory college and secondary levels to incorporate these resources in their courses; (2) to educate prospective
teachers to use technology effectively in their history classes; and (3) to test these activities in an actual U.S. history
survey class classroom. The participants—a historian who regularly teaches the large U.S. history survey class, a
specialist in instructional technology; and a specialist in teacher education and social studies education, have
brought complementary talents to this project.

The project established support for the development of an ongoing focus group including teaching of middle and
high school American History. These participants initially worked with faculty members to ensure that the materials
designed would be pedagogically sound, meet state and national standards, and be motivating and interesting to
students.

The seven participants are meeting once a week for approximately an hour. The initial charge is to explore the
project web site in detail. Participants were asked to meet twice and engage in "getting acquainted" activities.
Subsequent meetings dealt with generally discussions regarding technology in history education, history education,
and the status of teaching and learning in general. Additional meetings focused on general web site discussions and
specific discussion on various web site components.

Eventually participants decided that web-based interaction would enhance project development, evaluation, and
application. Consequently, web-ct was employed for weekly sharing and discussion and real time chats were
conducted twice a month. Web-ct also enabled various postings, web development, and web application ideas.

Evaluation

Data from formative evaluations were collected through a wide range of procedures and instruments, including
questionnaires, performance assessments, examination of student- and teacher-produced products, learning and
teaching journals, observations, interviews, focus groups, video and audio recordings, anecdotal records, and open-ended critiques. Progress toward accomplishing project goals and objectives has been disseminated on the project Website and through a formal report.

Project activities and research are in the process of being developed and disseminated by the project directors, other
local, state, national and international social studies faculty and students, in a number of ways. These include, but
are not limited to, (1) creating and presenting professional development workshops and seminars offered to local
school campuses, districts and education institutions; (2) developing and presenting progressive critical
constructivist teaching and learning models that integrate multimedia technology and the social studies at
conferences and forums including the Texas Council for the Social Studies, National Council for the Social Studies,
and other progressive general education organizations; (3) engaging in field based research and co-authoring
manuscripts for journals, monographs and books; and, (4) the uploading of all projects developed to ensure local,
state, national and international availability via the Gilder Lehrman web site for downloading.

Following are initial questions provided to participants to facilitate discussion (some are obviously demographic
needs):

2286
Page 2225
Gender - 5 M, 2 F
Subjects taught at present - 7 Am. History
Grade - 3 8th grade, 4 11th grade
Years teaching - 3 with 2 years or less, 4 with more than 2 years
Degree - 6 working on M. Ed., 1 working on Ed. D,

Personal use of internet - all use daily
Use of internet in teaching - 4 use daily, 2 weekly, 1 less often
Positive features of technology in education - variety, research, resources, information access, interest level,
graphics, can go beyond the text
Issues with technology in education - information overloads, tech as a tool, availability, support, censorship, tech for
tech sake, effective integration
Positive features in schools - increased access
Issues in schools - TAAS, accountability and achievement, content for content sake, costs
Positive features of history in schools - cultural awareness, social skills, learning skills, critical thinking,
exploration, beginning to move beyond transmission of facts
Issues with history in schools - coverage, textbook, testing, too much reductive knowledge: essential knowledge
privileged over contemplation of the issues; in other words, most students are not expected to, nor are capable of,
actually making history, they can only memorize it

Specific questions addressed during various discussions of the focus group (with sample responses) include
the following:

How can the site assist in teaching American History?
Can give quick reference to historical eras, events, people and times; organized around a chronology that provides
links to previous eras; quotations from teacher section offer lesson warm-ups, great access to resources

What specifically does the site offer in assisting your teaching? Same as above, speeches and primary sources

Critically analyze each section of the site.

What are the best / poorest features of the site?
Best: structure; everything is well formed and easy to navigate, site page
Worst: primary source documents; site does not allow creation of history because it lacks a broad selection of
documents that all students to form their own opinions; the site pre-interprets the knowledge so that it becomes just
another textbook, home is "messy"

-What needs improvement?
Primary source documents (see above)
Teacher section: sample lessons needed; links to educational sites based on that (whichever) subject/era/etc. or links
to documents or to other knowledge bases (I hate to mention it, but the CNN site does this very well. Thought it
keeps the viewer within its base - not a great thing - it provides heady connections and multiple source offerings.)
More links needed

What themes are present? What themes are missing?
Needs better articulation with state and national standards / themes (History, NCSS), integration with other social
studies disciplines

What issues are present? What issues are missing?
Multicultural, popular culture are present, examples of controversy
More with controversy, alternative views of history, more issues in history, more with earlier history needed

What are the best ways to integrate the site in schools?
Design a course so that the students are critiquing the site. Give students research responsibilities so that they decide the validity and shortcomings of the site. Use the site as a project resource, learning station for project development.

What lessons / units can be added?
see above

Conclusion

We are at a crossroads in social studies and history education, and the struggle continues. Should we continue with a transmission approach or move toward history and social education for transformation? Technology has a huge role to play in determining the direction. The increased and effective integration of technology in history and social studies education must continue to be addressed.

Web sites such as Gilda Lehrman (http://www.gliah.org) can only be as effective as those who design them and apply them. The ongoing focus group of teachers has continued with discussions and applications of the site in hopes of improving its design and application. We must allow all stakeholders input into integrating technology as a tool for history and social studies integration.

The internet has the potential to play a great role in improving history and social studies education. Increased access to information is one thing, but what we do and allow students to do with that information will truly make the difference.

Abstract: This paper is a description of various techniques for integrating technology skills into thematic units for use by pre-service teachers in teacher education programs involving elementary and special education preparation classes. Numerous software titles are highlighted as appropriate for use by primary and upper elementary/middle level students in integrated lessons. Also provided are ideas for using literature and writing skills in activities involving math, science, and social studies. Activities for using spreadsheets, databases, and graphing software are also described for use in collaborative and cooperative instructional settings.

Introduction

Reform efforts in schools have included the development of standards that school districts use to develop curriculum and instructional methodologies (Anderson and Anderson, 2000). Organizations that developed these standards began by making them disciplinary specific (Daniels and Bizar, 1998). Increasingly, schools that focus on authentic activities are finding this classification inadequate for effective use with students (Daniels and Bizar, 1998). School districts today that are attempting to utilize authentic instruction that integrates technology in the classroom are adapting their instructional methods to accommodate both technology and thematic approaches for their lessons (Pastorek and Craig, 2000). The technology becomes a tool to enhance the multidisciplinary environment (ISTE, 2000). In an effort to begin exposing pre-service teachers to more authentic instruction that includes the integration of technology, several sample activities have been successfully developed and used by the authors in teacher training programs, including elementary education methods courses and special education methods courses. These activities have been used in teacher education classes as a demonstration of how teachers can develop technology-integrated lessons emphasizing authentic learning. Beginning with the selected content gleaned from national academic standards in content areas, the lessons integrate technology in a seamless fashion and result in teaching products that can be used by the pre-service teachers in their own classrooms. These lessons also provide pre-service teachers with an opportunity to demonstrate the ability to use instruction reflecting the ability to teach to academic standards, mastery of pre-service teacher technology standards, and mastery of pre-service beginning teacher standards. These lessons also serve as a satisfactory element for pre-service teacher portfolios demonstrating mastery of content and technology standards. For each of these lessons, the teacher educators would involve the pre-service teachers as sample elementary or secondary school students and walk them through the lessons, discussing a variety of ways the lessons could be used with their own classroom students during practicum experiences or student teaching.
Integrated Lessons Using Technology

English/Language Arts

Two activities in the area of reading and language arts are described here, one for primary students and the other for older students. The lesson for younger students focuses on integrating science into the language arts, while the lesson for the older students integrates several subject areas to accommodate the model of different teachers for different classrooms. For the younger student, the instructor begins by reading a science-based picture book to the students that illustrates how animals look and move. A discussion with the children about how different animals in the story look and move follows the reading of the story. Next the teacher collects vocabulary words for animal colors, words that describe how different animals move, words that describe different animal body coverings, and finally, words that describe the size of different animals. The children then choose an animal of their own of which they will write a description, so that the other students can guess their animal. To do this story, they create a word web with Kidspiration (Inspiration Software) using the correct words from the earlier word bank for color, movement, covering, and size. This web is used to develop the story that describes their animal. Finally, they use KidPix Studio (Broderbund) to draw a picture of their animal. If desired, the children can also write their story in KidPix Studio using the typewriter function.

For the older children, the teacher could use a work of literature such as The Adventures of Huckleberry Finn by Mark Twain. This book is available in software format from Don Johnston Inc. for use on the computer by students needing a simplified version. Students may investigate the social relationships of people from different ethnic backgrounds during Mark Twain’s lifetime as an integrated social studies/language arts activity. Using word processing software, the students would be able to write a newspaper column or an editorial expressing the local views of race relations appropriate to the time period. For mathematics integration, students would be able to use a spreadsheet such as The Cruncher (Davidson) or Excel (Microsoft) to chart and graph distances and times traveled by Huck Finn on the river. Both of these programs allow the development of graphs that may be used to support a newspaper article about travels on the Mississippi River. As a science integration, students may use a database program such as Filemaker Pro (Filemaker) or Access (Microsoft) to keep track of different kinds of wood that might have been used for building rafts. Students could experiment with various woods in the lab to test for floating ability, the volume of water that was absorbed, and how much weight wood of varying degrees of wetness could support. This database information could then be used in writing an article on how to build the best rafts for use on the river.

Science, Math, and Social Studies

These lessons integrate math, science and social studies into lessons that can be done in collaborative or cooperative groups for student of all ages and abilities. As is the case for most integrated lessons, reading and writing skills are fundamental for the successful completion of the project and provide the framework for the description of results generated. For example, one lesson may begin with the CD-ROM of the fable The Tortoise and the Hare (Broderbund). After reading the story and exploring the CD-ROM, the students can discuss the elements found in a fable and make a flowchart of the elements using either Kidspiration or Inspiration. Amazing Writing Machine (Broderbund) may be used to write fables based on group discussions. Timeliner (Tom Snyder Productions) may be utilized to make a visual representation of the order of events in the fable. Programs such as Geography Search (Tom Snyder) and Mapmaker’s Toolkit (Tom Snyder) are useful for exploring and designing pictures of the geographical regions in the fables. For a more localized map for younger children, Neighborhood Map Machine (Tom Snyder) or KidPix Studio may be used to draw maps based on the areas in which students live.

Science and math explorations based on The Tortoise and the Hare can investigate speed and friction. Knowing that the tortoise and the hare traveled at different speeds and rates, students can devise practical analogies for classroom experimentation. For example, students can use two 2-liter soda bottles to correspond to the tortoise and the hare. One bottle should be empty and the other one half full. Students should predict which bottle will travel the farthest and which will have the greatest speed at a preset distance from the bottom of a ramp. They should also predict which bottle will behave more like the tortoise or the hare. These predictions may then be recorded in The Cruncher or in a graphing program such as The Graph Club or Graph Master (both from Tom
Snyder). The bottles are then rolled down an inclined ramp, with the students measuring both total distance covered and the time taken. They may also calculate the speed of each bottle at certain distances using their measurements. Using multiple measurements, students can graph and discuss the reasons for the results, noting that the friction of the sloshing water in one of the bottles probably impacted the results. Finally, students may write up a final lab report describing their observations and measurements.

E-learning as a facilitator in special education frameworks

Sari Bar-On, Levinsky College of Education, IL

Students in teachers colleges take courses for better use of computer skills. Yet in practice, it transpires that the work models applied at schools are outdated for the most part:

- Use of computers is limited to a rigid time frame according to the class setup.
- A great deal of use is made of rigid educational software for drills, especially in kindergartens.
- Teaching of computer skills is not carried out in a comprehensive manner.
- Many subjects are learned without computer work to begin with.
- Little attention is given to the social and therapeutic computer-assisted interaction.

A new initiative was taken at the Levinsky College of Education, in the Special Education Department: The methodology course is planned for distance learning. The site and its activities were open and accessible to all Special Education Department students. Several class meetings are held for active experimentation, discussion of syllabus and enlightening reflective and social thinking. In addition, we met for close on-the-job training. Computer skills are being taught while exposing the students to an interactive learning environment and tutoring them in their practical work.

The students experience the difficulties of acquiring skills concurrently, while learning new subjects. Such an experience is common in the learning process of young children, and in special education. Students are encouraged to share their feelings, thoughts, empathy and comprehension during class meetings, as well as in chat and discussion group.

Our assumption is that inculcating computer use as part of the teaching process would help students, by way of modeling, to plan similar work formats with their pupils. This knowledge is particularly important to special education teachers: computer-related teaching of children with learning disabilities and emotional and social difficulties, assists in interactive learning, organizing information and building up learning skills, thought processes and known environment.

Examining the students' practical work techniques in the wake of this course we found that there was a greater use of computers in instruction, use of the computers in an interactive manner and integrating them as an additional teaching method in the lessons. Improvement in social interaction was observed by the staff in the classes and kindergartens. Few younger children with different communication deficiencies revealed new patterns of interaction.

A content analysis attributes the success to a number of factors:

- The basic concept of combining teaching and alternatively learning: relevant subjects through computer-related activities. The students learn it all -- communication skills, self-awareness, empathy, how to collect and process information and how to execute tasks -- while learning topics relevant to their or practical work.
- Modeling as a basis for planning the students' both learning and teaching activity.
- On-the-job training and supervision follow up the process of learning the relevant subjects and computer skills.
- The creations of professional discussions in various learners' communities to which the students have complete access. The students regarded themselves as part of a professional group.
- Placing the responsibility of learning and communication in the student's hand.
- The change of teacher-student interaction towards mentoring and collegial relations.
- Sharing of feelings in a supporting group.
- Better options for allocating students' learning span according to learning styles and time limits.

A "ripple effect": Computer uses spread among additional college lecturers and new work models were adopted in the practical work frameworks. The impact on the mentors and college lecturers had not been foreseen but is a welcome outcome, with a positive influence on the educational system.
Educational IT:
How Students and Employees with Disabilities can Access IT

Sheryl Burgstahler, Ph. D.
Affiliate Associate Professor, Director of DO-IT (Disabilities, Opportunities, Internetworking and Technology), Co-Director Access IT (National Center on Accessible Information Technology in Education)
University of Washington, U.S.A.
sherylb@cac.washington.edu

University of Washington, U.S.A.
lylac@u.washington.edu

Abstract The National Center on Accessible Information Technology in Education (AccessIT) at the University of Washington serves to increase the access of individuals with disabilities to electronic and information technology in educational institutions at all academic levels nationwide. It is funded by the National Institute on Disability and Rehabilitation Research (NIDRR) of the U.S. Department of Education and is located at the University of Washington in Seattle. This paper promotes the use of accessible technology, provides examples of accessible electronic and information technology, and lists useful resources.

The National Center on Accessible Information Technology in Education (AccessIT) at the University of Washington serves to increase the access of individuals with disabilities to electronic and information technology in educational institutions at all academic levels nationwide. It is funded by the National Institute on Disability and Rehabilitation Research (NIDRR) of the U.S. Department of Education and is located at the University of Washington in Seattle.

Access to electronic and information technology, from telephones to computer software, is essential for people with disabilities to fully participate in today's high tech world. The increasing use of technology presents remarkable opportunities for people with disabilities. However, it presents new accessibility challenges to those who have sensory, mobility, learning, and other disabilities. If we do not address these challenges and assure that electronic and information technology can be used by everyone, the potential for technology as a great equalizer will go unrealized. The new Center develops and disseminates materials, training, and technical assistance that facilitate adoption of policies and practices leading to the increased use of accessible electronic and information technology in educational settings.

Examples of Accessible Electronic and Information Technology

Following are examples of accessible electronic and information technology in education.

- **Accessible web pages** allow students with disabilities, including those who have sensory impairments, to access information; share their work; communicate with peers, teachers, and mentors; and take advantage of distance learning options.

- **Accessible instructional software** (on disks, CDs or other media) and **documentation** allow students with disabilities to participate side-by-side with their peers in computer labs and classrooms as they complete assignments; collaborate with peers; create and view presentations, documents, spreadsheets; and actively participate in simulations and all other academic activities.
Accessible telecommunications and office equipment makes communication and educational administrative functions accessible to everyone, including those with mobility, visual and hearing impairments.

Goals and Activities

AccessIT helps educational institutions make electronic and information technology accessible to all students and employees. In so doing individuals with disabilities can benefit from all technology-based educational and school-related activities. AccessIT facilitates the implementation of policies, procedures, and practices that promote the procurement and use by educational entities of accessible electronic and information technology that applies universal design principles and meets recognized standards.

AccessIT works nationwide with NIDRR-funded Disability Business and Technical Assistance Centers (DBTACs). By providing training, support, dissemination materials, and technical assistance to the DBTACs, AccessIT utilizes and builds on this existing infrastructure for information dissemination and technical support. AccessIT also provides information and training to educational institutions through its web site and presentations at educational events.

AccessIT’s web site is growing to become a resource for educational entities and their constituents for information on accessible electronic and information technology. The web site will include accessibility checklists, case studies, best practices, frequently asked questions, and links to resources, and case studies, all tailored to applications of electronic and information technology in education.

AccessIT conducts training sessions and presentations at major educational, disability, and technology conferences to inform target audiences about how to make informational technology in education accessible to individuals with disabilities and of the availability of resources from AccessIT and of technical assistance from the DBTACs.

These types of activities benefit:

- **Policy makers**, including school principals, district directors, technology directors, and others who develop policies, guidelines, and procedures regarding planning for and procuring electronic and information technology;

- **Implementers**, including educators (both in general education and special education, precollege and postsecondary), computer lab personnel, library staff, and others who implement electronic and information technology and support its use by students, teachers, and other employees; and

- **Students and employees with disabilities**, as well as their families and advocates, who use or should be able to use electronic and information technology.

Conclusion

Electronic and Information Technology open doors to education and employment for those who have access. Assuring that individuals with disabilities can benefit from these opportunities, electronic and information technology at all academic levels must be accessible to students and employees with disabilities.
Resources

To learn about accessible electronic and information technology, consult the following resources:

Assistive Technology Basics in Education

Terence Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, Jacksonville, FL USA.
teavanau@unf.edu

Abstract: Currently in the USA about 150 million people are impacted by cognitive or physical disabilities in some form. And, according to some researchers, approximately half of the entire planet’s population, which is an estimated three billion people, are affected by disabilities. Because of the large and growing number of individuals in schools who have special needs and the number of laws and rules that apply to assistive technologies, assistive educational technology is growing in importance. Assistive Educational Technology is the theory and practice of design, development, utilization, management, and evaluation of processes and resources that are used to increase, maintain, or improve functional capabilities of individuals, with or without disabilities, for learning. As more regular education teachers teach mainstreamed students, they need understanding of how assistive technologies can support student learning.

Assistive Educational Technology

Disabilities rights leaders have said that the application of technology will be the equalizer of the 21st century (Flippo, Inge and Barcus, 1995). Through the use of assistive technology (AT) devices, many students can decrease their isolation and become an important part of a regular classroom. AT is a basic tool in the educational process for any individual who may be experiencing a disability. Screen readers that read aloud the text on the screen or web page can overcome barriers to accessing electronic information encountered by students who have vision disabilities. Captions can overcome barriers for students who have hearing disabilities. Some access solutions that use principles of universal design are built right into the hardware or software of most computers and programs (RESNA, 2001).

Assistive Educational Technology (AET) is the theory and practice of design, development, utilization, management, and evaluation of processes and resources that are used to increase, maintain, or improve functional capabilities of individuals, with or without disabilities, for learning (Cavanaugh, 2000). The distinction between assistive and educational technologies is becoming less clear as the concept of universal design is incorporated into conventional technology. As educational technology develops toward universal design it will go beyond just providing various forms of access to existing methods and materials; and will incorporate AT approaches and accommodations in the application of teaching for all individuals. This will have the impact of changing the learning goals, the teaching methods, and the means of assessment for all students.

What is Assistive Technology?

The Technology-Related Assistance for Individual with Disabilities Act of 1998 (PL 100-407) gave us the first legal definition of assistive technology devices and services. An AT device was defined as: any item, piece of equipment, or product system, whether acquired commercially off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities. AT then is a wide-ranging educational tool that is growing in its use and importance, and is required for consideration for all students classified with any form of disability and must be included on that student's individual education plan (IEP).

AT may be classified as high, middle or low tech. A high technology device usually requires electronics or microchips to perform some function, while bw technologies usually do not require a power source. An example of the application of AT could range from having a computer read a book (high tech) to printing out the material in a larger font or the student using a magnifying glass (low tech) to read the required material.
Assistive Technology Categories

Along with levels of the technology, there are levels of how the necessary AT item will be applied in the school situation which are: personally, developmentally, or instructionally necessary (Judd-Wall, 1999). Personally necessary items are AT devices that are used by an individual that enable a learner to more effectively interact with his/her environment. While developmentally necessary devices help with an educational need based on some developmental delay, ideally would be improved or overcome, eliminating the need for the assistive technology item in an individual's future. Lastly, instructionally necessary devices are ones that modify the instructional process at a course or grade level, and do not need to be moved with the user as her or she progresses to the next level. Progressing from individually to instructional necessary, the materials used are much more likely to be shared among various students. This application of AT to all students becomes a basic component of universal design in education, by allowing any student better access or access in a more appropriate alternative format to the information being taught.

AT has the ability to increase student independence while at the same time advancing academic standing, as it can also allow increased participation in classroom activities by students with special needs, letting them have equal access to their school environment. Rehabilitation Engineering and Assistive Technology Society of North America (RESNA, 2000) has identified twelve different areas where AT can be used. Of the twelve, four are areas that would have a major impact in any school situation, include: Work Site Modifications, Instructional Material Aids, Seating and Positioning Aids, and Sensory Aids. The other AT application areas are Aids for Daily Living, Communication and Augmentative Communication Tools, Environmental Control Systems, Leisure Time or Recreational Adaptations, Mobility Aids, Prosthetics and Orthotics, and Vehicle Modifications, and also apply in some way to the school setting.

Making a Difference

According to David Rose and Anne Meyer (CAST, 2000) AT tools can make a significant difference for students with disabilities. AT tools can allow access to information and activities that otherwise are inaccessible. The other side of AT application is that the tools can also make information and resources more available to those who don't have a disability or have not yet been identified as having a disability. The exceptional education teachers are not the only ones who need awareness of AT applications. All teachers are likely to have mainstreamed students, and the purpose for AT is to allow and support the student in the general student population. Professional organizations including the International Society for Technology in Education (ISTE, 2001 ) and National Council for Accreditation of Teacher Education (NCATE, 2001) have standards for all teachers and administrators regarding AT that require teachers and administrators to use technology to support learner-centered strategies that address the diverse needs of students and apply technology resources to enable and empower learners with diverse backgrounds, characteristics, and abilities.

Using technology to facilitate the academic achievement of learning disabled students in general education classrooms

Jerrie Jackson, Our Lady of the Lake University, US
Jean Kueker, Our Lady of the Lake University, US

Abstract This presentation will describe and demonstrate a sampling of the many ways that technology can assist in meeting the needs of students with learning disabilities. Ideas for how to use one computer in the classroom will be discussed as well as to demonstrate CD-Rom software (Tom Snyder), graphic organizers (Inspiration), and Text -Help programs. This presentation will provide previews of programs mentioned, along with an annotated bibliography of software and Internet resources.

Introduction

In the day of inclusion, most students with learning disabilities spend much of their school day in the general education classroom. By definition, students with learning disabilities have normal intelligence or above, but often are frustrated in content area subjects due to problems in reading and written language (Bos, C. & Vaughn, S., 2002). Students may be very interested in science or history, but if the text is the only avenue of gaining information, could fail the course. This presentation will describe and demonstrate a sampling of the many ways that technology can provide a means of accessing information and of providing means to assess the knowledge that a student may have but not be able to demonstrate through traditional means. Technology offers many avenues of providing an interactive way for a student to get the needed academic information without having the read the entire text.

CD-ROMs as a source of information

As long as a classroom has access to one computer, the CD-Rom becomes a tool that can provide access to current subject specific information in an interactive way. For instance, Dorling Kindersley markets numerous programs in the area of science and mathematics that offer the option of text being read and short video clips to illustrate a topic. By using a program such as this, a student is able to gain adequate information in an age appropriate way to allow him/her to be successful in the class.

Tom Snyder Productions offer many programs that integrate cooperative learning into the use of the software and supplementary materials. An example is The Great Ocean Rescue. Each team member has a role to play. Problem solving and higher order thinking is involved, but through the team and the information provided a student with reading problems could contribute and be successful.

Word processors with audio assist

Each year more and more user-friendly word processors that include speech capabilities are available. If the student early on accesses such programs as Read, Write, and Type, the written response becomes accessible. Also programs such as Text Help offers audio feedback options when just a few letters of a word are written. Now Text Help offers programs that are available so that multiple users can utilize the same disk, whereas earlier due to the software learning the style of the writer, each student needed a disk.

The use of the portfolio, the digital camera, along with such programs as PowerPoint, allow students with problems in reading or written expression to find success in a way that was not available before our "digital" age (SEDL, TAP into Learning, 2000).

Graphic organizers

One of the challenges that teachers face in the age of high-stakes testing and diverse-ability classrooms is how to cover the entire curriculum. Students learn lots of facts, but often they are not able to visualize how these isolated facts relate to each other. Connecting facts and seeing the big picture or concepts can be challenging for even experienced teachers. (Ellis, 2001). Graphic organizers and frameworks are effective research based strategies developed by the University of
Kansas Center on Research for Learning. Inspiration software has a variety of graphic organizers that can help teachers to frame information so that students see the relational understanding of the instruction. Graphic organizers also provide a means for elaboration and understanding how ideas hang together. This portion of the session will focus on graphic organizers as well as some tips on integrating technology and websites into the graphic organizers.

Internet

The Internet provides a tool that allows the student with learning difficulties an avenue to transcend traditional classroom tools that have previously brought failure. Through the web a student can link to many virtual trips and opportunities and access information about whatever venue "peeks" his/her interest. A list of Internet resources for teachers will also be provided. Evaluation of Internet websites is also important and tips for how to evaluate websites will be reviewed.

Infusing Instructional Media into Preservice and Inservice classes

Those of us who thrive on the wealth of opportunities provided by instructional media need to remember that many in preservice and inservice classes may not have access to technology in their classrooms. Also in certain areas the use of the computer as an instructional tool is just gaining attention. In poorer school districts, a current computer in the classroom is only beginning to happen. Also among teachers, varying levels of expertise as well as desire exist. As preservice and inservice educators, opportunities for them to experience and complete projects involving instructional technology helps them realize the potential for the use of technology in their classrooms. They can also become advocates for accessing different forms of technology for their campuses and classrooms (enc focus, 2000).

This presentation will provide previews of programs mentioned, along with an annotated bibliography of software and sources.
Bridging the Divide for Special Needs

By

Maribeth Montgomery Kasik, Ph.D.

Abstract

Educational Applications of Microcomputers for Teachers of Students With Special Needs are a critical factor in addressing the Digital Divide. Educators often have access to computers, but allow them to sit idle for fear of what to do with them. Access to quality education is about who has and who does not. This gap is often wider for those dealing in special education settings than regular education. The presenter teaches a graduate level computer application class for teachers of students with disabilities. The presentation will highlight the success of the course as well as present samples of student technology projects.

Dr. Kasik will present the curriculum of the course: Educational Applications of Microcomputers In Special Education as well as utilize the techniques she uses for teaching the class to graduate students at Governors State University in Illinois. She will provide participants with resourceful Internet sites as well as demonstrate student power point presentations and created websites.
ENHANCING SPECIAL TECHNOLOGY INSTRUCTION:
IMPROVING METHODS for TEACHERS
in GENERAL EDUCATION

Valerie Larsen, Ph.D.
Assistant Professor of Instructional Technology
School of Education
Indiana University South Bend:

Terri L. Demmon, Ed.D.
Instructional Strategies Coordinator,
University Center for Excellence in Teaching (UCET)
Indiana University South Bend

Abstract: Indiana University South Bend's School of Education endeavors to develop motivated
and committed educators to meet the needs of regional elementary, middle and secondary schools.
In keeping with its continuous improvement goals, faculty initiated an effort to enhance and further
integrate the role of technology in its year-round teacher training. We provide a brief overview of
the content, nature, and concerns with our approaches toward introducing preservice teachers to
adaptive technology. We next describe the role of adaptive technology in the current program with
special emphasis on exploring instructional strategies, techniques and methods that can enhance
the learning for all students. The Special Education program is reevaluating its curriculum to align
with new state standards. At the same time, the general education curriculum has expanded its
venue to address inclusion of special needs, exceptional, and at-risk children. Additional program
analysis is in process via surveys, focus groups and interdepartmental discussions.

Introduction

Indiana University South Bend's School of Education endeavors to develop motivated and
committed educators to meet the needs of regional elementary, middle and secondary schools. In keeping
with its continuous improvement goals, faculty at the IUSB School of Education initiated an effort to
enhance and further integrate the role of technology in its year-round teacher training. As we redesign our
programs to align with new state standards, we are expanding our focus to enhance special technology
instruction for special needs and other diverse populations. In this paper, we provide a brief overview of the
content, nature, and concerns with our approaches toward introducing preservice teachers to adaptive
technology and the various contexts in which those introductions occur.

Review of relevant literature

Over time, the lines between regular and "special" students have become less distinct to parents
and educators as more students are identified in the hazy middle ground of these descriptions (Roblyer
2000). The capacity of technology to empower students with special needs, especially physically disabled
students, has been well documented (Male 1994). The practical means for converting theory into practice
introduced into the classroom include mainstreaming, inclusion, and collaborative teaching or co-teaching

Teachers in general education settings are more likely to adopt technology tools that can benefit
the spectrum of students in a classroom than they are to focus on special needs children alone. Technology
tools available in many of these classrooms are flexible and can be adapted to the needs of individual
students. (Wallacorsa, Bettencourt, & Zigmond 2000; Roblyer 2000). The importance of finding tools that general education teachers can employ for all the students in the classroom has been explored for concept-mapping and organizational tools (Lenz & Schumaker, 1999). Janney & Snell (2000) describe other pragmatic approaches to the what, how, where, when, and with whom lessons are taught - curricular instructional, and ecological adaptations.

Laws, standards and recommended practices pertaining to educational accountability at state and federal levels are widely available. Modifications in adaptive technology within the instructional technology and special education curricula are driven by these regulations and guidelines (Overton 2000). Converting equal access legal theory into actual classroom practice includes strategies like mainstreaming, inclusion, and collaborative teaching or co-teaching. Both special and general educators need to be well aware of the range of special needs that can exist in a classroom. Teamwork skills and collaboration efforts between special and general educators are key to developing the instructional strategies that incorporate appropriate use of technology for special needs students (Ainscow 1999; Wallacorsa, Bettencourt, & Zigmond 2000; Vitello & Mithaug 1998; Vaughn., Bos & Schumm 2000).

**Courses for preservice teachers**

IUSB requires that all preservice teachers take an introductory course (W200) in instructional technology. Starting in the fall of 2001, incoming education majors are required to complete a three credit hour course on technology for teachers. Formerly a one-credit course for elementary majors, the course has been redesigned and particular methodologies are introduced that help address special needs students within a general education setting. Through discussion and reading, students explore the social, moral, and technological issues of educational computing, addressing such topics as adaptive technology (including special education in a general education setting), the gender gap, the “Digital Divide”, and multicultural sensitivity. The course sections are oriented to either elementary or middle/secondary school audiences to better address the varying instructional strategies, techniques and methodologies appropriate to the school populations IUSB teachers will eventually serve. Throughout the course, the instructors emphasize the flexibility of many of the software applications by modeling ways to construct, modify, or develop lesson activities that can optimize instruction for various learners.

Major topics include introduction to operating systems on both Apple and IBM-compatible personal computers, integration of the microcomputer into the school curriculum, and evaluation of computer assisted educational packages. Students acquire an introduction to integrated software packages including word processing, spreadsheet, database and presentation applications, They are introduced to simple web design using Netscape Composer, electronic grade books, concept mapping (Inspiration), a multimedia authoring tool (HyperStudio), and evaluation of various software and utility packages and hardware commonly employed in P-12 education. As part of web authoring instruction, we illustrate the importance of using headers instead of font sizes to provide necessary information for the visually impaired population that uses text readers. With instruction in concept mapping tools, we explain the importance of visual information to learners at all levels as well as the flexibility of letting learners select images or outlined text as an organizational tool. Preservice teachers are trained to apply advanced Internet search techniques on various search engines to locate and evaluate lesson plans, instructional sites and WebQuests on the World Wide Web. The ASSURE Model (Heinich, Molenda, Russell, & Smaldino 2002) employed for evaluation of lesson plans is among the first of various models the students encounter during their years at IUSB. The students routinely access Oncourse, a proprietary, online course management application developed by Indiana University. Analogous to commercial products such as WebCT and Blackboard, Oncourse (Indiana University 2000) contains chat functions, mail, conferencing/discussion groups, and the ability to integrate online testing, Web authoring, and multimedia resources and other tools for Web-based instruction and/or instructional support.

Following analysis of the fall 2001 classes, we plan to further modify the course by including a competency requiring students to illustrate how a project would be adapted for special education students in categories such as physically disabled, learning disabled, etc. They will also be required to demonstrate how their projects address other diverse populations.
In another example of modifying courses to address special needs and diverse learners, a segment on adaptive technology is now included in the capstone course for preservice teachers on track to obtain the state Computer Endorsement for teaching. This course change resulted from the initial research and needs analysis completed in 2000 (and presented at the 2000 SITE conference) directly responding to weaknesses identified through discussions with advisory groups and stakeholders from area schools.

Content and focus of specific courses in adaptive technology

Since 1992, the IUSB School of Education has offered a technology course for Special Education majors (K400 for undergraduates, K501 for graduates). This course has a pre-requisite of Using Computers in Education (W200 discussed above), the common technology course for all Education majors. The K400 and K501 courses taught many of the same skill sets at a more advanced level. In the spring of 2001, the chair of the Special Education program offered a second section of the K501 course with a new approach. The course was re-designed to reflect more of the same topics that are covered in a capstone course within the Computer Endorsement program. The primary skill sets in word processing, spreadsheets and databases were incorporated into the course, but not as a lesson on each topic, instead, word processing is assessed through papers requiring complex layouts, spreadsheets were assessed through case studies on planning field trips or grant money, databases skills were assessed through the development of IEPs within the database structure.

In the K400/K501 course taught for several years, students were exposed to various peripheral devices for special needs through teacher demonstrations. In the prototype course, students were responsible to demonstrate in class the use of various technologies designed for special needs students. These technologies were gathered from a variety of sources, some students had access to K-12 schools' equipment because they worked as aids and were given permission to bring the equipment to class one day; other students had special needs children and so were using such equipment in their homes for support in the child's education; another source came from the University, which provides equipment for special needs students on campus and, where feasible, instructional demonstration purposes. Two additional components were added to the course, software evaluation and staff development issues. The Software Evaluation component consists of activities starting with students contacting local schools to obtain copies of current software evaluation instruments used in schools, and then turning to literature to obtain additional examples of software evaluation instruments. After class discussions on issues to consider when selecting software for the classroom, students are divided into teams. With the materials collected in hand, each team works to design the best software evaluation tool to meet their needs. Once the instruments are completed, they are usability tested among the classmates. Each classmate writes a review of the software evaluation tool they used (not the one they developed), the reviews of each team's software evaluation tool is collected and shared with the respective teams. With the additional information to consider, the team revises their instrument and submits a final copy for grade. The Staff development component consists of activities where students are required to complete library searches for articles on staff development, share the information with the class and submit summaries and reflections on the information gathered. The students are then divided into teams based on interests and skill levels on technology topics. Each team presents a one hour Staff Development Workshop for the class. The topics range from the American Disabilities Act and its impact on technology to Inspiration, Hyper studio, Educational Games, etc. These workshops provide an opportunity for students to learn the fundamentals or expand their experiences with a variety of software packages available in many schools, enabling them to focus on real world strategies for special needs students.

Special needs equipment and software at IUSB

Cost and compatibility of special needs hardware and software form a source of ongoing concerns. The relatively limited market for assistive software and hardware is sufficient by itself to keep prices high. The rate of change for operating systems and underlying personal computers or other large-scale digital software often results in compatibility issues. Several items purchased in spring, 2000 are incompatible with the Macintosh G4s installed in the education lab. Similar difficulties are anticipated with the spring upgrade to multimedia PCs in the same lab. The rapid changes in technology can also adversely affect
resident equipment and software. Like other universities in Indiana, IUSB is facing severe budgetary constraints and the prospect of more draconian measures in the near future. One consequence will likely be careful attention to cost/benefit analysis where expensive purchases might benefit one or a few students or faculty.

The Office of Information Technology and the School of Education worked jointly to provide a variety of equipment that would be available for special needs students but also available for educational and instructional purposes. A partial inventory of the equipment includes Touch Screens by Edmark, IntelliTools, IntelliKeys, right and left hand keyboards, a trackball mouse, Window Eyes, ZoomText, a TeleSensory closed circuit television for text magnification, various types of switches, a Slim Armstrong mount, Discover Kenex, etc. We were also able to install copies of word prediction software (Co-Writer and Write Out loud). In addition to many of the items listed above, the Schurz Library also provides special needs students with access to voice recognition software (Dragon Naturally Speaking), a Kurzweil 3000 reader, and Open Book Unbound. Male (1994)

Limitations:

Many of the classrooms used by the School of Education faculty lack Internet connections. Installation of newer technologies was delayed for many years by university plans to move the School of Education. Now, severe funding cuts have left the faculty in classrooms with insufficient technology support. The IUSB Office of Information Technology (OIT) updated the infrastructure to the primary education building in summer, 2001 and is evaluating cost of Internet wiring and investigating some prototypes for wireless technology in some classrooms and the student lounge. Without scheduling classes periodically into the already-overbooked campus technology labs, it is difficult to model the technology integration. Several faculty members develop Web sites or employ Oncourse for web-based instructional support when the Internet is not available in a classroom.

Budgetary concerns, discussed previously, and faculty recruitment are also issues. Given the tight employment market for some years, there is ongoing concern about attracting sufficiently qualified personnel in the Special Education program and to a lesser degree, in the Instructional Technology program. In both programs, IUSB has been fortunate in acquiring a talented, dedicated pool of adjunct faculty.

Future Directions

In preparation for an upcoming NCATE accreditation, an education task force is conducting a needs-analysis of all stakeholders including area schools through the use of surveys, focus groups and inter-departmental discussions, including special education. Surveys were developed and mailed. An assessment grant has been obtained for analysis of the survey returns.

Faculty in the School of Education are gradually infusing newer technologies into their classroom activities. One of the critical roles of faculty is, of course, to model the use of technology in the classroom. We are attempting to model attentiveness to the needs of all learners throughout our courses by discussing diversity in the classroom, promoting visual and written literacy, and optimizing techniques, strategies and methods to reach a broad spectrum of students.

National Technical Institute for the Deaf  
Rochester Institute of Technology  
United States of America

Abstract: Each summer, the National Technical Institute for the Deaf (NTID) offers a one-week workshop for approximately 200 deaf and hard-of-hearing high school students, called Explore Your Future (EYF). These EYF students sample a variety of activities that are designed to educate them on different career possibilities. The Holland model is used to help students understand the various career areas and skill requirements.

One of the author's of this paper was responsible for the "Investigative" Holland category and was charged to set up a technology activity. It is not difficult to set up an enjoyable activity that uses technology, but the authors' wanted to have an outcome assessment in place to see if the students gained both an understanding of what the Investigative type of career was and to see what technical concepts were learned during a 45 minute activity. The technical activity and its outcomes are described in this paper.

Introduction

Technical educators of the deaf often wonder if and how quickly deaf and hard-of-hearing students can learn concepts pertaining to computer hardware, computer software/programming, and interfacing the hardware to the software. For the summer 2001 EYF activity, one of the authors developed a 45-minute activity for deaf and hard of hearing high school students enrolled in the Explore Your Future (EYF) program. This activity was developed around Robolab™ software programs in conjunction with Lego™ toys equipped with motors, lights, touch and infrared sensor peripherals interfaced to the Lego RCX controller. The authors also developed a 10-question assessment that tested the students' knowledge before and after the 45-minute activity.

Although students enjoyed these types of activities in years past, nobody really knew if and how much information they learned about the career area and about the specific content being taught. This activity needed an assessment in place to measure the outcomes that showed how much the students actually learned. The current study was an attempt to implement an evaluation process for this EYF technology activity.

The Study

A total of one hour was allotted to this technology activity. This included the assessment and explanation that took about 10 minutes before and five minutes after the activity. The learning activity itself was 45 minutes, with only five minutes of explanation and 40 minutes of hands-on activities.

During the 45 minute activity, students had to: set up and connect the hardware input and output devices, including touch and light sensors; set up and connect output devices, such as lights and motors; interface the input and output devices to the RCX controller; select a correct Robolab software program to run their hardware configuration; download the correct Robolab program to the RCX; run the hardware using the software program which they downloaded to the RCX.
Two questionnaires were developed, one pre and one post activity that consisted of 10 questions on the actual programming activity plus 4 other questions to find out about student demographics. The questionnaire had to be very brief due to the limited time available for students to fill it out. The 10 activity
questions dealt with specific technical details, two about input and output hardware, four about the software and two questions about the interfacing aspects of the activity. The questions had various degrees of difficulty, some fairly obvious and some were quite difficult. Approximately 200 students were asked to fill out the pre and post activity questionnaire.

7. What do these 2 software commands do?

? I don’t know.
? Start the program, turn the motor connected at Port A on so that it rotates in this direction shown at a speed of 5.
? Start the program, turn 5 motors on until the program tells it to stop at point A.
? Go when the motor 5 starts to turn.
? Turn port A item on 5 times

Figure 3: Sample of One EYF Software Question on the Questionnaire.

Findings

There were 215 deaf and hard of hearing students (93 females and 122 males) who participated in the “Explore Your Future” program. The average age for females (17.3) and males (17.5) was statistically similar.

With respect to previous experience with programming, there was a statistically significant gender difference, \( \chi^2 = 8.56, df = 1, p = .0034 \). Only 4% of the females had programming experience prior to EYF compared to 17% of the males. Interestingly, there were also gender differences with respect to students’ interests in pursuing an investigative programming career. A 2(male vs. female) \times 2(pre vs. post EYF interest) repeated measures analysis of variance showed that males expressed a higher interest in an investigative field, \( F (1, 199) = 13.2, p = .0004 \). Furthermore, there was a significant interaction between gender and interest, \( F (1, 199) = 8.1, p = .0050 \), resulting from the fact that males actually increased their interest in investigative programming from pre to post EYF experience (M = 3.0 to 3.5 respectively). In contrast, females showed no change in interest from pre to post EYF (M = 2.7 to 2.76).

Regarding students’ understanding as to what an investigative type of career was, there was also a significant increase in understanding from pre EYF to post EYF responses, \( \chi^2 = 75.7, df = 16, p = .0001 \). Prior to EYF, 44% of the students indicated they “did not know” compared to only 9% at the end of EYF. Similarly, only 34% indicated they understood that computer programming was an investigative type of career while 75% indicated this after their EYF learning experiences.

In terms of learning and knowledge growth relative to hardware and software, there were no gender differences for pre and post EYF responses on the hardware questions, \( F (1, 217) = 1.6, p = .21 \) and the software questions \( F (1, 191) = 3.6, p = .06 \) and no significant interactions. As a result, overall student learning and knowledge growth were examined regardless of gender. There was a significant difference between the students pre-EYF survey responses for the hardware questions and their post-EYF responses, correlated \( t = -12.88, df = 222, p = .0001 \). Similar significant results also occurred for the students pre and post EYF responses to the software questions, correlated \( t = -25.82, df = 193, p = .0001 \). Table 1 shows the students’ pre and post EYF mean responses and standard deviations for hardware and software knowledge.
Table 1: Pre and Post EYF Student Responses on Software and Hardware Questions

Another area of learning was relative to interface connections for input and output devices. For input devices, on the pre EYF survey, student responses indicated that 83% "did not know" with only 8% getting it correct. In contrast, the students post EYF responses showed that only 5% of the students "did not know" with 59% showing a correct response. No gender differences occurred. Similar growth patterns occurred for the question on connections for the output devices. The students pre EYF responses showed that 83% "did not know" and only 8.5% got it correct. At the end of EYF 58% got it correct and only 7.5% "did not know."

Conclusions

The students' pre and post EYF responses showed that a 45-minute activity using a Lego RCX controller and the related input and output hardware along with Robolab software can be an effective way to introduce computer software, hardware and interfacing concepts to deaf and hard-of-hearing high school students. Such an activity can also help clarify deaf students' understanding of an "investigative type of career," in addition to giving them a deeper informational basis for career decision-making when planning their college studies.

There was a statistically significant increase in pre and post activity results relating to the understanding of the investigative career category, regardless of gender. Prior to the EYF activity, 44% of the students stated that they "did not know" what an investigative type of career was compared to only 9% after the activity. Similarly, 35% knew that computer programming was an investigative type of career prior to participating in EYF, while 75% correctly indicated this after the activity.

The findings also showed a statistically significant increase in pre and post activity understanding of hardware, software and interfacing computer concepts, regardless of gender. For hardware input devices, for example, 83% of the students indicated that "they did not know" what an input device was, with only 8% getting the answer correct, whereas after the activity 5% of the students "did not know" with 59% showing a correct response.

This study uncovered some interesting gender differences among deaf and hard-of-hearing high school students. Prior to the EYF activity, only 4% of the females had programming experience compared to 17% of the males. There were also gender differences with respect to students' interests in pursuing an investigative type of career. Males increased their interest in investigative programming from pre to post EYF. In contrast, females showed no change in interest from pre to post EYF activity. These findings reinforce the need to have female role models helping lead these types of activities to further encourage more female participation in technology-related careers.

Acknowledgements

The authors would like to thank Dianne Heyden, Ron Till, and Scott Wolf at NTID for their assistance in implementing this EYF activity. Thanks also to Dianne Heyden for her assistance in running the activity and assisting with the student data collection. A big thanks also to Rob Adams and Jean Bondi-Wolcott, EYF administrators at NTID, for their assistance in acquiring student data and for financial support in acquiring needed equipment for this activity.
Technology Integration into Special Education Coursework: 
Instructor-Focused and Learner-Focused Integration

crawford@cl.uh.edu

Abstract: Instructional technology within the area of special education expands the teacher candidate’s opportunities to communicate with learners and their families. The support that can be available through the use of technology that aids instruction is an important element of the special education methods coursework; however, special education is an area that offers numerous assistive and adaptive activities and tools. Teacher candidates must have instructional technology integrated into the special education methods courses so as to further develop their instructional tools from which to choose, at both the instructor-focused as well as learner-focused integration levels within the learning environment.

Introduction

The integration of technology within a special education learning environment, especially significant within a methods course for teacher candidates, emphasizes the significance of technological tools associated with instruction as well as their appropriate and successful uses. The modeling of both instructor-focused and learner-focused uses of technology is of primary importance for teacher candidates. However, special education university faculty who facilitate special education methods courses may not have had the opportunity to research the integration aspects of technology at any significant length.

Special Education Areas of Coursework

Special education is a specialized area of instruction that maintains a stronghold within numerous areas of expertise. For example, special education not only focuses upon early childhood through secondary education, but the areas of focus also encompass the following specialized areas of influence: child development and learning; curriculum development and implementation; family and community relationships; assessment and evaluation; professionalism; and, application of technologies. From these specialized areas, the curricular scope and sequence is developed.

Supportive Learning Environment

As the topics of coursework are designed, numerous aspects within each of the courses must be fully developed. Expertise must be maintained within the areas of: instructional adaptation; multiple instructional strategies; motivation to learn; classroom management; assessment of learning; professionalism; and, universal design through technology. As may be gauged from the list of areas to be fully developed within the curricular scope, any entity that has the ability to aid in the dispersal of knowledge and aid the learner towards higher order thinking skills, is greatly desired. The instructional elements to be integrated into the learning environment, at both the instructor-centered level as well as the learner-centered level, are the following elements:

- Facilitator-Centered Elements
  - Philosophical Underpinnings: Behaviorist - Cognitivist - Constructivist
  - Clear Objectives
  - Comfortable Implementation
  - Assessment Methods
- Learner-Centered Elements
  - Clearly Articulated Expectations
But this is only at the teacher candidate's level of instruction. The teacher candidate is also offered the opportunity to delve into the technological tools available within the special education classroom environment. As a basis towards understanding the teacher candidates explore the instructional technology tools available, an initial review of significant areas of importance. These instructional design considerations are: learning environment enhancement; instructional implementation; ease of use; access, which may be further delineated as learner and the family support; and, monetary constraints. Once these areas are appropriately and successfully reviewed, then the instructional technology tools that are available and appropriate for the special education classroom environment are reviewed:

**Teacher Candidate Research and Integration**

As presented at nationally recognized teacher education conferences (Crawford & Martin, 2001), teacher candidates are beginning to develop an understanding of the forms and functions pertaining to technology and its appropriate and successful integration into the learning environment. Following are samples of technology that students implemented within the special education methods coursework:

- Loading the Dishwasher: the use of digital camera, graphs, tables, data collection forms, student-cropped photos to focus on action of loading so students with disabilities can use photos to follow steps accompanying directions in words include a literacy component.
- Going to the movies: movie World Wide Web sites, digital photos, clip art integration, data collection sheets, tables, charts, graphs.
- Going to the movies: Selecting a movie: newspaper ad & theater website; reading reviews on websites; accessing the "Connect" bus schedule at their website; mapping route to theater using Yahoo maps; Used Kodak picture program to crop photos, clip art. E-mailed a friend to join. Each of the steps the teacher candidates completed in order to develop a unit for the special education learning environment offers real-world opportunities for skills development and procedural understanding pertaining to technology integration and skills.

**Conclusion**

In conclusion, the significance of technological tools at both the instructor level and the learner level, as well as process versus product within the educational environment, are imperative elements that must be emphasized within the special education methods coursework as well as PreK-12 learning environments. However, a strong focus upon instruction must be maintained in order to ensure appropriate instructional design of learning opportunities. The availability of technological resources has overcome the desire to "reinvent the wheel", which has been a major consideration over the previous ten year period, and now the focus must be revised towards the appropriate and successful integration of technology within the special education environment.

**Reference**

Technology is being integrated into teacher education today, in preparing general educators and special educators, designing and planning curriculum content, and impacting delivery at both the preservice and in-service levels (Ludlow, 2001). In order to meet today’s societal expectations, special education teacher preparation programs are placing more emphasis on providing their graduates with competencies related to the infusion of special education technology (Langone et al., 1998). An impetus to establishing current technology standards and competencies for special education teacher preparation programs include influential entities such as The National Educational Technology Standards (NETS) an initiative of the International Society of Technology in Education (ISTE), The National Council for the Accreditation of Teacher Education (NCATE), Council for Exceptional Children (CEC), and many state licensing agencies (Ludlow, 2001). Federal and state initiatives (i.e. Preparing Tomorrow’s Teachers to Use Technology, http://www.pt3.org) provide resources, skill training, and an investment in technological advancement that otherwise would not be possible.

Smith (2000) states “If we expect preservice special education students to be prepared to integrate technology in the K-12 environment they must see the technology (assistive and instructional) modeled by their instructors rather than simply being told about its potential and how it might be effective.” (p 60)

One might ask the obvious question, Is modeling the use of technology enough? Recent research suggests the need to go beyond modeling and provide meaningful and real-life opportunities for hands-on integrated technology within the curriculum (Messenheimer, et.al. 2001).

Preservice and in-service educators need to acquire technological competencies for implementing computer support in the learning process. These competencies can be achieved through meaningful technology integrated projects infused within methodology courses and field experiences (Ludlow, 2001). Such projects would allow the preservice/in-service special educator to design, plan, and implement technological tools and strategies into the instructional process. Jonassen, Peck and Wilson (1999) states “student thinking is engaged by activity.” (p 2). Integrated technology projects could be viewed as learning tools that can be used to help the learner construct their own meaning and assist in guiding the meaning making process within the learner. Where does one begin to integrate technology and authentic student projects within the curriculum? To what extent should the role of technology be emphasized in the curriculum and be required by the preservice/inservice learner?

This presentation highlights specific examples of meaningful technology integrated projects and related research that helps answer the above preliminary questions. Technology projects shared will include both assistive technologies and instructional technologies that can be utilized across computer platforms (Mac & PC) and across the special education teacher preparation curriculum. During this presentation presenters will share their technology integration into an array of disability areas (learning disabilities, behavioral disabilities, deaf education and early childhood special education) and related coursework.

Integrated Technology Examples

Integrated technology projects provided the opportunity for university students to apply fundamental theory with essential teaching strategies taught in special education courses to create an innovative mechanism for learning to take place. Through the implementation of technology, twenty first century preservice and in-service special educators can provide their learners with choices and activities that match their learning styles and specific learning needs. Such examples are briefly described below:

**PowerPicture Books and Vocabulary Activities**
Student-made PowerPoint Picture Books and interactive lessons created in MS PowerPoint provides interactivity through a customizable electronic learning. Developing a hypertext learning activity, pre-service teacher begin to go beyond understanding and apply technology to develop students' higher order thinking skills, motivation, and creativity.

**iMovies and multimedia**
Using iMovie students generate literacy projects that essential come to life. Careful, planning of instructional outcomes and the assessment of these outcomes occurred. Collaborative learning activities provide the guidance and classroom environment to discuss principles of learning outcomes, benchmarks and assessment.

**Web quests and Web-based Learning Environments**
Experience and exploration are the cognitive backbone to preservice teachers projects involving the understanding and creation of webquests and existing web-based learning environments (i.e. www.literacyaccessonline.com). Student-created detail lesson plans, centered on the integration of innovative web-based learning tools provide new and innovative opportunities for student-centered learning in the special education classroom.

**Assistive technologies**

Taught in a stand-alone course and integrated within the special education methods classes, preservice special education teachers look closely at meeting the specific needs of the learner through the use of assistive technology. Through integrated assistive technology projects, preservice special educators discover their teaching passion and create a resource ready to be “carried out into the field” and provide to other educators, cooperating teachers, and parents on the “how to” integrate assistive technology within a particular content area or skill area.

**Providing Learner Support through the Teacher Preparation Curriculum**

Within the special education teacher preparation program students are taught and encouraged to utilize available technology resources on both on campus and within the community. The College of Education and Human Development Technology Resource Center is the first stop. The Technology & Resource Center is open 80 hours a week serving the 223 faculty, 47 Staff, and 4,905 students of the College of Education and Human Development. Usage rates at the Center averaged 1,570 patrons per week during the Spring Semester 2001, totaling over 25,000 patrons for the entire semester. Twenty-six education classes teach in the 2 computer labs. Students and faculty have a wealth of computer resources (hardware and software) and services to assist in building basic technology skills needed to generate effective technology projects. Computer labs and technology smart classrooms allow special education faculty and students to demonstrate technology and showcase and discuss hands-on technology projects and activities within the learning process.

**Guidelines for Successful Integration**

This presentation will also share essential guidelines that help assure the usefulness of technology integration into the special education teacher preparation curriculum. Listed below are a few examples of such guidelines:

- required assignments “force” students to practice technology and begin to develop skills
- learned to work and demonstrate across computer platforms, as students are stymied by this process
- created and bridged preK-12 schools and university program through partnerships that allow university students to “kid test” their ideas and refine the development process, thus allowing the preK-12 student with disabilities to clarify the problems.

**In this session, participants will:**

- Explore through demonstration, common technology projects, and real classroom examples of integrating technology into the special education curriculum.
- Exchange through an open discussion, other technology tips and strategies in using technology in classroom instruction and possible benefits to preservice and inservice special educators and in essence students with disabilities.

**Participant Outcomes:**

Through the implementation of technology, participants will be able to generate ideas and projects that meet their specific needs of their programs and provide the learners within these programs with choices and activities that will enhance the quality of special education.

Bridging the Divide for Special Needs

Paper or Workshop to be prepared for Conference

By

Maribeth Montgomery Kasik, Ph.D.

Abstract

Educational Applications of Microcomputers for Teachers of Students With Special Needs are a critical factor in addressing the Digital Divide. Educators often have access to computers, but allow them to sit idle for fear of what to do with them. Access to quality education is about who has and who does not. This gap is often wider for those dealing in special education settings than regular education. The presenter teaches a graduate level computer application class for teachers of students with disabilities. The presentation will highlight the success of the course as well as present samples of student technology projects.

Dr. Kasik will present the curriculum of the course: Educational Applications of Microcomputers In Special Education as well as utilize the techniques she uses for teaching the class to graduate students at Governors State University in Illinois. She will provide participants with resourceful Internet sites as well as demonstrate student power point presentations and created websites.
GIDL-PC: a Global Infrastructure for Distance Learning for the Physically Challenged

Dr. Warren Moseley
Department of Computer Science
Western Illinois University
Macomb, Illinois 61455

Abstract

This paper describes the prototype of a global infrastructure called GIDL-PC (Global Infrastructure for Distance Learning for the Physically Challenged). This system supports teaching and research sharing across interrelated disciplines focusing attention to the needs of the physically challenged (PC). Inter-linking of resources provides for a standards-based architecture-centric joint action global infrastructure. The goals of the project include developing new concepts to understand, analyze, invent research processes, and provide tools to help improve and manage knowledge and resource sharing.

Introduction and Background

The Americans with Disabilities Act of 1990 (ADA) is a United States federal anti-discrimination statute designed to remove barriers that prevent qualified individuals with disabilities from enjoying the same employment opportunities that are available to persons without disabilities. ADA stipulates that employers must make reasonable accommodations for those with disabilities. In order to accommodate ADA at the pace necessary to keep up with demands of industry, research must be shared through some standards and some common infrastructure.

In his yearly address to the National Academy of Sciences Dr. William Wulf suggested that progress in science and technology will depend on the participation of a global research community. In addition it will need broad public trust and support. The main goal of this research is to provide an integrated platform for educational research sharing for researchers and teachers working in the area of technological support for the physically challenged. Distance Learning provides a natural way for teachers to share information with each other, and with the participants in their classrooms especially when accessibility is an issue.

Resource sharing up to now has been through publications, conferences, and web pages. This project will extend the classroom past document and data sharing to integrated teaching and research communities that share documents, objects, data, hardware, lectures, power point presentations, multimedia presentations and software through standardized interfaces that simplify system usage.

Expandable repositories of material adapted to the physically challenged will provide a growth foundation for sharing new plans, new research ideas and educational results. It will allow participation in real-time experimentation with subjects in multiple locations around the globe. Sharing reduces duplication of hardware, software and other costly resources.

Other Research Sharing Efforts

The idea of people sharing their information and ideas is not a new subject to the research community. Areas such as Law Enforcement, Education and efforts such as the Center for Coordination Sciences at MIT demonstrate large research-sharing efforts. Somehow the Software Engineer's supporting research for the physically-challenged have kept a local focus. Given a simple standardized robust infrastructure, research, teaching, presentations and resources can now be shared globally. This prototype infrastructure produces a distributed object reference architecture that is standards-based, and architecture-centric.

Moseley described a reference architecture that serves as a context for design environments to create applications that allow the participation of people who are physically challenged (PC). This research is now extended to include the global community doing research for the physically challenged.

Some of the tools and techniques used in GIDL-PC are the Unified Modeling Language (UML), web-based documentation (preferably the eXtensible Markup Language - XML), OpenDoc, a CORBA compliant ORB with IDL (Interface Definition Language) as the preferred interface specification, and the World-Wide Web. IDL facilitates a multi-platform and multi-language, object interface.

Figure 1 shows a cooperative project between Western Illinois University in Macomb Illinois, St. Andrews Presbyterian College in Laurinburg, North Carolina, Abbot Laboratories in Laurinburg, NC, The Technical University of Ostrava in the Czech Republic, and The Technical University in Kaiserslauten, Germany.
This research explores real-time object-based direct manipulative user interfaces\textsuperscript{9} that are specially enhanced for the PC. The type of user interfaces used in Moseley’s research\textsuperscript{10} (eye-trackers, sensor-controlled processes, special hardware devices, etc) can often be prohibitive in cost when duplicated across platforms for distributed locations. Sharing the access to objects that control distributed devices provides a cost-effective means of research into this area.

This project goes deeper than just sharing documents and data. A researcher will access the GIDL-PC through the event services manager of a CORBA (Common Object Request Broker Architecture)\textsuperscript{11} Compliant Object Request Broker (ORB). It was critical to the universal nature of this project that it be open and vendor neutral. The OMA (Object Management Architecture) of the Object Management Group (OMG)\textsuperscript{12} is the only distributed component architecture available today that is open and vendor neutral.

GIDL-PC requires both time critical events and non-time critical events. For non-real-time transactions any ORB will suffice. There are several ORB’s that support real-time services but GIDL-PC decided on TAO\textsuperscript{13} as the standard for real-time events. In addition to sharing objects this project is sharing real-time location data via worldwide GPS Satellite Receiver. Software written by a researcher in Macomb, Illinois can be used by a PC person’s wheelchair in the Czech Republic.

ORB’s allows for connections of objects from the repository in any location to access the objects in any other location without knowing the location of the particular object. If not for research sharing through CORBA ORBs, each location would have to have duplicate installations. Duplication implies the possibility of configuration problems, as well as installation problems at either place in the project. As it stands now when the ORB places a request for an object one automatically gets the latest version.

A constant problem for emerging countries is the availability of resources. With the emergence of free ORB’s such as TAO, ORB-it\textsuperscript{14}, JavaORB\textsuperscript{15} the ability for these countries to provide excellent software development talent has increased the potential to produce cost effective solutions. The PC technology marketplace is not a volume-intensive market, and hence cost-effective solutions have not been prolific.

OMG - Object Management Group

In June 1995, an OMG-hosted meeting of all major methodologists\textsuperscript{16} (or their representatives) resulted in the first worldwide agreement to seek methodology standards, under the aegis of the OMG process. The UML is nonproprietary and open to all. It addresses the needs of user and scientific communities, as established by experience with the underlying methods on which it is based. This standardization of the UML boosts the possibility of a global research sharing platform, in that the modeling process is now standardized, and is available under the vendor neutral and open nature of the OMG\textsuperscript{17}. The parameters, vendor neutral, open architecture and standardization are essential to the success of such an effort.

The Unified Modeling Language (UML) is a language for specifying, visualizing, constructing and documenting the artifacts of software systems, as well as for business modeling and other non-software systems. The UML represents a collection of best engineering practices that have proven successful in the modeling of large and complex systems. It is important to the success of a project such as GIDL-PC to have a unified modeling language, and a unified modeling process. The approach to modeling promotes reuse and reduces duplication of effort.

Research Processes

Processes are viewed as being made up of activities that are inter-connected via dependencies along which resources flow. There are several kinds of dependencies\textsuperscript{18} including flow (one producer to one consumer), fit (many to one), and sharing (one to many)\textsuperscript{19}. Dependencies can be associated with coordination mechanisms\textsuperscript{20}, which are simply processes whose purpose is to manage that dependency. Dependencies and coordination mechanisms\textsuperscript{21} represent a powerful abstraction mechanism for revealing the key features of a process while hiding implementation details.

The OpenDoc Vision

Apple Computers had a grand vision for the future of computing. It was called OpenDoc\textsuperscript{22}. OpenDoc promised to end the age of bloated do-everything applications by providing an architecture where users could mix and match collections of highly focused “containers” or “parts” to suit their needs. Tough times hit Apple and they abandoned OpenDoc for economic reasons. Although OpenDoc in its original format is not used in GIDL-PC the concept is embraced in all aspects of its design and implementation.
Document Sharing is also important

Document sharing in GIDL-PC is also a very important component. The OMG is integrating XML into the CORBA technical infrastructure, so that new XML-based applications will plug and play with current applications. This was the goal of the original OpenDoc effort. Document sharing is enhanced by the eXtensible Markup Language (XML). XML is an extension of SGML, the Standardized General Markup Language. In XML, however, you can define your own tags (hence the “eXtensible”). Each XML file is prefaced by a link to Document Type Definition that describes the tags it contains and how they may be used. The next version of Microsoft Office will use XML as its standard file format.

XML’s goal is to facilitate the exchange of data and documents between applications (and platforms). It will make it easy to edit the same file in different applications, each one excelling at a specific task.

GIDL-PC is architecture-centric, and this center is CORBA. CORBA encompasses a series of standards and protocols for inter-process communication in a heterogeneous environment. Using CORBA, researchers can easily write applications that can be tailored for multiple platforms at once, in any number of languages. It thus comes as no surprise that the CORBA specification has caught on so quickly as the standard for interprocess communication, particularly in the research community.

The Object Request Broker (ORB) describes a “software bus”, a mechanism which handles communication between distributed objects. The ORB allows for client-server interaction between heterogeneous objects distributed over a wide-area network with meta-information describing the objects in a system. Through a standard interface (IDL) an object may access other objects as a client without prior knowledge of their existence or location. Any object connected to the ORB can play the role of both a client and server object. That is, it can initiate calls to other objects and respond to requests for services from other objects on the ORB. See the figure below.

Figure 2

At the heart of every CORBA application are objects. Objects reside on various machines throughout the distributed environment and are tasked with performing duties defined by their implementation and interrelationship. In the standard two-tier architecture, the objects are often thought of as the servers in the system. However, unlike such standard servers, objects have the ability to move around if needed. Approximately one year into a two year research cycle, Western Illinois University joined this effort. The server objects were move from computers at St. Andrews Presbyterian College, and Abbott Laboratories in Laurinburg, North Carolina without interrupting the flow of activities of the globally distributed researchers. For a research sharing effort such as GIDL-PC this is critical.

A client communicates to an object through an object reference. This is a pointer to the object that allows requests for operations and data access to be sent from the client to the server via an ORB.

Every object on the ORB must have an implementation. This implementation is code written to perform tasks on the server machine. In other words, the implementation is what does the actual work of the object. An implementation can be in any language. It is allowed to perform tasks supported by the language, operating system, and underlying hardware. GIDL-PC examples include wheelchair add-ons, digital manipulative devices, eye tracking mechanism and unique devices for each of the physically challenged. In addition to code designed to interface with a legacy library, it was necessary in GIDL-PC to have a common interface so that it was comfortable for the researchers to interface to the environment. KDE and GNOME are Linux-based user interfaces that are CORBA Compliant.

There are two common ways in which a client can receive an object reference by using interoperable object references (IORs) or by using the naming service. Every object on the ORB has an IOR. The IOR is a global identifier string that identifies the machine on which its associated object is located and the interface that the object supports. If given the IOR for an object, a client can use standard function calls on the ORB to turn it into an object reference. With the information contained in the IOR, the ORB knows what type of object is being referenced and the machine to which all requests should be routed.

**Wide Area Networking and GIDL-PC**

The World-Wide Web and the ease of access to the Internet is now radically changing our perception of worldwide distributed systems. Such systems should allow us to easily share and exchange information. This also means that it should be easy to track sources of information, even if these sources move between different locations.

Wide-area networks, such as the Internet, offer further motivations for adopting an event-based style. For one thing, the vast number of potential generators of events creates an opportunity for the development of novel applications that can effectively fuse the information associated with different events. Moreover, many existing applications that are already designed around the notion of event interaction can be increased in scale through the global connectivity provided by a wide-
area network. For example, a quadraplegic in Laurinburg, N.C needs support software for a robotic feeding mechanism to assist in serving food to this PC person. At the Technical University of Ostrava there is seminal research in the area of robotic feeding. Through GIDL-PC it is possible to demonstrate the feasibility of shared distributed robots and feeding mechanisms. In general, the asynchrony, heterogeneity, and inherent high degree of loose coupling that characterize wide-area-network applications promote event interaction as a natural design abstraction for a growing class of software systems.

The simplest way for a client to get the IOR of a server object is through the naming service. The CORBA COS (Common Object Services) Naming Service provides a tree-like directory for object references much like a file system provides a directory structure for files.

Object references are stored in the namespace by name and each object reference-name pair is called a name binding. Name bindings may be organized under naming contexts. Naming contexts are themselves name bindings and serve the same organizational function as a file system subdirectory. All bindings are stored under the initial naming context. The initial naming context is the only persistent binding in the namespace.

For an applet or application to use COS naming, its ORB must know the name and port of a host running a naming service or have access to a string initial naming context for that name server. The naming service can either be the IDL name server or another COS-compliant name service.

More on COS Event Services

GIDL-PC is a network-based software system constructed as assemblies of loosely-coupled components. A promising approach to supporting component-based systems is the so-called event-based or implicit invocation architectural style. Under this style, component interactions are modeled as asynchronous occurrences of, and responses to, events. The CORBA event model is the basis for events in GIDL-PC.

The CORBA Event Service introduces the concept of events to CORBA communications. An event originates at an event supplier and is transferred to any number of event consumers. Suppliers and consumers are completely decoupled: a supplier has no knowledge of the number of consumers or their identities, and consumers have no knowledge of which supplier generated a given event.

In order to support this model, the CORBA Event Service introduces to CORBA a new architectural element, called an event channel. An event channel mediates the transfer of events between the suppliers and consumers as follows:

1. The event channel allows consumers to register interest in events and stores this registration information.
2. The channel accepts incoming events from suppliers.
3. The channel forwards supplier-generated events to registered consumers.

Suppliers and consumers connect to the event channel and not directly to each other. From a supplier's perspective, the event channel appears as a single consumer; from a consumer's perspective, the event channel appears as a single supplier. In this way, the event channel decouples suppliers and consumers.

CORBA specifies two approaches to initiating the transfer of events between suppliers and consumers. These approaches are called the Push model and the Pull model. In the Push model, suppliers initiate the transfer of events by sending those events to consumers. In the Pull model, consumers initiate the transfer of events by requesting those events from suppliers. Both types are important to the GIDL-PC researcher and the users alike.

A key issue of event services is quality-of-service (QoS) in a real-time situation such as controlling latency, throughput and jitter end-to-end. In GIDL-PC we needed a communication model that not only de-coupled suppliers from consumers but simultaneously supports advanced quality of service (QoS) properties and event filtering mechanisms. The CORBA Notification Service provides a publish/subscribe mechanism that is designed to support scalable event-driven communication by routing events efficiently between many suppliers and consumers, enforcing various QoS properties (such as reliability, priority, ordering, and timeliness), and filtering events at multiple points in a distributed system.

Figure 3

In classic hard real-time systems the timing constraints are an integral part of the application. If these constraints are not met then the application is not correct. Speed or performance is not necessarily the issue. Predictability is. Speed and performance can contribute to meeting demanding timing constraints. However from a design standpoint the concern is that in the worst case situation the timing boundaries are not exceeded. Guaranteed behavior is required. Best effort is not sufficient. Average performance is not meaningful, but, bounded limits are.
For the real-time portions of GIDL-PC we chose the TAO's open source model and configurable design to enable the developer to understand exactly the intent of the software, and to select only those elements that are required to solve the problem at hand. Figure 3 shows a diagram showing the real-time portions of the TAO ORB. TAO can be configured and compiled to exactly match the need of an embedded systems designer.

Foundation of the Research Processes

Because the focus of this project is research-sharing, it is important that the process that controls the interaction of research participants be based on a solid theoretical foundation. At the MIT Center for Coordination Science significant research in the area of coordinated processes is being conducted. However, the foundation of these processes is not based on a solid theoretical foundation.

To correct the ambiguity Vondrak introduced Interaction Coordination Nets (IC-Nets) to represent a tool that provides for concurrent threads for coordinated process management and control. These IC-Nets provide a graph-grammar petri-net foundation for the coordination of networks. Vondrak originally used these to represent steps in the development process, but has since extended these to include process interactions and coordination in actual programs. Moseley extends IC-Nets to the area of coordinated process for people who are physically challenged. This includes interface processes as well as software processes.

The processes modeled using IC Nets are inherently concurrent and often distributed. Synchronization of object interactions is simplified by the visual nature of IC-Nets.

Importance of User Interface

As important as the theoretical foundations are for a solid support for GIDL-PC, the simplicity of the interface, and the consistency by which the researchers interface to the system are equally important. Simplicity of interface has become a consistent thread for the research for people who are physically challenged. The GNOME Interface provides a simple connection to the CORBA foundation that is the underpinning of GIDL-PC. It utilizes the GTK+ toolkit which requires the use of the IDL as the mechanism of linking components to the GIDL-PC desktop. In order to execute a program built with the GTK+ toolkit one must define the interface of the program to the environment by use of IDL. This encourages a standard interface mechanism by using the toolkit.

It is important to GIDL-PC that the pieces (CORBA, XML, UML, etc.) fit together seamlessly. GNOME provides the functionality of network transparency combined with component technology with the IDL to the ORB, and also the extensive use of XML and it is resident on the researchers desktop.

Future Enhancements

Current continuing research for the physically challenged is not only important but has become law in the United States. Employers must make reasonable accomodations to the Physically Challenged by law stated in the ADA. It is the hope of this research team that this effort can become a standard vertical facility under the OMG auspice. Future enhancements will be to add a Trader Service. A CORBA Trader Service locates appropriate objects that provide the desired functionality at runtime. To provide this service, the trader service federates a local trader and remote traders by considering the traders or link policies.

Summary

The initial direction and systems prototype for GIDL-PC has been in Computer Science and Software Engineering Techniques for Effective Software Engineering for systems that affect the Physically Challenged. We hope to extend this sharing to included Electrical Engineers, Psychologist, Sociologist, and anyone interested in research for the physically challenged.

The Numerical and Literary Six-Year Old, 125 IQ Dyslexic Explores IT and Opens Up New Avenues of Thought and Areas of Practical Experience for In-Service Education in a Bi-Lingual Environment

Daithí Ó Murchú
Principal, Gaelscoil Ó Doghair, Newcastle West Co. Limerick, Ireland
Research Fellow in ICT and Education, Trinity College, Dublin, Ireland
Department of Education MIC, University of Limerick, Ireland
omurchu.ias@eircom.net

Abstract: Because of their learning difficulties, dyslexic children are often looked upon as being the lowest common denominator on the academic scale, or even regarded as problem students. Using traditional methodologies and new technologies, this project allowed students with specific learning difficulties to utilise, examine, explore, plan and design new thematic programmes which permitted them to go beyond the apparent barriers of the ‘chalk and talk’ classroom to experience the joy of learning and explore avenues of thought. The results of their work are now benefiting all students and teachers, at all levels, as the lowest common denominator has become the highest productive factor. One such child is Tom. His case study epitomises the path this journey has taken and together with his story, the programmes which eventually resulted from all our experiences.

Introduction

In 1999, as co-ordinator of a locally-based national Schools Integrated Project in Technology (SIP) concerning the development of oral and aural language skills at the primary (elementary) level in Ireland, it became apparent to the author that traditional methods of utilising and reinforcing language acquisition skills were failing to meet the needs of specific groups of children, especially in a bilingual (Gaelic/English) school environment. In a variety of schools, there were obviously highly motivated and intelligent students who seemed incapable of absorbing the information being presented to them, albeit by excellent teachers employing a variety of non-technological methodologies, and teaching styles.

Investigating the source of the barriers to learning with the students themselves, their parents, and their teachers, the author discovered that a significant number of them had been previously diagnosed by developmental and educational psychologists as being numerical and/or literary dyslexics with above average IQ. It was only on discovering this, that the possibility of exploring, understanding and incorporating more effective learning strategies in language/second language acquisition presented themselves. An old Irish saying tells us that God never closes one door without opening another. In the case of these dyslexic children, all we had to do was allow them to give us the keys to enter and perceive their realm of thought and learning to begin more effective communication.

Our project, SIP 056, was entitled “The Development of Oral and Aural Language Skills at Infant and Remedial Levels in Primary Schools, in both Irish and English, through the Medium of Full Multimedia Programmes and I.C.T., within the Guidelines of the Revised Irish Primary School Curriculum”. (The term “Remedial Levels” refers to Learning Support.) The project undertook the task of addressing these challenges and presented both teachers and students, with a potential blueprint for the development of language usage. It was conceived that it might also open up avenues of practical applications for in-service education. Allied with this was the co-ordinator’s belief that technology-enhanced language learning could be more fully utilised to increase the possibilities of this project.

Tom’s Story

Tom came to our Gaelscoil (All-Gaelic, Bi-Lingual Primary School), at the age of five years, having already attended another elementary school. In consultation with his parents, he was referred for
assessment, because of concerns over reading and language difficulties. Tom’s cognitive functioning was assessed using the *Wechsler Intelligence Scale for Children III UK*, which yielded the following profile:

**Cognitive Ability**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Test</td>
<td>Predicted Score</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Verbal Intelligence Quotient</td>
<td>126 Centile 96</td>
</tr>
<tr>
<td>Performance Intelligence Quotient</td>
<td>116 Centile 86</td>
</tr>
<tr>
<td>Full Scale Intelligence Quotient</td>
<td>125 Centile 95</td>
</tr>
</tbody>
</table>

Table 1: Tom’s overall Cognitive Scores for the *Wechsler Intelligence Scale for Children III*

Strengths in Tom’s cognitive profile related to exceptionally high performance in Comprehension, Vocabulary and Similarities Subtests. This suggested exceptionally high ability in verbal fluency, word knowledge, word usage, social comprehension, and logical thinking and reasoning. An exceptionally high performance was also recorded for the Picture Arrangement Subtest, which suggested particular strength in visual perception and the ability to plan ahead. In contrast, difficulties were experienced in the Arithmetic and Object Assembly Subtests, which were a measure of numerical accuracy, reasoning and mental arithmetic. Low scores suggested inadequate memory and poorly consolidated reasoning skills.

**Literacy Skills**

Assessment using the *Wechsler Objective Reading Dimension Test*, yielded the following profile:

<table>
<thead>
<tr>
<th>Test</th>
<th>Predicted Score</th>
<th>Difference</th>
<th>Significance</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic Reading</td>
<td>115</td>
<td>34</td>
<td>P=0.01</td>
<td>&lt;1%</td>
</tr>
<tr>
<td>Spelling</td>
<td>113</td>
<td>29</td>
<td>P=0.01</td>
<td>&lt;1%</td>
</tr>
<tr>
<td>Reading Comprehension</td>
<td>117</td>
<td>45</td>
<td>P=0.01</td>
<td>&lt;1%</td>
</tr>
</tbody>
</table>

Table 2: Tom’s overall Literacy Skills Scores for the *Wechsler Objective Reading Dimension Test*

The above profile suggested that Tom’s degree of underachievement was statistically significant and that he had a specific and severe disability in relation to reading, spelling and reading comprehension. The subtests also indicated difficulties in identifying and distinguishing rhyming pairs in word strings and delays in processing numbers. It was further discovered that Tom’s learning style preference was towards a Kinesthetic and Accommodative Learning Style (Harthill and Busch, 1998). This led us to examine and explore areas of practical experience in understanding the various learning styles in second language classrooms both as in-service and on-line processes to more fully accommodate all students in language assimilation.

In summary, Tom presented with a significant and severe learning disability (i.e. dyslexia/specific literary difficulties) in relation to basic reading, spelling, reading comprehension, number reasoning, and number operations. The nature of his difficulties related to visual memory and sound processing. When his participation in the programme was proposed and explained to him, his immediate response was; “Don’t ask me to do this, Máistir (the students’ Gaelic term for Principal). I know I’m no good at remembering words and doing things like that. The others are better.” Tom’s words would seem to typify the dyslexic’s attitude to school and learning which McDermott argues is a natural by-product of the “schooling system (which) is inherently competitive… the inevitability of failure is built into the system…By the normal line of reasoning, the child is the unit of analysis and the (learning) disability is a mishap that scars a child’s road to competence”, (1993: 237).

**The Study**

The original idea for this project, SIP056, came as a natural development from the experiences of the principal of a Gaelscoil, an all-Gaelic primary school, in the areas of language usage and development, and information communication technology. It has long been recognised that the Irish language in particular has failed to catch the imagination of students and teachers. One could go as far as saying that most students dislike having to study Irish because the traditional methodology behind its teaching has become outdated. This also could be true of the methodology behind the development of language usage in some English, bilingual and multilingual settings (Nunan, 1988, 1989).
Within the guidelines of the Revised Irish Curriculum, particularly in the areas of the development of the Irish and English languages, it is proposed that teachers would embrace a new perspective in,

"Promoting positive attitudes and developing an appreciation of the value of language -- creating, fostering and maintaining the child's interest in expression and communication -- developing confidence and competence in listening, speaking, reading and writing -- enhancing emotional, imaginative and aesthetic development through oral reading and writing experiences".

Our project interpreted these curricular guidelines in a very simple way -- making language learning fun. We believed that through the identification of key words in the Irish and English languages, integrated into a thematic visual arts programme -- drama -- we could encourage children to develop confidence and competence in language usage. Not alone that, but by encouraging them to use I.C.T. (digital cameras, scanners, video cameras and multimedia programmes), we would place at their disposal a multitude of potential learning experiences, which would systematically lead them along the path of language acquisition and familiarisation. We also believed that if we succeeded with what may be considered to be the lowest common denominator in our schools (kids like Tom), from a language development perspective, then the project would naturally extend to all other students.

There have been some memorable milestones in our project to date, one of which was the identification and compilation of the key words used in Gaelic and English in the development of language skills. We examined, from a learning support perspective, the Dolch lists of words and in consultation with Tom, our staffs and other educational bodies, we supplemented these lists to include more modern words. We then divided all of these lists and words into both class and age group categories. From a Gaelic perspective, we looked at the work carried out in the early 1960s in the identification of the key words in the spoken language and, following a similar pattern of research, we compiled a comprehensive and yet not exhaustive wordlist. The project schools and others then tested these lists, to verify their appropriateness to age and class grouping, and their feedback allowed us to consolidate the lists. These lists are available for downloading at www.gaelscoil.com/site2002

Following that, we decided to design a full and inclusive, whole school programme in drama and phonetics, using the wordlists. The programmes in Gaelic and English, encompassed the various levels already recognised, allowing us to introduce language learning, in a fun and novel way, through the medium of eight themes which Tom and the other students had identified. These themes were:

Junior Infants - (4-5 years) - Our homes and families / Ár dtithe agus ár dteachlaigh
Senior Infants - (5-6 years) - People in our community / Daoine in ár bPobal
First Class - (6-7 years) - Nature all around us/ An Nádúr, thart timpéall oraínn
Second Class - (7-8 years) - Our school / Ár scoil
Third Class - (8-9 years) - Lots to do/ Rudáí le deanamh
Fourth Class - (9-10 years) - Customs and traditions / Custaim agus Traidisiúin
Fifth Class - (10-11 years) - Local history/ Stair in ár dtimpeall
Sixth Class - (11-12 years) - Local industry and commerce / Domhan áitiúil tionscail agus gnólachtáí.

Using these themes, the word lists, and the drama and phonetic schemes, we implemented the programme of language development and usage, in the hope that the children would use their experiences to transfer their thoughts and their ideas into computer-generated, multimedia programmes in the quest for creative technology-enhanced language learning.

Microsoft PowerPoint was chosen as the medium. In essence, we the teachers, in partnership with the students and parents, sent Tom and his fellow students out into the environment to research these various themes: to take digital images, to build story lines around them, to present them in the drama class and develop the whole concept, so that their experiences could be integrated with the curricular aims and objectives of the Revised Curriculum in both Gaelic and English.

In the infant classes, the teachers introduced the word lists in a phased manner using the drama programme as the medium of expression. In the learning support classes, already having experienced the
words in their drama schedule, the children were introduced to the various word and phonetic lists in a more formal and focused manner. The themes mentioned above were always utilised to help the children to focus on the possibilities of word usage. This was a very challenging task as the ability and age range of the students in question varied greatly, but in small group situations, the teachers were able to elicit responses from them without the students being under too much pressure. This proved to be very effective, and the teachers noticed that the responses of the students who were attending learning support were very positive in class.

The development of the programme has not been without its problems. As the old saying goes, "Is fada an bhóthar gan casadh – It is a long road, which has no turns". The fact that many of the teachers had not experienced any formal training in the use of ICT and multimedia presentations meant that a detailed, logical and sequential programme had to be designed by the author to ensure that they were equipped with the necessary skills to develop and implement the project. The provision of substitute cover by the Department of Education and Science for the teachers involved facilitated the implementation of the training programme and the project in general.

Because of the extension of the programme to a selection of pilot project schools (small rural to large urban), it was occasionally more difficult for the smaller schools to find time to implement the project. This was due to the fact that some schools were sharing learning support teachers and in some cases, the same teacher was teaching multiple class groupings. At times this was found to be an advantage, as older children were able to mentor younger children, and peer to peer teaching was seen to be very effective, as the teacher was afforded the time to be a more creative support.

In summary, all the above has entailed many, many hours of research, evaluation, implementation, assessment, re-design and re-implementation of the various strands of the project. Moreover, the challenge of identifying the learning styles of the children with learning disabilities, which "refers to a person's general approach to learning and problem-solving" (Reid 1995), and observing their learning strategies, which are “any specific conscious action or behaviour a student takes to improve learning” (Oxford and Nam 1998), dictated the manner in which the project and teacher in-service education evolved.

What Has Been the Impact on Teaching and Learning?

This project caught the imagination of the parents involved as they willingly offered their services to help with its implementation. This ranged from studying various words and themes with the children, to providing advice on the possibilities of implementing the chosen themes of the project and understanding their children’s learning styles. With this came a sense of true partnership in education.

The manner in which the aims and objectives of the Revised Curriculum, with reference to the development of language skills, has been implemented in the schools, is undoubtedly one of the major impacts of our project on teaching and learning. The use of technology and multimedia has become a natural ally in designing programmes, which are student-driven, and therefore more interesting to them. The teachers, on the other hand, having seen the benefits to the students, naturally adapted their learning and teaching styles to the advantage of the children. So both the academic requirements of the Revised Curriculum and the fun aspects of language learning have been successfully fused together.

Tom and many of the other children attending learning support, have developed their own personal programmes using the words which they themselves felt most comfortable with and we believe that this is one of the major, unforeseen successes of the project. The infants, on the other hand, may have needed a lot more mentoring, but they totally enjoyed looking at their work and hearing their voices on the computers. Parents were able to use some of these programmes on their home computers, and therefore to enhance learning by complementing the schools' programmes. The teachers were presented with well-constructed exemplars, which allowed for as much creativity as they wished to input, in the development of both the Gaelic and English language programmes.

An unexpected impact of the project, was the demand from a variety of schools for access to the phonetic and word lists, the drama programmes, and the multimedia presentations. The possibilities for using the project in the teaching of minority languages and other major European languages in a bilingual setting, was also recognised, as it was felt that the project addressed language teaching methodology in a novel manner. Some students attending teacher training college at third level requested permission to try...
out some of the Gaelic programmes and they found these extremely effective in classrooms, encouraging schools around Ireland to request permission to download the information.

Conclusion

Language and its usage is one of the most important means of communication in the world. Our project continues to show us that this is a very complex and challenging area of the Revised Curriculum especially in a bilingual environment. In essence, the major contribution of our project to understanding children with learning difficulties, the process of education and new technologies is that they should not be mutually exclusive. Not alone that, but young dyslexic children such as Tom, are like natural sponges, absorbing at deeper levels through body and mind, and well able to handle the challenges of the technological world and an extra language, through the medium of a more traditional curricular area -- drama. Teachers also, when presented with a curricular framework for the development of language skills, were able to integrate their own knowledge with ICT, to creatively produce exemplars for the development of confidence in language usage, which could be emulated by any school. These facts lead the author to believe that the project will continue to develop after SIP and more importantly, be emulated and replicated in other local, national, and international settings to open up new avenues of thought and possibilities for in-service education.

Tom, as a literary six-year old 125 IQ dyslexic, with all of his academic problems, has shown that IT, when creatively integrated with, and connected to, his preferential learning style, can open those other 'windows of wonder' to boost self-confidence and enhance the learning experiences of students and teachers both inside and outside the classroom. The most significant remaining challenge for us, the teachers, is to continue our work and be satisfied that we shall probably never reach a stage when we can say that we have actually realised all the ramifications of our own learning curve when dealing with children like Tom, in a bilingual environment. They say that from small acorns grow great oak trees. We look upon our project from the point of view of the well-planted acorn and hope that the participation of other schools and organisations will continue to nurture it.

There is no doubt in our minds that this project has incredible possibilities and far-reaching implications for teachers, learning support in schools, in-service education in a bilingual environment and the development of language skills internationally. It is hoped that schools will download the information and associated links to the 'Avenues of Thought and Areas of Practical Experience for In-Service Education', at www.gaelscoil.com/site2002 and eventually design their own programmes and multimedia presentations. All that remains is a recent comment from Tom as he sat confidently at his computer; "You know Máistir, even my Dad thinks this is great fun, isn’t it?"

Abstract: This paper provides real-life examples of ways technology are used to enhance parent-teacher partnerships in special education. A framework for identifying the needs and strengths of families as they interact with school professionals regarding the academic and social progress of their children in the school setting is presented. The use of various technologies in the schools and how they fit into the framework is then described. The availability of technology to both families and schools is a key issue when making decisions about what technologies can best support collaboration between home and school.

Introduction

The availability of technology provides an opportunity to communicate with parents in different formats. It is important to individualize the technology choices for methods of communication and collaboration as partnerships are developed between home and school. Understanding the needs and strengths of parents makes it possible for teachers to individualize involvement with families, just as they individualize programs for students.

The Mirror Model for Parental Involvement (Kroth, 1985; Kroth & Edge, 1997) is built on the premise that parents are a heterogeneous group. Educators could use the Mirror Model as a framework for identifying parents' information needs and special strengths as they interact with school professionals regarding their children's academic, social, and emotional progress. The Mirror Model is depicted in Figure 1. In addition, technology options and uses range from low to high tech, and need to be carefully selected to match parents' and teachers' needs and skills.

The Study

Information on technology use in the schools was collected from graduate students enrolled at the University of North Texas. Participants were special education and general education teachers in both public and private school settings. We then sorted the information into the Mirror Model framework. Examples of email communication were collected to describe how technology can be used to enhance parent/teacher partnerships. We selected email samples collected from teachers to illustrate how electronic communication fits into the framework provided by the Mirror Model. Specifically, we use the framework to categorize email messages that reveal parents' needs and strengths. We selected email because of growing accessibility of computers in homes, businesses, libraries, and schools. Teachers and parents can collaborate on a topic without coordinating when and where the communication takes place, as in communicating from different locations and at different times.

School and classroom web pages were examined based on the Mirror Model framework to determine if information needed by parents, was available. Phone and television systems used by the schools to communicate information to parents were also identified. We also examined teachers' and
parents' use of portable microcassette recording machines and videotapes as other means of communication.

Findings

E-mail communication illustrates how the Mirror Model framework can be applied to authentic examples of parent-teacher communication using technology. The various levels of the Mirror Model can be identified through actual samples. For Levels 1 through 4 there are parents' needs and strengths. For example, in Level 1 all parents need information regarding parents' and students' rights, school policies, and school events. A sample E-mail from John's mother to the special education teacher: **Will you tell me when Spring Break is? I also need to know about the next time for the parent training program on "Helping Your Child with Homework".** Level 2 of the Mirror Model relates that most parents need knowledge about their child's progress, school environment, and their child's friends are. A sample E-mail from Sue's father to Sue's special education teacher illustrates Level 2: **When I opened my E-mail today, I had a note from Sue's general education teacher. She said Sue is not turning in assignments. Will you check with the teacher? Could we get an assignment notebook going again? Thanks.** There are also E-mail samples of parents' strengths. For example, in Level 1, Steve's mother provides needed information to Steve's teacher. **Steve has new glasses, but does not like to wear them. Could you encourage him to wear them? I think once he gets used to them, they will be easier for him to wear.** Level 2 includes a parents' special information about their child. **Joe's been upset at home since his grandfather died last week. Our house has been filled with company and it is hard to focus or get any homework completed. Do you have any suggestions for us during this difficult time for Joe?**

Other technology uses were also examined and sorted according to the Mirror Model framework. Most uses were identified in Levels 1 and 2 on the Mirror Model framework. Parents need to know basic school information, school policies and procedures, calendar events, as well as how their own child is progressing in school, academically, socially, and emotionally.

Conclusions

E-mail messages collected and sorted in the Mirror Model framework show that E-mail is a powerful tool for use in enhancing parent-teacher partnerships. Parents have a direct line with the teacher, and the teacher and parent can communicate on an "as needed" basis. The availability of E-mail to parents and teachers is key when making decisions about its use.

Some web pages include daily and weekly reporting systems provided in a secure format for reporting student attendance, student progress and achievement. Parent support groups were also established through chat rooms on the Internet. A list of web sites used in the schools that focus on particular issues can be provided to parents with specialized needs. The National Rehabilitation Information Center (NARIC, web site: [http://www.naric.com](http://www.naric.com)) conducts computer searches for families who request information on disability organizations, funding opportunities, and products and devices. Parents who have expertise and strengths in particular areas can serve as resource people who can provide web addresses or search topics for particular issues. A parent could be referred to [http://www.ldonline.org](http://www.ldonline.org) for additional information on the topic of learning disabilities. In addition, parents serving on school committees can use the Internet to broaden the learning experiences for the school community. Discussion groups such as [SpedTalk@virginia.edu](http://www.speditalk.virginia.edu) deal with a large number and variety of topics in special education, including special education law. They distribute information with funding they receive through the U.S. Department of Education (Turnbull & Turnbull, 2001). The NICHCY (web site: [http://www.nichcy.org](http://www.nichcy.org)) disseminates free information about children and youth with disabilities and disability-related issues to families, educators, and other professionals. The Beach Center on Families and Disabilities (web site: [http://www.isi.ukans.edu/beach/beachhp.htm](http://www.isi.ukans.edu/beach/beachhp.htm)) conducts research and training to enhance professional practice, public policy, and families' quality of life.

Technology that is "low tech" should also be considered for some families and educators. Portable microcassette recording machines are easy to use and can relay messages, such as tips for homework completion or test taking, in a convenient way. Students and parents can listen together to the teacher's voice and record their responses. Students can record messages to homebound students, with the message content ranging from a simple greeting to an explanation of a homework assignment using a
student's voice. A videotape is another means of communication. Many parents, including some cultural
groups, benefit from the visual format for communicating and learning new information.

An option for enhancing parent/teacher partnerships is two-way audio/video desktop conferencing.
These types of systems can be used for meeting at a distance for a variety of purposes in a convenient way.
Accessing professionals, demonstrating teaching techniques, and conferencing can all be accomplished at a
distance.

Understanding the needs and strengths of parents makes it possible for teachers to individualize
involvement with families. The Mirror Model is one framework that can be used during the decision
process. As technology options increase, it is important to individualize the methods of communication
used. Effective parental involvement leads to improved teaching and learning in our schools. Technology
offers opportunities for collaboration to facilitate the goals and desired outcomes of those involved.

Using Microsoft Word's Tracking Changes to Improve the Writing of Students with Special Needs

Description of the Project and Literature Review

Beginning in Spring 2000, Linda Miller-Dunleavy and Lynn Schultz, of Old Dominion University, (ODU), began work to develop teaching strategies using technology to improve the writing of special needs students. Their extensive and numerous teaching experiences, and their work in technology, suggested that by using a unique editing feature built into Microsoft Word, Tracking Changes, teachers could use existing software and new teaching strategies to enhance writing instruction. Tracking Changes is a rarely used tool imbedded in Word that allows editing marks to be entered on any Word document. While this is a business feature, the authors have developed several strategies for using Tracking Changes specific to the education setting.

The opportunity to learn has long been considered one of the major factors influencing achievement (Carroll, 1963). Minimal requirements for improving writing achievement should be to provide effective writing instruction to ALL students. Additionally, students will not become better writers if they do not spend a substantial part of most school days engaged in productive writing activities. Graves (1985) stated that students should write for at least 30 minutes a day, at least four days a week, as opposed to a national average of writing one day in eight. Since written expression is the most complex language arts skill, it is generally not stressed daily in instructional programs for students with special needs.

Recent research has suggested that students with special needs in middle and high school benefit when strategy instruction is integrated with word processing to teach written expression (Graham, 1991). Furthermore, strategy instruction in writing has been used to help students learn to better internalize and regulate the cognitive activities involved in effective planning, production, and revision of text (Graham et al., 1991) & (Deshler, & Schumaker,1988).

Project Implementation:

The Chesapeake Public School (CPS) system in Chesapeake, Virginia was selected to pilot and field-test the project during the 2000-2001 academic year. The teacher-participants included 11 special education teachers from this system. Ten of the participants are located in middle schools, which serve grades 6 – 8, and the eleventh participant teaches high school. Eight of the middle school teachers have classes for students with learning disabilities that are taught either in self-contained or resource classrooms. The remaining two middle school teachers teach either students with emotional disorders or a mixed classroom of students with emotional disorders and those with learning disabilities. The high school teacher teaches resource students with learning disabilities.

Beginning in the Spring 2000 and continuing through the academic year 2000-2001, several planning sessions and workshops were held to develop a plan of action. The team of ODU personnel and CPS teachers developed ways to use Tracking Changes in the classroom, and shared writing strategies that assisted their special needs population through the difficult writing process.

The importance of selecting specific strategies based upon “best practices” was highlighted during the first summer workshop. A specific learning strategy, POWER (Plan, Organize, Write, Edit, Revise), was selected. Teachers selected different approaches for the Plan and Organize stage of POWER based upon their classroom needs (e.g. webbing, four-square). Directions for using Tracking Changes during writing instruction were created and field-tested. All teachers used Tracking Changes for the Write, Edit and Revise stages. A rubric was created and revised to evaluate different aspects of the writing process. A sample of the rubric and directions for Tracking Changes can be found on the project website:

During the academic year 2000-2001, three dinner meetings were held with participating teachers for reflection, encouragement, and problem-solving, and each teacher was observed in their school setting at least once during the year. The project leaders found this to be an invaluable part of the experience; for without periodic support and reflection, this would become just another summer workshop.

The project continues in the 2001-2002 academic year, with seven of the original teachers returning. In addition, one regular education English middle school teacher, an additional middle school LD resources teacher, and two high school LD resources teachers have been added. Teachers will continue to collect pre - and post- writing samples, which will be graded using the rubric from the previous year. Dinner meetings and school observations will also continue.
Poster Session Activity:
The poster session will take participants through a POWER strategy session. This strategy, a process approach to writing, begins with the Planning and Organizing stages of POWER. Examples of the various individualized writing approaches and activities used by the teachers will be displayed.

Next, participants will examine sample documents using Tracking Changes to edit and revise writing, thus allowing them to observe both the role of teacher and student (Writing, Editing, Revising). Adapting the business function of Tracking

Finish the story:

The July 4th weekend was quite exciting. Mom decided to jump in the pool...

The water wasn’t everywhere (sp). The whole bake (sp) yard was washed out and mom was nowhere (sp) to be found. She cracked the bottom of the pool and ended up (use different word) in China. She had swelled (tell me what you mean) for 10 days. The next day (no period make this one sentence) She saw her family (sp) in China. She side how did you get her (sp) run on sentence we followed your trail (sp) there (sp) — quote? the pool and end up her (sp) run on sentence they lived in China the rest (sp) of their (sp) life.

Changes, which encourages all corrections to be entered, presents a challenge to teachers using this tool. A method was devised, tailored by each teacher, to use Tracking Changes to SUGGEST changes to students, thereby not making all corrections for the student.

Preliminary findings:
The authors hoped to improve both quality and quantity of the writing processes and produce significant gains in outcome-based results for these students. Improvement was measured by scores on the writing rubric, with the ultimate achievement to result in an increase in mastery of Virginia’s Writing Standards of Learning (SOL). Recently compiled data show a significant gain in 7 out of the 11 areas of the writing rubric. These seven areas represent the mechanics of writing. It was felt that the use of the computer and editing features increased student scores. Of the 4 areas not showing improvement, it is the opinion of the authors that writing strategies for Plan and Organize could be improved and emphasized.

Conclusion
Teachers need to introduce students to the entire process of writing from the initial idea generation to editing of the final draft (Issacson, 1995). The inclusion of Microsoft Word’s Tracking Changes in the POWER strategy resulted in significant gains in writing skills of special needs students.
Reading + Technology = Literacy

Sean Smith, University of Kansas, US
Steven Smith, University of Kansas, US
Mary Ann Petrich, Kansas City, Kansas Public Schools, US

This presentation will focus on the sustained integration of a hypermedia-based software application called READ 180. Integrated across Kansas City, KS Middle Schools, Read 180 has had a significant impact of student reading, both general and special education students, over the past two years. Data will be shared with participants concerning its effectiveness and its overall impact on the reading process.

READ 180 infuses the anchored instruction model researched by Hasselbring and his colleagues at the University of Vanderbilt (Bransford, Sherwood, Hasselbring, Kinzer, & Williams, 1990; Hasselbring, Bottge, & Goin, 1992). Hasselbring and colleagues (1997) have examined the implication of READ 180 and its application to literacy development and the needs of the at-risk learner. In cooperation with the Orange County Public Schools, research has illustrated dramatic student improvement in the area of reading when instruction is anchored through multimedia applications. This presentation will also share findings from a study currently underway in the Kansas City, Kansas school district across seven middle schools.

READ 180 applies the components of anchored instruction benefiting from the interactivity of hypermedia. Hypermedia-based children's literature has several potential advantages for students with learning disabilities who are struggling to acquire basic reading skills. First is the motivational appeal of this body of software. For example, READ 180 with its dazzling graphics, realistic sound, and plentiful opportunities for interactions between the learner and the task, this type of software has the capability to capture and hold students' attention. As Erickson and Staples (1995) reported, even students with autism respond to the attractiveness of these programs with increased attention to the reading task. This level of motivational value may increase the probability that reluctant readers will persevere in their interactions with text. This would be a particularly valuable outcome because repeated readings of the same text have been found to be of value for students with learning disabilities (Sindelar, 1987).

Also, hypermedia-based children's literature offers students text that is speech-enhanced. Speech makes the text more accessible to readers or, in the words of Boone, Higgins, Falba, and Langley (1993), more cooperative. In addition, this software is a computer translation of children's literature. When transformed into computer-mediated "books," the quality of the texts and illustrations are preserved. Texts are typically heavily illustrated; also, they are often predictable and include narrative features such as repeated lines and rhymes. These features, like software speech enhancements, increase the cooperativeness of the text. Comprehension is aided because of the graphical cues and the predictability of the text. Also, if a computer-mediated book is used as a springboard for instruction in skills such as decoding, that instruction is easily "anchored," as Hasselbring and his colleagues (e.g., Bottge & Hasselbring, 1993) explain, to the student's experiences with that piece of children's literature.

This presentation will feature an extensive demonstration of the READ 180 software and how it has enhanced students with learning disabilities reading over the past two years. Data will be shared with participants concerning its effectiveness and its overall impact on the reading process.
Providing an Online Instructional Medium for the Deaf

John Thompson, Ph.D.
Buffalo State College
Buffalo, New York
United States
thompsjt@bscmail.buffalostate.edu

Abstract: Deaf and hard of hearing students can benefit from participation in text-based online learning. Such online learning avoids the use of audio information, or provides captioning or supplies a written transcription for the course activities. Deaf students can then participate on an equal footing with their hearing counterparts. The special assistance that would normally be required in a traditional classroom setting for the deaf student is not needed. With reliance on web-based learning, those students with hearing loss are provided with a level playing so they can participate unimpeded with their hearing colleagues and have full access to their academic program. By providing an equal educational opportunity to deaf students, online learning becomes not only anywhere, anytime learning, but also learning for anybody.

Introduction

Online learning, or distance learning using the Internet, provides a medium that allows deaf and hard of hearing students in K-12 and higher education an equal footing in their classes without the inconvenience of an interpreter in the middle of the communication. Using the text-based medium of such online instructional platforms as Blackboard, deaf and hard of hearing students can participate without assistance.

The use of Internet-based online learning (OLL) presents faculty and students with multiple opportunities not found in traditional face-to-face (F2F) courses. Using web-based instructional platforms, classes can be run without incorporating verbal communication. Instructors can post course information such as announcements, assignments, documents (e.g., PowerPoint presentations), and grades for viewing anytime from anywhere by their students. A threaded discussion board can facilitate "asynchronous communications (non real-time) where students and the instructor post questions, answers and comments" (Lorenzo, 2000, ¶ 10). Synchronous (live, real-time) text discussions using a form of virtual, text-based chat also can play a role in the class (e.g., virtual office hours, group meetings). For course readings, students can be referred to selected Internet sites or use other Internet-based alternatives such as XanEdu's electronic CoursePacks (http://www.xanedu.com/). Students can submit their work via electronic communication, using e-mail and digital drop boxes.

With the addition of online learning, K-12 and higher education classrooms can morph into interactive "24-7" experiences in which deaf and hard of hearing learners do not need communication help from others. Students communicate with one another and with the instructor through their keyboards, mice, and the Internet, not needing to hear the other course participants.

Why Online Learning?

Online learning offers many conveniences and upgrades for students and teachers over the traditional face-to-face (F2F) class. These advantages include:

- *Anywhere, anytime learning.* No longer is the educational process confined within the four walls of the conventional classroom at a prescribed date and time. OLL permits, even encourages, a form of 24-7 education that provides maximum flexibility. Instructors can teach their OLL classes right from their own offices or even homes. Students can avoid the hassles of driving to the campus and trying to find a place to park by accessing OLL courses from office or home. While it may be frowned upon and discouraged by some employers, students do use workplace computers to connect to their OLL courses, mainly because of the faster Internet connections found in many school and office settings. Even web-enhanced traditional courses, which use OLL to extend the teaching-learning relationship beyond the F2F setting, benefit from 24-7 access to course information and online discussion groups.

- *Increased communication.* OLL provides additional opportunities for student-student and student-instructor interactions. Participants in OLL have opportunities to post and reply to communication threads about course-related topics. Questions get raised and answers debated that might well not have been in the F2F classroom. Shy students, or ones with disabilities such as hearing loss, do not have to worry about speaking up, being called on by the teacher, or having their answers understood. If a question is posed in a discussion board, the student has time to craft a response either directly within the discussion board or first in a word processing program and then copy it later into the discussion board. Web-enhanced OLL allows the teacher to post additional information and create study groups that extend learning beyond the confines of the F2F class. In web-enhanced classes, OLL can necessitate additional time and effort on everyone's part, but the learning is
enhanced with the resulting richer exchanges (perhaps more so than many F2F classes) among students and between students and instructor.

- **Heightened awareness of others.** The quick pace and instructional methodology of many F2F classes does not permit students and teachers sufficient time to get to know one another. With the back and forth replies in an online discussion board format over the duration of a course, however, each participant gets additional insights into one another. Information is gained from the written exchanges and additional contacts (teacher-student, peer-peer) among course participants, adding to the quality of the learning. Graduate students can find out about one another, creating more of a bond than exists in a typical graduate classroom where the students rush in from work and flee to their homes directly after class.

- **Time considerations.** Time is one commodity that students and teachers cherish. OLL prevents the telephone tag time-waster with reliance on e-mail and discussion forums. Students appreciate the more immediate access their teacher (if the teacher checks his/her e-mail with regularity). No queuing in the hallway waiting to see the instructor during office hours as OLL provides opportunities for virtual office hours. Instructors and students are at their keyboards miles apart, yet communicating individually or as part of a live, real-time group discussion. However, these communications come at the price of increased time and effort in web-enhanced courses, especially for the instructor who has to reply to individuals and the class over the Internet, as these communications are in addition to the regular F2F class meeting times. Web-based courses can save time or at least not waste time. Web-enhanced courses, while more enriching and beneficial, can add to the time commitment of faculty. But, based on the student response, the extra time can be worth the effort.

**Personal Online Learning Experiences**

This writer's own experience with OLL started with participating in a six-week training program operated by OnlineLearning.net. This organization manages OLL courses for UCLA Extension online and the University of San Diego (USD) continuing education online. After successfully completing the training program, an opportunity was offered to teach a six-week web-based OLL graduate course, Mainstreaming: Teaching Individuals With Special Needs in the Regular Classroom, for USD. Subsequently, additional mainstreaming teaching opportunities were offered this writer by USD. While the initial course had only 10 students, the other courses have had enrollments in the high 20s.

The mainstreaming courses are primarily for California teachers needing to "clear" their teaching credential by taking a course which fulfills a state requirement for their teaching certification. Each student has been pursuing a master's degree in teaching. The students represent a wide range of teaching experience, including those teaching full-time for the first time, and an extensive breadth in grades and subjects (e.g., elementary, secondary, Spanish, GATE, band) found in public education. Since the instructor is located in New York State, teaching a California-based OLL course with a three-hour time difference can be a challenge.

The asynchronous nature of OLL, apart from the real-time virtual office hours, allows the arrangement to be successful. OnlineLearning.net uses Blackboard, which its promotion states is an "e-Education enterprise software platform that encompasses course management, academic portal, online campus communities, and advanced architecture allowing easy integration with multiple administrative systems" (Blackboard Inc., 2001). It provides a "skin" or shell that hides the programming underneath so that instructors do not have to do any programming, as they would if they were programming their own Internet sites for instruction.

Blackboard's core features include content management that supports most common file formats in an easy click-and-point process, communication and collaboration tools to support individual and group communications as well as group project work, online assessment and testing tools, and administrative tools with which an instructor can easily build and manage a virtual classroom. (Rochester Institute of Technology, 2001, ¶ 5)

The instructor merely types, copies-and-pastes, or uploads text into the appropriate sections of the course's Blackboard site. Instructors and students communicate by exchanging replies in discussion board forums or by e-mail. The latter can be directed to specific individuals, mailed to sub-groups, or sent to the entire class from within Blackboard. The instructor has control of settings for the Internet site appearance and contents. Tests can be taken online. The experience for the students has been positive, as judged by their informal comments during the courses and by their formal end-of-course evaluations.

Besides working with the University of San Diego, this writer has taught online classes for Buffalo State College using the Blackboard infrastructure. The first course was a graduate course in educational computing and used Blackboard.com, which is a free service available on the Internet for anyone's use. This was a web-enhanced course as the students and instructor still met in a traditional F2F setting once a week for a semester. The OLL component of the course presented the students and instructor with opportunities as previously outlined. This OLL course was the first for each graduate student. Again, as with the USD mainstreaming courses, after their initial skepticism, the students were enthusiastic about incorporating OLL into their course, perhaps because the course topic involved educational technology.

After this initial OLL course at Buffalo State, this instructor has taught five other web-enhanced OLL courses, including two for undergraduates, using Blackboard on the college's computer server. As one may or not expect, the quality and quantity of the discussion board forum conversations were higher in the graduate courses, although the undergraduates' discussions were engaging and with merit. The undergraduates enjoyed OLL, but their replies tended to be "short and sweet," while graduate students composed longer replies with more thought and substance. The only consistent negative comments were directed at the slowness of the Blackboard connection that was due to insufficient bandwidth and other technical issues at the college. Such problems are being addressed. Also, this writer is scheduled to offer a web-based OLL graduate course for Buffalo State College in fall 2001. This OLL course will be the first one at Buffalo State to rely on the State University Learning Network (SLN) for the delivery infrastructure.
Online Learning and Deaf or Hard-of-Hearing Students

Online Learning can be termed "deaf-friendly," if an OLL course steers clear of the use of audio information, provides captioning, or supplies a written transcription for that information. A deaf student is able to participate in a text-based online discussion without an interpreter clogging up the middle of the communication. By avoiding non-text information or providing text equivalent information, deaf and hard of hearing persons can be assessed on what they say rather than on how they say it. Using the Internet, people with hearing loss then have a level playing field with their hearing colleagues and full access to the academic program. Keyboard and mouse input constitutes the mechanism to facilitate communication among students and between students and the instructor. The instructor can post PowerPoint presentations, with slide notes or sans sound effects, onto a website or into a course infrastructure provider for easy anytime, anywhere access.

With text-based OLL, instructors do not have to adapt their instruction for deaf and hard of hearing students. The deaf student does not need special assistance "to become part of a mainstream educational setting" (Kinner and Coombs, 1995, ¶ 4). Time and expense do not need to focus on accommodations since deaf and hard of hearing students are on an equal footing in a non-verbal class. As long as the participants can read and type, no one knows if anyone in the course is deaf or hard of hearing. "Once appropriate access has been provided to the computer...students function as equals in the computer classroom, and their disability vanishes" (Kinner and Coombs, ¶ 5). No wonder that deaf and hard of hearing students feel more involved in OLL classes than in traditional F2F classes.

As such, online learning can provide fully inclusive classroom settings within the spirit of the least restrictive environment language found in the Individuals with Disabilities Education Act (IDEA). However, as the bandwidth of computer connections continues to increase, OLL will inevitably include fuller media communications featuring voice and video with sound in real-time, such as a streaming video and perhaps a "map with audio descriptions of historic locations which are activated by mouse rollover" (National Center for Accessible Media, Rich Media Accessibility, Frequently Asked Questions, 2001, ¶ 1). As this change occurs, OLL’s "silent web era" will parallel the change from silent movies to talkies that occurred in the early twentieth century. Now in a new century, deaf and hard of hearing students will brace themselves for another "advance" in presentation technologies. The hope is that this time technology also will aid these students with web-captioning, embedded media, and other solutions, rather than shut them out.

Buttressing this hope will be Section 508 of Rehabilitation Act that specifies that "Federal agencies' electronic and information technology is accessible to people with disabilities" (Federal IT Accessibility Initiative, ¶ 5). Additionally, other government entities may follow New York State in adopting the "W3C Web Content Accessibility Guidelines as a means to provide optimal access to State agency web sites and the content therein" (Natoli, 1999, ¶ 4). As stated in those guidelines, websites should "provide content that, when presented to the user, conveys essentially the same function or purpose as auditory...content" (Web Content Accessibility Guidelines 1.0, 1999, chap. 6, ¶ 1).

For the time being, though, deaf and hard of hearing students will benefit from the text-based aspects of OLL, at least as represented by instructional delivery platforms like Blackboard. Online learning will not only be anywhere, anytime learning but also anybody. As one OLL deaf student put it:

As a deaf adult, distance learning courses have opened additional opportunities and avenues that have long been available to my hearing peers...Besides allowing me to focus on learning as opposed to, say, wondering how much of the essence of a teacher's message the interpreter or note-taker has captured, distance learning provides a forum where deaf adults like me can share technical and non-technical expertise unhindered by language, negative attitudes, geography or distance. All told, distance learning gives me a fighting chance to stay current, competent and competitive in a fast-changing technological environment. (Lorenzo, 2000a, ¶ 16)

Abstract: This paper provides a rationale for using an Individualized Special Needs Software Evaluation (ISNSE) instrument, designed with teacher identified criteria for specifically recognizing each student's individual need, when evaluating software to be included in the Individual Education Plan (IEP). The Individuals with Disabilities Education Act (P.L. 101-467) mandates that all students with disabilities, regardless of the severity of the disability, be considered for any assistive technology needs. Specifically, the law requires that each child's IEP team must, "consider the child's need for assistive technology devices [§300.346(a)(2)(v)], and reflect in the child's IEP both the nature and extent of the assistive devices and services to be provided to the child [§300.346(c)]." Software is considered a type of assistive technology. Thus, IEP teams should carefully determine if a child could benefit from using a specific software program and then document the number of uses on the child's IEP.

Introduction

Selecting software for any classroom use is challenging. But, for teachers of children with high incidence disabilities (learning disabilities, behavioral disorders, and mild mental handicaps), the task may be even more daunting when the Individual Evaluation Plan (IEP) goals are taken into consideration fully. The tremendous growth in the number of commercial software programs is staggering, which makes the selection process for a special education teacher even more time consuming and crucial. In order to attain the goals set forth in the IEP and provide positive student outcomes with technological integration, which is now expected and written in the national and state standards, teachers would need to be trained and competent in the software selection process. Purchasing software for the special needs classroom should no longer be left to a generalist or the media/technology specialist. Responsibility for the selection must now fall to the special education teachers who know the specific needs of each learner as well as how appropriate a program is, for meeting IEP goals. A review of numerous studies have been conducted to assess the software evaluation process with evidence showing that special education teachers often rely upon external evaluations as the most commonly used evaluation process. Results of the authors' study suggest an internal evaluation process is necessary and ought to be considered in the writing of IEPs (Forgan & Weber, 2001).

External Software Evaluation

An external evaluation of software is defined as one in which someone reviews the software program other than the student's teacher. External evaluations rely upon another persons' opinions. In most cases, the external evaluator of educational software does not have a special education background and certainly does not know the students' individual disabilities. Although external evaluations often provide the teacher with an overview of the software program, this type of evaluation does not encourage the teacher to evaluate the software with a specific child in mind.
Internal Software Evaluation

An ISNSE is a type of internal software evaluation (one in which the teacher completes the evaluation). This type of software evaluation begins when the teacher creates a mental representation of the student(s) likely to use the program, by focusing on the individual’s characteristics and needs, before familiarizing themselves with the program features. After exploring the program thoroughly, the teacher completes an ISNSE instrument rating form with the particular students' needs in mind. This type of an ISNSE instrument evaluation procedure provides the teacher with powerful knowledge of the program and its relationship to the students' educational goals. A program that is suitable for one child with a high incidence disability may not meet the unique needs of all children with these disabilities. Thus, upon evaluating a program using an ISNSE instrument, teachers may confidently integrate the program into the curriculum to help each student master his or her IEP goals and objectives.

Including the ISNSE on the IEP

Sharing this information at the IEP meeting with the multidisciplinary team will help the members address the assistive technology component, as required by the Individuals with Disabilities Education Act (Public Law 105-17). Additionally, as the teacher completes this very comprehensive process using an ISNSE instrument, knowledge will be gained to provide a launching point for IEP team members and others to initiate dialogue about the appropriateness of the software for instructional enhancement. This process would be used to supplement the integration of technology for special education applications and could provide an additional measurable component for the IEP based upon the attainment of goals and objectives expected from the use of instructional software.

Existing Software Evaluation Models

A number of general software evaluation models exist which contain characteristics to assist teachers in evaluating educational software, but these models do not contain criteria special education teachers report as critical to consider (e.g., Bos & Vaughn, 1998; Lindsey, 2000). Taking into account the perspective of special education teachers is valuable since they interact with students and the software on a daily basis. The special education teacher also has the most comprehensive knowledge of students' educational performance and needs. The following introduction of the ISNSE model of software evaluation is based on characteristics reported in a study of 144 special education teachers as the most important criteria to consider when selecting software (Weber, Forgan, & Schoon, 2001).

Special Education Teachers' Software Evaluation Characteristics

Special education teachers of students with high incidence disabilities at the elementary level identified characteristics they viewed as important to consider when evaluating computer software. Qualitative data analysis revealed 10 major themes identified by the teachers. Six themes were comparable to indicators described previously in the literature and four themes showed a discriminating influence addressing the special needs perspective and distinguishable from current evaluation criteria. These four themes were classified as: (a) individual instructional integration; (b) narration; (c) curriculum encompassing; and (d) teacher functionality. The special education teacher identified themes similar in other evaluation instruments to aid in software evaluation were addressed as: (a) welcoming; (b) sensory stimulating; (c) learner program design; (d) learner empowerment; (e) technology adaptation; and (f) diversity. A copy of the authors' Special Needs software Evaluation Scale (SNSES) is available by contacting rweber@fau.edu

Supplemental Software Evaluation Forms

The authors recommend using supplemental software forms to help in the identification of the learners’ overall academic and social characteristics and to designate the frequency and duration of use. These forms were developed by the authors and could be modified to meet specific needs of the evaluator or the district. It is suggested that a supplemental software evaluation forms be completed to document the appropriateness of the selection for each learner.
Directions: In order to use this form, first think about your child's unique characteristics. Read the list of characteristics and determine which descriptors relate to your child and place a check mark in each pertinent box or write in your own characteristics. Focusing on the child’s characteristics helps with evaluating the software program and provides evidence that the software program can help meet their needs.

Figure 2: Recommendations Form

Recommending the Evaluated Program

A note of caution: some school districts are hesitant to write a specific software title on the child's IEP in concern that if the child changes schools, the new school might not have that specific software program. The school district may prefer to write a general statement about the type of software program recommended such as, “software to improve letter and sound identification.” We strongly argue against this and suggest that teachers and parents require the specific software title written on the child’s IEP. Overall, by using the individualized special needs software evaluation instrument in conjunction with the supplemental software evaluation form, school personnel and parents can discuss the assistive technology requirement for their child’s IEP and make well-informed recommendations that assure the software programs the child uses are instructional, educational, and enjoyable.

Conclusion

Fortunately, federal law gives each school district flexibility in creating and utilizing forms to document the assistive technology component of the IEP. The model presented here for software evaluation is based upon the perspective of practicing special education teachers of elementary students with high incidence disabilities. This evaluation model was developed specifically for special education teachers and related service providers to use when evaluating the appropriateness of a software program for meeting an individual child's IEP goals. With the national focus on student and teacher accountability, teachers must be certain and able to document that the integrated use of technologies, including the effect use of software programs, are used productively which hopefully will lead to improved student outcomes. Using the Individualized Special Needs Software Evaluation (ISNSE) approach for assessment reflects the most up-to-date knowledge in software evaluation and incorporates teacher identified characteristics that are vital for individual instructional supplementation. Teachers who use this model for software evaluation can be confident their results portray an accurate evaluation of the program's features and value to enhance the learning process.

Effectiveness of QuickTime VR as an Instructional Environment for Students with Special Needs

William R. Wiencke, Assistant Professor
Media & Instructional Technology
College of Education
State University of West Georgia
United States
wwiencke@westga.edu

Abstract: Virtual reality (VR) has been shown to be an effective tool to enhance and support a variety of educational activities. QuickTime VR (QTVR), developed by Apple Computer Corporation, is a technology for creating and moving through virtual environments. QTVR provides a number of advantages over "traditional" VR. These include lower cost of the development software as well as the hardware required to run it and it does not require advanced training or programming skills. The study will evaluate the effectiveness of using QTVR as a virtual environment to train students with special needs in developing life skills.

Introduction

Virtual reality (VR) has been shown to be an effective tool to enhance and support a variety of educational activities (Andolsek, 1995; Maule, Oh, & Check, 1998; Taylor & Disinger, 1997). In addition to instruction, VR has also come into increased use in diagnosis and treatment of severe psychological and emotional disorders. Although effective, its use has been limited primarily due to the high cost of both the equipment required to create and participate in the VR world, but also the time and expertise required to develop the environments (Dunning, 1998).

QuickTime VR (QTVR), developed by Apple Computer Corporation, is a technology for creating and moving through virtual environments (Kitchens, 1998). QTVR provides a number of advantages over "traditional" VR. The cost of the development software is very reasonable at less than $400. It requires no advanced computer system to run, only a Power Macintosh running System 7.5 or later. Software for creating similar environments is also available on the Microsoft Windows operating system. Creation of the QTVR environment is relatively simple, requiring only the step-by-step instructions in the user manual, not advanced training or programming skills. Traditional VR environments are created by building a 3D model which the computer uses to generate the virtual environment. Due to the complexity of this operation and the amount of possessing power required, the representations forfeit detail for economy of use. Consequently the virtual world resembles a low cost video game more than reality. In comparison, QTVR utilizes actual photographs to create its virtual world, making the scenes visually realistic. Lastly, Fully immersive VR requires costly technology such as head mounted displays (HMD) and movement tracking devices to allow the user to interact with the virtual world. QTVR movies only require the use of either a Macintosh or Windows based system and the free QuickTime Player for interaction.

QTVR creates VR environments by "stitching" together photographic images to provide either a panoramic view or a stationary view of an object which can be rotated and view from any angle. The QTVR movie allows the user to actively pan through the full 360° of the panorama. This provides the illusion of standing in one location and turning around to view your surroundings. Once these individual panoramas are created, they can be linked to allow the user to move from one to another by selecting "hot spots" or doorways (see Figure 1). The linking of multiple panoramas creates a virtual representation of a locality such as a school or historic site, which can be accesses remotely either over a local area network or the internet.
This paper will describe a pilot study currently underway to determine the effectiveness of QTVR as an instructional tool to assist students with special needs (mild to severe mental retardation) to develop life skills.

Uses of VR in Education

Currently the use of virtual reality in education and training can be divided into two general areas. First, it provides students with the opportunity to interact with environments or phenomena that would be difficult or impossible to work with in a traditional classroom setting. Examples of this methodology would be fieldtrips to distant locations measured both in miles and time (Pape et al, 2001), viewing biological, chemical, or physical reactions (Taylor & Disinger, 1997), and the visualization of complex data sets. The second use is when the students are actively involved in the design and creation of the VR environment. Activities based on this method promote a high degree of constructivism and cooperative learning environments (Roussos, Johnson, Leigh, Vasilakis, & Moher, 1996; Winn, Hoffman, Hollander, Osberg, Rose, & Char, 1999). Work with students with disabilities using VR technologies have included life-skill training for students with physical handicaps (Germann & Broida, 1999), students with severe learning disabilities (Neale, Brown, Cobb, & Wilson, 1999), and students with behavior disorders (Muscott & Gifford, 1994).

Project Description

The current project builds upon the work of Neale et al (1999), who utilized traditional VR environments to train students with special education needs in life skills. The VR environment provided very limited visual authenticity and required the development of 3D worlds representing a house and supermarket. The object of the VR training was to provide the students with multiple opportunities to work within a real life situation (e.g. shopping, cooking, etc) virtually before encountering the tasks in the actual environment. This is particularly helpful since it allows the students to gain experience without traveling to the location and encountering difficulties which may prove to be embarrassing, hazardous, or costly.

The current project utilizes QTVR to represent similar environments but will provide actual photographic imaging of the virtual world. If similar results are obtained it will show that effective virtual learning environments can be created utilizing the capabilities of QTVR. This would mean that educators could produce VR environments quickly, simply, and inexpensively.

The ultimate goal of the project is to create a QTVR representation of a local supermarket used by our school system to provide life skills training. The pilot study will determine if the subjects can interact with and learn from a QTVR environment. QTVR models will be created of the elementary, middle, and high
school in the district (see Figure 2). The elementary students will begin using the model of their own school, one with which they already are familiar. After they are comfortable with using the system, they will begin to use the model of the middle school, a building they do not know. When they can locate specific landmarks (media center, gym, cafeteria, etc.), in the virtual environment, they will visit the facility and will be evaluated on their ability to successfully navigate the building in real life. The same procedure will be conducted with the students at the middle school except they will be evaluated using the high school as their test environment. This will be done to see if there is a difference in the effectiveness based on age/grade level.

![Image](image_url)

**Figure 2. Examples of QTVR Scene at the Junior High School**

If the pilot study shows success, the students will move up to using the supermarket environment. Other QTVR models will be created based upon the recommendations of district's special education teachers to meet the educational needs of their students.

Papers in the Technology Diffusion section address issues associated with the implementation of technology in educational settings from K-12 through Higher Education. Successful ways to integrate the use of various forms of technology continues to be a pressing concern in this area. Integration efforts operate at several levels. It is a primary goal in federal Preparing Tomorrow's Teachers to use Technology (PT3) grants, State offices of education are taking an increasing role in promoting technology integration in State-level technology plans, university programs are attempting to infuse it into their teacher preparation programs through stand-alone courses and in methods and student teaching, districts and schools are exploring ways to support teachers efforts at integration, and even individual teachers in the content areas are examining ways that integration can be subject-specific.

One of the central issues associated with technology integration is making good educational usage of technology a sustainable and ongoing reality. That is, technology becomes integrated into the culture of the classroom in a meaningful and productive way. A fundamental problem with previous efforts to integrate technology into U.S. public schools has been an emphasis on installing and maintaining the physical equipment, without ensuring the technology is effectively used to support and enhance student learning. Recent work has examined various ways to motivate and support teachers and teacher educators as they begin to provide technology experiences for students. Helping faculty understand how technology integration differs across content areas and grade levels is a valuable part of this process, as is developing familiarity with the available technologies, the types of support systems available to them, and how to cope when the physical equipment is inadequate. Projects designed to promote teacher development are essential if we are to realize technology integration goals.

One road to professional development for teachers involves building cooperative partnerships among the many constituents who have a stake in integrating technology into classrooms. Effective partnership efforts can take many forms. Pairing K-12 teachers with university faculty has been mutually beneficial for both groups. University faculty gain an understanding of how classroom teachers use technology with students and K-12 teachers can benefit from ideas and resources available through university settings. Classroom teachers can also connect with parents and the local community through technology and technology-related activities. Cooperative relationships can help K-12 teachers, parents, librarians, university faculty, and administrators help each other understand the vital role that technology can play in educating children in schools.

Technology diffusion is also concerned with the use of various tools in the learning environment—whether that is in a traditional classroom, or through a virtual online experience. Devices like handheld computers, or "palm Pilots" provide an exciting new option for teachers and students to use in collecting, manipulating, and representing data. Other cognitive tools like databases and computer-based concept mapping software provide opportunities for students to use the technology to develop higher-order thinking skills. Some of the greatest potential in technology diffusion is apparent in the use of the Internet to provide a virtual environment for students and teachers. The nature of the World Wide Web is such that it provides access to information and resources in a widely distributed fashion. This allows for the creation of virtual communities for sharing ideas and experiences, cooperative online learning activities, and web-enhanced teaching opportunities. Widespread Internet access will likely spawn a new and expanded vision of technology diffusion in education.

The papers in this section will provide you with many insights into the various aspects of technology diffusion. The authors address some of the central themes from their unique perspectives. This work is valuable in that understanding technology diffusion seems to be central to our efforts to integrate technology into the educational system and use it effectively in classrooms.
Faculty Technology Integration Project

Comfort Akwaji
Curriculum and Instructional Technology Department
Iowa State University
Comfortakwaji@aol.com

Abstract: This paper is a case study report on the creation and ongoing implementation of a faculty technology integration project at a small liberal arts college in the Midwestern United States. The project seeks to prepare faculty to utilize computer technology in curricula, develop technology integration mentors and to foster ongoing mentoring and constructivist relationships in a community of teacher/learners. Experience in the project thus far has shown that factors originating in such disparate areas as equipment resources, faculty academic backgrounds, software currency and instructional perceptions have strong impacts on the conduct and progress of the project. Additionally, project management issues with partners and staff, largely unanticipated, have arisen and created discordance in the project, especially with respect to building a community of practice culture among the facilitators and the participants.

Introduction

Technology integration in the curriculum is becoming more widely accepted and implemented at most educational levels. New concepts of classrooms and formal schooling have come of age with the advent of the use of computer and communications technologies like desktop publishing, presentation and spreadsheet applications, the Internet and virtual classrooms. Preparing instructors for technology integration at the tertiary level, however, is problematic. The provost of this small college has long sought to enhance, and in some cases inaugurate, the faculty’s ability to use modern computer technology in their coursework as a result of numerous requests from the faculty. Consequently, I was asked to create a project for the faculty for the understanding, acquisition, and implementation of technology-based teaching and learning strategies. The project was to focus on faculty training and preparation along with the generation of a community of practice around technology skills acquisition, implementation and integration and the creation of a cadre of technology savvy mentors that would serve as resources for the faculty’s initial training and as support for the maintenance of post-project efforts. At issue were concerns about the adoption and use of the technology-based strategies due to a litany of factors including faculty member age, attitudes toward technology and its use in coursework, experience and competency with computer technology, anticipated use of the strategies, time and facilities for the project’s implementation and access to viable computer resources. Participants were asked to complete a pre-project familiarity, skills and attitude survey to inform the process of determining the appropriate initial level for the project content, and to provide ongoing qualitative evaluation for formative critique of the affective factors in the project as well as the project’s effectiveness. Evaluation sessions are also held with the provost and project partners to ensure all are informed and current with the project’s progress.

Project Definition

Creation of the project began with discussions with the provost. This particular aspect was very important in that this momentous change in how the college was to go about the practice of education was being initiated from the top of the administration. The provost asked me to generate and submit a proposal outlining the project’s implementation process, the projected schedule of meetings (sessions) and their agendas, specifying what would be required of his office and the participants and listing the facility and computer resources required.

My project partners and I approached the design/definition of the project from Instructional Systems Design (ISD), Constructivist and community building perspectives. First came the analysis of the audience. At this initial stage of the project, we used some general characteristics of the group as benchmarks for strategic planning purposes, e.g., the fact that all participants possessed advanced degrees. Next we determined and established an overall goal and a purpose for the project. We then established the structure of the project, which comprised five phases; I, II, III, IV and V, each containing several face-to-face sessions. The project has just begun; Phase I is being used to introduce the participants to the project – including what to expect and what is expected of them, the review of theoretical foundations for the project, the generation and collection of the audience’s entry data and the introduction and modeling of several
technology-based applications for communication and collaboration. Phase II is for mentor recruitment and training as well as community building. Phase III, then, involves participant training in computer and computer-applications knowledge and skills, in association with their mentors, based upon the entry surveys and the identification of participant-chosen technology-based projects to be completed in Phase IV. Phase IV features the "hands-on, minds-on" application of their knowledge and skills by the participants, again in concert with their mentors. Phase V provides culminating exercises and acknowledgements. The participants were asked to maintain a journal of their experiences and reflections of the project's implementation, to be collected as part of the summative evaluation facet of the project, and to share such thoughts as they may deem appropriate with the facilitators and colleagues during the course of the project. Subsequent to fashioning the overall structure of the project I generated goals and objectives for each phase to provide bases for project performance measurements. Then came the deliberation and decisions about the best strategies for effecting the technology learning, for the support for the participants' project assignment activities and for post-project scaffolding of participant efforts in applying their new-learned facility. Based in part on Knowles (1984) work on adult education, we chose the one-on-one mentoring approach for both the in-project learning and post-project support. Finally, for project formative evaluation, we opted to use surveys for the collection of participant affective, perceived skill change and project improvement data at the close of each session, and to use interviews of the provost and department heads at the end of each phase. Summative evaluation will be effected via post-project surveys, interviews and observations.

Project Implementation

The inaugural session of the project was attended by more participants than expected. The extra number were at once a bane and a boon since increasing the size of the audience posed additional logistics problems, while at the same time serving to keep the ranks at the expected number, later on, due to drop-outs. The session comprised an introductory session using a Microsoft PowerPoint electronic presentation, a discussion and the introduction of the first communications tool, "eBoard", via a PowerPoint presentation followed by a hands-on practice session. Interestingly, some of the participants balked at the requirement to do the hands-on portion. They explained that they had expected the project strategies to consist only of lecture style presentations from which they were to glean understandings about technology-based applications and interventions. This was a totally unanticipated issue that provided welcome insight into the need for ascertaining and addressing participant expectations in projects of this sort, as part of audience analysis.

Logistics was another issue. We had requested and received assurances of access to a number of machines. Instead we used a conference room where several computers, some older, and a digital projector had been set up. Few machines meant that participants accessed them in groups causing problems and affordances that generated interesting dynamics, e.g., there was only one mouse "operator" and, depending upon the operator's facility, learning the application was either facilitated or hampered. A constructivist dynamic surfaced when misunderstandings were assuaged by the expertise of others in the group. Additionally, computer shortcomings and comments by facilitation partners that drew negative comparisons between the resource capabilities at this institution versus Iowa State caused frustrations in that were not easily dispelled. Session evaluations pointed up the participants' satisfactions and disappointments.

Conclusions

Lessons learned so far in this project include the necessity for more enlightened audience analysis, more coordination among project partners, better resource coordination and modern equipment and applications. These issues were addressed in a meeting with the provost resulting in assurances of both logistical and coordination improvements. Some of these concerns could most likely have been mitigated through collaboration with others who have conducted similar projects.

Saved by Blackboard: Web-Enhanced Teaching

Anisa Al-Khatab
Associate Professor
Eastern Kentucky University

Web-enhanced courses are selected by some faculty to develop the competence, self-efficacy, and technical skills required for designing and delivering on-line courses. A faculty who was using Blackboard as an enhancement in teaching a regular course was struck by a severe health condition that required hospitalization. The nurses' station in the hospital brought Blackboard technology to her rescue and successfully completed the course. This paper tells that success story of Blackboard rescue.
Abstract: A major problem schools face is the maintenance of existing computers. Several studies have examined a school system’s technology capacity as defined as adequate technology, networks, electronic resources and support to meet the system’s learning goals. This study examines the technology capacity of a group of middle schools in Northwest Georgia. Teacher perceptions of the school systems ability to adequately support technology and the effect that has on using technology as everyday tools for learning are examined. The quality of the technology available for classroom use and its impact on instructional methods are also examined.

Introduction

One of the many problems schools face is the maintenance of existing computers. Computers in schools are more often community computers rather than personal computers. Classroom computers usually experience heavy usage and habitually need repairs.

School districts are regularly swamped with repair requests, and repairs are sometimes delayed for weeks, or even months. This delay creates a problem for teachers who have developed lesson plans that integrate the use of computers in instruction. Unless teachers can be confident that computer glitches will be fixed in a day or two, they are unlikely to invest the time and effort to modify their curriculum to include technology.

Many districts have begun placing computer resource personnel in schools, with the goal of helping teachers use the technology more effectively. These specialists, often centrally trained, deal with a wide range of skills among teachers and dramatic differences in the specific needs of individual schools. The problem is compounded when these resource people must provide support to multiple schools (Odden, 2000).

Other factors in a school’s technology capacity include adequate technology and networks. Classroom computers connected to the Internet have increased significantly over the past four years. The quality of technology in the classroom has also improved due to the fact that prices for technology have dramatically decreased over the same four-year period. School systems have purchased technology and connected classrooms to networks more than they have allocated funds for the repair of technology, software, and the training of teachers during this period of time (Solmon, 1999).

Study Demographics
The study identified five middle schools in Northwest Georgia. Locations ranged from small county schools to larger city schools. The average class was 23 students with teachers seeing approximately 100 different students per day. Most teachers in the study had taught twelve years with the most years of experience being thirty-one and the least being one. Eighty percent of the reported operational computers used some form of the Windows operating system, 16 percent were Macintosh and the remaining 4 percent were Apple //e. Sixty-two percent of the computers were connected to the Internet. In a recent national study the percentage of computers in instructional rooms connected to the Internet was seventy-seven percent (Cattagni, 2001). The study did not assess the quality of the computers found in the classroom and therefore many of the computers reported are obsolete for today's classroom standards (i.e. Apple //e's still in use).

**Technology Access**

Most schools reported having both computer labs and computers in individual classrooms with the average number of computers in lab being twenty-five and the average number in a classroom being less than two. Computer labs were also identified as being used by a special technology class rather than subject specific (i.e., reading, math, science, language arts, etc.). The placement of classroom computers was equally balanced in the major academic areas (1.5 / classroom) with no specific area averaging more computers than others.

Technology placement was also equally balanced between grade levels with no significant difference found between sixth, seventh, or eighth grade classrooms. The student-to-computer ratio based on average class size and average number of computers in a class is approximately 14 students to each computer. The student-to-Internet access is approximately 16 students for each computer. When lab computers and special education classes are removed from the total, the ratio changes to approximately 17 students per computer and 24 students-per-Internet access computer. The most frequent classroom computer to student ratio is 25 to 1. The most frequent Internet access to student ratio is 0 to 1 due to the fact that over fourteen percent of the classrooms have no Internet access. National trends for students per instructional computer with Internet access were 7 to 1 (Cattagni, 2001).

**Technology Usage**

Teachers were asked to identify how often they used technology with their students and specifically what applications were used and how often. Frequency of usage was defined as daily, weekly, monthly, once or twice a year, never, and not available. Forty-two percent reported using computers in general on a daily basis. The most common daily usage related to word processing (15 percent) and Internet activity (11 percent). Databases, Desktop Publishing, and Integrated Learning Systems were reported as never being used by a majority of the teachers. Other applications reported as never being used by a high percentage of the teachers were Spreadsheets (49 percent), presentation software (41 percent), and search engines (44 percent). The data on individual schools reporting using computers in general on a daily basis varied from seventy-two percent of the teachers at one school to twenty-five percent of the teachers at another. The school that reported the highest daily usage was the school that did not have a computer lab or special computer/technology class. Integrated learning systems and simulation programs were reported as either never used or not available in eighty percent of the classrooms. The percentage of daily use with students is much higher than any one application. Teacher productivity applications were not a listed usage on the survey since the intent was to measure how technology is used with students. Additional comments from several teachers detailing how they use the technology to prepare tests, scan tests, and store grades help to explain the computer in general usage being much higher than any listed application.

Student time on computers in classes averaged 1.5 hours per week. The range was from no time to as many as ten hours. The most frequent amount of weekly time was thirty minutes. All classrooms identified in the study reported having at least one computer. In as many as thirty-six percent of the classrooms it was reported that students spend no time on computers during the week.
Repair Time

In most schools the amount of time to fix the problem of a computer breaking down was measured in days rather than hours. The average number of days a computer was unavailable due to being broken was five days. The longest reported time for a computer to be in need of repair was thirty days. The average repair time for Windows-based computers was measured in days and the average repair time for Macintosh-based computers was measured in hours. The repair time for computers in labs was most often reported in hours as opposed to days for classroom computers. The highest average repair time was over seven days to fix the problem. The fastest repair time average was two days. National averages for repair time were reported to be 5.6 hours to 3.6 days for an average range of 53.6 hours to repair a broken computer (Solmon, 1998).

Sources of Repair

Maintenance to computers was most often provided by either local school staff specializing in that service (computer lab teachers, computer aids) or library media teachers. Classroom teachers provided technology support more often than district level technology specialists. Students and commercial providers were rarely if ever used to support technology. The sources of repair identified are very similar to a national study that found on average 68.5 percent of schools reported lab teachers or special computer staff provided technical support for the maintenance of technology (Solmon, 1998). The same study found that library/media teachers and classroom teachers to be the next level of support with students being rarely used (4.9 percent). Nationally, school districts provided greater technology support than found in the schools in the study.

Constraints to Technology Integration

When asked to identify the most frequent barrier to technology integration the most common barriers were too few computers in the classroom, not enough computer labs, and limited budget for technology. Broken computers in need of service were reported as a problem either occasionally or frequently by over 70 percent of the teachers. Other barriers that were reported as either occasionally or frequently impeding the integration of technology included obsolete technology (77 percent), too little or inadequate software (88 percent), and teachers’ lack of experience with technology-oriented pedagogy (64 percent). Teacher lack of computer skills and student lack of computer skills were seen as never being a limitation by over sixty percent of the teachers. Teacher and administrator lack of interest in technology was viewed as never limiting integration by eighty percent of the teachers. The findings for this area are similar to national studies. In the 1998 Solmon report to the Milken Foundation outdated computers were seen as a constraint to technology usage by 63.2 percent of the states reporting. The percentages for lack of teacher training (31.5 percent) are also similar to the population identified in the study.

Study participants identified other constraints to the daily integration of technology in teaching. Such factors as pressure to prepare students for accountability testing, lack of freedom to install software, having only one computer for as many as twenty-five students, lack of access to the Internet, and a lack of on-staff technologist to repair computers and train teachers were provided in the additional comments section of the study.

Conclusions

Technology is often placed in classrooms in a top-down fashion with more emphasis placed on acquiring the artifact than supporting its daily use. Teachers are expected to make the classroom usage of
technology a natural part of instruction. The study found that teachers on average had less than two computers in their classroom to share with an average of 23 students. In many cases classrooms had no access to the Internet and therefore the usage of the computer was limited to the installed software. Many teachers found the lack of software, low number of computers, and time to repair broken computers to be constraining in their ability to adequately use technology in their instruction.

Teachers did not see their skill or interest as a barrier to technology in the classroom nor did they perceive school administration as a limiting factor. The most common barrier was a lack of adequate funds to support technology and a limited number of computers with Internet access. The quality and quantity of the technology available for classroom use creates a negative impact on instruction.

The technology capacity of school systems has not been sufficient to adequately support teachers using computers as everyday tools for student learning. In order to increase system capacity the additional budgetary requirements to support, maintain, and replace classroom technology will be enormous. The challenge that districts face is finding cost effective methods to sustain and support existing technology as well as identify resources to obtain new technology.

Abstract: In the paper we present Lezi II, a tool to easily transform normal lessons or lectures into powerful multimedia applications based on a very simple and regular structure. The tool has been conceived and produced at our Lab to simplify the production process, especially for non technical users. Lezi II is extensively used in our computer engineering department to produce educational multimedia applications.

Introduction

In general, the production of hypermedia applications is a complex and expensive task, requiring both technical skills and communicative abilities. Nevertheless, some specific kind of multimedia production can give good quality results, even without specialized IT skills, and at low costs. We have concentrated on this particular field, with the aim to supply with a valid tool the teachers who want to publish their educational material easily and at low costs.

We can in fact observe that traditional lessons/lectures, when performed from good teachers, can be easily transformed in good quality multimedia applications for both on-line (the Web) and off-line (CD/DVD) distribution. The key point is that for a good teacher it’s easy to speak, to explain using images and slides, to show objects, to write on the blackboard and to use his mimic to grab and hold the attention of his students. In our opinion this kind of educational contents can be effortlessly transformed in a very usable multimedia application based on the video of the lesson, on a simple and regular navigation structure and on a little set of user-friendly multimedia objects.

The Lezi II Tool

Starting from these requirements, and from an accurate bibliographic analysis, the project of a complete prototype, called Lezi, was started at the SET-Lab of the University of Lecce, within a large research project aimed to the development of innovative educational tools and applications. The prototype includes two distinct parts: the authoring part, suitable to create a new Lezi lesson, and the fruition part (also referred as “lesson player” in the following), used to navigate among existing lessons and to select and play the desired one.

Two version of the prototype have been produced, with the same functionalities, for both on line and off line operation. The off line version is suitable to create and/or use stand-alone Lezi lessons, most of all for CD/DVD production, while the on line version allows remote users on Internet to create and/or play Lezi lessons. At any time is it possible to port stand-alone lessons on the Internet and vice versa. The fundamental requirement, for Lezi, is a very high ease of use, so that it can be truly accessible even to users with very basic computer knowledge. This is essential for many good teachers or scientists who have, a great communicative strength and could easily offer high quality lectures and lessons.
Experiences with Lezi II

In the poster presentation we describe both the Lezi tool and the experience we gained at the University of Lecce by using Lezi to produce various real courses and other teaching events (conferences, scientific seminars, on-line training resources, etc.) in different authoring situations.

The first experience we describe is based on the class of Informatica Grafica given by Prof. Paolo Paolini and Prof. Franca Garzotto in three Italian Universities (Milano-Lecce-Como 1999). In the lesson we can see a classical authoring situation: a teacher exposes his concepts in a classroom with a blackboard or with some slides. In the second example we describe the use of Lezi to document a preliminary meeting for a large research project supported from the European Community. Other specific real productions based on Lezi (on-line training etc.) are also described.

Conclusion

In conclusion, the idea described is very simple: it is possible to publish good educational multimedia applications developed by academic staff with very little technical effort, in a short time and with limited financial resources.

In our opinion, Lezi can enable a teaching staff without a specific technical preparation in multimedia production, but with valid contents and good didactic skills, to easily prepare good multimedia interactive lessons, both for off-line (CD/DVD) or on-line (the Web) purposes. More in general, the widespread use of Lezi II or other similar tools can effectively support the development and the use of educational multimedia contents into universities and into schools. Obviously, this kind of multimedia contents is not intended to replace the publications of professional editors.

The Diffusion of Communication Highways
Connecting Parents and Schools

Susan Borzych
Geraldine DiPalma

Parental involvement has continually been an important piece in the development of student learning and success in school. The increasing availability and access to the Internet provides schools with an effective way to communicate with the community via school web pages. However, there is still a large void in reference to timely communication between schools and parents regarding personal information, such as grades, attendance, demographic information, discipline, and health issues. New software programs are now being made available to address this void and provide timely information through the use of technology—specifically, the Internet.

Parental involvement is not restricted to a physical presence in the building but includes involvement outside school and in the home. With the increase in single parent homes, working parents, and situations that prohibit many parents from frequently visiting the school building and talking one-on-one with teachers and principals, it has become increasingly difficult for parents to stay current with their child's progress in school. If information about student progress were provided to parents on a timely basis—in a format that was easy to understand and access—necessary interventions could be provided that would help students experience increased success in and out of the classroom. These strategies would increase the probability of improved student performance on assessments and standardized tests. Information about assignments, projects, upcoming events, and due dates would require students to be accountable for their progress and would provide information to parents and guardians about a student's development and growth in the classroom. This would discourage excuses and claims of miscommunication amongst the involved parties, promoting increased interaction and understanding of expectations.

Critical to the communication between schools and parents is the inherent meaning, or the subjective perception of the innovation of communicating about student progress via the Internet (Rogers, 1995). The diffusion of this type of communication system is an "authority innovation-decision" that is subscribed to and made available by individuals in the educational system that possess the technical expertise to realize the inherent value that such a system would be able to provide (Rogers, 1995).

A large school district in the central part of the United States—a district of approximately 87,000 students, attending 165 schools—agreed to pilot the NCS software product ParentCONNECTxp for the 2000-2001 school year. The pilot took place at a newer high school serving approximately 1,500 students in grades nine through twelve in the west corridor of the district. The pilot project followed the district-approved process, which included piloting the web-based program for one year at a district school. At the end of the year, a feasibility survey was conducted with the staff of the school, and a survey was conducted amongst participating parents and guardians. The data were analyzed, and the resulting report has been made accessible to all schools in the district. The challenge of this pilot was to convince the parent population of the advantages of this type of communication and the value that timely information could provide for them in their quest to be effective parents and provide an adequate support system for their students.

The results of the surveys were very positive, and suggestions were reflective and reasonable. Parents valued being able to access timely student data on-line and felt that it was a positive step in helping students avoid pitfalls and be successful in their academics. Parents who received e-mail notifications for unexcused student absences, felt that early intervention was critical and beneficial in addressing student attendance issues. A recommendation has been generated, addressing the possibility of implementing the product district-wide.

This poster session will illustrate the results of the feasibility study and the parent survey and will address the possibilities and the restraints that accompany the accessibility of student information via the Internet, as well as address issues directly related to the diffusion of the software product amongst parents. This session will also address the structure of the socio-economic system, communication channels, social order and their association with the "s" curve, as well as the implementation of a new innovation (Rogers, 1995). Also included in the session will be technical information about installation issues, security concerns, hardware requirements, and software performance. CD's will be available that contain a PowerPoint presentation illustrating points of interest for those who might be considering implementing such a program.

Developing a State Technology Plan to Promote State-Wide Technology Integration in K-12 Education: Preparing Arizona Students for Future Success

Jeannie Brush, CRESMET, Arizona State University, US
Donovan Evans, CRESMET, Arizona State University, US

Purpose

Constructing a framework for technology integration in Arizona K-12 will establish a "roadmap" enabling the state to consistently and coherently promote a coordinated state-wide infusion of educational technology in the K-12 education system. It will bring direction to and support for all activities that impact the integration of educational technology across Arizona elementary and secondary education.

A comprehensive state technology plan seeks to ensure that an educational technology vision is reached for every student, every teacher, and every school in the state of Arizona. It is intended to support and to align the growing movement of teachers, administrators, parents, industry and business leaders, and government officials that recognize the need in Arizona for a new comprehensive state educational technology framework. By integrating Arizona's many educational initiatives, a statewide educational technology framework has the potential to maximize resources, coordinate efforts, and guide all education partners to move in the same direction with minimal duplication or conflicting goals.

This paper will provide an overview of the Arizona K-12 technology plan, and describe the processes involved in developing the plan. These processes involved determining key stakeholders in the state, acquiring input from stakeholders to develop a framework for the plan, disseminating a draft framework to teachers, administrators, and business leaders in the state, and using feedback from these individuals to refine and enhance the plan. After the plan has been refined, key stakeholders will take the plan to the Arizona Department of Education for review and adoption. Each component of this process will be discussed, and the resulting technology plan will be described in detail.

Educational Technology is Important for Student Success

The use of educational technology is no longer the path to future success for Arizona children. It is the path to current success. If used appropriately, research shows that it enriches the learning environment leading to better student performance. Educational technology can:

- Allow learning to occur in ways not possible otherwise;
- Be a means for improving learning in all subjects;
- Expand students' creative abilities;
- Promote students' taking responsibility for their own learning;
- Impact at-risk student populations positively;
- Promote students' interaction with a larger community (e.g., discussions directly with experts, with other students working on the same or similar projects, etc.).
- Give students experience with modern workplace tools.

In short, technology, when implemented appropriately, has great potential to give Arizona K-12 students an enhanced learning environment. As an additional benefit, Arizona children will be exposed to and utilize technology that will better prepare them to enter today's society and economy as an active participant.

Providing Access to Technology

Educational activities that integrate technology in meaningful ways are useless if students do not actually have access to that technology. The significant enhancement to teaching and learning afforded by resources available on the Internet is lost if schools do not have the infrastructure necessary to deliver...
broadband voice, video, text and graphic data to adequate multimedia computers available in the classrooms. Thus, meeting professional development and student achievement goals relies upon the creation of a networking infrastructure and provision of adequate numbers of multimedia computers in every classroom throughout Arizona. This goal is even more crucial in the remote areas of Arizona where community resources are insufficient to provide students the opportunities that more affluent students in the more dense population centers may enjoy in their homes.

Since 1999, Arizona has made groundbreaking strides in this area. Initially, each of Arizona’s 228 public school districts were provided enough computers to ensure a 1:8 computer:student ratio. The second phase of the statewide educational technology initiative will connect every network-able computer to a local area network (LAN). Also in phase two, every school in every district will be connected via a wide area network (WAN) with a district aggregation point that is then connected to the Internet with a broadband connection that allows transmission and reception of voice, video, text and graphic data.

This initiative is making an Application Service Provider (ASP) available to every public school at no charge to the schools until June 2005. The ASP will host school and teacher websites, e-mail services for staff and students, student information management systems, student assessment tracking systems, and teacher resource management systems. The ASP will enable schools to access productivity software, over 250 educational titles, (i.e., content, courseware, reference materials), and communications software. These resources will be available over the Internet, making them accessible to students, staff, parents, and teachers whether working from school or home. Students will be able to access their own work and the school district’s software from any location that has access to the Internet.

As cutting edge as these initiatives are, they are only the beginning of a continuing challenge. Given the speed with which technology information systems are changing, this State Framework, covering all aspects of educational technology including provisions for assessment and updating, is necessary.

Components of the K-12 Technology Plan

Focus groups consisting of K-12 administrators, teachers, parents, industry stakeholders and university faculty determined twelve key issues that should be included in a comprehensive state framework. Review of other state educational technology plans and interviews with state technology directors helped determine the corresponding benchmarks of these components. These components were combined into the following eight categories following a stakeholders meeting:

1. Integrating educational technology into the curriculum
2. Professional development for teachers and staff
3. Pre-service training for teachers
4. Capacity, infrastructure, staffing, and equipment
5. Collaboration and partnerships
6. Equity of use
7. Review, evaluation, and accountability
8. Current and future funding requirements

Addressing these issues requires a framework of vision and implementation strategies. All of these categories may be considered interdependent, often with considerable overlap of concept and, where possible, shared use of resources. Each component is described in more detail below:

1. Integrating educational technology into the curriculum. The purpose of education is to help students think, learn, and achieve in new ways in and across disciplines. Educational technology is a necessity in fulfilling this purpose. Educational technology (ET) will help students in all subject areas develop and nurture the ability to access, to analyze and to communicate information. In every school there must exist a positive and supportive attitude toward ET. Six critical objectives for educational technology integration are:

- Build the foundation for the integration of educational technology within schools
• Address technology and content/curriculum standards complimentarily by teachers and administrators
• Structure the reward system to strongly provide the incentive for teachers and administrators to integrate educational technology
• Provide training for teachers and administration of all schools
• Align school educational technology plans with State Framework
• Assess student and teacher competency using state educational technology performance standards

2. Professional development for teachers and staff. Teachers must be comfortable using educational technology if it is to be integrated effectively into the classroom. Providing access to resources along with time and support to develop educational technology competency represents the most logical means by which to ensure effective curriculum integration. To develop teachers and administrators into confident professionals with the educational technology skills to use educational technology resources appropriately three issues must be addressed:

• Build an infrastructure to support the design and delivery of professional development for teachers and administrators
• Provide incentives and encouragement for teachers to engage in educational technology professional development
• Assume ownership of teacher and administrator roles as educational technology leaders and integrators

3. Preservice teacher training. Future teachers must enter their respective fields equipped with educational technology skills and experience. Teacher education programs are responsible for preparing future teachers to integrate educational technology. Teacher education programs must also work collaboratively with the school systems to ensure that student teaching experiences occur in learning environments that support the integration of educational technology.

4. Capacity, infrastructure, staffing, and equipment. Technical standards will provide a foundation for collaborative planning and support efforts among local, regional, and state-level groups, including the worthiness of the individual school educational technology plans and the ultimate success of the technical infrastructure at the local school buildings. Comprehensive plans regarding the required capacity and infrastructure issues include the following steps:

• Establish policies and procedures whereby the infrastructure for broadband Internet connectivity delivered to public school classrooms is regularly upgraded to provide capacity commensurate with state-of-the-art information systems delivery;
• Ensure that numbers and technological configuration standards of multimedia computers available in the public schools stays abreast of the increase in student enrollment and the increase in technological configuration standards as the industry standards advance,
• Provide affordable ET resources (people, professional development, technical support, etc.) to every school district;
• Create plan for equity of access to technology for all students, schools and districts, ensuring that resources are provided in an equitable manner throughout the state regardless of the socio-economic status or ethnicity of the students
• Provide for continued cost-effective delivery of curriculum software that is correlated with state education standards... not just technology standards (Objective 1.2)

5. Collaborations and partnerships. Educational technology plans are better poised to succeed if they include support and partnerships from state and community resources. These include universities, community colleges, libraries, museums, community resources, industry, and state and municipal governments. Successful partnerships and collaboration require a commitment to:

• Provide access to and aid in applying information that promotes collaboration and partnering, and;
• Build and highlight models of exemplary partnerships and collaboration
6. Equity of use. A comprehensive educational technology framework will ensure that all of Arizona's children will have equitable use to educational technology regardless of socio-economic status, race, gender, language, or special needs. The success of statewide equity of use relies upon the commitment to:

- Disseminate data widely regarding issues posed by ethnicity, minority, gender, and physical and mental ability, and
- Address equity of use issues in educational technology widely

7. Review, evaluation, and accountability of the framework. Educational technology is not stagnant; better and better hardware, software, and networks appear each day. Although this Framework is written in a rather generic way, any effective plan for educational technology usage must address the need to periodically update its elements. Regular review of progress in implementing a plan will ensure a timely pursuit of the goal of ubiquitous educational technology infusion in the K-12 system as well as an effective and efficient investment of public and private funds and resources. Of course, the ultimate goal of K-12 educational technology plans is to provide the resources and processes necessary for enabling students to meet the technology education standards. Thus, the ultimate accountability is that students make reasonable progress in meeting these standards. Three specific areas must be directly addressed:

- Maintain currency of the Framework
- Monitor progress in implementation
- Monitor student progress in educational technology use

8. Current and future funding requirements and sources. Providing the technical infrastructure, equipment, human resources, and professional development needed to implement educational technology into K-12 schools requires significant Funding Requirements and planning. Critical steps would include:

- Determine funding requirements
- Determine funding sources
- Acquire and allocate funding to meet requirements
On-line SITE Forums: Joining and Participating

Roger Carlsen, Wright State University, US
Niki Davis, Iowa State Univ & Univ. of London Institute of Ed., US

Abstract
Educators increasingly live more frenzied professional and personal lives. Yet, the demands to stay connected, collaborate, and learn continue to exert pressure on us. Participation on professional forums can provide educators with possibilities to rearrange their time while remaining intellectually and professionally active. Attendees of the initial sessions will be given a working knowledge and skill set for joining and participating on AACE forums. More electronic forums for educators are available and it is increasingly important to join and participate in on-line forums.

A follow-up session will be offered for initial workshop participants and on-line forum leaders. Once the skills and on-line protocols are mastered one may wish to moderate or lead an on-line conference. This presentation will provide attendees with handouts and follow-up support for participating on AACE forums.

Objectives
This presentation has two main objectives. First, this session will provide skill and knowledge for novices who desire to participate in on-line communities. Second, leaders and moderators will be provided with an understanding of techniques and responsibilities of their role as a leader of on-line communities. Follow-up on-line opportunities will be offered to all attendees of these sessions.

Intended Audience
There is no experience requirement for attendees for either of the initial sessions. This presentation is designed to provide individuals with the requisite skills and knowledge to participate in AACE on-line forums. There are also no prerequisites for participation in the either initial sessions.

Attendees to the second follow-up session should have attended the first session or been designated as moderators or vice presidents of AACE affiliated forums. Other forum moderators or leaders may attend the follow-up session.

Proposed length
Two 1-hour beginning sessions beginning and mid conference.

Topical outline of the content
Note Well: This panel will primarily focus on AACE sponsored forum participation. Discussion of other on-line applications will be presented only if time allows and in response to audience questions.

Initial sessions for participants
Different kinds of educational forums
Why join an on-line educational forum
Unique aspects of AACE forums
Discussion of hand out materials
How to join AACE forums
Special considerations related to forums
Potential embarrassing situations to be avoided
Where to find support

Follow-up session for leaders
The forum leader’s mission –
making the community work
Making the experience one that is enjoyable and useful
Anticipating and resolution of forum member needs
Selection of key participants
Humanizing on-line experiences
Getting support fast and when you need it

Instructor's qualifications

Roger Carlsen supervises or has developed approximately 100 on-line fora and conferences using various on-line products. Among his current duties are graduate educational technology advisor at Wright State University in Dayton, OH. He currently serves as moderator for Association for the Advancement of Computers in Education (AACE) announcements, moderator for Educational Technology Review, and supports on-line forums for the Society for Information Technology in Education (SITE).

His current has teaching responsibilities that include graduate courses in telecommunications, on-line education, and distance education. This academic year he is scheduled to provide in-service to 54 school districts. During the past 3 years he has prepared or supervised approximately 400 educational or corporate web sites. Since 1984 Roger Carlsen has served as an officer of 3 technology corporations.
Preparing Technology Proficient Teachers

Dr. Teresa Franklin
Instructional Technology-College of Education

beach@ohio.edu

Abstract: This paper presents initial findings of a U.S. Department of Education – Preparing Tomorrow’s Teachers to Use Technology grant at a Midwestern university. The grant seeks to create models of technology integration in which a university faculty member and a K-12 teacher are paired together to create meaningful uses of technology in university content and/or education courses as well as in the K-12 classroom. Preservice teachers will be given opportunities to see examples of and to practice technology integration in the K-12 classrooms of participant K-12 teachers.

Introduction

As the United States enters the 21st Century, teacher preparation programs across the nation are assessing their capacity to adequately prepare new teachers to embrace the use of technology in the education of young people who will live in a global, information-based society. In investigating the status quo, recent studies have produced somewhat disheartening data. Relatively few teachers (20%) report feeling well prepared to integrate technology into classroom instruction (International Society for Technology in Education, 1999; National Center for Educational Statistics, 1999 January). Although technologies are increasingly available in K-12 schools, teacher professional development both preservice and inservice has not kept pace (International Society for Technology in Education, 1999). With the estimated need for 2.2 million new teachers over the next few years, it is vital that teacher preparation programs answer the call for change.

Studies have documented improvement in the amount and quality of course work in educational computing but have recognized that one required class is inadequate to prepare teachers to use technology effectively in the teaching/learning process (Hunt, 1994; Strudler, 1991; Weitzel, 1993). In addition to computing courses, it is recommended that preservice teachers need to observe appropriate modeling throughout their university course work (Kariuki, Franklin and Duran, 2001; Franklin 1999; Huang, 1994; Hunt, 1994; Gunn, 1991; Novak and Berger, 1991; O’Bannon, Matthew, and Thomas 1998; Strudler, 1991; Weitzel, 1993). Teacher education faculty need to serve as role models; their uses of, and attitudes towards, technology in the classroom will strongly influence the implementation of the technology by preservice teachers (Kariuki, Franklin and Duran, 2001; Franklin 1999; Barker, Helm, and Taylor, 1995; Huang, 1994; Handler and Marshall, 1992). Some researchers have even indicated that until faculty members participate at their own comfort level and use technology, the students they teach may fall behind in the 21st century (Mims and McKenzie, 1995).

Ohio University, located in the heart of Ohio Appalachia, is a major educational institution serving the southeast quadrant of Ohio. There are five regional campuses located throughout the region, in addition to the main campus in Athens. The College of Education accredited by the National Council for Accreditation of Teacher Education (NCATE), graduates approximately 600 undergraduate students per year who typically seek employment in Ohio schools. The University and the College had exerted some effort to entice faculty to use technology in the teaching/learning process. However, inroads had been minor. Students experienced somewhat random exposure to models of using technology in the teaching/learning process in their content and
education classes. In general, faculty members had the technological knowledge and skills comparable to that of students completing the technology course. Furthermore, in field and student teaching experiences, students viewed only scattered examples of technology use by practicing teachers in spite of statewide efforts to infuse technology into the education of all P-12 students in Ohio.

Supported by the Ohio Legislature, SchoolNet, a statewide technology project, has encouraged and supported public school improvement efforts in the state by facilitating the installation and use of computer and network technology in Ohio's public schools. Complementary to the SchoolNet initiative, SchoolNet Plus provided districts at least one interactive computer workstation for every five K-4 students. However, in southeastern Ohio, where school districts are typically classified as poor/disadvantaged districts, the infusion of technology into the teaching/learning process has been progressing at a slow pace. Actual models of appropriate uses of technology have been scattered, at best.

In reviewing the situation described above, the Ohio University, College of Education identified the following needs with respect to technology use.

- The College of Education did not have a long-range, articulated technology plan focusing on the integration of technology in teaching and learning.
- Faculty members throughout the University only randomly modeled appropriate uses of technology in the teaching/learning process within content areas.
- Pre-service teachers had little opportunity to apply technology during field experiences.
- There was little communication among faculty who teach technology courses, faculty who provided content instruction, faculty who provided pedagogical instruction, and P-12 teachers who provide field and/or student teaching experiences.

The project activities are designed to improve teacher preparation programs at Ohio University through the infusion of technology into the teaching and learning. The project is a collaborative effort of the Colleges of Education, Health and Human Services, Arts and Sciences, the five regional campuses, and P-12 schools.

The Study

Data collection used a qualitative case study methodology in which graduate students and the project directors were assigned to content area groups composed of P-12 teachers, College of Education faculty, Arts and Science Faculty and Health and Human Services faculty. In the first year of the study, the groups were divided into the content areas of math, science, social studies and language arts. At least two P-12 teachers, two content area teachers, one College of Education methods teacher, an instructional technology graduate assistant and one project director was assigned to each group. Data was collected from each group in the following manner:

1. University faculty responses to pre-project and post-project surveys were analyzed to determine changes in faculty perceptions about technology and self-assessment of skills in using technology. Faculty kept reflective journals of the uses of technology modeled in their teaching and responded to open-ended questions such as “How did your role as teacher change as you increased the use of technology in the teaching/learning process?”

2. Teachers, who participated in the revised courses, were given pre-project and post-surveys to determine changes in perceptions of the inclusion of technology in the teaching/learning process.

3. The instructional technology graduate assistants acted as mentors to their assigned group and provided technological support to the faculty. The instructional technology graduate students maintained journals concerning their mentoring of faculty and observational data throughout the year of the project. Tape recordings of meetings, minutes from meetings, graduate student field notes and observations as well as project director field notes, meeting notes and observational notes were triangulated to examine the outcomes of the project.

In addition all projects were submitted for review by each content group (math, science, social studies, and language arts) in which an evaluation rubric was used to determine if technology had been incorporated appropriately into each course syllabus and project. The faculty and P-12 teachers then field-tested the projects and course syllabus and a cycle of revision and review was completed a second time. When completed, the projects and course syllabus were placed on the web for the other content groups and the larger Department of Education: Preparing Tomorrow’s Teachers to Use Technology Grant (PT3) to review.
Results

The Preparing Technology Proficient Teachers project provided faculty in Arts and Sciences, Health and Human Services and the College of Education opportunities to discuss a common question concerning “what teachers should know and be able to do when they leave colleges of education concerning content and technology”. What was most interesting in this discussion was the common theme voiced by both the university faculty and K-12 teachers:

*Teachers should look to their content standards and learned societies for guidance on what teachers should know and be able to do in both content areas and technology. These organizations provide a much more national and global view than a state organization. The people who make up the committees of these organizations often have a much wider range of experiences and education and typically are not politically motivated.*

Several K-12 teachers nodded agreement with the statement,

*I never knew that university faculty worried about the same things that we [P-12] worried about. You guys have just as much trouble using the technology as we do!*

Some of the conversations about what “teachers should know and be able to do in the classroom” followed the line of classroom management and understanding how to discipline in the classroom. Most of the K-12 faculty indicated that the knowledge of content was not really a problem for the preservice teachers coming into their classrooms and that classroom management skills were more of a problem. The university faculty contributed that many of their students used PowerPoint presentations as part of their assignments so technology skills by students were increasing. Most university faculty felt that Internet searching and email skills were common practices by many preservice teachers. Both the university faculty and P-12 teachers reported that these technology skills were the result of the required technology course and experiences in P-12 due to SchoolNet funding.

Faculty and teachers were able to learn new technology skills that could be used to support the development of technology proficient preservice teachers and to model appropriate uses of technology in the Arts and Sciences content areas as well as the College of Education methods courses. One teacher stated the following at a presentation of “lessons learned”:

*I can’t believe I learned so much in one year. I now have my courses on the web so students can access them at any time. I would have never been able to even think of doing this had it not been for this project.*

A university English faculty member stated,

*I learned so much from the team members I had in my group from P-12. I saw the searching methods they used with their 6th graders and was amazed! I even borrowed a few ideas for my own literature class from them. And...we are creating an e-pal correspondence between my university students and the student teacher’s class.*

The university faculty had an opportunity to use an instructional technology graduate assistant to help them learn new technology skills and to work with the development of new technology-enriched syllabi. University faculty members who participated in the project redesigned methods courses to include models of using technology in meaningful and appropriate ways in the teaching of mathematics, science, social studies, and language arts.

Conclusions

The P-12 teachers presented a wealth of insight into the current status of classroom teaching and technology use that was often unknown to the content faculty in Arts and Sciences and Health and Human Services. P-12 teachers, Arts and Sciences, Health and Human Services and College of Education methods
The faculty reviewed the content standards for each content area and the NETS for Teachers developed by ISTE. The ISTE standards were basically unknown to all participants before the project began and an evaluation of technology skills with respect to the NETS provided the participants with a review of their own skills with respect to the NETS for Teachers. P-12 teachers who participated in the project modeled the use technology in meaningful and appropriate ways in the teaching of mathematics, science, social studies, and language arts when preservice teachers are present in their classrooms as field students or student teachers. A final outcome of project participants will be to develop an articulated plan to infuse technology into the teacher preparation programs at Ohio University, including common content courses as well as education courses.

The Human Cognitive Functions and the Cyberspace: a Brazilian Point of View

Susane Lopes Garrido
Department of Human Science – Education
Vale do Rio dos Sinos University (UNISINOS)
Brazil
Susane@bage.unisinos.br
susanelg@terra.com.br

Abstract: This paper focuses on questions related to the human cognitive after the appearance of cybernetic technology. Carried out by well-known professors of Education, it intends to consolidate an urgent need to deeply investigate the human cognitive functions that generate the learning in this new economical, political and social scenery around the world. A scenery created by the new relations within the knowledge, not only capable of broadening and changing one’s way of thinking, but also capable of leaving one at his/her own luck and out of the process.

Facing the new paradigm of information/knowledge technologies, represented by the cyberspace involving the internet itself, the distance learning, the On-line learning, among others, we are once more going through a moment of big and meaningful changes. Changes that directly interfere/aff ect our behavior, the way we see the world, our relationships, our learning and therefore, our survival.

My questions as a University Teacher of the teacher training courses at Vale do Rio dos Sinos University (UNISINOS South of Brazil), refer to the reflections we need to do regarding the simple access to the information technology, that in the brazilian reality, does not guarantee a place in this scenery that appears. It is necessary to learn how to read it, to be able to integrate yourself, or re-create it.

Historically we know that certain events, phenomena of social-economical-technological order, promote the knowledge path that the humanity is facing at this moment. The old times metaphysics that was carried to the middle ages, did not correspond to the wishes of the new Man that was appearing, so the rationality did it. If the reason as the space for and to a change is the order, the new possibility of uniting the knowledge, being then ontology and the passive contemplation become excluded elements of the way the Man thinks and acts. Those transitions have always brought elements of exclusion being those generated by option or lack of conditions for the change. With the new technological paradigm that was born, we are again facing the fact that someone will be left out!

With the new technological paradigm that was born, we are again facing the fact that someone will be left out! But the issue is that today, even though we are not able to deal with a certain predictability of the facts, we are more aware of the existence of the changing process that we are going through. We can also conclude that the exclusion generated by the technology management nowadays will cause a deeper and inevitable impact than the changes of the past. Now, we can count on the speed the events happen, an element that before was not relevant in the process. If in the past we had centuries, years to establish a new order as well as time to adapt, nowadays this order changes every minute. “At every minute gone, new people access the internet, new computers are connected, new data is fed into the web. The more the cyberspace expands, the more universal it becomes, and the least united the information world becomes (...). This event is effectively changing our society life condition. However, we are talking about an unknown universal that intends to remain like that, because each new knot in constant expansion in the web can become a producer or a sender of new unpredictable information. And it can also reorganize part of the global connectivity by itself.” (Levy, Pierre; 1998, p.1)

During almost all our philosophical studies, we have searched the control of knowledge, the control of wisdom. If before being UNIQUE was a possibility, now with “Descartes” the idea of fragmenting is better for controlling. And now that the control itself, not matter the choice, is not possible anymore because the fact that the knowledge is universal objects directly to the unification? What do we do?

We are facing a new paradox. Everything we have done so far was to better control/dominante, but now, the way of thinking changes.
This made me reflect about how we teachers of Universities facing this situation of many alterations, are developing with our students, cognitive functions such as memory, imagination, perception, comprehension, and logical thinking.

Are we providing knowledge to some, very few, in a politics of cognitive segregation? Or are we really preparing people to continue this process of knowledge management that is appearing?

About the Web – Cyberspace

For this type of analysis we first need to see the world after cyberspace. If the knowledge of frontiers, of cultures and from people finished then the possibility of relations became infinite. Then new information, new styles of thinking and the knowledge of simulations that do not belong neither to the logical deduction nor to the induction from the experience appear. (Levy; 1998).

If the individuality of the people and the knowledge gave shape to an era before, nowadays the collectivity and cooperation come naturally. What’s more, the job market itself does not look for professionals who hold information or that simply execute their tasks anymore. The job offers in our days are for people who change information into knowledge; for people who take advantage of different resources and people to generate learning; for people who communicate using all the languages; for people who administrate their space and time themselves, we are talking about the entrepreneur.

But this person is not born ready, not even adapt easily to this new profile because of the individualist structure promoted by our educational system. This change is a social-educational process. In this Digital Era, the Knowledge can not be mistaken by information. Using the Internet as a place of only bibliographical searches, or using CDroms, electronic books, and visiting sites as mere observers is a way of looking the paradigm today with the eyes of the metaphysics of the past. (Ferreiro, E.: 2001)

The information itself does not have characteristics of days before. A sender can be the addressee, a mediator, the end or the middle of a message, and from this point everything can start again with another order. This is what Roy Ascott defined as a flood, a flood of information. (In: LEVY; 1998)

The WEB gives the information/knowledge a new, atypical, collective, not temporal meaning, different from everything we have known so far. Everything has been changed forever, the language, coding and decoding signals and symbols. For instance, we take the reading in the Occident. Done and interpreted structurally from the left side to the right side, this reading gets a new dimension now, the depth. The Hypertexts do not allow us to only read in the two-dimensional plan. Either we get in the universe of hyperlinks or we will not be able to decode the messages interconnected.

If the hypertext generates a new structure of textual comprehension, how can we develop processes of learning and teaching that can be capable of naturally originate this thinking? Perhaps a possible answer can be found in the exercises with estereograms[1], I mean, structures of vision in depth from the 90’s; perhaps not!... Another aspect born from this new diagram and of vital importance is to establish the collectivity as a tool to interpret new knowledge. The knowledge net, the collective intelligence, the interactivity, represent the arrival of cooperation as well as a way toward the inter-culture or at least, the perception of numerous other cultures, values and thoughts. (Barrueco, A. 1992-1993)

Through this point of view the nowadays teacher can not repeat the models of yesterday. (Peters, O.: 2001). If before the consequences of these acts caused this outdated knowledge to spread, nowadays it causes complete exclusion.

"It is obvious that one of the main intentions of Education is to prepare the individual to acquire the best possible conditions to his/her adult life. And this acquisition happens when this individual is capable of acting freely and with responsibility and when he/she has access to most of the goods and economical and cultural values (...)" (Barrueco, A 1992-1993, p.97)

Thinking and acting under the new paradigm of information/knowledge, is not only thinking about the development of the knowledge, but also about the development of the new Man that is coming. Those traces of a split Man, of disconnected devices, of reason and emotion as different departments of their context, will soon be over.

The human development needs to be seen as an original and inseparable group whose unit is made of contrasts and conflicts, subjected to innovations and expanding. (Wallon, 1979).

[1] estereograms structures of vision in depth; three-dimensional vision developed in the 90’s. (PINKER, S. 1999)
About the Human Cognition

The first aspect of the need of a thorough investigation about the influence of technology in our lives, mainly in the way we think, can be found in one of the Cognitive Science Definitions by Michel Imbert Andler (1998; p55). This definition refers to the study of human intelligence from its formal and biological structure to its psychological, anthropological and linguistic expressions. And thus, it can only be understood taking into account an inter-relation between the sciences that study the brain such as, psychology, computer science, anthropology, linguistics and the philosophy among others. With this definition we are once more facing the problem of revealing how our cognitive functions (affect) and are affected by the new representation of information that technology offers. Even the place where the investigation is held does not belong to one or another area of knowledge, but it belongs to its connections, considering multiple dimensions as the time, history, culture, neural nets, psyche.

It will not be enough for the teachers to know about the cognitive functions development in the past, not even analyze them with the same tools, the same knowledge and hypothesis. The memory, the imagination, the logical thinking, the perception, the comprehension will have to be structured again so that they will be able to interpret and create the new phenomena of the knowledge. It is not a privilege of functionalists and dual philosophies or even of the neurology to know about the mind and the Human Brain. More than never we, teachers, should try to unravel the phenomena of this relationship as a matter of survival (social Darwinism), ours and of our students.

One of the questions I ask myself when I try to work with the cognitive functions of my students during a cybernetic path is: - Do you think that with the Web, the information and the accesses have an intention of self-conducting and with this, conduct their own cognitive functions? I do not believe in this hypotheses very much but this would mean abandon all our History and rely on the lack of knowledge/neutrality. This would re-affirm the social segregation already imposed by the several languages used in the internet. That is why there is an emergent necessity of getting to know our cognitive process better.

The perception is also an element affected by the technological process. The truth is not unique, it is of different kinds. The truth depends on how the person looks at anything. If the mind is the brain or mind is part of the brain.... the crucial point here is that, Putnam (1970) as well as Nagel (1995) (In: Teixeira, 2000) and Chalmers (1996) have as their aim to make the Man worry about getting to know himself to better know.

The Cyberspace take us towards pluralists perceptions of the representation of meanings. The representations allow the meaning, I mean, a perceived relationship network that give meaning to what is lived. The pluralism comes before the sense of the meanings, therefore the comprehension of the plural is not to look for the truth but try to promote the syntheses of the dialectic , the one that results from the theses and anti-theses in a chaos situation; philosophical chaos.

"The social world is every day formed and designed because of a system of meanings, and these meanings exist, once formed, represented by what we call effective imaginary (or the imaginary). (...) However, there is a previous thing in the man, something that is not there to represent another thing, something that is before “operative condition of all previous representations, but that already exists in the representative mode” (Castoriadis, 1982 p.177 and p.172)

If this plurality of meanings is established as the new communication process, once more, we, teachers, are called for this awakening. We have the role of expanding the human capabilities, so that the people can intervene in the formation of their own subjectivities and also being able to act with power. (Giroux and Simon; 1994). The inter-subjectivity and the group of inter-subjectivities will be necessary fundaments for the new knowledge relationships.(Berger & Luckmann, 1985). When we deny the studies of the mind, be it in the Neurology, in the Reductionism or in the Functionalism we are moving a cycle of rationalist blindness. We know the problem, we just do not want to deal with it. At the moment we get over the new destinies of the human cognition facing the new information technologies, we are denying our existence in this planet. If before Man was blind and even though survived, nowadays, at every minute, we are targets of the past, we are just memory of the future. We are excluded by the creation. It is a good idea to get to know our brain. It means to create a new identity, create new relationships, to get free from the positivist, rationalist and individualist traditions. It means to create, maybe, a new theory about the Mind in its several different social-educational contexts and therefore, the beginning of a new History.

Abstract: The Clinton administration sought to assure that every public school would become connected to the Internet. (Oliva, 2001) This meant that curriculum in the schools would change all over the nation. Students would be able to surf the web, chatter with newfound friends around the world, play video games connected to class assignments and much more. Glenn (1999, p.16) reported that there were several essential aspects of technology that educators should consider incorporating in school, among them: up-to-date technology to build management systems that can track individual student progress, intelligently developed software to provide students with real-world experiences not possible in the traditional school, 21st century technology-based assessment tools, and telecommunication technology that provides access to multiple-tiered digital libraries. Glenn's report signified how important technology needs to be integrated into the public school curriculum. This paper is a pilot study of where some public schools stand in the scheme of technology integration into the curriculum.

Introduction

Olivia (2001 p. 318) said that schools have only scratched the surface of the computer-assisted instruction and the use of the Internet as an instructional tool. The U.S. Census Bureau reported that accessibility to computers in the schools increased between 1984 - 1985. The report showed 63.5 students per computer and between 1996-1997 reported 7.3 students per computer (Market Data Retrieval 1997, p. 171). Another report stated that the percentage of public schools with Internet access jumped from thirty-five percent in 1994 to seventy-eight percent in 1997 (National Center for Educational Statistics 1998, p.40). Does this mean that technology has been integrated into the curriculum?

This pilot study investigated how has technology has been integrated into the curriculum by answering the following questions:
What technology is available for use by students and teachers on the public school campus?
How do teachers perceive technology integration within their curriculum area?
Who is responsible for the technology effort in the school?
What kind of assistance has enabled teachers to meet society's technological need?

In addition to the answers to these questions, the researchers will make recommendations based on the results of the study. This paper gives insight into how this challenge is being met in accomplishing the nation's goal, "going beyond technology literacy".

The Study

The target population of this investigation was 49 graduate students who were teaching in the k-12 grades in the public school. They were enrolled in technology or curriculum courses at a regional university for the fall semester 2001. The data collection for this pilot study was done at the end of the semester. The procedure for collecting the data began with three instructors passing out a survey form for graduate students to fill in after they had completed technology or curriculum courses. The survey was
divided into five sections. Some of the variables involved in the study were grade level, subject, and years taught in the public school; availability and use by teachers and assistance from the administration; and the connection between class and computer activities.

Findings

Section A contained demographics of the teachers, which include grade level taught, subject, years teaching and size of school district. The results showed that there were 16 elementary, 10 middle school, and 23 high school teachers. The subjects taught included the following: math, Spanish, Web Mastering, all subjects, science, English, technology, career and computer investigation, computer application, keyboarding, history, reading, business, writing, theater, physical education, biology, physics, journalism, industrial technology, sociology, debate, English as a Second Language and criminal justice. The average number of years taught was 7.57 years. In this number teacher's experience ranged from one to twenty-eight years, and worked in small to large school districts.

Section B focused on the availability of computers used by students. The survey sought answers to questions about the location of the computers, Internet connections and technology usage. The results showed that 43 of the students said that they had computers available to them in the classroom; 47 had availability in computer labs; and 42 had availability in the library. Forty-five had Internet connection in the classroom; 45 responded that they had connections in the computer lab; and 42 had connection in the library. The last question in this category asked how the technology was used. The chart shows how the computers were used.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

* Because students could mark more than one time in the different categories, the categories equal one hundred percent.

Table n: description

The chart shows that of the 49 teachers, 42 used the computers for drill and practice; and 41 responded that they used technology for specific assigned lessons. In all of the areas teachers are using the computers to help students practice, enhance their thinking skills or create assignments.

In Section C, the question of how is the use of technology integrated into the curriculum the following responses were recorded:

"In algebra, we use the classworks gold for extensions, drill and practice and remediation, and we also use algeblaster, and the Internet for projects. As a teacher I use the projector to present lessons. We also use the graphing calculator on a regular basis."

"I use different power point presentation with my Spanish lessons. I also send out lesson plans and activities via e-mail for the teachers."

"I use Internet lessons for each Science chapter. Usually these involve research, then tutorials and games are available for leftover time (or at home)"

"I use many math games sites to remediate low students. I use Internet sites to expand on the information in science, social studies... Occasional I use it for collaborative projects. I also use many Internet sites for lesson plans, activities, and teaching ideas."

"Students in my classroom practice phonics skills on the Buggles each week. They do very limited research because of the reading level. They check the weather daily for our math meeting. Sites are book marked that pertain to our topic, periodically; and we allow the students to explore that particular site, such as "The American Flag" and a "Betsy Ross" site. Students also use the computers for Accelerated Reader Tests and to practice their keyboard skills. I find it hard to integrate technology on the second grade level from the web."

To the second question in Section C, who is responsible for the technology being integrated into the curriculum, the following responses were listed: of the graduate students most felt that the teacher was responsible for designing lessons that integrated technology; implementation must be done by the teacher; modeling effective use of technology is and should be done by the teacher and technology coordinator; training, support and computer maintenance should come from the administration and it does.

Section D of the survey focused on assistance through Technology Application TEKS standards, district professional development activities, regional service center activities, online resources and other professional development activities. It was recorded that 38 of the respondents felt they received help from the Technology Application TEKS standards; 42 received help through the district; and 33 received help from regional service centers. Thirty-nine received online assistance, and 13 received helped from other sources.

Section E focused on the number of computers in the classroom and lab, how they are used, where students do their
assignments (lab, classroom, library, or home), how often and how long. The final questions focused on the connection between classroom and lab activities, and campus and district administration contributions to technology integration. Respondents said that they had computers in the classroom. The average computers in the classroom was 6.98; and they did the following activities: projects supported by the internet, word processor, classworks gold, algeblaster, web information, interactive web sites, web creation, teacher administrative duties (grades, attendance, memos, announcements, email etc.), tutorial or drill practice skills, newspaper productions, power point presentations, art books, classroom instruction, content integration, lectures and notes for absent students, incomplete work in the lab, and as a reward for students. Of the 49 graduate students, 32 take them to a computer lab. The least amount of days students spent in the lab ranged from once a month to a daily occurrence. The amount of time they worked in the computer lab ranged from 30 to 90 minutes. Activities done in the lab were: accelerated reading test, state practice test, internet activities, accelerated math test, projects word processing, power point projects, research, webquest, quizzes, guided search activities, virtual field trips, math, keyboard drills, grammar tutorials, KidPix, dictionaries, informational CD Roms, power point presentations, class assignments, fitness spread sheets and interactive lessons. It appears that most students work on assignments in class or in the lab. Fewer numbers work on them in the library or at home. If they do not have access to the classroom or lab they probably completed assignments in the library or home. Then the connection between lab and class work is closely related. The lab supplements or extends, reinforces, or follows up on classroom activities. The administration's contribution to technology was to provide hardware and professional development, maintain equipment, reward incentives for participating in technology training, and continue to apply and receive grant money for laptops in an attempt to stay abreast.

Conclusions

The survey showed that technology was available to teachers in three different locations: classrooms, computer labs or libraries. More technology usage could come through more computers being placed in the classroom. A computer (laptop for each child) would greatly enhance instruction. Teachers do perceive that they are integrating more technology into their curriculum, and they feel that they are responsible for meeting state technology standards. Assistance to teachers comes from district and campus technology coordinators, administrators and regional service centers in the form of professional development.

The public school is trying to meet the challenge. Universities, businesses and communities need to provide support by partnering, and obtaining grants, so that more computers can be placed in the classroom for student usage. Public school district need to provide professional development activities on a continuous basis to make sure that teachers stay "up-to-date" with the world.

Abstract: This presentation examines models that have been devised to explain how teachers acquire and become proficient in teaching with technology. One characteristic common to all models is that teachers progress in stages from novice to expert users. Hypothesizing the existence of stages predisposes one to: a) describe the characteristics of each stage, b) develop methods to accurately pinpoint one’s stage of development, c) study progression from one stage to another, d) determine if progress may be accelerated through direct intervention and, e) apply the theory and research findings that result from one’s hypothesis and investigations in designing effective learning experiences for beginning and experienced teachers. The validity and utility of stage theory models of technology acquisition and use are examined and implications for both research and practice are discussed.

Society places a premium on preparing a new generation of students who will “... become literate, self-directed learners, problem-solvers, and productive members of a technology-oriented society” (Utah State Office of Education, n.d., para 2). Teachers who can integrate technology into the teaching/learning process are viewed as being essential to achieve this goal. The general lack of technology expertise by teachers has been the subject of numerous national reports (Market Data Retrieval, 2000; National Center for Education Statistics (NCES), 2000) and repeated calls to strengthen the preparation of teachers in this area.

Indications are that computer use is increasing among American teachers. Between 1998 and 2000 the percentage of schools reporting that the majority of their teachers used computers for planning and/or instruction increased from 47% to 76%. Similarly, the percentage of schools reporting that the majority of their teachers used the Internet for instruction increased from 39% to 77% (unpublished Market Data Retrieval data as cited in Myers, 2001). While teachers’ use of technology in schools is rising (Myers, 2001) and their skill levels are improving “...only 8% of public schools in 2000 report that the majority (50% or more) of their teachers have advanced technology expertise. This fact confirms that teachers need additional training to get their skills to a more acceptable level, especially in the area of technology integration into the curriculum” (Piazza, 2001, para 3). Teachers themselves recognize the need for more technology-related professional development. In a recent national study, 82% of teachers cited the lack of time allocated for training, practicing and planning as a major barrier to using technology in teaching (NCES, 2000). In our zeal to accelerate teachers’ proficiency in using technology, renewed emphasis is being placed on studying the development of technology acquisition and use among teachers.

Several models have been devised to explain how teachers develop expertise in integrating technology into teaching (Hopper and Rieber 1995; Mandinach and Cline, 1992; Rieber and Welliver 1989; Rogers, 1999; and Sandholtz, Ringstaff and Dwyer, 1997). “Many of these were based on teacher concerns about innovations involving the use of computers in the classroom, often referred to as concerns-based models” (Newhouse, 2001). According to Byrom (1998), Everett Rogers’ more general Diffusion of Innovations (1983) model may also help to explain the development of teacher expertise in using technology.

While the various models differ in some respects, one characteristic common to all is that teachers progress in stages from novice to expert users. The notion of stages is perhaps the most compelling feature of the models because merely positing their existence prompts one to ask a series of questions, including: What are the promises and pitfalls associated with proposing a continuum of stages from novice to expert user of technology? What teaching behaviors are thought to be indicative of each stage of development? Are valid and reliable assessment devices available to assess teachers’ stages of development? What strategies have been employed to
help teachers progress along the path from beginning to experienced users of technology? How successful have these efforts been? What are the implications, for both research and practice, in adopting the view that teachers progress in stages from novice to expert users of technology?

The presentation provides a framework for examining the development of teacher expertise in incorporating technology into teaching. The intent is to critically examine research in this area and stimulate discussion regarding the validity, utility, and practical implications of these models for future research and for developing effective pre-service and in-service experiences for teachers. An attempt is also made to relate research on the development and use of technology by teachers to the broader literature on the diffusion of innovations.

Online Challenge: Teaching Teachers to Share the New Hi-Tech Wealth in the Classroom

Dr. Lesia Lennex, Associate Professor of Education, Leadership and Secondary Education, Morehead State University, Kentucky, USA, email: l.lennex@morehead-st.edu

Abstract:
The multimedia collaborative project with schools (MMP) was designed to increase teacher skills in K-12 education. The project goal was to provide Morehead State University teacher education candidates with more realistic field experience in using technology to enhance learning among K-12 students. Students visited assigned schools and the assigned teacher at least six times during the semester. During the six visits, they planned a unit plan with the assigned teacher and taught, or assisted in teaching, the unit plan and evaluated student learning from the unit plan. Teachers were assigned based on student certification area. Although a secondary education class, students may have been assigned to an elementary teacher if their certification included those grade levels. This paper reflects some requirements of students for the MMP and self-reported data on use of technology in the classroom.

Introduction to the MMP

The Multimedia Project is an active learning service project in the public schools. Pre-service teachers participate in three hours of observation, then twelve or more hours participation with a specified classroom teacher. The students and teachers in this study were chosen on a volunteer basis. Teachers in the public schools were not compensated beyond the usual “student observation rate.” Students received no compensation, but they gained invaluable experience working with technology in the public schools. The following were requirements for each visit. This ensured successful planning, delivery, and evaluation of a unit plan.

First Visit: Observe the teacher and record the answers to the questions from syllabus under the “multimedia project” section.

Second Visit: Participate in teacher-directed activities this visit. Teacher-directed activities are those designed by the teacher with students following direction in some way. Work with students in a one-to-one situation so that you can get to know them better. Grade papers from assignments that the teacher has made! Begin discussion with the teacher about the lesson you all would like to teach with technology.

Each visit from this point forward requires an email to Dr. Lennex. You must include information from your teacher, such as comments, or suggestions, to demonstrate the collaborative nature of the project. You should write the information requested in Word and either attach it or copy and paste it to Dr. Lennex. I prefer copy and paste. Can’t be too careful with viruses! In the subject line of the email, title this “Visit Two.” If you are working with a partner from EDSE 312, please send only one email with your partner CC’d (copied). I expect you to take turns sending the emails.

In your email, due by the following Sunday, midnight, detail the following information: 1) behavior of the students in the classroom—note any having IEP’s and what must be done for reasonable accommodation in using technology, 2) possible considerations for using technology in this classroom such as software that is approved or existence of technology that is used by students, 3) the topic for your collaborative unit plan that will be taught using technology in this classroom.

Review software in the classroom applicable for the unit being taught. You may need to check out the software or equipment and bring it into the classroom. Please make sure to test this in the classroom on each computer being used. Note any bugs or malfunctions with the technology.
In your email, titled “Visit Three,” due by the following Sunday, midnight, detail the following information: 1) specific goals for your unit plan to be taught in this classroom, 2) specific objectives for your unit plan, 3) length of the unit plan in days, 4) Location of technology – software or hardware - to be used in the lessons.

Visit Four:

Obtain from your teacher a scoring guide (or several if the differ among units) that could be used as a sample for your unit plan. Grade student open response papers along with your teacher or as directed from your teacher. Be sure to use a scoring guide! Compare your scores with the teacher based on their scoring guide standards. How did you differ? Think about “what would Piaget do?”

In your email, titled “Visit Four,” due by the following Sunday, midnight, detail the following information: 1) Specific procedures for each day of the unit plan to be taught in the classroom, 2) a SIMPLE scoring guide that may be used to evaluate a student’s learning with the technology used in the lesson, 3) evidence that you have reserved the technology to be used in the classroom and a back-up plan in case the technology should become unavailable or fail.

Visit Five:

Test your teaching “withitness” by teaching a small lesson with students. This can be a group activity or a whole group lesson. It may designed by the teacher.

In your email, titled “Visit Five,” due by the following Sunday, midnight, detail the following information: 1) complete unit plan outline with all components required for each day’s lesson plan. This may be a draft version.

Visit Six:

Finish teaching and evaluate the final lesson in your unit plan for the multimedia collaborative project.

Comments on the MMP

Commentary on the project was very positive from both teachers and MSU students. Students had been somewhat apprehensive in using expensive equipment with public school students. Several stated that they did not feel comfortable allowing young children to use videocameras or laptop computers. In most cases, once the teaching unit was settled upon, students were using computers and equipment in the classroom. One of the best examples of use of technology occurred in a 4th grade classroom, an art student, who professed technology insecurity, used a videocamera and iBook for editing of a student made movie. The student was very surprised that public school children were so careful of the equipment and that they had made such a fantastic product. The entire unit plan taught creation of drawings for cartoons using Microsoft Word. The 4th grade students then made a movie of themselves practicing for a play. They edited the video in order to see how movies capture still frames to produce motion, just like a cartoon! The MSU art student in her comments on the project was not only pleased with student learning but also very happy with the professionalism and trust given to her by MSU for using the equipment.

Prior to the project, MSU students were asked to respond to this question: I can appropriately use technology to enhance student learning in the classroom. They (N=35) reported as 4 novice, 24 apprentice, 4 proficient, and 2 distinguished. The post-survey (N=28) indicated 11 proficient and 16 distinguished. When asked in the pre-survey if they could use a Windows operating system, 13 reported as proficient; the post-survey showed 22 as proficient. Most interesting is the increase in students claiming knowledge of Macintosh operating systems. Eastern Kentucky is almost entirely a PC supported school area and the MSU campus relies nearly totally on PC’s. The pre-survey indicated 5 novice, 16 apprentice, 8 proficient, and 4 distinguished. The post-survey reported 2 as novice, 8 apprentice, 10 proficient, and 6 distinguished. Yes, I am a Mac fan and require their use in my classes. It is safe to say that students displayed a gain in perceived proficiency with technology.
Using Technology to Improve Instructional Planning

Guan-Yu Lin, Feng-Kwei Wang
School of Information Science & Learning Technologies
University of Missouri – Columbia
gylqz6@missouri.edu, wangfeng@missouri.edu

Abstract. Lesson planning is considered a critical but complex task to attain effective instruction. The traditional paper-based approach was found to be cumbersome and consequently detrimental in the willingness and effectiveness of teachers’ lesson planning. A Web-based lesson planning system combining instructional planning and calendaring functions to support Missouri’s education reforms was in the process of development and testing. Early usability tests proved the system to be positive in helping Missouri teachers plan their instruction. Some design issues were identified.

Introduction

The success of Missouri’s education reforms, to improve student performance as measured by the Missouri Assessment Program (MAP), will require new and different teaching and learning strategies that align curriculum and state standards using inquiry-based instructional strategies and infusing instructional technologies. Successful teaching and learning does not occur by chance. It relies on careful planning of instruction. Since lesson planning is considered to be critical to the success or failure of teaching and student learning, it is vital that teachers are competent in planning daily lessons that support Missouri’s education reforms.

Lesson planning is an essential but complex task (Borko & Livingston, 1989; Doyle & Holm, 1998; Johnson, 2000; Ornstein, 1997). Various theoretical models were developed to help teachers plan lessons (Eisner, 1967; MacDonald, 1965; Tyler, 1950; Yinger, 1980). While numerous studies exist to discuss lesson planning and its effects, the research on the effect of technology-based lesson planning systems is conspicuously lacking.

The use of technology to support lesson planning is not new. Several systems such as Computer-Prompted Instructional Planning System and Lesson Plan Maker appeared shortly after personal computers gained acceptance in early 1980s. Several studies have showed the positive effect of using personal computers to support lesson planning. Today, the advancement and prevalence of technology in schools makes it a very viable option for teachers to utilize in planning, sharing, and communicating instructional information. In particular, the Web allows teachers to create and access instructional plans without time and space boundaries. However, a search revealed that a Web-based lesson planning system combining instructional planning and calendaring functions to support Missouri’s education reforms does not exist.

Issues

While Missouri has undertaken a State initiative to support Missouri teachers as they integrate multimedia technology into inquiry-based, student-centered instructional practices (http://emints.more.net), most teachers are still using pencil and paper to do lesson planning. Major drawbacks of this paper-based lesson planning include:

- The process is very labor-intensive and cognitively arduous. The task becomes perfunctory to many teachers. They feel obligated to write out lesson plans only because it is required by the administration.
- There are no systematic prompts or built-in links to information that can guide the teachers’ lesson planning to focus on Missouri’s education reforms.
- Lesson plans are not accessible to colleagues or school administrators unless special requests are made. Consequently, sharing instructional information among teachers is difficult.
- Parents have no access to lesson plans and, as a result, must rely on other methods to know what their children are learning on a daily basis.
- It is difficult to modify the contents of lesson plans once they are written on paper.
- Paper is not very durable and thus, valuable instructional information can be easily damaged.
Implementation and Preliminary Results

To help resolve these issues in lesson planning, a Web-based lesson planning system is under development with "teacher friendly" tools. The objectives of the system are threefold. First, it streamlines the lesson planning process to align with curriculum and Missouri standards and provides guidance with checklist functions to help teachers focus on addressing Missouri's education reforms. Second, it preserves valuable lesson plans developed by teachers for dissemination and facilitates the sharing of lesson planning knowledge and skills among teachers. Third, it promotes better lesson planning results through sharing and collaboration and enhances communication between parents and schools, thus increasing parental involvement in their children's education.

This Web-based lesson planning system is a work in progress; consequently, only formative evaluation is available. To date, a preliminary working system developed in Lotus Domino has gone through several rounds of prototyping and usability testing to collect user feedback. Early indicators suggest the system will be particularly helpful in the areas of:

- searching and adapting existing lesson plans for other uses,
- communicating instructional plans with other teachers and students, and
- developing lesson plans to meet Missouri academic standards.

User feedback also reveals several issues that need to be resolved before the objectives of the system can be fully realized. Among them, the following two are most critical:

- The system has to be flexible to accommodate different instructional needs and processes of schools and teachers.
- Other non-technical arrangements such as training and support have to be in place to motivate teachers to use the system and to share their instructional plans.

Conclusion and future research

Preparing teachers for technology integration in their instruction and enhancing teachers' instructional quality are two important endeavors to advance K-12 education reforms. This initial phase of this project is to develop, implement, and pilot test the lesson planning functions. Later phases will include additional functions to support communication with parents via the Web and to scale-up the lesson planning model for statewide access and use, and to disseminate to a national audience. From a research perspective, this project will lead to a better understanding of:

1. How teachers plan instruction using technology?
2. How teachers share instructional information through technology, how technology can assist with instructional planning?
3. How the Web can serve as a communication means between parents and schools?

The on-going process of building the lesson planning system and preserving instructional plans in a sharable library enables teachers to better plan their instruction and share their instructional materials. As the system matures and the content grows, it will have the potential of improving instructional planning process and products of Missouri teachers and thereby advancing the entire K-12 education enterprise at Missouri.

Enthusiastic Teachers About Infusing Technology:
Increasing Teachers' Use of Technology in the Classroom
Annette B. Littrell
Tennessee Technological University

Abstract

For the past decade, our schools have rushed to put computers in the classroom, in preparation for the 21st Century. Millions have been spent as the ratio of students to computers decreased from 125:1 to less than 6:1 in the state of Tennessee alone (Education Week, 1999). Internet connections increased, as school after school gained access to the Information Superhighway. No one offered a dissenting opinion when broad educational statements were made about the new Information Age replacing the Industrial Age, or about the need for technology in the classroom. And now that those computers are in the classroom, how are they being used?

Those struggling the most with this new technology seem to be today's inservice teachers — all 2.8 million educators in kindergarten through 12th grade — who lack the skills, background, and opportunity to use technology as they should. A call was issued by the Office of Technology Assessment report (1995) for the technology training of teachers to become a national priority. For preservice teachers, technology training did become a priority of sorts: most all teacher education programs now require at least one course in technology in their degree program, some require two.
However, is it possible that only one or two 16-week undergraduate classes, primarily stressing computer competencies, are sufficient to ensure that once the students graduate from the university and find themselves in a classroom they will know how to integrate technology into the curriculum?

Of all the possible barriers to technology use, one that we certainly should address is the lack of adequate training to use technology effectively. Though most inservice teachers see the value of technology, and though most claim at least a novice-level of computer literacy, few are truly prepared to use technology resources in a classroom. Most of the instruction preservice teachers receive is about technology, rather than providing experiences in using and integrating technology into the curriculum. Therefore, when they transition from preservice to inservice teachers, in charge of their own classroom, they feel ill-prepared to make use of a technologically-enriched classroom.

Studies have shown that stand-alone technology courses, such as those taught in most teacher education programs, only develop basic computer literacy skills and do not prepare educators to use instructional technology in the classroom. A survey was completed by 168 teachers within a county school system to assess classroom uses of technology, dividing uses into classroom management (using such skills as taught in literacy courses) and instructional technology (infusion of the technology into the curriculum). Results supported the hypothesis, showing that most teachers were using classroom computers only for management tasks. Strategies for increasing the instructional use of computers in the classroom are discussed.
National SMETE Digital Library for Teachers: Process, Promise, Progress

Ellen S. Hoffman
College of Education
Eastern Michigan University
United States
ehoffman@online.emich.edu

Marcia A. Mardis
Center to Support Technology in Education
Merit Network, Inc.
United States
mmardis@merit.edu

Abstract: The emerging National Science Math Engineering and Technology (SMET) Education Digital Library, which is being constructed by a variety of educational institutions, is an "online network of learning environments and resources for SMET education at all levels" (NSF, 2000). It is envisioned as a premier portal to a rich array of current and future high-quality educational content and services, and a forum where resource users may become resource providers. Technical, social, and economic issues involved in developing the library are reviewed, with emphasis on implications for teacher education and instructional support.

Introduction

The National Science, Mathematics, Engineering, and Technology Education Digital Library (NSDL) is an educational vision and goal with initial funding from the National Science Foundation (NSF)—a vision that is different from any existing library today. Formal and informal partnerships and projects among universities, K-12 entities, professional associations, government agencies, non-profit organizations, and corporations are part of the Library's realization. When the NSDL opens its virtual doors in Fall 2002, it will be the culmination of over a decade of research and collaboration among librarians, technologists, and educators in the public and private sectors (Wattenberg, 1998).

The NSDL will serve not only as a “gateway to a rich array of current and future high-quality educational content and services,” (NSF, 2000), but also it will encourage users to engage with and to create resources. Recommendations for a national digital library for science, mathematics, engineering, and technology education (SMETE) have focused on the need to define and interconnect user communities, establish subject-specific and interdisciplinary collections and services, and develop tools that focus on learning and teaching needs. This paper is a review of the vision, history, current progress on organization and technical infrastructure, and the potential for new avenues in teacher support and education.

The Internet Paradox: Is More Less?

With the rapid growth of the Internet, education has augmented access to information and resources and increased opportunities for collaboration and community building. Yet, these benefits have also proven to be problematic. The Internet can be a powerful resource to improve teaching and learning because of the wealth of freely available information resources and tools, but it too often overloads the user. The high-quality content educators seek can be difficult and time consuming to locate despite the increase in sites that attempt to provide searchable, usable materials for teachers and students. Further, challenges related to intellectual property have
hindered creators from contributing quality materials and establishing economic models for the sustainability of content and services.

Clearly, current models for searching and archiving materials are inadequate to meet educator expectations and requirements. As a result, digital library development must go beyond simply producing another site with selected links on specific topics. Critical barriers for digital libraries today are as much human issues as technological ones. Even when good collections are developed, getting them known and used remains problematic in this age of Internet information overload (Zia, 2001). Further, when confronted by the overwhelming amount of content, learners may not have the experience or basic knowledge to evaluate and use the resources.

While the Internet contains an incredible diversity of resources, it also offers the potential to combine authoritative collection development with highly sophisticated tools that can enhance research efficiency and provide scaffolded support for learners. An interactive and personalized research environment can unleash the power of digital information and improve information analysis, synthesis, and application (Scribner, 2000). The NSDL has the potential to encourage and support inquiry-driven, collaborative learning while incorporating distributed architecture to provide stability, reliability, and smooth interoperability. At last, the NSDL has the possibility of allowing pre-service and in-service teachers to bring innovative tools and practices into their classroom in a supported and effective manner.

While concerns about organization, access, economics, and educational applications are well documented, the technological barriers to achieving a new Internet paradigm are less clear-cut. In the case of the emerging NSDL, questions have been raised about the extent to which existing protocols and applications could be recombined to achieve technical objectives and the identification of gaps that will require new development. To some degree, the Library's debut is premised on the concept that given the right funding and organizational structure, technical solutions are either in existence but not yet well placed for optimal use and interoperability or can be developed within known frameworks in a relatively short timeframe.

A Virtual Library Vision

While numerous projects have explored the digital library paradigm, no project has yet met the potential imagined for such an enterprise. A prime consideration in building digital libraries is meeting users' unique needs. Therefore, the NSDL will have to provide value-added services that enhance the user experience; users must have a compelling reason to visit the Library rather than to use public search engines.

A 1997 National Research Council digital libraries workshop (NRC, 1998) raised important issues for in-service and pre-service teachers: faculty want to change their methods of teaching but have no single point of contact to search for useful ideas and journals often do not discuss what techniques failed in the classroom. Reform efforts need an easily accessible and searchable source of programs and resources that have been used successfully and have been evaluated for effectiveness.

The Library will have many resources and services beyond traditional books and journals, including non-textual sources, lesson plans, curriculum guidelines, and tutorials. “Beyond providing traditional library functions such as the intelligent retrieval of relevant information, indexing and online annotation of resources, and archiving of materials, the digital library will also enable users to access virtual collaborative work areas, hands-on laboratory experiences, tools for analysis and visualization, remote instruments, large databases of real-time or archived data, simulated or virtual environments, and other new capabilities as they emerge” (NSF, 2000).

The NSDL intends to support pre-service and practicing teachers through its commitment to assuring resource quality, supporting contextual learning, fostering critical literacy skills, acknowledging access inequities, and advancing scientific understanding. The Library will not enforce clear boundaries between users and contributors and will encourage active sharing and community building among participants. Educators will have the ability to access a broad range of learning objects and to utilize tools that allow those objects to be repurposed for classroom application. Of course, issues of sustainability and intellectual property will need to be addressed. As a result, all stakeholders are expected to be active participants in the Library's development and future success.

While NSDL's focus is on SMET education content, services, infrastructure, and community, the tools and techniques that are developed and tested in this program will apply to other virtual library development. The NSF effort is seen as a prototype that can lead to further deployment in fields such as medicine, humanities,
and social sciences. In addition, NSF is developing international linkages that have the potential to create global resources for SMET education.

**Progress and Achievements**

The NSDL efforts began in 2000 with projects focused on development and deployment rather than basic research. Projects are grouped into four tracks: Core Integration, Collections, Services, and Targeted Research. Universities and professional societies lead most efforts with nascent private sector and publisher involvement. All projects represent more than one institution and many have K-12 linkages. Project abstracts and links to project sites can be found at [http://www.nsdl.nsf.gov/](http://www.nsdl.nsf.gov/).

Core Integration projects are designed to provide management and coordination, technical infrastructure, standards and requirements for participation, and outreach to providers and users. Collections projects are those which focus on content, generally within a specific discipline or coherent theme. These projects are also focused on content use issues like discovery and access modes, classification and cataloging, acquisitions, and referencing. Collections may include non-textual resources, such as data sets, analysis software, visualization tools, or reviewed commentary. Initial Service projects are focused areas that content providers will need to integrate their materials rather than direct user support or evaluation. Services include learning systems that tap digital content, metadata translation, quality and peer review, content identification systems, and mechanisms for categorizing and searching non-textual resources.

Key organizational concepts that guide NSDL progress are its distributed nature, the need for active governance that involves all stakeholders beyond grantees, a variable collections structure that includes those following prescribed requirements, harvested through targeted selection, and gathered with smart agents. The NSDL also prioritizes the development of a technical infrastructure that will support multiple portals for entry, and the use of multiple metadata standards to meet the diverse needs of the different disciplines and users.

**Future Challenges and Considerations**

How will the NSDL differentiate itself from other Internet services or resources? What participation incentives will be sufficient to bring all stakeholders to the table through grant programs? The NSDL will need to consider a distinctive program for intellectual property rights, support and training for users and contributors, a way for organizations to maintain individual identity while benefiting from collective branding, professional recognition for individual participation, and evolution of NSF programs and policies that will bring together this large community and rich potential.

How to Successfully Implement Change — Build It and They Will Come

Donna Musser, University of Missouri-St. Louis, US
Cheryl Bielema, University of Missouri-St. Louis, US
Robert Keel, University of Missouri-St. Louis, US

Rogers (1995) and Light (1998) have described the diffusion of innovation according to a series of transformational stages. After early adopters successfully integrate new technology in their teaching and research activities (largely on their own), the institution is often faced with pressure to bring the masses of faculty and staff to the innovative approaches adopted by the risk-takers. The diffusion of technology innovation at the University of Missouri-St. Louis (UMSL) has occurred in a textbook fashion, with a few exceptions. These exceptions, successes, and proposed recommendations learned from this process will be discussed in this paper.

The University of Missouri-St. Louis is a typical urban campus serving more commuter than residential students, utilizing a high percentage of adjunct faculty, and a history of telecommunicating both programs and distinct courses to remote sites. Lessons learned from these experiences prepared campus technology administrators to identify potential barriers to moving courses online. Beginning in the mid-1990's campus innovators had integrated online content into their courses utilizing a variety of means to accomplish their goals. These innovators increasingly wanted to do more, and campus technology administrators were faced with providing more and more support to a myriad of hardware and software needs as resources and technology personnel were diminishing. Standardizing campus technology hardware and software was the first step, while identifying and adopting one Web Course Management System to be used campus-wide was the next. Change agents, in both the administration and faculty, recognized the need to identify potential sources of power (innovators and visionaries), and to use these relationships to move the campus forward. These change agents recognized that by sharing their visions, power, and influence the campus, and its students, would all benefit.

Cummins and Worley (2001) delineate the critical change stages as motivating change, creating a vision, developing political support, managing the transition and sustaining momentum. UMSL began motivating institutional change in the mid-1990's by instituting a plan to provide desktop systems for faculty and staff, and systematically replacing them every four years (replacement has since accelerated to every three years). Faculty and staff choose from one of the standard (PC or Mac) systems, with the option of the unit paying for additional features beyond the standard system. Two years later, Information Technology Services (ITS) identified standard platforms and software the campus would support. In 2000, one Web Course Management System was adopted campus-wide to further standardize the technology on campus. This enabled the campus to concentrate its resources and develop expertise in specific technologies, and this has led to further standardization of needs and support. These processes helped shape an institutional culture oriented towards change. Resistance was managed by providing faculty and staff with new hardware and resident software support specialists. By committing resources to the vision and putting structures in place to support the transition, this process additionally reflects Cummins and Worley's fourth stage, managing transition. Cummins and Worley's second stage, creating a vision, emerged as key innovators and stakeholders worked to communicate their ideas to the campus community. However, this vision was not adequately articulated campus-wide due to a lack of consistent and clearly defined technology terminology. These barriers in communication led to confusion as to where the campus was headed, and how proposed changes fit into the mission of a land-grant institution. As with any higher education institution, resistance is often articulated in comparing new practices to "traditional practices." Key innovators and stakeholders are now in the process of influencing other stakeholders on campus via a well-planned and orchestrated process of providing instruction, in-mass or on demand, and involving all who wish to participate in monthly "conversations" on how to utilize available technology to improve and/or enhance instruction and to further engage the student in learning.

What we did right was to first standardized hardware and software to maximize limited residential technology support. Second, we adopted one Web Course Management System and put faculty support services in place. Those support services have expanded as additional faculty and students adopted the change to web-assisted course development. Additional right moves include:

2385

Page 2324
• Unilateral creation of all courses in the web course management system, and populating these courses with students and faculty;
• Ongoing orientation, problem solving and support for faculty;
• An organized effort aimed at providing new and adjunct faculty with access to online technology;
• Help documents and orientation for students (web-based and on site); and
• Focus on teaching implications and enhancements while integrating technology.

The University of Missouri-St. Louis has followed a classic change process, and is creating desired change by following the advice of those change agents and researchers who have successfully led change. The adoption of the online technology has been dramatic and beyond expectations. The experiences on this campus can be used to facilitate change and encourage innovation on other campuses.
Interest in educational reform has reached new heights in recent years. Grappling with the problem of achieving large-scale reform educational reform has become the new challenge. There are many new examples of initiatives and corresponding lessons of change to be mined (Fullan, 1991). But much of the research on educational reform has neglected the human side of change. Little research has been done into educational change from the perspective of teachers who are simultaneously the subjects and objects of change (Nolan & Meister, 2000; Fullan, 1991).

People react to new experiences by attaching their own construction of reality to them regardless of the meaning assigned to them. Thus, the implementation of educational changes is never fully envisioned until the people in the particular situations attempt spell them out in use (Fullan, 1991). The purpose of this research is to provide in-depth stories on the lived experiences of public-school teachers who are engaged in a school restructuring effort intended to transform Spring Cove School District into the Digital School District. This rural school district in central Pennsylvania was recently awarded $4 million from the state in an attempt to become an integrated district that combines the Internet with the best emerging educational technologies.

The research will be yearlong study during which the researcher will spend considerable amounts of time living with six teachers. The goal will be to capture and portray as vividly as possible the teachers' experiences during the restructuring implementation and their attempts to make sense of their experience. In doing so, the researcher hopes to flesh out and give life to many concepts that are used to analyze and explain school change. The researcher also intends to highlight the critical role teacher's play in the change process.

In response to calls for research that will enable educators to achieve a deeper understanding of the meaning of educational change for teachers (Nolan & Meister, 2000), this study will be designed to describe and interpret how public school teachers define and make meaning of becoming 'Digital'. By focusing on the questions, what did these teachers experience? And, how did these teachers understand these experiences? This study is rooted in phenomenological inquiry, a form of interpretive inquiry that focuses on human perceptions.

Research in the phenomenological mode attempts to understand the meaning of events and interactions of ordinary people in particular situations (Bogdan & Bilken 1992). An effective way to study program implementation and educational change is to get detailed, descriptive information about what is happening (Patton, 1990). Since educational change and program implementation is characterized by a process of adaptation to local conditions, needs, and interests, the methods used will be open ended, discovery orientated, and capable of describing development processes and program changes. As linked to Patton's beliefs, this qualitative research case study is designed to describe the meaning the teachers attached to the change process of becoming a Digital School District.

The researchers' interests, values, and experience with the research problem are a source of motivation for the study. Supervising preservice teachers in the school district for over two years, the researcher has experienced the change personally and witnessed the ways in which it was affecting teachers. Thus, the researcher has a vested interest in the outcomes, not that a certain outcome is expected, but that the interest generated from the researchers' personal experience will keep them focused on the details of the inquiry.

The best way for us to know what others are experiencing is to find methods of data collection that allow us to devise procedures and strategies to consider experiences from the participants perspectives. Therefore the researcher will utilize fieldwork as the primary research instrument. In-depth interviewing, participation, and observation in the setting, document review and field notes, which are the fundamental methods that qualitative researchers rely on for gathering information will be used in this study (Marshall and Rossman, 1995).

The data will be analyzed through a process of systematically searching and arranging interview transcripts, field notes, documents and other materials to increase one's understanding of those data and present the discoveries to others (Bogdan & Biklen, 1992). The researcher will use a modified version of Straus and Corbin's (1990) coding procedures.

Through the eyes and the experience of teachers, the researcher intends to create and recreate a picture of how teachers make sense of and understand Spring Cove's school restructuring efforts to become a Digital School District. The overarching goal is to open a window in the realities of this major educational reform at the classroom level.

Western Illinois University
United States

Less than six months ago, 25 colleagues gathered for a celebration. We were recruited for the Innovators in Teaching and Learning cadre, lured by the dangle of a wireless laptop and the desire to become edge users of technology. Today we again celebrate the modest, but steady diffusion that our team members have made. We’ve come to think with you about the strengths of our cross-disciplinary team, the formation of a community of learners, and the application of our new skills in our teaching.

Technology has had an impact on our lesson content, the thinking processes we employ with our students, and the products our students produce. The diversity of the cadre was one of its strengths. There were experienced distance teachers, newbies and converts in the group. We were united around the Blackboard course that gave structure to our development plan. Participation in the course gave us much need support in the earliest stages of our endeavor. Relevant readings were the focus of our discussion and served to re-focus our commitment to the project. After a particularly globe trotting summer, we are back in harness digesting Kurzweil’s book, The Age of the Spiritual Machine (Kurzweil 1999). The futuristic scenarios spun out by this author lend further motivation to our work together.

Panel members will briefly share their story. You’ll hear about electronic portfolios and website development, concept mapping in teacher education, on-line teaching and learning, and integrating technology and content standards with student products that include hotlists, treasure hunts, webquests, and desktop publishing. We’ll document our learning and challenge participants to join the fun as part of their professional development.

The Use of Laptops within the Gulf and Islamic Culture

Bradley Saunders, Zayed University, AE
Emad Bataineh, Zayed University, AE

This paper describes the experiences of both students and faculty in a university for women in the Middle East which requires all students to purchase a laptop computer. It examines the benefits and drawbacks of laptop use within the Gulf and Islamic culture. The positive reaction of female students toward the use of laptops is compared with less successful uptake by female students in the West.

Consideration is given to how laptop use has impacted university planning. To what extent has the provision of laptops to students precluded other means of instruction? How can laptop use be regulated and standardized given the intrinsic freedom that laptops make possible? To what extent do societal pressures reduce the possibility for these young women to benefit from their laptops when away from the University Network and Intranet?

The impact of unexpected technical problems and the need for institutions to develop and implement integrated plans for change are discussed, as is the effect on faculty, who have to cope not only with a new workload created by the introduction of laptops but also with an unexpected new learning paradigm.
Communication in the Virtual Teaching and Learning Space

Antonio Simão Neto  
Pontificia Universidade Catolica do Parana  
Brazil  
4simao@terra.com.br

Abstract  
This research project addresses broadly the issue of whether the new media, being potentially interactive (and thus bridging teachers, students and other educational agents) may open new ways of teaching and learning, which are more adequate to contemporary life and the global society.

"Technology is the campfire around which nowadays we tell our stories."

Laurie Anderson, American artist and multimedia pioneer, chose the image of the campfire to drive our attention to the central role of technology in our society, shaping out collective views of the world and mediating human relations.

The university, as a social and cultural institution, could not be untouched by this phenomenon. In fact, there are many similarities between the mass media and the traditional teaching model. Both are marked by the separation between the main agents (producers/audience, teacher/student) of the communicative process.

New media, being potentially interactive, may help educators in their efforts to close the gap related above, creating new learning environments which are more "in sync" with post-modern society and culture.

More directly, it aims at identifying the degrees of teacher awareness and understanding of the communicative changes brought by the new interactive media such as the internet and its impact on the learning process as it happens at the Pontificia Universidade Catolica do Parana.

This project is part of the research being carried on by the research group Virtual Learning Communities, itself part of the broader Theory and Practice of Higher Education project, linked to the Masters and Doctoral programmes at our institution.

Our university began to implement last year a new educational model, for all its 51 undergraduate majors, based upon "learning programs" developed jointly by teachers and students. This model leans heavily on problem-solving, investigative skills as well as on collaboration and tutoring.

Eureka is a collaborative learning environment, developed at our university, in cooperation with Siemens Corporation. As many other such environments, Eureka offers discussion forums, e-mail, chat room, scheduling, message board, repository, and other online and offline resources aimed at facilitating collaboration and learning.

At the end of academic year 2000, there were more than 20.000 Eureka registered users, of a 26.000 (staff and students) academic population.

Eureka's 850 virtual rooms are our research universe. They are the environment in which the central issue of the use of new technologies as support for educational changes can be addressed. We will follow the tutors from the moment they open their virtual rooms until the end of the academic year, looking into the ways they communicate with their students in this environment, the tools they use and how they use them, the ways the students react to stimuli and how they start and keep their own forms of collaboration and communicative exchange.

So far we have been able to identify a close resemblance between the way mass media mediates communication and the way traditional teaching happens.

We want now to find out whether new media can be associated with a new learning paradigm: a student-centered, problem-based, research-oriented, knowledge-building model, where collaboration and interaction are essential.
Mass-Media and Traditional Teaching Common Characteristics.

Centralized control: messages (content and form) are constructed by the few who control the medium
One-way communication: messages travel in one direction only, from those who control the medium to those who receive them
Prevalence of “cold” media prevail: as defined by MacLuhan, the more finished the message is, the less space the medium leaves to the spectator, the colder the medium
The spectator: from the Latin expectare (to be there, just watching); spectators/students are expected to sit quite and listen/watch, without interfering with the production of messages.
Linearity: messages built along a pre-defined, pre-built sequence, in a linear flow with its own temporality, independent from the spectator, who cannot alter this direction or speed, nor choose alternative ways.

New interactive media characteristics

Decentralization: one the main characteristics of the internet, the first big media without owners and central controllers, opened to all
Two-way communication: information flows in multiple directions, allowing new communicative exchanges
Interactivity: hot media prevails (if we take the potential for interaction in its fullest sense).
The “users”: so new that there isn’t a good word for it, these new spectators refuse to “just watch”; they want to participate, to interact, to wet their hands in the ocean of information, to manipulate messages and create new meanings
Multimedia: more than just a new audiovisual medium, multimedia is opening a universe of multiple stimuli
Non-linearity: the wide use of “water metaphors” (to navigate, to surf, to dive...) to describe user movements in the information “ocean” reveal the non-linear structure of the new media; one can move in the surface, or dive into depths never made possible by linear media

New media and contemporary education

As we develop and spread new tools around campus, new forms of communication between teachers and students can take place. New tools, however, are not enough to make a difference. It is the attitude of the learning agents that counts more.
If we want to depart from traditional, informative teaching, and move towards new directions for learning, we must try to establish new communication spaces and to develop new communication skills, alongside with the ones we are familiar with (at least as consumers of media products).
That is the challenge for nowadays educators. New forms of teaching and learning surely will employ new technologies and resources, more interactive and flexible. On the other hand, educators must change their views and attitudes accordingly. It is imperative that we find a common ground upon which true, rich communication exchanges with our students can occur.
Learning can and must be a joyful, stimulating activity.
The university (and the school as well), as a communicative space, must go beyond the model based on the mass media, reaching for the new digital, interactive communication - if education is to keep on being significative and important to students and to society.
Sustaining Technology Integration: Lessons Learned

Sean Smith, University of Kansas, US
Joseph O’Brien, University of Kansas, US
Steven Smith, University of Kansas, US

This presentation will focus on the effort of one School of Education's effort to sustain technology integration across the preK-12 classroom environment. Having successfully integrated technology across several teacher preparation programs, project emphasis has turned towards creating and sustaining technology rich environments for appropriate student teaching and internship placements. Current efforts will be shared and idea and suggestions will be discussed amongst participants.

Teacher education students are capable of serving as significant players in the effort to integrate instructional technology into programs. While the students though become more competent and frequent users of instructional technology, they encountered some of the implementation barriers identified by National Council for the Accreditation of Teacher Education (2000) and the Office of Technology Assessment (1995) as they move into classroom settings. One student, for example, ran afoul of the traditional classroom operation when he attempted to use instructional technology during his student teaching. This suggests that addressing one implementation barrier, teacher training, in isolation runs the risk of failure in the long run. More importantly, this does a disservice to the teacher education student. Marcinkiewicz (1996) reported that while student teachers possessed high expectations about the use of instructional technology in their future classroom, their first year of teaching dramatically lowered these expectations. The challenge facing us not only is how to better prepare our students to use the technology, but also how to work with K-12 educators on the implementation barriers unique to their setting.

This demonstration/poster seeks to identify the challenges faced in sustaining technology use across student internship as well as student teaching experiences. In cooperation with Professional Development Schools, this PT3 Project (Learning Generations) is currently developing ways to enhance preservice teacher education students use of technology during their critical teaching development experiences.

Why should we motivate teachers to use instructional technology in their teaching process?

Panel discussion prepared by Dr Armand St-Pierre

Learners are moving from a traditional educational environment into an open learning society where they can learn anywhere anytime. They are brought up in a multimedia and technology environment where new media are available to promote learning outcomes. More learners are connected on a daily basis to the Internet and they have the opportunities to surf virtual libraries and electronic journals to enhance learning outcomes. The web offers a rich platform of educational contents. The use of information technology could help to support new ways of collaborative learning, electronic communication, and independent learning. Research shows that conservative institutions entering into an information and communication age still emphasize the university professor as the classic information-giver, while nowadays several research studies advocate a collaborative learning environment where the professor becomes a mentor to his/her students.

The author of this article believes that Web media and technology should be used simultaneously in the teaching and learning processes, i.e. there should be equilibrium between the left-hand side (teaching) and the right-hand side (learning) of the equation with respect to the uses of Web resources in the curriculum. If the professors were using Web media in the delivery of course contents, the students should be learning how to integrate these tools into their learning process and vice versa. The technological delivery platform for the curriculum is ineffective if the students are frequent users of Web resources and technology in their learning process; whereas, professors do not know how to integrate these media into their teaching process. Based on the author's experience in using technology in teaching for several years, the author firmly believes that Web media and technology had to be in equilibrium if the institution wants to effectively deliver the curriculum. In fact, empirical results of different surveys done by the author corroborate the theoretical justification for using Web resources and media in the teaching and learning processes.

The goal of this panel is to discuss the pros and cons why any school, college, and university should introduce in an efficient and effective ways instructional technology in their teaching process. Some of the issues to be discussed could be: what is the tradeoff between increase in student learning with traditional methods versus time invested in learning new technology—Is it worth the effort? Technology integration takes valuable time and effort .... Are we willing to do it?

Participants from the floor will have the opportunity to present their experiences with respect to this topic. A summary of key factors will be presented at the end of the panel discussion to help participants to introduce technological media in their educational environment.
BE THE TECHNOLOGY:
REDEFINING TECHNOLOGY INTEGRATION IN CLASSROOMS

Independence (KS) Unified School District 446
USA
btincher@indy.schools.com

Abstract: One way to better understand the difficult instructional issues associated with the integration of computer technology in classrooms is to analyze the teaching practices of teachers using technology in classrooms. We established a set of technology standards and educational best practices to describe how teachers use technology for teaching and learning in the classroom. We learned that technology integration is more than just using and operating computer hardware and software. By establishing technology standards and associating specific educational best practices to the standards, teachers were able to progress from using the technology to being the technology.

The goal of transforming teaching and learning by increasing access to and use of technology in schools and classrooms has been near the top of most educational reform agendas since the early 1980s (Cuban, 2001). We launched a technology professional development initiative in a school district with the hope of revolutionizing classroom teaching practices and preparing a new generation of learners for a 21st century workplace driven by the acquisition and manipulation of information. Our model was based on a set of technology standards and indicators that clearly described the educational best practices for teaching and learning with technology. For technology to transform teaching and learning in the classroom we knew it required more than teachers just using technology—we wanted teachers to be the technology!

The technology standards on which our technology professional development model was established were formulated by synthesizing national, state, and local technology standards and then identifying educational best practices that supported these standards within the local context. We discovered in our literature review that although many reasonable and appropriate technology standards for teachers exist, these standards were are often stated in abstract or general terms. Additionally, since there was a high degree of variability in educational beliefs, technological availability, and state and community expectations, technology integration should be locally defined, using available research models and national standards as a foundation (Pierson, 2001). To support and reinforce this be the technology professional development model, we devised a set of performance assessments whereby teachers could demonstrate various levels of proficiency in technology integration and receive financial incentives.

To appraise our accomplishments, we undertook a process to evaluate the technology integration practices of teachers before and during this initiative. Although several models or strategies have been employed by educational researchers and practitioners to provide a systematic approach for determining the quality of innovation implementation, the Concerns-Based Adoption Model (CBAM) (Hall, Wallace & Dossett, 1973) fit our evaluation requirements because it emphasized change as a developmental process experienced by individuals implementing innovations within an organizational context. Over time CBAM has evolved into a comprehensive systemic change model that allowed change investigators and facilitators to understand organizational change from the point of view of the persons affected by the change (Surry, 1997).

CBAM is based on the assumption that change is best understood when it is expressed in functional terms—what persons actually do who are involved in the change. Since change involves developmental growth, the focus of facilitation is with individuals, innovations, and the context (Hord & Huling Austin, 1987). CBAM provides for the development of diagnostic tools based on the design of the innovation being evaluated and the
operational patterns of those using the innovation. One of these tools is the Innovation Configuration Matrix or Map (ICM). The ICM delineates an innovation in the form of a two-dimensional matrix along a scale that renders closer approximations of conceptualized implementation or use along one dimension of the matrix and the various configuration components along the other dimension of the matrix. Rather than being a static measure, the ICM has a procedural definition that allows an innovation configuration to be designed relatively easily for a specific instructional innovation. Thus, we formulated an ICM based on the technology standards and indicators of our professional development model to evaluate the quality of technology integration among teachers in the school district.

METHODS

Instrumentation

An instrument for analysis of technology integration and implementation in classrooms was developed. This instrument, the Technology Standards Integration Configuration Matrix (TSICM) was based on a consensus-building process that followed a procedure developed by Heck, Steigelbauer, Hall, and Loucks. (1981) and used previously by the researcher (Mills & Ragan, 2000). Relevant national, state, and local technology standards were reviewed and evaluated by the researcher in conjunction with the district technology committee and technology coordinator. The committee agreed upon 18 technology integration standards that were appropriate for the school district. Technology integration standards were organized into three skill sets or phases: Using and Operating Technology in the Classroom (Standards 1-6), Facilitating and Managing Classroom Technology (Standards 7-12), and Technology Integration (Standards 13-18). Each successive phase was intended to identify a set of instructional strategies that exemplified a more appropriate application of technology or a higher quality of technology integration into classroom instruction and learning.

Each technology standard was established as a component of the TSICM and then variations for each component were identified. Variations for each component consisted of discrete categorizations of technology implementation for the corresponding component. Component variations were designed to represent educational best practices along a continuum from unacceptable use to ideal use. The component variations were refined by the technology committee to reflect the actual practices of teachers using computer technology in classrooms. The components and component variations were organized into matrix comprised of four variations for each of the 18 components with each successive variation indicating a level of use representing a closer approximation of ideal or appropriate educational use. The TSICM was deployed as a paper- and Web-based checklist.

Data Collection

The school district used in this study was located in a small town in a Midwestern state. The school district had a total enrollment of almost 2,200 students in grades K-12 with 147 certified teachers. Computer technology was used in all the schools in the district. All schools except the high school had computer labs and all teachers had classroom computers.

The school district had made a substantial investment in computer technology and was beginning a district-wide technology professional development initiative. To collect data regarding computer technology implementation occurring among teachers, all teachers at all grade levels were provided with a paper version of the TSICM checklist and the option to complete a Web-based version of the TSICM checklist on the school district Web site. The checklist was designed in a multiple-choice format in which respondents could select more than one response for each TSICM component.

Data collection occurred at both the start and end of a school year. A usable TSICM was completed by 70 teachers at the start of the school year and 84 teachers at the end of the school year. 57 teachers completed both the start and end of year administration of the TSICM.

Data Analysis

The rubric for rating teacher responses on the checklist was to rate to the highest level of use for each component on the checklist. The responses to the TSICM checklist were analyzed by cluster analysis to identify relatively homogenous groups of cases based on the TSICM components. Discriminant analysis (DA) was then used
to assess the adequacy of the groupings from the cluster analysis by using the TSICM implementation components as predictor variables. A step-wise methodology was used to enter variables into the discriminant functions. One-way analysis of variance was used to determine if the component attributes of each group were statistically significant. Comparisons were made between the start and end of year data collections using a paired-samples t-test. Descriptive statistics for the data collections are provided in Table 1.

Table 1. Descriptive Statistics for Start and End of Year Administration of TSICM.

RESULTS

Beginning of Year Data Collection

Since the initial cluster centers and the number of dominant patterns were unknown, cluster analysis was performed on the first administration of the TSICM using all 18 technology standards or components of the TSICM and incrementing the number of clusters until a reasonable model was obtained. The cluster analysis was run for 2, 3, 4, and 5 clusters before a reasonable model was selected. A reasonable model occurred with the number of clusters set at 3. When the number of clusters was set at 3, the number of cases in Group 1 was 21, Group 2 was 33, and Group 3 was 16. In order to make comparisons between the start and end of year data, this same grouping model (3 clusters/groups) was used for analysis of the end of year data collection.

In order to assess the adequacy of the classification of implementation pattern groups derived from the cluster analysis, a Discriminant Analysis (DA) was performed. The 18 TSICM components were used to separate the groups into the discriminant functions. As a result of this procedure 97% of the cases or 68 of 70 cases were correctly classified. The DA reclassified 1 case in Group 2 for Group 3 and 1 case in Group 3 for Group 2.
The TSICM components were entered into the DA using a stepwise model in order to discard variables that were weakly related to group distinctions. Based on the discriminant coefficients, Component 13—Integrate Technology-based Learning Experiences into Classroom Instruction made the most important contribution to Function 1 and Component 8—Facilitate Regular Student Use of Computer Technology made the most important contribution to Function 2. Teachers identified with Group 1 (Technology Operators) were characterized by low or inverse relationships to Functions 1 and 2, Group 2 (Technology Facilitators) by high Function 2, and Group 3 (Technology Integrators) by high Function 1.

End of Year Data Collection

A cluster analysis was performed on the end of year data collection with the number of clusters set at 3 to compare with the clusters from the first of year data collection. With the number of clusters set at 3, the number of cases in Group 1 was 35, Group 2 was 18, and Group 3 was 31. The DA was repeated for the end of year data collection of the TSICM and as a result of this procedure 92% of the cases or 77 of 84 cases were correctly classified. The DA reclassified 1 case in Group 1 for Group 2 and 6 cases in Group 3 for Group 1. Based on the discriminant coefficients, Component 9—Conduct Learning Activities using Computer Technology made the most important contribution to Function 1 while Component 1—Operate Common Technology Input Devices made the most important contribution to Function 2. Teachers identified with Group 1 (Expert Technology Users/Operators) were characterized by high Function 2, Group 2 (Beginning Technology Users/Operators) by low or inverse relationships to Functions 1 and 2, and Group 3 (Technology Facilitators) by high Function 1.

Paired samples correlations for each of components of the TSICM (technology standards) were computed for matched cases on the start and end of year administrations of the TSICM. Almost all components of the TSICM indicated significant differences on the t-test (p<.05) between the start and end of year administrations. Additionally, paired samples correlations were computed when TSICM components were grouped by skill set or phase and significant differences on the t-test (p<.05) were indicated for all three phases.

CONCLUSIONS

When we examined only the start of year data collection for this population of teachers, we discovered that proficiency in the use and operations of computer technology (Phase 1 standards) was not necessarily a distinguishing attribute of high quality technology integration. In other words, there was pervasive use of computers by teachers in preparing for instruction, but limited use of computers by teachers for delivering instruction. This finding had relevance for the provision of future technology professional development activities. These results clearly demonstrated that technology training activities needed to focus more on instructional strategies and methods to integrate technology in the classroom than entirely on activities to increase skills in the operation of computer hardware and use of software applications.

By the end of the school year, the characteristics that delineated differences among the teachers in technology integration was more sharply defined by teachers who were beginning or expert operators of computer technology and those who were facilitators and managers of classroom technology. Thus, there was a clear progression among the teachers from technology operations to technology facilitation—from using the technology to being the technology.

While the technology professional development program at the school did not make technology integrators out of all participants, it clearly accommodated reasonable growth and advancement in the technology integration skills of the participants. When we considered only those teachers for whom we had both start and end of year data, a significant pattern of growth across technology standards and at all skill levels was indicated. This observation suggests that when educational best practices for teaching and learning with technology are clearly defined and established, the professional skills of teachers will begin to exemplify the stated expectations.

We have learned from this study that classroom technology integration was not so much about the quantity of teacher interactions with technology, but rather it was about the quality of teacher interactions with technology. When teacher interactions with technology were accompanied by expert teaching practices and related to curriculum objectives, the quality of technology integration was increased.

Over time we have refined our technology integration professional development model to include more powerful technology integration strategies in classrooms beyond that of computer technology use and operations. We have learned that through the establishment of a well-defined set of technology standards and corresponding best practice indicators, higher levels of technology integration in classrooms can be identified and achieved.
Consequently, the potential for improving and enhancing teaching and learning in the classroom is increased when teachers know how to use and then actually use all the tools at their disposal.

IMPORTANCE OF THE STUDY

Although many school districts have established benchmarks or standards for the integration of technology in classrooms, no model or methodology exists for substantiating technology standards with actual classroom practices. The TSICM represents a flexible and adaptable approach to the evaluation of technology integration in classrooms because the TSICM components reflect a set of widely-used standards that can be contextualized.

A methodology to provide comprehensive and continuous analysis of technology implementation is needed to sustain high levels of use and integration of computer technology in classrooms. This study demonstrated that the TSICM was an effective tool to determine technology integration in classrooms, to reveal the technology integration characteristics of teachers integrating technology in classrooms, and to distinguish appropriate technology training themes that focus on specific technology standards.

**Abstract:** Handheld computers, such as Palms and Visors, are quickly becoming a common tool in the business world and this innovation has much potential to be used in education. This paper will focus on the initial integration of handhelds in a college of education. Activities include the training of faculty, administration, and staff, integration into undergraduate and graduate courses, researching of elementary, middle school and high school students’ use of the devices, and the development of applications to be used in teacher and student teacher observations. In addition, the paper will highlight reasons educators should be learning to use handhelds, why educators need to develop effective ways to use handhelds in their classrooms, and why these devices should be integrated into the teacher preparations curriculum. Also, important issues that need to be discussed when implementing this new innovation will be addressed.

**Introduction**

Handheld computers (Palms, Visors, PocketPCs, etc.) are just beginning to be used in classrooms around the country, paralleling the acceptance of these devices in the U.S. business world. The uses and applications are usually different; business people use the handheld as an organizer and personal data center, and educators use the technology for such applications as writing, visualizing, data collection, data manipulations, and simulations. These devices have much potential for helping students learn and produce.

The College of Education at the University of Nebraska at Omaha is focusing on effective uses of handhelds in the learning process and is designated as a Palm Research Hub. Several faculty members are actively developing curricular ideas and researching P12 applications of handhelds in Nebraska classrooms as well as developing curriculum activities for its own teacher education courses. This paper will outline the rationale for using handhelds in schools and document five projects in Omaha area schools.

**Handheld Use in Schools: Why, When and How**

**Why Use Handheld in Schools**

Before using any tool or innovation in schools, educators need to identify reasons the new innovation should be used. There are several reasons that handheld computers are a logical choice for schools and classrooms.

1. Handhelds are becoming a widely used technology in the "real" world. More and more business people are finding these devices to be an integral part of their work world. Many companies have made the handheld a
tool used for scheduling, addresses, to-do lists, and document exchanges. It makes sense that if many adults are using handhelds, educators need to investigate whether these devices will help our students learn and produce.

2. Constant and consistent access to handhelds for students can have a positive effect on their learning. The impact of computers in schools has been disappointing to many. One of the reasons for this is the limited use by students. In a 2001 survey [http://www.snapshotsurvey.com] of Nebraska teachers, Topp, Soloway, and Norris found that 50% of the teacher-respondents have their students use computers for 15 minutes or less per week. If this is truly the case, no wonder there is disappointment in the impact of computers on student learning. But, the handheld computer may allow the student to have their "computer" with them at all times. The low cost of a handheld provides the opportunity for full time access for each student. And the small size of the handheld allows for easy portability. Students can pull their handheld out of their book bag or desk any time they need it.

3. The versatility of the handheld makes it an efficient learning tool. In addition to the date book, address book, etc. usually associated with handhelds, these devices are very versatile for creative teachers and students. Writing, creating animations, developing concept maps, drawing pictures, collecting data using probes, using spreadsheets, manipulating databases, reading documents, taking quizzes, and picture taking/editing, are all possible with most handhelds. In addition, much of the educational software is free to education.

4. The connectivity possibilities of the handhelds facilitates sharing and collaboration. Students can beam documents to each other, they can print their work, or they can sync their handheld to a computer. All three of these features provide the creative teacher with options that are important for a student-centered, active learning classroom.

How Can Handhelds be Used in Schools

As noted above, handhelds are versatile tools in schools. Many types of applications are now available, and many more are in the developmental process. The possible uses of handhelds are many. Some of the ways we have seen them used are: personal organization, writing, document reading, document sharing, simulations, data collection, visualizations, concept maps, database manipulation, spreadsheet tasks, calculating, assessing, and concept mapping. Also, teachers are using the handhelds for downloading documents from the web. With each visit to handheld-infused classrooms, we see more ways teachers are using these devices. It should be noted that the Center for Highly Interactive Computing in Education at the University of Michigan (http://www.handheld.hice-dev.org/) has developed several applications that are free to education. Many of the uses in the classrooms we are researching use these software applications.

When Should Handhelds be Used in Schools

The decision of when to use any innovation is very important for effective use and efficient learning. The guidelines for handhelds are similar to other learning tools. Handhelds should be used to help the student meet course objectives, whether it helps them learn faster, better, or transfer easier. Also these devices are effective in active learning situations, where students ask questions, gather information, analyze information, and share results. The tasks should be meaningful and connected to real world situations. And finally, the handhelds facilitate a collaborative learning environment. Students can share a document or parts of documents by beaming to each other, or they can upload or download documents to or from the web.

How are Handhelds being Used in Schools

Although the uses of handhelds are in an early stage in Omaha area schools, there are five teachers that are beginning to use handhelds with their students. Some have just begun the process and others are a few months into the project. Although it is too early to judge the impact of using handhelds, teachers are reporting successes with the devices. As the school year continues, we will be documenting the impact on the students, teachers, and schools.
Watershed Study

King Science Center is an Omaha Public School District 4-8 science magnet school located in urban Omaha. In 7th grade science class, the students are currently involved in a local, long-term water quality ecological research study called “Watershed.” Students are taught ecological interrelationships between biotic organisms, pH, dissolved oxygen, sunlight levels, and temperature. Students are then transported to several area lakes and the Missouri River to collect water quality data several times throughout the school year, thus enabling them to observe how seasonal changes affect abiotic and biotic water quality factors. Currently, all data is collected with individual test kits. The data is recorded on paper worksheets and graphed after returning to school. In this Palm project, handhelds with expansion modules and probeware will replace disposable test kits. Data will be collected on handhelds and returned to school for centralized analysis and incorporation into a single database. The data will be transferred during a technology applications class, then manipulated and graphed in math class, and subsequently analyzed in science class. In addition to the scientific aspect, some students will be assigned to document the field experience through digital photo expansion modules and descriptive essays, creating an interdisciplinary approach to the Watershed field experience.

Marketing and eCommerce - A Real World Simulation

At Omaha North High School, the handhelds will be used as an integral part of the current eClassroom initiative ("paperless classroom" with a 1-to-1 student to computer ratio using email as the primary communication tool). The seven marketing classes are already being taught "paperless." The handhelds, coupled with IntelliSync and other software, will extend the classroom beyond the school to mirror a real-world business environment. The handheld will become the "textbook," using web-based sources of information downloaded via AvantGo, groupware functions provided by GroupWise (mail, calendar, scheduling etc.) and other applications, both purchased and developed for our use by the South High portion of the proposal. The eClassroom is already a model for classroom instruction; the introduction of Palms pushes its development to a higher level, opening new and exciting possibilities for students.

Academy of Information Technology

The intent of the use of handhelds at Omaha Public School’s South High School is to determine if high school programming students in the Academy of Information Technology can do the following:
1. Learn and develop software programs for the Palm OS system using CodeWarrior for the Palm OS
2. Interact with middle school teachers and students at King Science Center on issues and challenges of integrating the Palm into the science curriculum.
3. Utilize the potential of handhelds to increase student skills in computer technology.
4. Interact with North High School marketing students to market the innovative use and development of applications and integration of the Palm technology into the Academy of Information Technology curriculum.

6th Grade Math

An elementary teacher at Carriage Hills Elementary in the Papillion LaVista School District is using a classroom set of handhelds for her math classes. At this point, only free software is being used in order to keep costs to a minimum. Her handheld-infused curriculum is aligned with the NCTM Standards, and includes web page viewing, drawing, simulations, writing, calculating and drill. The handhelds are used by four different sets of students each day and are not used outside of the classroom.

5th Grade Self-Contained
A handheld is provided for each student in one fifth grade section at Willowdale Elementary, Millard Public Schools. The students use "their" handheld all day and keep it with them each day. Also, a keyboard is provided for each student. The teacher uses the handhelds in all subject areas and has developed or revised many activities to include the handheld. This teacher makes extensive use of web page syncing and the students do some of the web page development of their own learning documents. An interesting aspect of this project is that two models of two different brands of handhelds are used and both Windows and Mac computers are used to sync the handhelds. We are beginning to learn advantages and disadvantages of each variable in this classroom.

Summary

Handhelds show much promise in helping students learn. As more and more teachers use handhelds in their classrooms, we will continue to add to our knowledge of the uses of these devices. Education colleges must keep informed and continue to learn about "best practices" in the use of these versatile tools. Also, education programs will need to infuse handhelds into their own curriculum so that they can model effective use of this new technology. By partnering with local schools, Colleges of Education have an opportunity to not only watch innovative teachers and practices, but also to contribute to the development of effective activities that will not only help teachers teach better, but more importantly, help learners learn better.
An Investigation of Traditional and Constructivist Models for Internet Training and Effects on Cognitive Gain

Dr. Chenfeng Zhang
Department of Education and Special Education
Mansfield University of Pennsylvania
czhang@mnsfld.edu

Abstract: There has been an emerging body of literature on computer training and its impact on the use of computers, including the use of the Internet. Research has shown the two models of training - the Traditional Model and the Constructivist Model - each has a positive impact on students' achievements. These studies deal with topics such as math, science and geography, but not computers and the Internet. The results of the studies on the two training models are confounding. This current study determined which Internet training model - the Traditional Model or the Constructivist Model - could produce greater cognitive gain for pre-service teachers, as well as which model could produce greater positive changes in attitudes toward the use of the Internet. A nonequivalent control group pretest-posttest quasi-experimental design was used in this study. The participants of the study were exposed to alternative teaching strategies - the Traditional Model and the Constructivist Model of Internet training. A pre-and-post Achievement Test was administered to each group to assess the changes in the extent of learning. A Pre-service Teachers' Attitude Survey was administered to assess their attitudes toward the use of the Internet. In the analysis of data, the analysis of covariance, a t-test, two sample dependent means, and a t-test, two sample independent means were used. Results showed the Constructivist Model of Internet training produced a greater cognitive gain. After experiencing the Constructivist Model of Internet training, the pre-service teachers developed a more positive attitude toward the use of the Internet than before the training. After experiencing the Traditional Model of Internet training, the change of the pre-service teachers' attitudes toward a more positive direction was not statistically significant, but there was a shift toward a more positive direction. The study also showed that there were no significant differences in attitudes toward the use of the Internet between the two groups of pre-service teachers after experiencing either model of Internet training.

Introduction

This study investigated the impact of two training models, the Traditional Model and the Constructivist Model, on pre-service teachers' achievements and attitudes toward the use of the Internet. There has been an emerging body of literature on computer training and its impact on the use of computers that includes the Internet. Research has shown the two models of training - the Traditional Model and the Constructivist Model - each has a positive impact on students' achievement. These studies deal with topics such as math, science, and geography, but not computers and the Internet. These studies on the impact of the two training models are confounding. Some research favors the Traditional Model and other research favors the Constructivist Model. It is not known, however, which training model produces greater cognitive gain or which model brings forth more positive attitude changes. This study was based on the following hypotheses: 1) Pre-service teachers experiencing the Constructivist Model of Internet training will experience greater cognitive gain than pre-service teachers experiencing the Traditional Model of Internet training; 2) Pre-service teachers will experience a more positive attitude toward the use of the Internet after experiencing the Traditional Model of Internet training; 3) Pre-service teachers will experience a more positive attitude toward the use of the Internet after experiencing the Constructivist Model of Internet training; and 4) There are no significant differences between the two groups of pre-service teachers in their attitudes toward the use of the Internet after experiencing either model of Internet training.

The Design

A nonequivalent, quasi-experimental, pre-and-post survey design was used to study the effect of the Traditional and Constructivist training models on pre-service teachers' achievements. Pre-service
teachers taking part in this study were divided into two groups – a control group experiencing the
Traditional Model of training and an experimental group experiencing the Constructivist Model of training. The two models of training were carefully designed by the researcher to reflect the characteristics of each model. Distinctive teaching methods for each model were used. The Internet training focused on the
Internet search engines, search strategies and applications of using search strategies to solve daily
problems. The contents for the two training models were the same, with differences in the methods of
instruction. After experiencing the Internet training, students took a Student Perceived Classroom Learning
Environment Scale survey. Another similar survey, the Observer Perceived Classroom Learning
Environment Scale survey, was filled out by two observers who sat in both models of the training class
sessions three times: once before the Internet session, once during the Internet session and once after the
Internet session. The purpose of the two surveys was to validate the methods used in the Internet training
intervention, i.e., it measured the methods used in the training to determine if they contained the
characteristics of the Traditional Model or the Constructivist Model. When the mean score of the survey for
a training model is over 84, the model is a Constructivist Model and when the mean score of the survey is
under 84, the model is a Traditional Model. Students also took a two-section Achievement Test before and
after they experienced either model of training. The first part of the test was written according to the first
objective – pre-service teachers will be able to list and describe the differences between common search
engines and meta-search engines and differences in search results when different search strategies are used
with 100% accuracy. The second part of the test was on the second objective – pre-service teachers will be
able to use basic search strategies to locate information to solve daily problems with 100% accuracy. The
pretest score for the Achievement Test was used as the covariant for the analysis of covariance to determine
if there was a gain in the posttest score for pre-service teachers in the two training models and which group
had a higher cognitive gain. The Survey of Pre-service Teachers’ Attitudes toward the Use of the Internet
gathered data of pre-service teachers’ attitudes toward the use of the Internet. A t-test, two sample
dependent means was used to analyze the attitude change before and after the training in each of the two
model groups. A t-test, two sample independent means was used to compare the after training attitudes
between the two model groups.

The Findings

To test the hypothesis that pre-service teachers experiencing the Constructivist Model of Internet
training will experience greater cognitive gain than pre-service teachers experiencing the Traditional Model
of Internet training, ANCOVA was used. The result of the analysis indicated that there was a significant
difference between the posttest scores of the Traditional Model and the Constructivist Model. The mean
score for the Constructivist Model was significantly higher than that for the Traditional Model. Besides,
both of the Perceived Classroom Learning Environment Scale surveys indicated that each model of training
was carried out according to its own characteristics. Data indicated that pre-service teachers experiencing
the Constructivist Model of training developed a more positive attitude toward the use of the Internet after
the training than before the training. After experiencing the Traditional Model of Internet training, the
change of the pre-service teachers’ attitudes toward the Internet was not statistically significant, but it did
change toward a more positive direction. To analyze data for the fourth hypothesis, a pooled difference in
posttest scores were measured by using a t-test, two sample case, independent means. The data indicated
that there were no significant differences in pre-service teachers’ attitudes after experiencing either model
of the Internet training. Further study could be conducted. Researchers could study the effects of different
training models on pre-service teachers’ cognitive gain, for example, compare the Traditional Model with a
“mixed” model where both traditional and constructivist methods are used. Researchers could also study
the effects of the training models on pre-service teachers’ attitudes when they had a low positive attitude
toward a subject matter.
Telecommunications and education – the two are becoming increasingly intertwined in our classrooms and programs at all levels, especially in teacher education programs that are preparing educators to effectively use these technologies in their classrooms. The range of applicable technologies is growing as new ones are emerging and current ones are expanding. The number of schools with Internet-connected computers in libraries, labs, and classrooms continues to grow, providing potential opportunities for students and teachers to participate in global learning communities, and to both retrieve and produce educational resources. Teachers must learn to use and feel comfortable with these technologies, as tools to enhance teaching and learning. So where and how does this take place? The papers in this section demonstrate the wide range of approaches, for both preservice and inservice teachers, in university, field-based, and alternative programs, with delivery ‘sites’ being online (Internet), videoconferencing, university classrooms, or k-12 schools – either individually or in combination.

Both video-conferencing and online Internet-based courses are described, as are uses of these technologies as integral components of classroom-based courses and/or faculty development. Also discussed are general support and community resources that are not course-connected, and that speak to the concept of lifelong learning. Taken as a whole, these papers provide a snapshot of ways that telecommunications can be used to support and promote effective teaching and learning in today’s educational settings. Accounts of both successes and lessons-learned, as well as discussion of methods of assessment of the use and/or effectiveness of various technologies provide guidance for current and future educators.

The Internet may be a veritable goldmine of resources, or it can be an endless maze through which educators wander in a fruitless quest for those resources. Growing numbers of portals and other methods of organizing Internet resources are appearing. Levin and Grotto introduce one such effort – discussing how resources are selected and evaluated for inclusion in a database, and how teachers can become a part of that process. In addition to finding resources, the Internet also provides a forum in which educators can share resources they have created, thus contributing to others in their profession. Repman, Carlson, and Downs describe and provide links to a number of web-based tools that they have found helpful for productivity and instruction. Gersh, also explores web-based tools, discussing those that facilitate “Internetized” lessons and internet-based projects. Specialized applications provide opportunities such as the use of remote scientific instrumentation technology in K-12 and teacher education classrooms, as described by Thakkar, et al. This use of Internet-based activities is basic to the world of telecommunications for classroom instruction, and opportunities to learn more are often available at universities and colleges, as well as at school districts.

E-mail has become almost as common, if not more so, than the postal service it sometimes seems, and is but one of the methods of communication enabled by telecommunications. Several papers explore the communication and community building aspect of the Internet and related tools. Thomeczek examined electronic communication in an undergraduate teacher education course, and compared an e-mail discussion list with a web-based discussion board. Collier and Yoder suggest techniques, based on existing literature, for conducting successful online discussions and collaboration. Tuzun and Yilmaz describe an online learning community of inservice and preservice teachers, communicating via ICQ Active List. Leh and Winograd present some moderating strategies for instructors who are managing online computer conferences. Online communication forums may promote life-long learning, as students continue with these communities after completing their university studies.

Communication is also enhanced by the use of telecommunications to link university classrooms with those in K-12, a practice that has provided unique opportunities for preservice teachers to
observe and interact with schools at a distance. Adcock and Austin discuss their experiences with a preservice observation project that connected the university with public school classrooms via a two-way audio/video conferencing system. Lehman and Razzouk describe a method of observation/interaction using IP-based videoconferencing. Boccia, Fontaine, and Lucas describe a “two-way television teaching, debriefing, and general mentoring” program that led to the development of a CD to help better prepare preservice teachers for observations. Videoconferencing permits students to broaden their perspectives and experiences, as they ‘visit’ schools, often at a distance.

Online courses also provide experiences ‘at a distance,’ and studies relating to faculty and students are being conducted to help guide the development of successful educational experiences for all. McKenzie, Waugh, Bennett, and Mims report the findings from their study of what faculty should know about course preparation for online learning. Tucker and Blocher review characteristics of successful distance education students and then describe their study of students and online collaboration. Other papers describe online courses for high school students, and for faculty development.

Integration of technology is one of the ‘buzz-words’ of the day – teacher preparation programs debate whether to have a stand-alone computer course, or whether to integrate technology throughout the teacher preparation program. What is the best method of introducing preservice teachers to ways to integrate technology into their future classrooms? Redmond and Albion used a newsgroup and a guest ‘expert’ in communication with preservice teachers to explore that question, and they report the results and explain their choice of methodology. Koro, Kumpulainen, and McManus have also addressed the integration issue – they describe a survey they developed to obtain information about technology integration from faculty and students, on an institution-wide basis.

The papers in this section demonstrate a wide range of uses for telecommunications throughout the educational arena. There are full courses offered via video-conferencing, while others are online over the Internet. There are classroom-based courses, with online or video components. The modes of communication vary, as do the uses to which this technology is put, and the authors provide a view into successful implementations, as well as a discussion of lessons learned and some suggestions for improvement. The body of literature is expanding, as are the technologies. These papers provide a snapshot of ways telecommunications technologies are being used in support of teaching and learning.
Behind the Scenes: The Process of Implementing a High School Web-Based Course

Merry Boggs, Department of Teacher Education,
Holly Patterson-McNeill, Department of Computing and Mathematical Sciences

Abstract: This paper describes how a team of university faculty with knowledge of computer science content, web-based content, and curriculum development content worked together with a high school teacher to implement a high school web-based course.

Introduction

Byun, Hallett, and Essex (2000) found four guiding concepts for online course development. (1.) The instructor needs to have content organized while integrating technology, (2.) The instructor needs to establish procedures for frequent and clear communications, (3.) The instructor needs to collaborate with outside technology experts for support, and (4.) The instructor needs to enculturation him/herself to online/web-based instruction.

This paper describes how a team of university faculty with knowledge of computer science content, web-based content, and curriculum development content worked together with a high school teacher to implement a high school web-based course. Through this collaboration TAMUCC teacher educators and a high school teach to implement for an effective implementation of a web-based platform for a high school course. But everything that could possible go wrong did. This paper examines through the two-and a half-month period it took to get this single high school web-based course started.

Behind the Scenes

At the beginning of the summer, this collaborative team delegated responsibilities to prepare for the 2001/02 school year. Mr. Boggs, high school computer science teacher, prepared computer science content. He has previously taught this course, but he prepared by re-organizing materials as to re-format homework, daily work, test, and lesson presentation for web format. Additionally, Mr. Boggs spent June and July at work making sure his computer lab would be ready for students on the first day of school. Drs. Boggs and Patterson-McNeill took care of purchase orders and research preparation.

Simultaneously, we spent time taking WebCT’s on-line training. During this time, TAMUCC sponsored WebCT training for faculty only. So, Dr. Boggs took this course while Mr. Boggs took on-line WebCT introduction class. During this time, we decided to purchase epack to use with the web-based course. We felt that this would help transition into a web-base format smoother.

Each of us gave precious summer hours in preparation for beginning our web-based course the first day of school. Little prepared us for the events of August through October. As Mr. Boggs walked into his class with, Visual C++ install on all computers, WebCT, and epack curriculum on-line waiting for him to point and click or at least we though we were prepared. We first realized that there was trouble when he found that the classroom’s network infrastructure had been ripped out and taken to another campus. There was no Internet or network access in his classroom.

Challenges
Without the network infrastructure, the web-based component could not be implemented. Meanwhile, computer science classes started. Students were informed of the upcoming web-based component of the computer science course and what to expect. To prepare students for taking tests and reading their textbook online, students in the proposed web-based class used the library research classroom.

Problems implementing a web-based component at the high school occurred at several levels. Since university and high school budgets were involved, beginning and ending dates of these budgets did not coincide with the actual starting dates of students coming to school. Several weeks were spent trying to purchase epack textbook.

During the summer months, network and Internet capabilities were in place. However, infrastructure fell apart when LAN switches were taken from the high school to the junior high to support their new grading and attendance software. Thus, leaving the high school without needed network equipment to implement a web-based component in the computer science class. The switches were replaced in the last week of September, five and a half weeks after classes had begun.

Finally, Internet access was solved, but some of the computers still do not have printing capability. Then, the Nimda virus struck through the ISP located at the school district central office. We were shut us down for another week. Luckily, this extra week gave us time to finalize the purchase of the epack textbook. Once we were ready with textbooks and Internet access, students needed time to adjust to WebCT and epacks.

Conclusions and Implications

We found that the summer months are not enough for planning and implementing a web-based high school course. A year is needed to plan, organized, and purchase software and materials before beginning the actual course. Also, this year is needed for learning the course delivery system. Mr. Boggs spent hours every weekend in the fall semester trying to master the basic navigation procedures and tools of WebCT. Any teacher implementing this system needs this time to dedicate to conquering the new software. We were naive thinking we could spend only the summer months preparing for this endeavor.

Students were frustrated with the transition from starting the school year with traditional classroom instruction then having to move to the web-based format. Traditional instruction in the history of computing was used to ease the pain of learning logon procedures, accessing epacks, and communication procedures via WebCT. Then, programming instruction began once Mr. Boggs felt all students could use the basic materials. Epacks were great for getting the students started and freeing the teacher from entering all content in WebCT. Epack textbooks were still incomplete because limited examples and program samples are not included. We found that traditional lecture time is still needed to supplement web instruction. Students still need daily teacher help, talk, motivation, and encouragement.

As the first semester ends, teachers, students, and researchers are finally comfortable with the WebCT format. The second semester brings the hope of focusing on C++ programming and measuring student achievement.

Abstract: The purpose of this study was to identify technology teachers' attitude toward videoconference applied in education. Technology teachers are always playing the pioneer role to adopting new teaching technology into their professional works. Their attitude toward certain teaching technology would consider an indicator of implementing technology in education. Videoconferencing technology allows two or more people at different locations to communicate each other at the same time. In addition, it is often possible to share computer applications. It is a rich communication technology which could offers new possibilities for schools, colleges, and libraries including formal instruction, connection with guest speakers and experts, multi-school project collaboration, professional activities. Based on literature review, an investigation tool was design for collecting data of technology teachers' attitude toward videoconference applied in education. There were three attitude categories in the questionnaire. Those categories were advantage of using videoconference, type of using videoconference, and effective using videoconference. According to the result of statistical analysis, the technology teachers' attitude toward videoconference applied in education was concluded and discussed.

Technology teachers' attitude toward videoconferencing was the major issue of this study. There were three dimensions of attitude toward videoconference. Those were advantage, usage type, and
Effective strategy focus. Effective use of videoconferencing technology for interactive learning requires practice and planning as well as attention to a few important instructional strategies.

Methodology

An investigation method was applied to this study. Based on literature review, research instrument was layout and designed. Questionnaires were delivered to random sampled technology teachers for collecting data. Technology teachers were asked to mark a Likert scale from "Strongly Disagree" to "Strong Agree". The population of this study was technology-practicing teacher in Taiwan. The total was around 300. The Random sample procedure was applied to distribute 45, 15%, questionnaires. There were 37 returned. The research instrument divided into two parts, profile information, and 15 Likert-type questions focused in three dimensions. The Alpha reliability coefficient of this instrument was 0.82. The separate Alpha values of each dimension were 0.87, 0.70, and 0.79.

RESULTS & CONCLUSION

The profile information listed as follows:
1. Gender: male (89.2 %), female (10.8 %)
2. Age: 20-25 (89.2%) 26-30 (8.1%) 31-35 (2.7%)
3. Teacher/Administrator: Teacher (56.8) Administrator (43.2)

The results based on statistical test results were discussed as following lists.
- Based on the one-sample Test of each Likert-type question, it was concluded that technology teacher agree video-conference providing following advantages:
  1. Heightens Motivation
  2. Improves Communication, Presentation, and Reading Skills
  3. Increases Depth of Learning

It was concluded that technology teacher agree video-conference could be arrange as following types:
1. Courses, Lessons, and Tutoring
2. Virtual Field Trips
3. Multi-School Projects
4. Professional Activities
5. Community Events

It was concluded that technology teacher agree effectiveness of video-conference based on as following factors:
1. Focus on Learning
2. Set Expectations
3. Provide Supporting Materials
4. Engage Students with Variety and Interaction
5. Encourage Dialog

There existed no attitude difference between gender.
There existed no attitude difference among different age range.
There existed no attitude difference between teachers and administrators.
Successful Online Discussion and Collaboration: Techniques for Facilitation

Abstract: As more and more instructors enter the world of online teaching and learning, a body of knowledge is emerging around the challenge of facilitating online interaction and fostering online collaboration. This paper draws from the literature on asynchronous learning and the authors' own experiences with online discussion and collaborative online projects. We identify a variety of techniques for focusing student dialogue, fostering an online learning community, and promoting successful collaboration. Instructors who are teaching wholly online courses or simply integrating online components into face-to-face classes will benefit from the observations and discussion.

Introduction

Instructors who teach online, whether a fully online class or one that incorporates online components, face the challenge of facilitating online interaction and fostering online collaboration. Drawing from the literature on asynchronous learning and the authors’ experiences with online discussion and collaborative online projects, we can identify a variety of techniques for focusing the dialogue, fostering an online learning community, and promoting successful collaboration.

Face-to-face vs. Online Discussion

Face-to-face and online communication are noticeably different for the instructor and the student. Differences arise from the spoken word vs. the written word and asynchronous vs. synchronous communication. There are advantages to asynchronous interaction that instructors can use to their benefit in facilitating online discussion.

In a spoken discussion, the facilitator makes the effort to encourage participation across the class, to acknowledge all contributions without being judgmental, and to avoid having participants interrupt others. This can be done by calling on people whose hands are raised and encouraging non-contributors to participate.

No special skills are required to participate in spoken discussion. Some people participate in face-to-face discussions with confidence. They may be effective and productive but can sometimes be controlling or opinionated. Some people may be introverted or shy in a face-to-face setting and are reluctant to contribute to class discussion. Both problems may require intervention by the instructor to insure equitable, productive discussion.

Typically, verbal contributions are spur of the moment, spontaneous reactions. Tone of voice, accents, and body language help convey a message in face-to-face discussions. Unless someone is taking notes, there is no written record of what is said.
Written discussions differ in important ways. Both the participants and the facilitator have a written record of contributions throughout the discussion and as a reference following the discussion. Taking turns does not involve bidding for the instructor’s attention; each student simply writes a contribution when ready. Online discussion contributions tend to be more thoughtful and deliberate. They are often well constructed, and attention is paid to spelling, grammar, and punctuation. Emotion is conveyed with words and sometimes emoticons. Capital letters and punctuation may be used for emphasis.

The facilitator can send private email to non-contributors and can carefully plan interventions. Some problems arise when participants are not coherent writers or become impatient when they have to plan and write their thoughts. On the other hand, introverted or shy people may shine when they can plan what they are going to say and carefully construct an online entry.

For written discussion to be productive and effective, participants must be comfortable with online conferencing and able to navigate within the discussion area. They may need guidelines on writing subject lines for their postings and knowing when to begin a new thread. As with spoken discussion, the instructor may need to intervene occasionally to correct a problem, emphasize a point, or refocus discussion.

**Facilitating Effective Online Discussions**

With asynchronous interaction in mind, how can the instructor facilitate online discussion? In a face-to-face classroom discussion, the instructor needs to carefully listen to what is being said. Online, the teacher must read the written contributions and decide how and when to intervene. The literature and our experience show that fewer, but carefully constructed, instructor interventions can be effective in promoting thoughtful and thought provoking contributions by students. Effective online facilitation begins with observation of the participants to see what guidance they need from the facilitator. Sometimes this is a private e-mail reminder to an individual student to use meaningful subject lines or to reveal emotion. Often the most help an instructor can provide to the discussion as a whole is to intervene very little, merely asking a probing question or sharing a relevant story that will help refocus the discussion or motivate the participants to think at a deeper level about the topic.

Markel (2001) writes that instructors must be responsive. Feedback has long been recognized as critical to the learning process, and timely feedback is potent. This is especially true in an online course. A student assignment, question, or bid for response can come directly to the instructor via email or as part of a discussion forum posting. Feedback needs to be personal, specific, and timely (within 24 hours). Online students report checking back to see if there is a response. If they are left dangling, they lose a feeling of connection. This is a negative loop that contributes to a lessening of participation in the discussions.

Sarah Haavind emphasizes the responsibilities of a facilitator to deepen the dialogue and focus the learning. Knowing how and when to intervene is critical. Using a variety of voices and tones, the facilitator acts as "guide on the side", develops a rationale for an intervention, and carefully crafts an intervention that targets an obvious tension, an unresolved issue, or a gap in the thinking of the group. (Collison, Elbaum, Haavind, & Tinker 2000)

The best facilitators are flexible, adaptive, proactive, responsive, and resilient. They take into consideration the participants and the interaction, and they adapt their techniques to fit the situation. Sometimes this means encouraging more cooperation and less competition; other times it means emphasizing process over results. The goal is to maintain a balance that will best serve the participants and help them reach their learning goals. (Thiagarajan 1999)

**Fostering Online Community**

Creating a safe and challenging online community includes requiring participation and monitoring the quantity, frequency, and content of student contributions. Strategies that promote effective discussion include motivating inquiry with thought provoking questions, intervening effectively in group discussions, and supporting individual students. It is important that the instructor not be the central focus of the discussion; nor should the instructor be an equal participant; yet the instructor’s guidance is crucial. The following techniques place the instructor in a thoughtful, useful role as a facilitator.
1. **Incorporate community-building activities.** In order to develop a comfort level among students, an instructor should not launch a serious discussion without first allowing an online community to develop. Ice breaking activities can be used where there is no right or wrong answer, where humor is welcome, and personal and professional information is encouraged. An instructor can share his or her own background and outside interests as an example. Activities that encourage imagination and creative writing sometimes work well. Student introductions could remain available on a class Web page for the duration of the semester.

2. **Clarify class requirements.** Class requirements should be clear, including the expectations around contributions to discussions. Stating the number and frequency of discussion contributions is not enough. The type of contribution should be described. "I agree", "Me, too." and "No way!" are not sufficient or acceptable. Opinions should be accompanied by a rationale. Responses that answer other participant's questions should provide clear explanations and examples. Participants should be taught how to include illustrative examples in their online postings, including Web links for further reading, images for enhancing a thought, and colored and bold text for emphasis.

3. **Know when not to intervene.** Effective online facilitation begins with the reading of conference contributions to see what guidance students need from the facilitator. Often the most help an instructor can provide is to intervene very little, merely asking a probing question or sharing a relevant story that will help refocus the discussion or motivate the participants to think at a deeper level about the topic.

4. **Privately acknowledge high quality contributions.** Instructors should refrain from publicly praising an individual participant or using one posting as a good example. Instead, the instructor can privately acknowledge how the posting helped to move the dialog in a more thoughtful direction or how it prompted others to participate that had not previously contributed. Lee (1994) explains that students who receive feedback by email are "active producers of meaning," rather than passive recipients of data (p. 152). The feedback is evidence that the instructor has read the student's work and cares enough to provide a personalized critique. Positive feedback from the instructor reinforces a student's accomplishments and encourages further good work.

5. **Address unsatisfactory student involvement.** If a student is not participating, or is contributing in an inappropriate way, the instructor has a responsibility to communicate with them. This should be done privately through e-mail, though sometimes a phone call is necessary. Research has shown that negative comments can result in a more positive reaction when delivered by electronic mail, rather than delivered in person. (Fishman 1999) This may be because the student is less likely to take comments and criticism personally when they are delivered asynchronously without personal contact. (Olaniran, Savage, & Sorenson, 1996)

6. **Remain neutral in heated discussions and debates.** A good facilitator acknowledges the many perspectives that have been voiced, but does not take sides or voice a personal opinion on an issue. The facilitator who voices a personal opinion runs a risk: some students will attempt to please the instructor, possibly for a better grade, by agreeing with the instructor's opinion. In this case, a spirited debate with many viewpoints is curtailed. The instructor's role is to encourage thoughtful discussion, not enter into it as a participant.

7. **Acknowledge different viewpoints, without summarizing.** Many lists of conference guidelines encourage the facilitator to summarize the contributions in order to focus the dialogue. The danger, however, is that the facilitator infuses his or her slant on student opinions and imposes an interpretation of student contributions. Instead, the facilitator should acknowledge that there are a variety of views, citing some general ones, and encouraging further exploration of the issue. A good strategy is to state the importance of respecting other people's opinions and urge everyone to support their views with additional information. Sarah Haavind refers to this as setting a "landscape", rather than summarizing. (Collison et al. 2000)

8. **Encourage student feedback to other students.** Some instructors mandate peer interaction by requiring students to react to postings made by other students. The practice can reinforce the student's desire to participate and encourage thoughtful reflection. A student logging into an online forum may find that other students have commented positively on a posting, or that there are six new messages in a thread that the student initiated. This feedback is both affirming and motivating.

**Collaborative Experiences**

Collaborative online projects are another aspect of online learning that benefit from careful design, monitoring, and effective instructor intervention. The design of online activities should include attention to logistics (such as grouping students), checkpoints to insure quality and timeliness of student contributions, and options that allow for joint and individual products.
When a significant online assignment is done collaboratively, the stakes are high. Students are unlikely to succeed as collaborators until they have, as Wegerif puts it, crossed the threshold from outsider to insider. (Wegerif 1998) Students may be reluctant to engage in collaborative projects or papers for a variety of reasons. Some have doubts about their ability to contribute and are concerned about pulling down another student's grade. Conversely, they may feel superior to the class and not want their own grades pulled down. The instructor addresses these and similar concerns by encouraging students to know one another well and to value their contributions before having them engage in high-stakes collaborative activities. This process is facilitated by preceding a major collaborative assignment with several smaller collaborations. Each time students are required to work with different classmates and encouraged to think about their current partner(s) as possible collaborators for the major assignment. By the time the major assignment begins, students are well prepared to choose their own partners.

While these community building activities are underway, the instructor assesses individual students' strengths, weaknesses, styles, and skill levels. The instructor can determine which students need prodding to respond in a timely manner, which students need assistance with technical aspects of collaboration, and which students are reluctant to ask for help. In this way, the instructor and students are accustomed to timely, targeted interventions when the major collaborative assignment begins. Andriole (1997) uses the term “choreographing” to describe the careful design of pre-course, mid-course, and end-of-course activities that support successful collaboration. In particular, it is useful to step through the phases of the project, anticipating difficulties, and designing in contingencies to circumvent or respond to problems.

Experience at Lesley University has shown that online students in collaborative projects are likely to work independently and to skip any required exchanges unless these steps are clearly defined and graded. (Collier & Morse 1999) When students receive clear instruction on what material will change hands, and when they know they will be graded on the exchanges, they comply. Hiltz's research bears this out while emphasizing that students are motivated to work hard on assignments when they know other students are reading their work. (Hiltz 1997)

Recent experience at Lesley University suggests that instructors may want to examine the components of major assignments to identify those that need to be done collaboratively and those that could be done independently. In a collaborative writing assignment, for example, Lesley students were given the option to produce individual or joint papers, but they were required to give peer feedback to their partners at several checkpoints during the collaborative assignment. The combination of providing options while requiring and grading peer feedback resulted in higher quality papers and greater student satisfaction.

In summary, techniques that contribute to successful online collaborative projects are the following: through preliminary, small collaborative assignments, encourage students to know one another and value their contributions; establish a climate of intervention early in the course to deal with the problems that will arise during a major collaborative assignment; build in checkpoints and grade those collaborative activities that are essential to the assignment; provide options for individual vs. joint efforts for some components when this will not compromise the goals of the assignment.

More Organizational Techniques

Throughout an online or face-to-face class, there are different types of online discussion that can support course content, stimulate debate, and promote collaboration among students. The following four discussion forums can be incorporated into any course.

1. *Discussion of course content, readings, and debatable topics.* This forum is the most academically oriented of the four and the most closely tied to the course objectives. The discussion is instructor driven, but populated by students in the class. The instructor largely controls the topics and questions, but after the initial input, the instructor can retreat, letting students take the most active roles.

2. *Logistics of course, assignments, and group formation.* A separate discussion area should be available for students to ask questions and discuss the logistics of the class. The instructor may be asked to clarify an assignment, or a student may contribute or request a resource that is useful for completing a project. The formation of groups for collaborative projects could be accomplished in this area.

3. *Technical support.* Sometimes a technical problem poses a barrier for a student trying to complete an assignment. Often another student in the class has the resources and experience to solve the problem. Having problem-solving information available on a public forum can benefit other students who may need the information in the future.
4. Social interactions. In this area, opinions on current world events and stories of personal triumphs and tragedies can be shared, along with informal discussion on any topic of interest to the students. The instructor may have little or no involvement in this discussion and does not need to facilitate or monitor. Often instructors "lurk" in this area, reading but not commenting, to get a sense of the culture and community of the class.

In addition to serving specific purposes, each of the four provide valuable feedback for the instructor about students’ understanding of the content and students’ ability to articulate their thinking.

Conclusion

Online learning is a challenge for instructors. Facilitating online discussion requires monitoring of the quantity, frequency, and content of student contributions. The instructor motivates inquiry with thought provoking questions, timely interventions, and private support for individual students. Facilitating collaborative work requires the establishment of community, timely interventions, checkpoints and grades for required exchanges, and thoughtful options for joint vs. individual products. These techniques can be learned by any instructor to provide a valuable online learning experience.

Abstract: The purpose of this study was to identify how technology teacher using Internet searching engine for initiating and updating their lesson plan. An investigation research method was applied for this study. There were two phases in this research. In the first phase, an on line recording system for browsing path, screen images and operating video was setup for technology teachers who were experienced searching engine users. By reviewing recorded data the goals, procedures and functions of using Internet searching engine for lesson plan were drawn. In the second phase, a investigating tool was design based on the result of the first phase. Questionnaires were delivered to random sampled technology teachers for collecting data. The statistical process was followed for analyzing collected data. Conclusion of research problem was drawn from the analysis result. Based on the result of data analysis of both phases, a portal type environment of technology teacher professional searching engine for lesson plans was discussed and suggested.

When a technology teacher edits a lesson plans, he/she often needs much information for his/her lesson plan. However, when he/she wants to search his information in demand on the WWW, he/she just can find information in the shortest time by searching engine besides finding information at known professional webs or relative webs. But each searching engine provides different searching functions and information range. For this reason, it is necessary to build a portal type environment of technology teachers professional searching engine for lesson plans. Before reaching this purpose, we must know how technology teachers using internet searching engine for lesson plans. Therefore, the purpose of this study was to identify how technology teachers using Internet searching engine for initiating and updating their lesson plans.
Methodology

There were two phases in this research. In the first phase, an online recording system for browsing path, screen images and operating video was setup for technology teachers who were experienced searching engine users. In the second phase, investigating tools was designed based on the result of the first phase. Questionnaires were delivered to random sampled technology teachers for collecting data. Technology teachers were asked to mark a Likert scale from "Strongly Disagree" to "Strong Agree".

The population of this study was technology-practicing teacher in Taiwan. The total was around 300. The Random sample procedure was applied to distribute 45, 15%, questionnaires. There were 39 returned. The research instrument divided into three parts, profile information, terminology explanations, and 36 Likert-type questions. The Alpha reliability coefficient of this instrument was 0.87.

RESULTS & CONCLUSION

The profile information listed as follows:

1. Gender: male (89.2 %), female (10.8 %).
2. Using computer attitude: 88.9 % of them liked using computer, 11.1% of them were neutral.
3. Learning computer experience: 1~5 years (78.3 %), 6~10 years (19 %), above 15 years (2.7 %).
4. Using computer time a week: 0~30 hours (62.2 %), 31~60 hours (32.4 %), above 60 hours (5.4 %).
5. Contacting to Internet time: 1~5 years (86.5 % ), 6~10 years (10.5 %), and above 10 years (3 %).
6. Using Internet search-engine time: 1~5 years (94.6 %), 6~10 years (5.4 %).
7. Internet instrument accessibility: 2.7 % were hard, 18.9 % were neutral, 40.5 % were easy, 37.8 % were very easy.
8. Self-estimating operating search-engine (scale degree from 1 to 10): scale 5 (8.1 %), scale 6 (5.4 %), scale 7 (24.3 %), scale 8 (37.8 %), scale 9 (16.2 %), scale 10 (8.1 %).

- Based on the one-sample Test of each Likert-type question, it was concluded how technology teacher using search-engine for their lesson plan. They used Internet search-engine in following ways:
  - Synonym search; Key-word search; Semantic search; Subjects browsing; Initiating new lesson plan; Editing lesson plan; Contract filtering data; Verifying data; Parallel filtering data; Comparing data.

- There existed no difference between gender among different search-engine operations. The attitude toward computer would be a factor influencing using search-engine in verifying data manner.
- The person with higher level of positive attitude was with higher intention to verify data from search-engine.
- The instrument accessibility factor made no difference among types of search-engine usages.
- The ability of operating search-engine also made no difference among types of search-engine usages.

According to these findings, an environment of technology teacher professional search-engine for lesson plans could be designed to reduce technology teachers searching information time and frequency, help teachers selecting information, and editing lesson plans.
Using the Internet to Create Web-Based Activities
Sheila Offman Gersh, Ed.D.
City College of New York
sogcc@cunyvm.cuny.edu
http://www.schoollink.org/twin

The "Internet Style of Learning" has provided teachers and students with new ways to approach teaching and learning. Teachers can easily take one of their traditional lessons and turn it into an "Internetized" lesson using resources from the Internet or take a topic they want to teach and create a collaborative inquiry-based Internet project that can be shared with a class in another location, nationally or globally.

Stage One

By going to http://www.epals.com, teachers can search for educators around the globe and create an opportunity for sharing, collaborating, etc. There are so many ways that teachers around the globe are using the Internet to bring the world into the classroom. Examples of projects and collaborations can be found at sites under "projects" at the Web site http://www.schoollink.org/twin

Most traditional lesson plans can be enhanced by adding Internet activities. These activities include research exercises, communications with other students or experts, virtual field trips, publishing, collaboration, interactive activities, or Internet searches. It is always good to have students use the search engines that are designed for students (http://www.yahooligans.com or http://www.ajkids.com -- Ask Jeeves for Kids). Teachers can learn a lot from each other when they join listservs. You can find out about listservs by going to http://www.liszt.com. Many teachers have already created lessons that include Internet components, so we should take the time to view such lessons.

Some teachers find it better to start with new lessons when they introduce Internet activities into their lessons. They use their traditional lessons as outlines for their new lessons. It can take a long time to create the new lessons. Time has to be spent searching for the right site for the lesson. Once the site has been chosen, the next procedure is to develop some meaningful activities for students to complete when they visit the site. If the students are going to communicate with other students/experts, make sure they understand time zones and realize that they won't get responses immediately. Once students are proficient in using the Internet, they can do scavenger hunts on the Internet to find information. Of course, it's a good idea to try out the lesson before teaching with the Internet. Be aware that there might be technology problems so always have a backup lesson. WebQuests are always a good way to get started with Internet lessons. Go to http://edweb.sdsu.edu/webquest/webquest.html for great information about WebQuests. You should read "Some thoughts about Webquests" at http://edweb.sdsu.edu/courses/edtec596/about_webquests.html

Once Internetized lessons become the norm for teaching, Internet projects should be the next step. Such projects should include students collaborating with other classes to
exchange data, share writing activities, and create discussions on topics of interest. In addition, mailing lists often post requests for participation in hundreds of Internet projects. There are many commercial project commercial projects available for those who prefer to “buy in” to a packages project.

**Stage Two**

What is a project? Projects are collaborative, interactive learning activities that allow students and teachers to interact to carry out a research activity that supports the existing curriculum in new and exciting ways. Students use the Internet’s research, communications, and publishing tools to get involved in data exchanges, team writing projects, world explorations, and even global shopping. The classroom walls become invisible as students connect to global partners and experts via the Internet. Through such projects, students around the world work together, sharing the experiences, research, and learning resulting from their work.

Ideas for projects come from students and teachers, and projects vary as widely as the people participating in them. Some projects consist of writing assignments, which are then posted to conferences and eventually gathered into a publication. Others consist of art projects, in which students from different schools exchange works of art. Still others provide ways for students to get directly involved in helping to solve problems in other countries.

Projects are usually organized according to the age/grade levels of the participants and by curricular subject matter. Participation is open to either students of all ages, primary/elementary students, or intermediate/secondary students. Subject areas include environmental or natural sciences; social studies, politics, and economics; arts and literature; language-based; and other/interdisciplinary.

Projects have been classified in a variety of ways. I*EARN (http://www.iearn.org), The Global SchoolHouse (http://www.gsn.org), Judi Harris (http://www.esu3.k12.ne.us/institute/harris/Harris-Activity-Structures.html) and Bernie Dodge (http://edweb.sdsu.edu/webquest/webquest.html) have made outstanding contributions to the use of Internet projects. For example, I*EARN has categorized projects as structured, unstructured, and Learning Circles. Judi Harris has done extensive research in the area of Internet projects. As a result, she has classified projects into the following categories; Online Correspondence and Exchanges, Information Gathering, Problem Solving, and Competitions. On Thursday, October 25, 2001, President Bush highlighted the launch of the Friendship Through Education Consortium --is called Friendship Through, a resource network for schools wishing to interact with schools internationally. To learn more about the project or to get involved go to http://www.friendshipthrougheducation.org/.

**Getting It Right**
Suggested Design Criteria for Internet Projects

Internet project should:

- Focus on getting students to use their minds well; raise real questions and allow students to do authentic work rather than exercises from a workbook;
- Develop instruction around the questions, ideas, and concerns of students;
- Recognize and use learners’ purposes for learning; view learning as meaning-making and constructive rather than passive reception and regurgitation of transmitted information;
- Develop active approaches to learning and encourage students to express their ideas and opinions;
- Give students ownership of their learning;
- View teachers and students as co-investigators-- both should seek knowledge and solutions to problems; foster collaborative/cooperative learning and devise activities that help build a sense of community;
- View students as producers of knowledge and publishers of their work;
- Provide moments when everyone takes time to reflect on what they have learned;
- Contribute to the understanding of other cultures;
- Strengthen students’ literacy and academic skills; and
- Provide ample opportunity to strengthen students’ technology and Internet skills.

The Internet can make teaching and learning exciting while encouraging students to become lifelong learners, contributing members of society, and valuable members of the world of work. The research, communications, and publishing skills learned by students through Internet activities are essential for now and in the future. I have been using the Internet for 14 years. I often ask teachers who aren’t using the Internet – How are you accessing information? How are you communicating? How are you teaching? Are you, also asking these questions?
The Concord eLearning Model for Online Courses

Sarah Haavind, Concord Consortium (sarah@concord.org)
Cynthia McIntyre, Concord Consortium (cynthia@concord.org)
Ray Rose, Concord Consortium (ray@concord.org)
Alese Smith, Concord Consortium (alese@concord.org)
Bob Tinker, Concord Consortium (bob@concord.org)

Abstract: The Concord Consortium has been designing and implementing netcourses since 1994. In our work with the Virtual High School (www.goVHS.org) and NSF-supported professional development project for mathematics and science teachers enhancing their inquiry pedagogy called INTEC (intec.concord.org), a model of collaborative, online learning emerged that now serves as a standard for effective netcourse design and facilitation. Concord staff have co-written two books on the topic, Facilitating Online Learning: Effective Strategies for Moderators (Atwood, 2000) and Essential Elements: Prepare, Design and Teach Your Online Course (Atwood, forthcoming). This paper describes the Concord eLearning Model.

Introduction

The netcourses developed and/or offered by The Concord Consortium (www.concord.org) are organized around online student collaboration as the core vehicle for learning. To this end, a scheduled, asynchronous format works best. It allows for the deepened focus, extended reflection time and flexibility of "anytime, anywhere" while at the same time fosters learning communities who move together through content and learning dialogues simultaneously on a weekly or bi-weekly schedule. But there is more that makes eLearning quality learning. These additional facets are embodied in the following nine key characteristics:

Sound inquiry pedagogy. "The new and more powerful opportunity available to educators today is to use (internet) technologies to help individuals collaboratively construct networked learning communities that will accelerate and augment the community's learning, as well as each individual's learning" (Carroll, 2000). There are many specific design elements in the Concord eLearning Model that contribute to best practices for inquiry teaching including varied smaller group problem-solving activities, explicit objectives matched to qualitative assessments, rubrics for postings that ensure discussions provide embedded evidence of learning, and the effective use of graphics, simulations and visualizations that support exploration and sensemaking activities for collaborating learners. Our extensive course standards (http://www.govhs.org/Pages/Main+Office-Course+Evaluations) that incorporate these design elements and sound pedagogical practices should be part of any effective course but are essential in this medium.

Ongoing Assessment. Continuous assessment is essential in online courses because one cannot be sure whether a high-stakes test would be closely monitored. Rather than taking advantage of quantitative testing options made easy by the electronic medium, our strategy allows the teacher to learn each student's voice and typical approaches to problem-solving thus avoiding the problem of secure monitoring. We find the learning is enriched by this alternative approach. Required discussion postings must contribute more than "I agree" or "I disagree". Additional credit is given for contributions that point others toward productive exploration, coin useful phrases or offer analogies that help others express their thinking and pursue new areas. A rigorous academic experience is ensured by augmenting the learning dialogue as a vehicle for evaluation with unique projects where content is explored in local settings or using additional Internet technologies (creating an original web page of resources for a specific audience, building an electronic portfolio of work, or posting original designs, new problems or findings, music, or other appropriate original work).

Asynchronous collaboration. The core learning strategy in our model uses asynchronous discussions and group problem solving collaborations between students in threaded discussion groups. Compared to synchronous technologies (chats, shared whiteboards, shared applications, audio conferencing, and video conferencing), these discussion groups are less expensive, more thoughtful, and far easier to schedule, particularly across time zones. A typical face-to-face sequence in a mathematics or science course includes a demonstration or modeling by the teacher, lab work or practice problems in class with a group and individualized homework for group review the following day. Online, the demonstration or modeling might be via an online, visual simulation activity (or offline experimentation with simple materials) that students can then explore or play around with to answer questions. The collaborative discussion would then revolve around gif images of interesting or surprising findings, unexpected outcomes or questions about aspects of the content to be learned. Students then help students with the instructor intervening only when others cannot assist. Research shows that this learning environment is inclusive and supportive of students with disabilities (Hsi & Hoadley, 1997).

Expert facilitation. Each course section must be led by a qualified person specifically trained in online facilitation. Leading an online discussion is a skill that must be developed; it is not sufficient to simply assign to online teaching to an excellent face-to-face teacher. Effective strategies in person have unintended effects online that halt rather than seed deepened dialogue (Haavind, 2000, Collison et al, 2000). In addition, many beginners make the mistake of putting themselves in the middle of the conversation by either asking all the questions or...
These nine characteristics define the Concord eLearning Model, and position it as a major refinement of the more generally implemented scheduled asynchronous, instructor-led model for online instruction.

**Excellent materials.** Learning resources of many kinds are needed to provide the content and common experiences.

**Limited enrollment.** For meaningful online collaborations, the number of participants in an online discussion group needs to be limited. We find that 20-25 is the maximum number in one group for general discussions and that sub-groups with as few as two or three are needed for the intense collaboration required to produce something complex, like a cumulative project. However online discussions need a critical mass, so smaller is not better—and the minimum number of participants for effective online discussion is approximately 15. If the enrollment in a course is larger than 25, independent sections of approximately 20 are formed. When smaller working groups are needed for a specific task, the section is divided into public or private subgroups (depending on whether cross-pollination among groups has valued potential).

**Explicit Schedules.** Online courses that rely on collaborative discussions must be tightly scheduled so that those participating share similar experiences and insights. We schedule a major topic for each week and usually schedule a set sequence of activity, discussion, and reflection within each week. For instance, if the content of a video is essential for a scheduled discussion, then the schedule must have all participants view the clip before beginning the discussion. While it is not important that all participants view the video simultaneously, it is best if each person views it within the days just prior to the beginning the discussion group. The assignment will then have each participant make an initial entry. Another assignment, within a few days will have participants make responses to comments already posted. The best schedule preserves the “anytime, anywhere” flexibility of online courses while also ensuring that all participants bring similar experience and currency to the discussion.

**Limited enrollment.** For meaningful online collaborations, the number of participants in an online discussion group needs to be limited. We find that 20-25 is the maximum number in one group for general discussions and that sub-groups with as few as two or three are needed for the intense collaboration required to produce something complex, like a cumulative project. However online discussions need a critical mass, so smaller is not better—and the minimum number of participants for effective online discussion is approximately 15. If the enrollment in a course is larger than 25, independent sections of approximately 20 are formed. When smaller working groups are needed for a specific task, the section is divided into public or private subgroups (depending on whether cross-pollination among groups has valued potential).

**Excellent materials.** Learning resources of many kinds are needed to provide the content and common experiences needed for effective discussions. To appeal to different styles of learning, we advocate using the widest feasible range of media and activities. We do not attempt to supply all material over the wire: books, media, kits, and labs might require supplies that are mailed or obtained locally. We encourage course authors to engage students in explorations, surveys, creative works, and self-reflection as appropriate. Multiple, short assignments in different styles and media are helpful in preserving course flexibility, reinforcing key concepts, and addressing different learning styles.

**Purposeful virtual spaces.** For most courses, several conversations are needed, each with different goal. At a minimum, four kinds of conversations are needed: An academic one about the content, and a technical one about the interface keep tech inquiries together and out of content threads. The facilitator only has to answer technical questions once, since others are encouraged to check the tech thread before asking the same question twice. Also needed is a social conversation thread for the group to meet and greet, de-brief and exchange resources or network. Finally, a weekly or bi-weekly "class meeting" thread is where participants can share with the facilitator and peers how its going, what's working, what's being learned and appreciated about the course and what challenges participants confront as they move through the material. In many courses, multiple content threads, possibly time-limited, might also be needed. The conversations in these threads need to be set up in separate virtual spaces with clear learning goals and supporting rubrics for effective communication and growth (no "I agree/ I disagree"). The facilitator must nurture the appropriate use of each virtual space to keep dialogues clear and focused, and thus ensuring the content thread(s) are more fluid and rich.

These nine characteristics define the Concord eLearning Model, and position it as a major refinement of the more generally implemented scheduled asynchronous, instructor-led model for online instruction.
Collaborative Efforts through Tele-Mentoring to Increase Technology Effectiveness of Teacher Education

Abstract: The study examined the technology skills of the pre- and in-service teachers in the teacher education program. The two courses in the teacher education program established a cross discipline partnership creating a mentor/mentee relationship. The data was collected in quantitative and qualitative formats. The quantitative data was collected through technology surveys and online interaction. The qualitative data was gathered by classroom observations, mentoring technology activities, technology journals, electronic portfolios, instructors' notes, qualitative perspective discussions, and semi-structured interviews. This collaborative tele-mentoring activity offered students opportunities to expand use of e-mail in meaningful ways, to explore World Wide Web resources relevant to course topics, and to apply multimedia skills in the creation of electronic presentations and portfolios.

Over the past several decades educational professionals and practitioners on every level have struggled with the issues of how technology can be integrated into curriculums and increase students' technology skills in preparing for the future. Research reveals that core and specialized content professors in teacher education programs may be under-utilizing technology tools (Carlson and Gooden, 1999). According to them, modeling of technology by teacher educators was occurred only for word processing and most technology is underutilized. Therefore, pre-service teachers have little opportunity to see it modeled in their college classroom setting by their university professors. Moreover, Volk and Ming (1999) state the attitudes towards technology students receive is derived from prior experiences in formal education are important factors in their abilities to engage actively in any technological endeavors. Uses of technology in teacher education programs may motivate the pre- or in-service teachers to use it in their own instructional setting and maximize the quality of their research and presentations.

For innovative and motivational uses of technology into teacher education courses, three major goals were addressed in this present study. Those goals were: 1) to model the effective uses of technology for teaching and learning, 2) to develop the appropriate technology skills of the pre- and in-service teachers, and 3) to utilize technology tools to support their learning experiences. The study investigated the following research questions: 1) How does students' access of technology during the course differ in the experimental and control groups? 2) How does students' utilization of technology tools to conduct educational research and class assignments differ in the experimental and control groups? 3) How do the technology self-efficacy beliefs and attitude toward technology of students differ in the experimental and control groups? 4) How does students' expectancy of utilizing technology in future teaching differ in the experimental and control groups?

In the spring semester of academic year 2000, approximately 80 graduate students enrolled in the Child Development and Telecommunications in Education courses participated in this study. The two courses established a cross discipline partnership creating a mentor/mentee relationship. The participants in the Child Development course were divided into two groups which consisted of experimental and control sets. The instructor of the Child Development course encouraged students in experimental group to use technology for the research assignments as well as cooperative learning presentations. Also, the students were assigned to dialogue with mentors through a collaborative listserv maintained by the instructor of the Telecommunications in Education course. Ongoing support by the mentors was provided to the mentees for their educational
research and learning practice utilizing technology tools. Participants in this collaborative mentoring activity were asked to write personal reflections related to integrating technology into their course work and personal use.

The data was collected in quantitative and qualitative formats. The quantitative data was collected through technology surveys and online interaction. The qualitative data was gathered by classroom observations, mentoring technology activities, technology journals, electronic portfolios, instructors' notes, qualitative perspective discussions, and semi-structured interviews. During the semester, the researchers collected three primary forms of data from the mentors in order to learn how mentors responded via listserv: each mentor's responses to his or her students, interviews midway and at the end of the study, and journals. All forms of data were a regular part of the Telecommunications in Education course. Additionally, the mentees in this study were requested to write a technology journal of integrating technology in their learning or teaching. There was a significant difference between two groups on e-mail access and interaction (Table 1). While the students in experimental group used technology as a research or collaborative tool for their learning, those in control group shown limited uses to ask questions or excuses to the instructor.

Table 1. Analysis of e-mail interaction between two groups

This research study revealed progress made in the integration of technology in teacher education courses at this institution. This collaborative tele-mentoring activity offered students opportunities to expand use of email in meaningful ways, to explore World Wide Web resources relevant to course topics, and to apply multimedia skills in the creation of electronic presentations and portfolios. The students in the experimental group expressed positive attitudes toward technology and competency for utilization of technology in classroom teaching. For example one student remarked:

*When I began your class, I felt a little overwhelmed. I completed my undergraduate degree 10 years ago. I am glad you introduced me to technology. Whether I continue to further my education in education, I will need to be familiar with technology. So when my nephews need to work on the computer using the Internet, e-mail, Words, etc., I can assist them.*

As the result of this study, the participants in the Child Development course increased their proficiency level of technology, web-based research abilities, and analyzing online research materials. On the other hand, the participants in the Telecommunications in Education course linked their skills and knowledge to practical situation and had an opportunity to examine in detail the technology implementation process in the teacher education program.

Abstract: As part of an on-going European project whose aim is to establish a Center for Distance Education Development, the University of Maribor developed a survey on use of information technology in teaching and learning at our University. In this paper we described the context and development of the questionnaires as well as the process of conducting the survey. Our goals and purposes of collecting the data included: (a) evaluating the current nature of experiences related to ICT shared by members of staff and students of the University of Maribor, (b) assessing the needs of the University staff in implementing new media in their professional practices (such as developing teaching material in electronic form and establishing new forms of collaboration and dissemination within the University and beyond), (c) giving foundations for developing new skills of teaching and learning in the information society.

Introduction and background

In order to improve the quality of technology in teacher education it is first necessary that we determine the current state of technology integration within the institution. In our case we chose to examine the use of technology by our entire faculty as well as the student body rather than just looking at those in our teacher education programs. The idea was not to investigate on the technology (software and hardware) but to focus on applications, while also trying to assess some subjective impressions, opinions and prevailing factors influencing the openness and acceptance of ICT in university teaching and learning.

Two questionnaires - for teaching staff and students - have been carefully compiled by an international project group and presented to 600 members of staff and close to 16,000 regular and part time undergraduate students, both in paper and electronic form. To keep the effort requested from participants low, special care in preparation has been devoted to the number of questions, their structure and compact, yet clear, formulation.

The survey described was proposed as one of the final activities in the scope of the European Tempus DETECH project, whose goal was to establish and develop the Department for Technology Supported Distance Education within the Centre for Distance Education Development at the University of Maribor (CDED at UM). The Department should offer consulting and technological services in the area of open and distance learning for pedagogical staff of the faculties (9 of them and one University college compose UM).

Survey Overview

Main goals and purposes of collecting the data are listed in the Abstract and will not be repeated here.

Target group The survey has been performed both on teaching staff and students. As teaching staff all employees of the University of Maribor, full and part time, who are taking part in the educational process are considered. This includes professors (full, associate and assistant), teaching assistants (with PhD, MSc or BSc) and technical staff (laboratory workers and demonstrators involved in some parts of the educational process and having some kind of responsibility regarding students). Their total number was 600.
With *students* all students, full and part time, with some experience in university education are described. Because the survey has been performed in the beginning of the school year students of the first year (freshmen) were not included in the survey, leaving us with 15,657 students.

**Structure of the questionnaires** Based on ideas of the team members, material from other surveys and a brainstorming session a large number of possible questions was accumulated first. These were then arranged into groups to build the basic structure of the questionnaire. Six main groups, listed in Table 1, were formed. A set of questions in each group was then carefully studied, discussed and refined. The main goal was to minimise the number of questions and to make them as simple, uniform and clear as possible while still retaining large amount of information in the possible answers.

**Survey conduction** Both paper and electronic form were used in order not to bias the results in favour of the population with better access to Internet. We delivered one copy of the paper form to each staff member through the administration of each faculty. Also each student received a paper form at the time of his/her inscription in the beginning of the school year. Reference to the electronic form was clearly indicated on all paper questionnaires so everyone was offered both options to participate; members of staff were additionally informed by two e-mail notifications. Of course, the approval from the University management had to be obtained prior distributing the questionnaires.

In the scope of the survey we announced a prize drawing to: (a) stimulate the response and (b) provide a means for participant identification, which should allow us to neglect possible multiple entries.

Collection of paper forms was again organised through the faculty administrations and student offices, although it was also possible to send the form directly to the Centre for Distance Education Development.

**Conclusion**

We believe that the described survey is a good proposal for investigating the overall climate regarding the computers and Internet as the educational media among all participants in the process of university education. We were searching for measurable proofs of a shift toward information society in an environment of a traditional University. We were also hoping to relate current and desired ICT skills to the overall openness and level of adaptability to new educational paradigms and/or technologies. Complete results, which will be ready soon, should also allow us to draw some comparisons between teachers and students.
How Telecommunication Technologies and Moderating Strategies in Online Instruction May Benefit Teacher Education

Abstract: The purpose of this presentation is to share how two educators use varied moderating strategies in managing online asynchronous computer conferences to facilitate learning of in-service and pre-service teachers. Although the strategies were used slightly differently, commonalities of experience were found dealing with issues of levels of participation, intervention, learner autonomy and the effect of learner-to-learner interaction. The advantages of using moderating strategies both for the teacher and the student are discussed.

Introduction

Online instruction is a current trend in higher education and is greatly influencing the practices of both institutions and educators. At present an increasing number of faculty members in teacher education are implementing telecommunication technologies such as listserv and asynchronous computer conferencing both in courses delivered at a distance and as enhancements to hybrid courses. Course management systems such as WebCT and BlackBoard are being used for instruction in the hopes that an online learning environment enhances learning. The purpose of this paper is to share how educators may use these varied telecommunication technologies and useful strategies to structure and moderate computer conferencing to reach this goal.

The authors are two university professors who use moderating strategies in their instruction both online, and as online enhancements to face-to-face courses in their instruction of pre-service and in-service teachers. One instructor taught online courses to in-service teachers who did not meet the instructor every week while the other instructor taught pre-service teachers in a classroom setting, using computer conferencing for issues of technology in education as enhancement to classroom discussion.

Subjects

During two semesters, instructor A studied a course that was an undergraduate requirement in the teacher education department of a small Northeastern College. The course dealt with the integration of technology into curriculum and was the only technology requirement in the teacher education program. The students were comprised of pre-service secondary Math, Spanish, History and English teachers. Student computer experience varied widely. Some had grown up with computers and had a great deal of experience in working with technology while others had minimal experience and only had vague ideas of the meaning of terms including: hardware, software and networking and telecommunication. Both semesters the class consisted of 20 students with a fairly even distribution of males and females.

Instructor B studied a graduate course in the Instructional Technology program of a teacher college in the Western United States. The course was offered at two campuses. The subjects were in-
service teachers who were pursuing their Master's degree at the university. Since they had taken two technology courses for their teaching credentials and were working on their MA degree in Instructional Technology, their technology skills were relatively good. Many of them offered technology training to their colleagues at their schools, and some of them played technology leadership roles, such as being technology coordinators. The class consisted of approximately 20 students at the main campus and 10 students at another campus with a fairly even distribution of males and females.

Methodology and Structure

Instructor A

The course was divided into two groups of ten based on nothing more than their place on the class roster. Ten is a reasonable number since, if messaging is mandated, reading and responding to a large number of messages can become unwieldy while in much smaller groups the students may feel pressure to constantly perform and there might not be enough stimulus to maintain engaging discussions (Cifuentes, Murphy, Segur, & Kodali, 1997).

The entire class was instructed in how to moderate a computer conference through lecture and a non-theoretical written moderator training written by the instructor. The class was directed to subscribe to the ‘Educause’ listserv that deals with topics related to technology in education. This was done to expose the students to a diversity of issues and to offer a continuing stream of potential topics that could be used as source material. The BlackBoard course management system was used for asynchronous discussion. Within the two groups, one student per week was assigned to moderate a one-week conference. On Saturday two students, one per group, emailed the instructor a ‘welcome message’ including a topic, a number of propositions and a minimum of four open-ended questions. It was always important in a ‘welcome message’ to create a friendly and personal tone (Mason, 1991). The instructor would either make suggestions on improving it and having it resubmitted to him, or inform the student that the message was fine and should be posted to a special forum on BlackBoard by Sunday night. Hacker and Wignall (1997) found that in the participation in conferences lessened over time if students had little computer experience. Therefore everyone who was not a moderator for the week was required to post a minimum of three messages per week. The first must be a response to the ‘welcome message’ and must be posted by Tuesday night, the second should be a response to a non-moderator written message and should be posted by Thursday night. The third message, which would be posted by Sunday night, could be in response to anything previously posted. The moderator then wrote a summary, making liberal use of participant quotations, and posted it by Monday. It was suggested after the first semester that the moderator read the first and last message to the class since half the class was not party to the discussion and that was done during the second semester. Eastmond and Ziegahn (1995) proposed, along with mandating a certain number of messages per week, that there be standards established for the quality and relevance of the message. They suggested that participation accounted for 30% of the course grade agreeing with Cifuentes et al. (1997) who proposed that quality and quantity of messages should be able to raise or lower assessment by a full letter grade. In one semester online participation of Instructor A accounted for 30% of assessment, and the second semester an additional 10% was assessed for individual moderating.

The instructor made a choice not to participate in the conference. If the conference was going off-track or needed intervention, personal email was written to the moderator who was responsible for taking remedial action.

Instructor B

The course of Instructor B was a hybrid course in which the instructor met her students four times throughout the quarter—twice at the beginning, in the middle, and at the end. She valued active learning and meaningful learning (Grabe & Grabe, 2001; Brown, 1992; Knapp & Glenn, 1996; Means et al., 1993). Agreeing with Palloff and Pratt (1999), she designed her courses in a way that her students had to interact with other students to enhance learning. In a manner similar to Oliver (2000) and Santema and Genang (2000), she invited students to construct course materials together with her. All assignment submissions and discussions were conducted online via WebCT. She constructed a variety of forums (discussion boards) for students to communicate with each other and to share resources. Examples included forums for conducting discussions, making announcements, asking questions and receiving help concerning technical issues, submitting assignments, and providing feedback and critiques to their classmates.
During the first meeting, the entire class was instructed in what moderating was and in examples of moderating an online community. The students took turns to moderate their online community for a week, and chose the week when they would moderate. For the class with 20 students, they selected a partner who they would like to moderate with during the week. They needed to post discussion topics, host online discussions, answer questions posted by their classmates. They could also conduct any activities they created to enrich the online community, such as "happy hour" on Friday evening in chat rooms. The students were encouraged to explore new ways of moderating. It was understood that the instructor would not interrupt to answer questions unless it was necessary and that the moderators would receive credits based on how well they moderated the community. For example, if a question or a problem on a discussion board remained unanswered or not acted upon, the moderators of the week would be marked down. Moderators did not have to answer all questions or solve all problems but they needed to facilitate discussions about the issues within the community.

All students are required to participate in online communication by visiting the community on a daily basis and posting at least two messages with substance every week. Participating and moderating weighted 15% of the course grade.

Findings

Both instructors found that the level of discourse in the conference of all groups was quite high. Students who rarely speak up in class wrote eloquently and at length when engaging in online discussion. One student in the graduate course said, "I'm often quiet in class. I think I'm influenced by my family; I'm the youngest one in my family. However, I noticed that I was very eloquent online and felt very comfortable of expressing myself online."

It was virtually unanimous that students enjoyed the experience and would attempt to use it in future classes as long as the schools, in which they would work, had the required equipment. They also mentioned that they would recommend instructors who teach hybrid or online courses use moderating to enrich their online community.

Participation

Both instructors thought that the level of participation required was considered appropriate by a great majority of the students and that participation credits provided good incentive for students to engage in online communication. Nearly all students met the participation requirements and a good number of them posted many more messages than the minimum. Both instructors agreed that online participation was crucial for online community and recommended that participation credits be part of course grade.

Autonomy and Ownership

The majority of students felt a sense of ownership of their discussions both because they had control over how the discussion progressed and also because the instructors' decision not to participate. Instructors' involvement might have restrained discourse due to the intrusion of a figure of authority. Here are a few comments from the classes:

I did enjoy moderating and controlling my discussion. I felt it allowed me to really think about each response...It was also interesting to see if I could spark some thought within the group, since that will be a main focus of being a teacher: "sparking thought."

Having only students participate allowed the discussion to stay on a more familiar level with everyone. If teachers enter the discussion, it might be more advanced for some, and in return the students might be hesitant to ask certain questions, or they may be more self-conscious of what they say. I think that students learn very valuable information from discussion amongst each other.

I've taken your online courses before and enjoyed this course much better because of the moderating. When I was the moderator, I tried to be creative and felt a sense of ownership. When I was a participant, I also observed how my classmates moderated and many of them had cool
ideas. I learned a lot from them. I felt that the moderating allowed me to see personalities and creativity of my classmates.

Interaction and Cohesiveness

Most messages contained support for the current moderator and a great deal of positive reinforcement. Phrases like: "Interesting topic," "Keep up the great work," "Great Post!" "Good comments, You sum it up quite well!" and "Keep up the good work" were to be found in just about every message. The amount of politeness, words of agreement and general good manners tended to increase participation and create an atmosphere of warmth and cordiality. Of the undergraduate course, group members reported that they felt closer to other members of their group than they did to the half of the class they did not engage in computer conferencing. Of the graduate course, the students also expressed that they knew their classmates in the hybrid course better than their classmates in a traditional class. A student said, "In a traditional course, I only got to know people who sat close to me. In our online [hybrid] course, I talked to everyone and got to know everyone although I might not recognize his/her face. I felt much closer to my classmates." Several students of the graduate course expressed their sadness during the end of the quarter. A student said, "I feel sad that the class is over now. I really enjoy our online communication and hope to continue."

Advantages of Using Moderating Strategies

The advantages for students of learning and practicing moderating strategies included a sense of ownership of the discussion and a sense of freedom to direct discussions into areas that they believe might not be allowed in a traditional course setting. In addition, they learned how to form a community that could contain many resources and reveal a way of learning. A student of the graduate course said,

There were so many resources in our discussion forums. I downloaded the messages and can use them later. This seems to be an effective way of learning. See! I can't keep taking classes in the university, but I may keep learning by forming such a community. Actually this should be how we learn once we are in the field.

This practice in class management should prove valuable in their later careers.

For instructors a major benefit is that putting the onus of moderation to the students saves a considerable amount of time while instilling skills of critical thinking in students. Although it is true that all conferences must be attended to quite closely, not writing responses, outside of occasional email to provide direction, frees up time for other activities. In addition, putting the moderation to the students may stimulate students to conduct active and meaningful learning.

Conclusion

The two university professors used telecommunication technologies and moderating strategies in their online instructions. Although they used the strategies slightly differently, they found commonalities of experience dealing with issues of levels of participation, intervention, learner autonomy and the effect of learner-to-learner interaction. Both instructors thought that the moderating enhanced students' learning and benefited teacher education. They invite educators to use the technologies and strategies and to explore their potentials in education.

Abstract: MERLOT (Multimedia Educational Resource for Learning and Online Teaching) is a database of high quality online resources that can be used to improve learning and teaching within higher education. The resources in MERLOT include (a) links to thousands of learning materials, (b) sample assignments that show how the materials could be used in the classroom, (c) evaluations of the learning materials by other individual users and panels of faculty, and (d) links to people with common interests in a discipline and in teaching and learning. This paper describes the peer review process used for materials submitted to the Teacher Education Discipline section of MERLOT at http://merlot.org and the process for becoming an external reviewer.

Introduction

Many teacher education faculty members are reluctant to develop web-based instructional materials for use in their classes. Others have difficulty finding quality resources to use in their online courses. To encourage the effort that is required to develop these resources, MERLOT (Multimedia Educational Resources for Learning and Online Teaching) offers a peer review process that is comparable to the peer review process for journal articles. The purpose of MERLOT is to identify high-quality web-based materials that are appropriate for use in teacher education. While there are many databases for K-12 materials, MERLOT's Teacher Education discipline group at http://teachered.merlot.org focuses on sites that are used by other teacher educators and/or have been prepared by teacher educators.

MERLOT's Peer Review Process

Professionals within the field evaluate sites that have been submitted to MERLOT, a database of instructional materials available on the web for student learning and online teaching. The peer review process for evaluating teaching-learning materials follows the model of peer review of scholarship. Each review is conducted by a minimum of two reviewers and results are linked to information about online learning materials that are submitted to MERLOT at http://merlot.org. The review process is quite rigorous in order to provide the best information to potential users. Three major areas are evaluated: (1) Quality of
Content; (2) Potential Effectiveness as a Teaching-Learning Tool; and (3) Ease of Use. As a result of the peer review process, many institutions are now considering websites that have been evaluated by the MERLOT Peer Review Panels as comparable to peer reviewed journal articles.

Evaluation of these three areas (quality of content, potential effectiveness for teaching and learning, and ease of use) guides comprehensive assessment and peer review of the site. The review process yields high-quality peer reviews that support faculty members in validating the importance of online learning materials they develop for their students to use. For reviewers, engagement in the peer review process provides an excellent means of examining sites in their own instructional areas that they might use in their own classes. For all of us in teacher education, the review process provides a means of acknowledging and highlighting worthwhile sites. Finally, as the MERLOT database grows and more sites are reviewed, we will all be able to save time when looking for ways to incorporate web-based teaching and learning activities into our university classes.

**Quality of Content**

Reviewers with content expertise and experience with online teaching evaluate the quality of the content based on specific criteria. For example, the material must present correct concepts, models, and/or skills within the area of teacher education addressed. In addition, the concepts, models, and/or skills must be considered significant. This means that the content addresses core curriculum areas or areas identified as important by professional organizations. For example, if a site presents material about learning theories, we would expect to find up-to-date information about current theories of learning, such as constructivism. Additional areas examined in the area of quality of content include whether the material is considered difficult to learn and whether the material is essential for building more complex concepts, models, or skills.

**Potential Effectiveness as a Teaching/Learning Tool**

Another area that is evaluated is the potential effectiveness of the site as a teaching-learning tool. This simply means that the site is viewed through the lens of possibility. Can the reviewer envision how the site might be used for teacher education? This question is at the core of what occurs during this part of the review. Developers of online learning materials can aid this process when they include their learning objectives, characteristics of target learners, and how they use the materials. Reviewers also consider whether the site can be used to improve the teaching/learning experience. Another consideration is whether a site can be easily integrated into the teacher education curriculum. Several other areas that impact potential effectiveness of how the site can be used in the teaching/learning process are also considered and evaluated: potential for improving the teaching/learning process, ease of integration into a variety of courses and pedagogies, and potential for developing a variety of good learning assignments around the web-based learning material. Evaluation of this area is contingent on how authors and reviewers envision using the material under review. For example, “if this site is used with graduate students as an independent homework assignment for them to learn X, but for undergraduates it might be more appropriate to use this site during class with the goal of teaching X.”

**Ease of Use**

Ease of use deals with accessibility for the teacher educator and by teacher education students as well. The user/site interface is of major concern here. The design of the site needs to be consistent and navigation through the site should not interfere with the learning process. Users should be able to travel through the software without getting lost or trapped. Appearance of the site is also important and requires consideration of font types (are they readable?) and background/foreground contrast, among other things. Also considered is the balance between how difficult the site is to use compared to its instructional value. In other words, if the site requires that users spend time learning how to use it, then the learning experience
must have high value relative to the time involved. For example, if a site is a simulation about classroom management, does the time needed or the difficulty of using the simulation negate the value of what students learn about classroom management? Other considerations include whether special plug-ins are needed to access the site and whether using the site requires a lot of documentation, technical support, and/or instruction for students to be successful.

Expanding the Peer Review Process

The Teacher Education Editorial Board for MERLOT want to make MERLOT’s criteria for evaluation of online learning and teaching materials public to those who develop or contribute learning materials to the MERLOT database. We are also interested in expanding the pool of peer reviewers. Ultimately, we hope that peer review of online resources for teacher education will be a shared venture among those of us with interest and expertise in web-based learning and teaching.

In order to increase the number of online learning materials that are peer reviewed and to ensure adequate coverage of all the areas within the field of teacher education, members of the Editorial Review Board may invite an external reviewer to participate in the review process. External reviewers are qualified faculty from institutions of higher education who (a) are selected by the editorial board and approved by the Co-Editors, (b) come from any institution of higher education (they do not need to be MERLOT sponsors), and (c) will be partnered with and mentored by editorial board members for their first reviews. People interested in becoming an external reviewer can also apply by joining MERLOT and creating a MERLOT member profile, which contains a narrative summarizing their context expertise, teaching excellence, use of technology in teaching, and connections with professional organizations. Applicants should also designate the subject/discipline areas that they are qualified to review. An applicant should then email the Chief Co-Editor(s) about his/her interest in being an external reviewer. Contact information and more details about being an external reviewer can be found at http://taste.merlot.org/join/external.html.

Other Ways to Become a Part of the MERLOT Community

Other ways to contribute to the MERLOT community of teacher educators who use online learning materials include adding user comments and assignments. User comments are usually brief remarks that address the same criteria as more formal peer reviews: quality of content, potential effectiveness as a teaching-learning tool, and ease of use. User comments include both general remarks and technical remarks. Anyone who has used an item in the MERLOT database is invited to add a user comment. Authors and users of learning materials in MERLOT are also invited to submit details of assignments they have developed for particular courses or specific classes based on learning materials in the MERLOT database. Assignments include information about the course in which the site was used, the level of students in the course, relevant topics covered, student learning objectives, any needed prerequisite skills, and details about the assignment including assessment procedures and time frame required. Assignments are very useful to members of the MERLOT community because they provide guidance about how others have used a particular site in the MERLOT database. Because MERLOT is a resource for all faculty (and their students) engaged in online teaching and learning, contributions in the form of new sites, user comments, assignments, and peer reviews are welcome. MERLOT is a free and open resource, which is made viable by the community of people who contribute to and use MERLOT to enhance online teaching and learning.
A STUDY OF HOW TECHNOLOGY TEACHER USING INTERNET SEARCHING ENGINE FOR LESSON PLANS

K.H. Lo & Hung-Jen Yang, & Rong-Jui Fong & S.F. Chaw & Yi-Shian Jong
Department of Industrial Technology Education, National Kaohsiung Normal University, Kaohsiung, Taiwan, R.O.C.
fork@ms26.url.com.tw & hjyang@nknucc.nknu.edu.tw

Jui-Chen Yu
National Science & Technology Museum, Kaohsiung, Taiwan, R.O.C.,

Abstract: The purpose of this study was to identify how technology teacher using Internet searching engine for initiating and updating their lesson plan. An investigation research method was applied for this study. There were two phases in this research. In the first phase, an on line recording system for browsing path, screen images and operating video was setup for technology teachers who were experienced searching engine users. By reviewing recorded data the goals, procedures and functions of using Internet searching engine for lesson plan were drawn. In the second phase, a investigating tool was design based on the result of the first phase. Questionnaires were delivered to random sampled technology teachers for collecting data. The statistical process was followed for analyzing collected data. Conclusion of research problem was drawn from the analysis result. Based on the result of data analysis of both phases, a portal type environment of technology teacher professional searching engine for lesson plans was discussed and suggested.

When a technology teacher edits a lesson plans, he/she often needs much information for his/her lesson plan. However, when he/she wants to search his information in demand on the WWW, he/she just can find information in the shortest time by searching engine besides finding information at known professional webs or relative webs. But each searching engine provides different searching functions and information range. For this reason, it is necessary to build a portal type environment of technology teachers professional searching engine for lesson plans. Before reaching this purpose, we must know how technology teachers using internet searching engine for lesson plans. Therefore, the purpose of this study was to identify how technology teachers using Internet searching engine for initiating and updating their lesson plans.
Methodology

There were two phases in this research. In the first phase, an online recording system for browsing path, screen images and operating video was setup for technology teachers who were experienced searching engine users. In the second phase, investigating tools was designed based on the result of the first phase. Questionnaires were delivered to random sampled technology teachers for collecting data. Technology teachers were asked to mark a Likert scale from "Strongly Disagree" to "Strong Agree".

The population of this study was technology-practicing teacher in Taiwan. The total was around 300. The Random sample procedure was applied to distribute 45, 15%, questionnaires. There were 39 returned. The research instrument divided into three parts, profile information, terminology explanations, and 36 Likert-type questions. The Alpha reliability coefficient of this instrument was 0.87.

RESULTS & CONCLUSION

The profile information listed as follows:

1. Gender: male (89.2 %), female (10.8 %).
2. Using computer attitude: 88.9 % of them liked using the computer, 11.1 % of them were neutral.
3. Learning computer experience: 1-5 years (78.3 %), 6-10 years (19 %), above 15 years (2.7 %).
4. Using computer time a week: 0-30 hours (62.2 %), 31-60 hours (32.4 %), above 60 hours (5.4 %).
5. Contacting to Internet time: 1-5 years (86.5 %), 6-10 years (10.5 %), above 10 years (3 %).
6. Using Internet search-engine time: 1-5 years (94.6 %), 6-10 years (5.4 %).
7. Internet instrument accessibility: 2.7 % were hard, 18.9 % were neutral, 40.5 % were easy, 37.8 % were very easy.
8. Self-estimating operating search-engine (scale degree from 1 to 10): scale 5 (8.1 %), scale 6 (5.4 %), scale 7 (24.3 %), scale 8 (37.8 %), scale 9 (16.2 %), scale 10 (8.1 %).

Based on the one-sample Test of each Likert-type question, it was concluded how technology teacher using search-engine for their lesson plan. They used Internet search-engine in following ways:

- Synonym search; Key-word search; Semantic search; Subjects browsing; Initiating new lesson plan; Editing lesson plan; Contract filtering data; Verifying data; Parallel filtering data; Comparing data.

There existed no difference between gender among different search-engine operations. The attitude toward computer would be a factor influencing using search-engine in verifying data manner.

The person with higher level of positive attitude was with higher intention to verify data from search-engine.

The instrument accessibility factor made no difference among types of search-engine usages.

The ability of operating search-engine also made no difference among types of search-engine usages.

According to these findings, an environment of technology teacher professional search-engine for lesson plans could be designed to reduce technology teachers searching information time and frequency, help teachers selecting information, and editing lesson plans.
The Responsive M.Ed.: Using Technology to Reinvent the Master’s Degree
Cheryl Mason Bolick, University of North Carolina at Chapel Hill, US

The M.Ed. for Experienced Teachers was specifically designed to meet the needs of experienced classroom teachers. This cohort-based degree program offers practicing teachers a unique opportunity to engage in action research throughout their academic experience that is directly related to their classroom teaching. It is our intent that teachers enrolled in the program will not only be able to immediately apply what they are learning in their graduate coursework into their classroom, but that the program will also help combat the growing attrition rate of our state’s teachers.

To most effectively address the expressed needs of classroom teachers, alternative modes of instruction are used throughout the graduate program. Combining face-to-face instruction with Internet-based instruction allows practicing teachers to maximize their participating in the program. Teachers engage in intensive face-to-face instruction during the summer. Courses offered during the fall and spring semesters employ alternative delivery methods. That is, a percentage of the courses are delivered through web-based instruction, and a percentage is delivered through off-campus face-to-face instruction.

The goal underlying this effort is innovation rather than efficiency. “Technology’s true potential is realized when it is employed in innovative ways which do not necessarily correspond to traditional classroom practices” (Pinheiro, 1998, p. 118). Distance education strategies are typically aimed at reaching as many students as possible to increase revenue (Garrison, 1993). The M.Ed. for Experienced Teachers, however, seeks to use distance learning strategies to maximize and enrich the students’ academic experience and allow the teachers flexibility of pursuing a graduate degree while continuing to teach in the classroom. The potential of virtual communities for collaboration has been noted almost from the beginnings of the Internet. “The technology that makes virtual communities possible has the potential to bring enormous leverage .... But the technology will not in itself fulfill that potential; this latent technical power must be used intelligently and deliberately by an informed population” (Rheingold, 1993).

Teacher education programs have been mandated to prepare and support teachers who are well-versed in technology and able to collaborate within buildings and with other K-12 schools to share resources and strategies (Merryfield, 1999; NCATE, 1997; USDOE, 2001). Consequently an additional goal of this graduate program has been to model effective pedagogical strategies for teachers, who may then serve as change agents when they employ similar collaborative methodologies in K-12 schools.

Modeling collaborative education methods for K-12 teachers increases the likelihood that they will employ similar methods in their own classes. Recent data suggests that professionally engaged teachers differ significantly from classroom teachers who are isolated in their classrooms. (Riel & Becker, 2000). By using collaborative education tools, we are taking a step towards restructuring teacher education and preparing teachers to form “collaborative community activity” (Riel, 2000) of their own within and among classrooms, schools, and districts. Thus, our M.Ed. for Experienced Teachers’ graduates are better prepared to act as change agents (Rogers, 1995).

This short paper will present initial data analysis from the first year of the program.

Assessing Distributed Learning: Student Perceptions and Future Directions

Barbara K. McKenzie, Department of Media & Instructional Technology, State University of West Georgia, United States, bmckenzi@westga.edu

Elizabeth Bennett, Department of Media & Instructional Technology, State University of West Georgia, United States, ebennett@westga.edu

Nancy G. Mims, Department of Educational Leadership and Professional Studies, University of West Georgia, United States, nmims@westga.edu

Abstract:
This study assessed distance students' perceptions of distributed learning, the advantage and disadvantages; the impact it had on their learning. Graduate students were surveyed fall 2000 through summer 2001 (N=242). Using UPSS, frequencies and percentages were calculated to determine the rank order findings for the advantages and disadvantages of web-based courses. Means were calculated for the Likert scale items, student attitudes toward web-based instruction, Chi-square tests were also run to determine if any relationships existed between selected student characteristics such as gender, technology background, degree program, and online experience and attitudes toward web-based courses. Major advantages of web-based courses included decreased travel requirements, ability to communicate electronically with the instructor and class, easy accessibility of course materials, and flexibility in completing the course. The greatest obstacles reported by students were the frustration that resulted when they were unable to get online and having technical equipment problems.

Introduction
Advances in distributed learning have provided students with a wide variety of teaching/learning alternatives that have expanded the educational process beyond the traditional classroom. In addition to the face-to-face mode of instruction students now receive instruction through teleconferencing, online and/or web-based instruction, e-learning, and other advancements currently taking place with telecommunications technologies. The advancements have been rapid and will continue to expand and impact our educational process (Hooper, 2001; Kearsley, 2000; Schreiber & Berge, 1998; Trent, 2001).

The effectiveness of distributed learning and students' receptivity to the new delivery modes must be more closely examined to ensure effective learning is in fact taking place and students do favorably receive the various types of distributed learning (Berge, 1998; Berge, 2001; McKenzie & Mims et.al, 2000; Palloff & Pratt (2001). To gain a more in-depth understanding of how distributed learning impacts students, a yearlong study was conducted at a medium university in the southeastern United States. The investigators' goals were to understand students' perceptions of the advantages and disadvantages of web-based instruction; the impact that web-based courses that on students and future directions for web-based courses.

The Study
In order to study student perceptions of web-based instruction, students enrolled in web-based courses in media and instructional technology, educational leadership, and curriculum and instruction between fall 2000 and summer 2001 were surveyed (N=262). All classes used on-line instruction and were delivered by experienced distance instructors. The vast majority of the courses used on-line instruction more than 50% of the time.

Using the research findings and a review of the literature, the survey was constructed. Closed and open-ended questions were used to generate the study's data on advantages and disadvantages of web-based courses, types of skills web-based instruction develops in its participants, to determine whether or not different learning styles are accommodated, and to evaluate changes that may be needed to enhance web-based courses. The study was
pilot tested by eight members of the target popular and distance experts. Revisions were made before the final version of the survey was distributed.

Twelve instructors distributed the surveys to students near the end of the semester through electronic or paper survey. If a student had completed the survey previously they were instructed not to complete the survey again. Respondents were asked to reflect on their experiences in a web based on-line class and respond to the questionnaire honestly and return it to their instructor as soon as possible. They were informed the data would be kept confidential and used to make more informed decisions on the use of on-line instruction in the future. Most of the students agreed to participate in the study.

The returned surveys were entered into SPSS. Frequencies and percentages were calculated and rankings determined for each web-based course advantage and disadvantage. Means were calculated for the Likert scale items in part two of the survey. Chi-square analyses using gender, degree program, technology background, and prior experience in web-based courses as independent variables and identified advantages and disadvantages to web-based courses as dependent variables were also calculated.

Findings

A total of 262 students completed the survey. The gender demographic was 77% female, 23% male. A majority of the participants were enrolled in graduate degree programs: 68% were pursuing a Masters degree, 23% were working toward an Educational Specialist degree, and 7% were studying for a doctoral degree. One percent of the respondents were undergraduates, and the remaining 1% were not working toward a degree. Most of those replying were majoring in Media and Instructional Technology (44%) or Educational Leadership (28%). Other majors represented included Special Education (5%), Elementary and Early Childhood (4%), Middle Grades (3%), Counseling (3%), Physical Education (2%), Art Education (1%), and Business Education (1%). Other majors (9%) had less than 1% representation in each field of study.

Most students enrolled in the web-based courses were moderate to heavy users of technology. Twenty-seven percent indicated they used technology between 7-12 hours per week, 23% reported technology use of 13-18 hours per week, 21% utilized technology over 24 hours per week, 15% said their weekly use of technology averaged 19-24 hours, and only 14% used technology less than 6 hours per week. However, most students were relatively new to web-based instruction. The majority (61%) were taking their first or second web-based course when they responded to the study, although 24% were enrolled in their third or fourth course, 11% were in their fifth or sixth, and 4% had taken seven or more web-based courses. Most students (71%) reported that the current course they were enrolled in was 51-70% web-based, 24% of the respondents indicated that the web-based component of their course was 50% or less, and the remaining five percent of the students noted their course was 71-100% web-based.

Respondents were asked to identify which of a list of 11 attributes they perceived as advantages of web-based instruction. The majority of students (between 60 and 94%) categorized seven of the listed characteristics as advantages. A decreased travel requirement to campus was identified by more students (94%) as being an advantage of web-based education than any other attribute. Other attributes clearly identified as advantages of web-based classes included the ability to communicate electronically with the instructor (84%), easy access to course materials (82%), and flexibility in completing course assignments (81%). Some students indicated that timely feedback from the instructor on assignments (65%), the opportunity to enhance personal computing skills (64%), and the opportunity to use web resources (60%) were advantages of web-based courses. Fewer respondents indicated that ease of expression (45%), support of varied learning styles (41%), collaborative opportunities for students (38%) or teachers (38%), and opportunity to interact with a wide range of students (37%) were web-based course advantages. Table 1 lists the attributes that students responded to, and ranks them in order according to the percentage of respondents identifying them as web-based course advantages.

More collaborative opportunities are available for student work 38%
More collaborative opportunities are available for instruction 38%
Opportunity to interact with a wider range of students 37%

Table 1: Perceived advantages for web-based courses

Participants were also asked to identify web-based instruction disadvantages. Seven attributes were listed, but none were classified as a disadvantage by a majority of the respondents. Difficulty in securing online/computer access was identified as a disadvantage most frequently (49% of the respondents), followed by technical problems (42%) and students' inability to communicate effectively online (41%). Some noted that lack of student computer skills was a disadvantage (37%), as was lack of face-to-face interaction with teachers and classmates (36%). A few thought web-based courses did not address diverse learning styles (19%) and only 9% perceived lack of feedback to be a disadvantage. Table 2 lists the attributes that students responded to, and ranks them in order according to the percentage of respondents identifying them as web-based course disadvantages.

</tr>
</tbody>
</table>

Table 2: Perceived disadvantages for web-based courses

Respondents were also asked whether they agreed or disagreed with a variety of statements regarding the value and future use of web-based courses. A seven-point Likert scale (1=Strongly Disagree and 7=Strongly Agree) was used. Students strongly supported the expansion of web-based (u = 5.84) and the use of the World Wide Web (u = 5.55). They were also agreed that the course they were enrolled in had been enhanced through the use of web-based instruction (u = 5.49), and that participating in a web-based course had improved their general computing skills (u = 5.31) as well as their electronic communication and Internet skills (u = 5.29). Students were relatively neutral about team teaching in web-based courses (u = 4.40) and about the ability of web-based courses to address different learning styles. Table 3 identifies the Likert scale items, ranked according to positive mean response.

Table 3: Attitudes toward value and future of web-based courses

Chi-square analyses were performed to determine if any significant relationship existed between the demographic characteristics (gender, year of study, major field of study, amount of weekly technology use, prior experience with web-based courses, or percentage of current course that was web-based) and attitudes toward the value and future of web-based courses. For this analysis, Likert responses ranging from 1-3 were recoded to represent the disagree category, a response of 4 was recoded to represent the neutral category, and responses from 5-7 were recoded to represent the agree category. Only one significant relationship was found and that was the attitudes of men and women toward the efficacy of web-based courses in addressing different learning styles. The
majority of women were neutral or disagreed that web-based courses were more effective in dealing with different learning styles, whereas the majority of men believed that web-based courses were more effective in addressing diverse learning styles. Table 4 summarizes these findings.

\[ X^2=8.498, \text{df}=2, \ p=.014 \]

Table 4: Gender differences in attitudes about web-based courses and learning styles

The results showed students perceived a variety of advantages to web-based courses, and few, if any, real disadvantages. Most students believed that the number of web-based courses should be increased, and that web-based courses improved their technology skills. The main concern identified by students was whether web-based instruction could address a variety of learning styles.

Conclusions and Recommendations

Based on this study, the researchers found that while most students were familiar with technology, web-based learning produced some anxieties. The ability to work from home, and having instructors and classmates virtually on a 24/7 basis appeared to be the biggest advantages for this instructional format. Instructors who are aware of the perceived personal contact and who enhanced courses with digital pictures and small group projects are perceived by students as more accessible. Recommendations for future studies include addressing student gender issues and learning styles and how instructors go about addressing these needs.

Abstract:
The purpose of this study was to explore how instructors using distance education/online teaching and learning technologies (DE/OL) are using these technologies in their classes: their practices, problems, solutions, and any emergent patterns. Faculty were surveyed to determine what technologies they use and how they use them to support teaching and learning. Participants responded to questions dealing with a variety of issues such as incentives for teaching using DE/OL, time allocated to DE/OL teaching, preferred class size, formal training received, perceived return on investment. The survey data were content analyzed and entered into SPSS and analyzed.

Introduction

Telecommunications advancements in the past decade, the increasing importance of information technology in our lives, and the emphasis on lifelong learning today have been major factors encouraging faculty to change their traditional methods of teaching and jump into distributed learning to better meet the needs of distant learners (Berge, 2001; Kearsley, 2000). An increasing percentage of our students in higher education find themselves limited by time and/or distance constraints and need alternatives to traditional instruction to obtain professional development, certification and/or advanced degrees. Distributed education is one popular solution to this growing problem (Hooper, 2001; Phillips & Merisotis, 1999). Ely stated, “Community colleges and universities are offering more than 52,000 courses at a distance and many more are in the planning stages (2000, 26). Piccano reported, “The U.S. Department of Education indicates that in the two-year period between 1995-96 and 1997-98, the number of postsecondary institutions offering Web-based distance learning courses had tripled, far exceeding the growth of any other distance application (2001,164). Hooper (2001) concurred, “Online teaching has become an important element in the gathering momentum of the Knowledge Age” (35).

The effectiveness of distance courses is dependent on faculty members’ ability to deliver their courses using this new format (Betts, 1998; Berge, 2001; Rockwell, S.K. & Schauer, et.al. 1999). Faculty must learn to adapt their traditional face-to-face classes and put it into an electronic format. Ko and Rossen stated, “Because teaching online is relatively new, many people don’t know what it is, or how it’s done, or even what some of the terms used to describe it mean. Others may have a notion of what’s involved, but they don’t know how to get started, or they feel some trepidation about handling the issues they may encounter. Perhaps this is because the online environment is so different from anything most instructors have encountered before.” (2001, 2). Hooper cited Calhoon stating, “educators are learning how to teach on the Internet as they go along and, predictably, there are risks, mistakes, and failures” (2001, 39). Courses taught through distance technologies have a number of significant differences from the traditional face-to-face classes. Faculty need to be aware of these differences and how to modify their courses, especially their teaching strategies, to be successful in this environment.

Distance learning is ever-changing and it requires faculty members to keep up with the latest developments in pedagogy as well as enhancing their skills. (McKenzie, B.K., Mims, N., et.al; Williams, 2000). Faculty teaching courses through distance education technologies are confronted with many decisions that include the type(s) of distance technologies to utilize, the number of times students will meet in a face-to-face setting vs. through a technology-mediated “distance education” environment. Faculty are concerned about how much time to devote to interacting with students. Other questions to answer may include: Do faculty know just what to expect before jumping into teaching distance classes? What are the teaching practices of instructors who engage in distance education? How are instructors in higher education using distance education technologies? What problems are these
instructors facing and how are they solving them? To answer some of these questions, a two-year study was undertaken by faculty at the State University of West Georgia.

The Study

In order to study how instructors are using distance technologies in their classes in the state, the researchers used two existing distance education listervs (one that linked users of WebCT around the state of Georgia and the other one that linked distance education instructors at Georgia College and State University) and a series of faculty contacts on many of the campuses in the Georgia university system. These sources were used to distribute the electronic address of a web server-based survey instrument that was used as the basis for collecting participant input. Although the respondents to this on-line survey were self-selected, they represent a sub-set of those higher education instructors in Georgia who are pioneering the use of distance education/on-line learning (DE/OL) technologies. Therefore, the opinions and perceptions of this sample should provide valuable information for administrators and others interested in DE/OL efforts about the issues and problems facing DE/OL instructors.

The survey instrument used for the present study was adapted from a previous survey administered in 2000 to UWG “distance education” instructors. Findings from the 2000 survey and a review of the literature were used to construct the survey instrument used in this study. Participants were asked to respond to open- and closed-ended questions. The instrument revisions from the first year study included the following: (1) the instrument was put into an electronic format; (2) respondents were asked additional demographic questions (i.e., where do you teach, academic department, gender, number of courses presently teaching using some form of distance technology, and percent of course that uses distance technologies) and (3) respondents were asked additional questions specifically related to distance education/on-line learning (i.e. what is distance education/on-line learning? Does your technology-mediated course involve any face-to-face meetings?). For these open-ended questions boxes were provided for text entry. For closed-ended questions participants were required to select choices from a list of alternatives or to check all responses from a list that applied to their situation. The survey was pilot tested by a three distance education experts in the state and revisions were made before the instrument was used to collect the data in this report.

To examine how faculty are using DE/OL technologies for instructional purposes, the types of problems that are occurring and possible solutions that might be offered, DE/OL technology-using faculty from the State University of West Georgia and other higher education institutions in the state of Georgia who belong to one or two listervs were surveyed (their involvement was directly solicited, i.e., they were asked to complete the survey. However, we also asked them to forward the e-mail to any others whom they knew who were also using distance education and would have experience to share). All participants had taught at least one distance class during the year and voluntarily agreed to participate in the study.

After a series of discussions with distance experts in Georgia about the survey and its revisions, and another review of the literature, the research team designed an electronic survey to assess DE/OL instructor’s practices, problems, and solutions to problems. The first part of the revised survey asked participants for demographic data (i.e., where they taught, academic department, rank, gender, and prior teaching experience. The participants were also asked to define in their own words “distance education/on-line teaching.” The remainder of the survey utilized both open and closed-ended question to query participants about the: technologies they use for distance teaching, training they received, experience teaching courses in face-to-face and distance format, teaching format they prefer, optimal class size, importance of face-to-face meetings, and the assistance they need to be more effective in teaching.

E-mail messages sent to UWG faculty requesting their participation in the study were sent the end of April 2001. Two weeks later, reminder e-mail was sent. The first week in May, two distance education listervs were used to contact other DE/OL instructors in higher education in Georgia and solicit their participation in the study. Listserv members received a message explaining the nature of the study, the types of participants requested, and where to go to complete the online survey. Two weeks later, a reminder e-mail message was also sent to the members of these two listservs. A total of sixty-six participants completed the survey.

All of the participants responded by completing an on-line survey that submitted their responses to a web server/ Filemaker database. The quantitative data from the survey were analyzed using the Statistical Package for the Social Sciences (SPSS v10). The qualitative data were analyzed by examining the content of the responses and grouping the responses into categories. These categories were summarized by reporting their frequency of occurrence or by reporting selected, representative comments.
Findings

Sixty-six faculty members from 19 different higher education institutions in Georgia responded to the survey. There were an equal number of male and female respondents (n=32). Two respondents did not report their gender. Assistant professors had the highest participation (34.8%) followed by Professors (25.7%) and Associate Professors (25.7%). Most of the participants came from the Health, Nursing and Medical fields (29%), Social Science and Humanities (23%), and Education (18%). Respondents reported having from 1 to 15 years of teaching experience. The majority of the faculty who responded to the survey reported teaching six years or longer.

The participants reported receiving between zero and 20+ hours of training with DE/OL technologies prior to teaching their first DE/OL class. Most of the participants (29%) reported receiving between 1 and 5 hours of training related to DE/OL technologies prior to teaching their first DE/OL course. Twenty-three percent of the respondents reported that they had received no training before teaching their first distance education class. Twenty percent of the participants reported receiving 20 or more hours of training prior to teaching their first DE/OL course.

In order to ensure that the participants held similar views regarding the meaning of DE/OL, they were asked to offer a brief definition of the expression. Most respondents offered similar definitions for the expression, although they were worded in various ways. The major concepts associated with DE/OL as reported by the survey respondents were the following: 1) use of electronic media (video conferencing, Internet and others), 2) teachers and learners are separated by time and/or space, and 3) interactions may be synchronous and/or asynchronous.

The survey respondents reported using a variety of electronic communication tools as part of their DE/OL environments. The survey offered a list of twelve items from which participants were asked to choose all that might apply. They also were asked to elaborate on any “other” tools they used.

The following is the list of twelve electronic communications tools included in the survey: 1) WebCT (adopted by the University of Georgia system as the recommended software for use in the creation of on-line courses), 2) GSAMS (Georgia Statewide Academic and Medical System, a proprietary videoconferencing system adopted and supported by the University System of Georgia), 3) web-based course materials, 4) Internet e-mail, 5) private e-mail system, 6) bulletin boards, 7) Internet newsgroups, 8) private conferencing software, 9) Listservs, 10) web-based course calendar, 11) chat rooms, 12) other.

Respondents were asked to indicate which communications tools they used during their first DE/OL course, and to indicate which tools they used during their most recent course. Forty-one unique combinations of communications tools were reportedly used during the respondents’ first DE/OL course. Thirty-six unique combinations of communications tools were reportedly used during the respondents’ most recent DE/OL course. Although many of these combinations of tools were reported by a single respondent, a clearer picture is possible by examining those combinations that were reported by more than a single participant. Figure 1 summarizes these data.

Eighty-six percent of the survey respondents reported having taught the same course in both face-to-face and DE/OL formats. Of these, 22% reported preferring the face-to-face format, while only 10% reported preferring the DE/OL format. However, more than half, 53%, reported preferring to teach their courses using a mixture of both formats. Fifteen percent reported having no preference for one format or the other.

When asked which medium of instruction required the most time involvement, 89% of the respondents reported that DE/OL requires the most time involvement. Two percent of the respondents reported face-to-face instruction as requiring the most time involvement and 9% felt that the two media were equally time consuming.

The respondents were asked to estimate in two ways the additional amount of time they spent preparing for a DE/OL course. In terms of additional time per week, respondents reported spending approximately 5-10 hours per week.
longer preparing for a DE/OL course. In terms of additional time per course, respondents reported spending approximately 60 hours more teaching/conducting the DE/OL course. However, the variation in the responses was extreme, and very nearly as large as the average itself. The calculated average was 59.5 hours and the standard deviation was 56.5 hours. The range of responses was from 2 to over 300 hours of additional time spent per course.

Many respondents indicated that the amount of time required depended strongly on whether or not this was the first time the course was taught or whether it had been developed previously and merely re-taught. The typical response indicated that the DE/OL course did not require as much time to teach subsequently as it did the first time it was developed and taught, however no estimate of this time differential was possible from the data provided.

These two estimates of the additional time required to teach using DE/OL technologies are somewhat inconsistent, but they provide a clear indication that it takes a significant amount of additional time to design and provide instructional experiences through DE/OL media.

Having worked with DE/OL instruction for many years, this research team has witnessed and experienced the value associated with combining traditional face-to-face instruction with DE/OL. As a result of our experiences, a question was included on the survey to probe the respondents regarding their perceptions of the value of face-to-face interactions as a component of courses that utilize DE/OL technologies. Eighty-one percent of the respondents indicated that they felt that their courses benefited by incorporating a face-to-face component. Nineteen percent of the respondents reported that face-to-face interactions were not seen as a valuable aspect of their DE/OL courses.

Respondents were asked which format, DE/OL or face-to-face, produced the better return (in terms of student learning or their perceptions of the quality of the instructional experience) for their efforts in planning and teaching their courses. The results are somewhat surprising but also reveal the complexity of this issue. Slightly over one-third of the group (38%) felt that a face-to-face format produces the "most bang for the buck". What is surprising about this is that these are the "pioneers" in using an electronic format for instructional delivery. One might imagine that they would be "ardent" supporters of these new technologies and would tend to see these new media as perhaps even more effective than can be demonstrated by hard data. However, such was not the case.

The next strongest view is held by those in support of DE/OL formats. Twenty-five percent of the group felt that DE/OL formats produce the greatest return on instructor investment. Fifteen percent felt that it depends upon the students. Eight percent felt that both are equal in terms of return on the instructor investment. Three percent felt that it depends on both the course and the students. If we combine those subgroups that list students, course and course and students as conditionalists, we see that 25% of the respondents feel that the relationship between the instructional format and the results that can be expected by that format depend upon the students involved and the nature of the course itself. One interpretation of these data is simply that these instructors recognize that a relationship exists between the student characteristics, the nature of the content to be learned in the course and the optimal instructional strategy(-ies) as manifest in the nature of the instructional experience that is attainable through particular media.

When faculty were asked why they were motivated to begin teaching through distance technologies a number of factors emerged. The most frequently mentioned was distance education provided students with more hands-on technology training opportunities (n=39). Other factors identified were distance technologies enhanced the quality of their courses (i.e., more up-to-date information) (n=36), the educational needs of students at a distance were provided (n=35), students' requests for distance classes were answered (n=32), more flexible working conditions (i.e., teaching from anywhere, electronic office hours) (n=27), more opportunities to interact with students (n=20), and some faculty were required to teach through distance technologies (n=17).

When asked to respond to the optimal DE/OL class size fifty-three respondents responded to the question. Responses varied with some indicating that it depended on the nature of the medium used (GSAMS vs. WebCT). Others indicated that it depended on the nature of the course and the students and the degree of interaction that is felt to be essential between the students and the instructor. The mean of the respondents' estimates was approximately 20 (19.8) students. The range was 43 and the standard deviation in the responses was approximately 8 (7.7). Based on these data, the optimal class size for a typical DE/OL course would be approximately 12-28 students. Given the respondents' considerable experience with DE/OL instruction (collectively, the respondents had taught nearly 300 courses in a DE/OL format) and the considerable variation in their responses, this figure would seem to represent a rather robust estimate that acknowledges the multiple extenuating considerations that attend the teaching of such courses.

Faculty identified a number of concerns they had with distance programs. The most frequently reported were providing release time to faculty who teach through distance technologies and offering more faculty support for classes (i.e., instructional design support, more training opportunities). Other problems that surfaced were
administrators not being aware of the time faculty spend planning and teaching through distance technologies, the need to improve the student orientation program for distance learners, providing more support for distance instructors such as graduate students and/or instructional designers, limiting the enrollment in distance classes, provide student access to computers for distance classes, the need for more planning before the delivery of distance courses, and improving the distance equipment for faculty and students.

Conclusions and Recommendations

Distributed Learning and On-Line instruction can provide a richer instructional experience, however, there are costs associated with this gain. If these media are used to provide more interaction with students, this requires more time on the part of the instructor. Therefore, the data from this study suggest reducing class size in these courses to enable students to have greater interaction with the instructor, factoring increased instructor effort into workload and personnel policies, and increasing support for faculty engaged in this effort. If support is lacking, then organizations can expect distributed learning efforts to be less interactive and potentially less successful. Face-to-face interactions with students are highly valued. When possible, instructors should use mixed instructional models. At this time, research on the necessity of face-to-face is unclear but its value may far outweigh its inconvenience or expense. It is suggested that instructors understand this need and provide appropriate media for appropriate aspects of the instruction. Arranging for physical meetings may be awkward when students reside a considerable distance from the instructor but such meetings may be critical to the success of the instruction.

Faculty Development through Online Courses: Results from an Evaluation of the PT3 Netseminars

Babette Moeller, EDC/Center for Children and Technology, Bmoeller@edc.org
Sarah Haavind, Concord Consortium, Shaavind@concord.org
Louisa Anderson, EDC/Center for Children and Technology Llanderson@edc.org
Patrick Carrigg, EDC/Center for Children and Technology, Pcarrigg@edc.org

Abstract: In the Spring of 2001, the Concord Consortium developed and conducted 10 Netseminars that were offered to members of the PT3 community. The Netseminars were 6 week, scheduled asynchronous courses that were offered on Blackboard 5 courseware over the web. They covered a variety of topics, including online teaching and learning, supporting inquiry-based learning, using simulations, technology tools for assessment, and using technology to support spatial visualization. This paper summarizes the results from an online survey of Netseminars participants that was conducted by EDC’s Center for Children and Technology. The survey yielded information about the demographic background of Netseminar participants, teacher educators’ motivation for participating in an online course, as well as perceived effects on knowledge and skill with technology and teaching practice. Results are discussed in terms of their implications for the design and use of online courses for faculty development.

Introduction
Integrating technology into pre-service teacher education programs often requires intensive professional development for faculty, since many teacher educators have not had the opportunity to use technology in their own teaching. In providing professional development, technology itself plays an important role—both as a means to model exemplary use, and as tool to deliver instruction. Professional development that is delivered online through the Internet offers the unique advantage to be accessible across distances and independent of the time constraints of face to face meetings. Recognizing the potential of online learning for providing continued professional development to teacher educators, the Concord Consortium has begun to offer a variety of online courses, or "Netseminars" to the teacher education community. This effort has been supported, in part, by the Preparing Tomorrow’s Teachers to Teach with Technology (PT3) Program (through a subcontract with the University of Virginia in Charlottesville) and the National Science Foundation (through the Center for Innovative Learning Technologies (CILT) Consortium).

Netseminar Overview
During the spring and early summer of 2001, the Concord Consortium was able to offer a total of 10 different Netseminars to the PT3 community. The Netseminars covered a variety of topics, including online teaching and learning, supporting inquiry-based learning, using simulations, using technology tools for assessment, and using technology to support spatial visualization. They were moderated by staff from the Concord Consortium and post-doctoral fellows based at several different CILT research centers across the U.S. With one exception, the Netseminars were designed as 6 week, scheduled asynchronous online courses (one Netseminar was conducted over a 12 week period). They were offered on Blackboard 5 courseware over the web, and followed a common format. Learning was organized around a variety of assignments (e.g., readings, evaluating resources, design of curriculum activities) and discussions among participants around those assignments. Participation was free of charge. A total of 106 PT3 grantees enrolled in the online courses.

Methods
The purpose of the evaluation was to collect information that would help to inform the refinement of the NetSeminars as well as to document their impact on teacher educators. The Center for Children and Technology, in collaboration with the Concord Consortium decided to conduct an online exit survey to address the following for major questions:

- Who are the participants in the Netseminars? What is their demographic background? What experience do they have with technology?
- What motivates teacher educators to participate in a Netseminar, and how well do the Netseminars meet participants’ expectations?
- How do participants evaluate different components of the Netseminar and their online learning experience?
- What are the perceived effects of participation in a Netseminar on teacher educators’ knowledge about and skill with technology? What are the anticipated effects on their teaching practice?

The survey was made available through the world wide web. Netseminar participants were contacted upon completion of the online course and invited to participate the online survey. A total of 35 participants completed the survey, representing 33% of the teacher educators who originally enrolled in the Netseminars.

Results
1. Netseminar participants were relatively homogenous in terms of their demographic background and technology experience. Seventy-four percent of the respondents were female and 88% were white. Seventy-eight percent of the respondents were 41 years or older. All respondents (100%) indicated that they had used computer-based or other electronic technology in their teaching. More than half (57%) of the respondents reported that they had taken an online course before, and nearly half (49%) had taught an online course themselves.
2. We found that a variety of different factors played a role in teacher educators' decision to enroll in a Netseminar. Key considerations were the ability to gain access to professional development that is otherwise not available and to learn about new ideas in their content areas. Other significant factors were the opportunity to interact with and share with faculty from other colleges and universities, to learn from leaders in the field, to learn about technology, and being able to learn at their own time and pace as well as to learn more about the process of online teaching and learning.

3. Overall, participants' reactions to the Netseminars were very positive. Ninety-five percent of the respondents indicated that they would take another Netseminar. The Netseminar components that respondents found particularly useful include readings, interactions with the seminar leaders, review of technology resources, private feedback from the facilitator, and guest visitors. The components that the respondents found less useful were interactions with other participants, working in small or large groups, and getting feedback from other participants.

4. Participants indicated that they acquired a variety of technology-related knowledge and skills through the Netseminars. Three-quarters or more of the respondents reported that they learned strategies for online teaching, and developed an understanding of what it is like to learn online. Half or more of the respondents noted that their Netseminar helped them learn how to integrate technology into their teacher education courses, including teaching strategies, technology skills, what technology tools are available, and how to design technology-enhanced learning experiences. Respondents anticipated that what they learned will influence their professional practice in a number of different ways including: the design of their online courses and the use of online teaching strategies; the use of specific technology tools in teacher education and K-12 settings; the use of strategies for technology integration at their local teacher education program; the use of contacts with professionals in the field at other organizations to expand teaching and learning activities; and the articulation of professional development goals in relation to technology and the pursuit of further professional development opportunities.

Discussion
Online courses like the Netseminars can play an important role for faculty development, connecting teacher educators to professional development opportunities and resources that otherwise are not available at their organizations. Teacher educators have found them particularly valuable for preparing them for the design and facilitation of online courses as well as the integration of technology into their face-to-face courses.

The results of this survey suggest a number of ways in which the Netseminars could be refined to serve the needs of teacher educators even better. First, several of the participants noted that the workload was difficult for them to manage especially during a very busy time of the academic year (end of the semester and graduation). Offering the seminars over a longer period of time with a reduced number of hours of work required per week could help to make the learning experience more manageable for them. Offering the Netseminars during semester breaks or early during an academic semester when teacher educators have more time available may be helpful as well. Second, participants indicated that they would like to have more interactions with the other participants in their courses. A revised weekly schedule allowing more time for discussion and additional online activities that support interaction could help to facilitate more exchanges among participants. Third, only a small number of participants reported that they learned about technology use and integration in K-12 settings. Yet, learning about technology integration in teacher education can be enhanced if connections to the use of technology in K-12 education are made. Involving K-12 teachers alongside teacher educators in the Netseminars could facilitate valuable interactions along these lines. Finally, to reach the broadest number of teacher educators with the Netseminars, the diversity among participants needs to be increased. Recruitment efforts should be broad and reach out to teacher educators from traditionally underrepresented groups and those who have little or no prior experience with technology. To insure the retention of teacher educators who are hesitant to enroll in an online course, ongoing support may be necessary. One strategy could involve having small groups of teacher educators from the same program enroll together in a Netseminar to help to establish local support.
As K-12 schools continue to add initial technology purchases and upgrades to their yearly budgets, the need for professional development for teachers increases as well. With a diverse and often distant population, web-based technology courses speak to the needs of these learners. By providing web-based instruction, participants are able to log on and interact with the course material at a time that is convenient to their individual schedules.

This study looks at the use of the web as a way to provide technology instruction to alternative licensure middle and high school teachers. The course, Technology Tools for Science Teachers, offered as a graduate level course at North Carolina State University, provides web instruction in a number of technology-related areas.

The Learning to Use Technology web site was constructed during the summer and fall of 2000 with the topics for the site taken from suggestions made by the Cumberland County, North Carolina science teachers. The web pages that made up the instructional modules were structured based on research that focused on web-based instruction. Thibodeau (1997) suggested that the content of a web site should be broken down into smaller units of instruction and the screen design should be simple and uncluttered. In addition, Thibodeau contends that web-based instruction can “teach content at least as effectively as traditional instruction” and reduces a number of negative aspects associated with continued learning and the updating of teaching skills.

In the spring of 2001, the web site was the foundation for a North Carolina State 3 credit distance-learning course entitled, Technology Tools for Science Teachers. This course was structured primarily for the Cumberland County teachers, but was also open to lateral entry teachers who were working towards their teacher certification. An online syllabus was developed which contained links to all the instructional modules, which were broken down into weekly instructional units. Each unit of web-based instruction spanned a week to two-week period.

The teachers were asked to provide a computer with Internet access and demonstrate proficiency in the prerequisites that were presented to the teachers before the start of the course. These prerequisites included the ability to navigate the web, access to e-mail and the ability to send and receive e-mail messages. In addition, the instructor stressed the importance of scheduling the time necessary to devote to learning the course materials and completing the assignments.

With the exception of the four face-to-face meetings, the course was web-based in nature. A course of this type addresses both the time and place constraints that often hinder teachers’ continued professional progress (Huntley & Mather, 1999). An additional advantage to web based courses is the reinforcement of technology skills that are necessary in today’s society (Chute, Thompson, & Hancock, 1999).

In addition to the online instruction, the teachers were provided with a technology kit that included all the necessary software and hardware to complete the assignments associated with the course. The kits contained a digital still camera, a LabPro and Calculator-Based Laboratories interface, probes and sensors which were compatible with the LabPro and Calculator-Based Laboratories, and software which included...
Dreamweaver 4, Adobe Photoshop LE, and much more. Vernier Software and Technology provided the LabPro and Calculator-Based Laboratories interfaces, probes, and sensors for 16 of the technology kits.

Besides allowing the teachers to complete the assignments, the technology kits gave the teachers hands-on experience with technology tools they could use with their students during the duration of the course. Teachers were also provided with a stipend, which covered the cost of the course, but were not notified of this until the course was in its final week. This reduced the possibility that teachers would sign up for the course because of the stipend involved which would give us a more representative set of teachers who may reflect the characteristics of future participants.

Assessment

The evaluation process transverses several phases:

- Pre-Survey—self report measure on their technological expertise.
- Meyers-Briggs Type Indicator (MBTI)
- Pretest and Post-Test for each instructional unit.
- Simmons Emotional Intelligence Survey
- Post-Survey—self report measure on their technological expertise.
- Web Portfolio of their accomplishments during the semester.

The pretest was used to determine previous knowledge as it related to each unit of instruction. WebAssign was used for the pretest administration as well as for several of the assignments and post-test administration. WebAssign is a web-based program that collects, grades, and provides feedback as a means for instructors to evaluate their students' progress. WebAssign can be set to provide student feedback in varying degrees. For this course, WebAssign was configured to provide only a grade to the student after the pretest was administered to the students.

A post-test was administered after each unit of instruction was completed to determine the level of knowledge acquisition from the start of each unit until it was completed. Feedback on the post-test was more elaborate in nature in comparison to the pretest and included a key as well as the student responses. This enabled the students to compare their responses to the correct responses for each question.

Also included as an evaluative tool were two to three assignments for each instructional unit. The completed assignments were delivered to the instructor in different formats that included e-mail file attachment, uploading a file to the listserv, using WebAssign, and uploading web pages to web space with the URL provided to the instructor via e-mail. The majority of the assignments and projects built on the previous assignments and culminated in a web portfolio that incorporated the majority of the skills developed during the duration of the course.

Results

Each student reported a gain in technological expertise from the administration of the pre-survey to the administration of the post-survey, a fourteen-week period. A gain was also noted in the content knowledge pre and post-test, which were developed for each instructional unit with the exception of one area in which they were already well versed. In addition, the overall student impression of the course was quite favorable. The comments focused on the ability to work at one's own pace and not spend time and money to commute to campus to participate in the course. The following are just a few of the positive statements made by the teachers in a final evaluation:

- I enjoyed the flexibility of the course.
- The course was very adaptable to my busy schedule.
- The web page resources were very helpful and informative.

The entrance survey also contained several open-ended questions, which asked the students about expectations for the course and whether they had participated in a distance-learning course previously. Out of 11 students, only four had previously participated in a distance learning type course, but they all had similar expectations. They wanted to become proficient in the use of technology so they could share this expertise with their students.
The exit survey also contained several open-ended questions. The first asked if the teachers would take another distance learning course. The second questioned whether their expectations for this course had been met. Ten of the 11 students responded that they would take another distance learning course and that their expectations for the course had been met or exceeded.

Personality variables were also measured with the use of the Myers-Briggs Type Indicator (MBTI) and the Simmons Emotional Intelligence Survey to indicate student success in the course. There were high correlations between personality characteristics and predictors of the success in the course. In addition, the degree of direction or self-motivation correlated highly with the level of benefit a student derived from the course. Lastly, a strong negative correlation was observed between self-esteem and the timely submission of assignments.

A “distance scholarship” model for teaching and learning about technology supported assessments

Jason Ravitz
Buck Institute for Education

Abstract
The results of an innovative Netcourse are presented that sought to provide teacher educators with access to leading research-based and technology-supported tools for assessment. The course was delivered via the Web and Blackboard and featured a different assessment tool each week that teacher educators were allowed to try. The Netcourse seeks to address the preparedness of teachers to adopt assessments of complex learning using technology. With the wide variety of technology innovation taking place in schools, assessment remains one of the outstanding challenges that teachers and researchers face. At the same time, providing better and more timely feedback to teachers and learners and creating better technology-supported assessments is very effective a way to improve learning.

Overview
The work presented here was developed as part of the author’s postdoctoral research with the Center for Innovative Learning Technologies (CILT). CILT is a distributed center involving SRI International, University of California, Berkeley, Vanderbilt University, and the Concord Consortium. The center serves as a national resource for stimulating research on innovative, technology-enabled solutions to critical problems in K-14 learning. The center is designed to leverage contributions from the country’s top experts, regardless of institutional affiliation.

The Netcourse presented here leveraged expertise on the design and delivery of online courses (Concord Consortium) at the same time it provided access to leading research-based tools for assessment. Examples of technology-supported assessments that have been available for distant learners via the Internet include IMMEX (Underdahl, Palacio-Cayetano, & Stevens, 2001), Intelligent Essay Assessor (Foltz, Laham, & Landauer, 1999), Knowledge Mapper (Baker, 1998), and the Analysis Toolkit for Knowledge Forum (Lamon, Reeve, & Scardamalia, 2001). In each case, there is evidence that assessment-related information can be provided to teachers and learners in a way that supports understanding of learning outcomes.

The paper will provide pointers and a summary of each of these and how they were used in the Netcourse. In addition, numerous technologies are available that, perhaps subject to debate, are not directly based on teaching and learning research but that can still be used to support assessment (e.g., Inspiration for concept mapping, Profiler for tracking human resources, curriculum and standards mapping software, rubric-generating software, databases of reusable objects, and others).

By providing the opportunity to try various tools “safely” within a distance learning setting it was hoped that the teacher educators would then be able to re-use all or part of what they learned. This means they might re-use materials from the online course while teaching others about the tools (say in a university-wide training session) or they might try a version of the tools themselves with learners in their own courses, including in face-to-face sessions.

The Netcourse, hosted in Blackboard™ by the Concord Consortium, was entitled PT3411: Technology Supported Assessments (TSA). It was developed as part of a Preparing Tomorrow’s Teachers with Technology (PT3) “catalyst” grant and utilized principles of online facilitation developed by (Collison, et al, 2000) and as taught in the course Moving out of the Middle. For TSA, the goal of moving out of the middle was accomplished by highlighting external resources and expertise, as well as participants’ own analyses and use of these resources. The weekly “routine” was for each learner to first read about the research base for use of the particular assessment tool being studied. Then they would try it out and discuss the results. Sometimes they would be asked to discuss both prior to and after using the tool. This Reading, Activity, Discussion (RAD) format was intended to efficiently help learners identify their requirements and possible tools of interest. The discussion was shaped to help extract pragmatic lessons from each weekly assignment, and to begin to develop a broad and sharable (through conversation) understanding of available technologies for assessment.

Research Questions
While the course was not structured as a research project per se, the experience allows us to address a number of important research questions, such as those highlighted by Haertel & Means (2000). The problems facing educational researchers are often overwhelming (not allowing “clean” studies such as those done in other fields) and a key stumbling block is the perception, shared by teachers and others, that standardized and multiple choice tests more often than not do not meet the objectives of instruction (Ravitz, Becker & Wong, 2000). The rationale for the Netcourse is that it would accomplish two objectives: 1) developing the capacity for delivery of technology supported assessments, and 2) creating an audience of informed users in the educational community. Some key questions that are being addressed include the following:

1. What kinds of technology-supported assessments are available via the web and where are they found?
2. What pedagogical framework supports teaching and learning about web-based tools in a Netcourse?
3. To what extent is the Netcourse viable as a vehicle for dissemination of technology supported assessments more broadly?
4. To what extent can user-centered Netcourses provide viable pilot test sites for the R&D community, while supporting the needs of the individual learners involved?

5. What kind of partnerships are envisioned between content experts, instructors, designers, and providers of Netcourses? What about between course developers and other users?

6. What web-accessible tools are ideal for side-by-side comparison of assessment techniques, e.g., examples that can be used in a classroom such as constrained vs. open-ended concept mapping techniques.

Why Assessment?
Assessment is an important aspect of any educational innovation or reform. Often when another complex innovation is introduced assessment is used to help guide the teaching and learning process, shaping student self-monitoring and opportunities for learning. In fact, providing formative feedback to the learner may alone have a greater impact on learning outcomes than any other aspect of instruction. “Strengthening the practice(s) of formative assessment produce significant and often substantial learning gains ... effect sizes are larger than most of those found for educational interventions” (Black & Wiliam, 1998, pp. 140-141). Formative assessment, where feedback is given to learners in time to make a difference, can help learning for all students. Black and Wiliam write that such assessments can help low performers most, while still benefiting all students: “Improved formative assessment helps low achievers more than other students ... while raising achievement overall” (p. 141). There may also be a “pedagogical divide” so that teachers of high achieving students are more likely to offer opportunities for innovative technology assessments, while prescriptions for routine assessments are offered to those who are less able to pursue innovative pedagogical uses of technology. The Netcourse seeks to address the preparedness of teachers to adopt assessments of complex learning using technology.

Why technology?
As Internet connectivity becomes more and more ubiquitous in schools, teams of researchers and educators have been developing ways to use technology to help create improved systems for learning and assessment. This includes new activity structures and new social structures that will make instructional tasks more meaningful and learning deeper. The challenge for schools of education is to effectively model these types of uses of technologies in their own courses.

Technology can be an extremely effective tool for giving feedback during the learning process to learners and their teachers. The ability of technology to rapidly provide feedback to learners is one of its most salient features for education. Consider how quickly young people learn complex video games by being bombarded with constant feedback on their performance that proves to also be highly motivational. Examples from the educational research community include simulations, dynamic modeling tools, teachable agents, and other tools that give students and teachers tools they can use as feedback on their thinking. Some allow students to view consequences of their actions on the screen in near real-time and then provide tools for students to modify their thinking and test the results again. The assessments that are provided are valued over traditional “right vs. wrong” judgments because they facilitate analysis of student reasoning processes.

What is Distance Scholarship?
Learning is generally viewed as a process of individual enlightenment and insight. As a result, our traditional models of teaching do not help students share these insights in a meaningful way with others, i.e., in a way that would generate real value from their hard-won knowledge. Instead, we typically teach and test in order to demonstrate individual competencies, focusing on internal processes within the learner, in isolation from others. Alternatively, we do our own personal learning and then have no mechanism for sharing. At an organizational level, this means that once a problem is solved, its solution is invisible for all others.

The goal of distance scholarship is to encourage distant learners to try out ideas that seem relevant to them and to report the results back for use by others. Given the capabilities of the Internet to foster communication and to provide structures for sharing and collaboratively developing knowledge, it is simply not acceptable to continue focusing our efforts on producing individual knowledge and competencies with no apparent relationship to a broader community of investigators, be they teachers, learners or researchers. If there is frustration with the lack cumulative progress in educational research, the solution is not in the publication of better research reports and evaluations, but it lies in changing the very structure of projects to support the dissemination of new ideas within and across them. The Netcourse provides a vehicle for identifying, delivering, and spreading key ideas and tools across communities of educators, really in an unprecedented way. The proposed model of learning places ideas into a public arena, subjecting them to critical evaluation and peer-review, and seeks to put them into a form that can be used or built upon by others. This Netcourse demonstrates how emerging technologies can play a key role in this process.

The focus is on finding exemplary tools that open up new avenues for teachers and finding a way for sharing this information with teacher educators. What makes this approach called “distance scholarship” is that as a result people are trying ideas in different settings and sharing the results in a way that is useful to others. This contrasted to a more atomistic view of distance learning that does not privilege use of solutions found by others. The Netcourse provides a vehicle for social filtering (Wiley, et al, 2001) of assessments and other learning objects, but including this as the pedagogical focus of the Netcourse is an innovation, and one that builds on prior instructional use of web-based evaluation tools (Ravitz, 1995; 1997). The unique course structure also allowed experts and technical support personnel from the research centers to be notified when opportunities for intervention presented themselves.
Web-Based Tools For Teachers
SITE 2002 Short Paper Proposal

Judi Repman
Randy Carlson
Beth Downs
LTHD, Box 8131
College of Education
Georgia Southern University
Statesboro, GA 30460-8131

In addition to being a rich information resource, the web provides access to many time
saving tools for teachers. As faculty members, we've found these tools useful for our own
personal productivity and instruction. This short paper session will provide an overview
of some of the most useful tools in the following categories:

**Bookmark utilities.** Bookmark utilities make it possible to access bookmarks or favorites
from any computer connected to the internet. They also make it possible to easily rename,
annotate and organize bookmarks. An example in this area is Backflip
(http://www.backflip.com).

**Rubric generators.** As K-12 education and higher education move toward outcomes and
performance based assessment, different assessment models need to be developed.
Rubrics have become one of the most popular methods of assessment. Several sites on
the web provide downloadable rubric templates (http://landmark-
while tools such as Rubistar (http://rubistar.4teachers.org/) allow users to generate rubrics
online.

**Test generators.** Online puzzle makers have been available on the web for several years
and they are popular with teachers. Web sites such as Quia (http://www.quia.com/) allow
users to produce tests, activities and web pages online.

**Survey generators.** Surveys are a popular data collection tool with many opportunities for
use in a K-12 environment. Zoomerang (http://zoomerang.com/) allows users to create
and collect data using a simple, free online survey process. Profiler
(http://profiler.hprtec.org/) is an online collaboration tool specifically designed to help
individuals within a school assess technology skills.

**Weblogs.** Weblogs (http://www.weblogs.com/about) are can be used to promote current
awareness of any subject. Serious Instructional Technology
(http://instructionaltechnology.edithispage.com/) is an example of a weblog in the field
of instructional technology.
Example of resources in each category will be briefly demonstrated and discussed in terms of their application to teacher education and teacher education faculty personal productivity. A complete webliography of all sites presented will be provided.
The 21st Century is an age of Edutainment where students want to be entertained when obtaining knowledge. The more involved a student is in the teaching/learning process, the more knowledge he/she will obtain. Brain research, media, video games, technology and interactive computer programs provide information about how students are motivated to learn. The Dale Cone shows that the least effective way to learn is the lecture. According to Edgar Dale direct, purposeful experiences promote greater knowledge. The days of lecturing, taking notes, and rote assignment are over. New instructional methods that have emerged during the past few years include cooperative group work, hands-on activities, use of manipulatives, building/making models, videos, interactive computer software, and Internet research. These all have their place in the age of Edutainment.

The WEBQUEST is a new method of instruction that has emerged from Internet research. The blanket "just go look on the Internet" method of instruction has several weaknesses. Students who merely surf the Internet end up "chasing rabbits". The student gets so much information that he/she loses sight of the research objective. Information given is so broad that students have trouble sifting through it to decide what is useful. Determining whether the Internet source contains true or reliable information is another problem. Students tend to believe that everything on the Internet is true. Also, students have limited time in the computer lab and may not have access to technology in the home to continue this research. Another weakness is accessing appropriate sites. Although schools have filters, students can still contact some inappropriate sites.

A WebQuest is a guided research activity that addresses the weaknesses of using the Internet for research. WebQuests are constructed as inquiry-oriented activities that encourage higher-order thinking skills. Other traditional research sources can be used in conjunction with the Internet. A WebQuest activity is considered an inquiry lesson by which students obtain knowledge through investigating facts as directed by the instructor. Advantages of using a WebQuest include: 1) students are directed to web sites whose primary focus is information to be used in the WebQuest, 2) the objective of the research is in constant view, 3) the amount of information is limited, 4) information is true/reliable, and 5) a student may stop and start at will and always locate the information sites. The WebQuest “fits” into the Edutainment Age that is motivating to students. WebQuests can be on any subject/topic.

The objective of the WebQuest is the end product as determined by the instructor. An instructor can motivate student work by directing the inquiry, i.e. setting up a mystery scenario interests the students to discover answers. Using a journalistic approach, students assume the roles of investigator, reporter, editor, etc. The instructor uses a grading rubric to ascertain specific objectives have been met as students progress through the tasks.

This Tutorial Session will define a good WebQuest, show examples of WebQuest, and demonstrate how a simple WebQuest is designed. Examples from different disciplines will be shown to demonstrate the usefulness of a WebQuest in the classroom.
Facilitating Teacher Collaboration in On-line Environments

Abstract:
The research study set out to ask what part can be played by well-researched and designed on-line activities in shaping the future of, and meeting the needs of, teacher professional development. Over time the community of practice (Lave & Wenger 1991) emerged as a complex yet attractive solution and the focus of the research clarified to mapping the development and efficacy of a web-mediated community of practice in advancing implementation of an innovation. This research explores how a Web-based network can become a community and in what ways this community can support the professional needs of its individual members? The StageStruck On-line Community http://www.stagestruck.uow.edu.au is the focus of this study and its development raises a roster of important issues as the theory of communities of practice is applied to a specific case of on-line teacher professional development.

Defining the community

The StageStruck On-line Community is the result of an action research program in which in-service teachers are being offered professional development towards implementation of an innovation. The research examines the classroom practices of teachers of the performing arts and their adoption of a CD-ROM based knowledge construction tool (Hedberg, 1997) StageStruck developed by the partnership of the University of Wollongong's emLab and Australia's National Institute for the Dramatic Arts (NIDA). This paper is a bounded history of the research project to date. The full background to the selection of online community for delivery of professional development in this study is detailed in Stuckey & Hedberg (2000), Stuckey et al (2001a). Suffice it to say that through the study of the literature and available cases, the community of practice (Lave & Wenger, 1991) emerged as a nexus between best practice in professional development, innovation and pedagogical use of on-line technologies. What is unclear is whether community is really required in all of the situations that we see it applied. Would another form of connectedness better serve teacher needs, the specific context, the developer return on investment and the time available to all?

It also remains to be seen whether a 'true' community can be established for distributed classroom teachers through a wholly web-based structure. The concept of community, while widely viewed as very marketable, is falsely portrayed by the owners of many on-line architectures. The cautionary tale about community is perhaps best articulated by Grossman & Wineburg (2000, p.6) when they offer a warning about the confusion created by a proliferation of different uses of the word 'community'. This confusion is most pronounced in the ubiquitous "virtual community", where, by paying a fee or typing a password, anyone who visits a web site automatically becomes a "member" of a community.
It has become clear that not all groups meeting on-line are communities and that the term ‘virtual community’ is a misnomer. True communities are much more than just Web sites, communication tools or gatherings of people. Communities require member participation and contribution, ownership, quality support and facilitation, shared direction, goals and projects (Wellman & Gulia, 1997; Palloff & Pratt, 1999; Kim, 2000). They are an investment in time and nurturing. That old adage of ‘if you build it they will come’ certainly does not apply to community, for it is the members who create the community not the web site developers. Stuckey et al (2002) identify and propose distinctions between current Internet-based architectures that are self-declared as communities and explore the ways these architectures serve teacher education. It is known that connecting teachers is key to successful knowledge and change management. Educators are "islands of excellence" with no ferry service to connect them to each other or to groups of their peers. (Reilly 1999 pp.60) Reilly’s statement describes the problem that exists for in-service educators, where in reality, they find themselves operating in isolation once the door to the classroom closes. That 'ferry' Reilly speaks of might variously be put into service for widely distributed individuals through on-line technologies. Whether the ferry service in this case it is the simple network or a richly interpersonal community environment is what remains to be seen.

Developing the community

At present stage of development they represent a potential community. Andrews (2001 pp.1) describes these potential groups. Demographic groups normally do not constitute communities. However, they have the potential for becoming on-line communities when individuals share common interests, needs and goals, have a desire to communicate with a peer group, and can easily find each other to establish relationships. The StageStruck On-line Community is taking the demographic group of K-12 teachers of the performing and creative arts and linking them together firstly through an on-line network then through to an opportunity to build community with active facilitation and support.

The group being formed at the centre of this research did not exist before people were drawn to become members on-line. They are each member of other communities and may have ties through these to some members but no one community already exists to ties all the teacher groups (primary, secondary, drama, dance, design, creative arts, English) together. They do constitute a demographic group with the potential to become a community if ties can be effectively established.

It has taken two years in planning and web design and development and promotion to get to what Wenger (1998) describes as the second phase of community development; Coalescing. The plan for community development and the period of research is shown in Table 1. The focus of 2000 was the research, literature review and study of cases of on-line professional development and the design of the web site in response to teacher needs and concerns. During this year contacts were made and groups identified that might be integral to design of and dissemination about the community site. Finding out just who is in this demographic group has proven to be an ongoing task. In 2001 the development of the architecture became the focus. Time was spent in promoting the site and reaching out to teacher groups to elicit membership and teacher concerns about focus innovation CD-ROM technology. Establishing a critical mass of members for the network and connecting those people through the web site has taken much longer than was anticipated in this phase. In 2002 members will see the main activity, communication, collaboration and facilitation targeted specifically toward community building.

Table 1 maps the research program and the community development against the Wenger Community of Practice (CoP) stages of development. Wenger describes the typical evolution of community and the facilitator activities that promote community development at each of the stages.
The site remained largely as it was for the first six to eight months of 2001. While registrations had grown steadily, involvement had not. It has taken a very personal face-to-face and one-to-one approach to elicit the initial teacher contributions. Teachers registered on the site were each approached by email to ask their experience level with StageStruck and their interest in being a contributor. Teachers described themselves as newbie, experimenter or expert in using StageStruck. No-one identified him/herself as an expert so the experimenters became the targeted participants for this stage. The experimenters were encouraged to explore ideas for contribution to the site. Email communication, neither broadcast nor personal, was working as the way to communicate and encourage these members. So meetings and phone calls were scheduled where time and geography allowed.

It was decided to tap into some of the existing communities that teachers belong to and to attend functions and workshops at these to promote involvement on the Web site. The need for this type of active leadership or facilitation was noted in the early work of Hiltz & Turoff (1981). The requirement for personal communication from the coordinator is also borne out by the research findings of Cothrel & Williams (1999 p.23) when they studied 15 different on-line communities. They state as part of their findings that; Often community managers would place phone calls to the individuals who they wished to participate in the community. One organization created a “social weaver” role, responsible for initiating a small number of members into the group. Such roles are key to bringing (and keeping) people on-line. This personal approach and face-to-face activity seems even more critical when the community has no existing ties or relationships to rely on, as is the case here.

Most recently activities and events have been structured to focus teacher attention individually on each of the parts of the site and how these might be used. A team of ‘experimenters’ has been formed to develop an Innovation Configuration Map (Heck et al 1981) for StageStruck, working wholly on-line. This innovation configuration map will describe what classroom practice using StageStruck looks like as teachers move towards implementation. The kernel for the map was created through focus group meetings with the original designers and developers of StageStruck and now the map moves into the hands of the experts and experimenters for fleshing out and a classroom reality check. It is planned for this collaborative writing activity to begin in February of 2002 and for a draft map to be in place in March for teacher self-assessment and professional development planning. The development of this map will be an iterative process throughout the year. The final map will be employed as an evaluation tool in the research project to gauge and describe teacher use of StageStruck.

What lessons have been learnt to date?

A raft of questions has arisen from the research and infrastructure stages of the StageStruck On-line Community to date. These questions can best be summarized under three major issues: Access, Readiness and Culture.

Access
Issues surround access to hardware within the school and at home, to the speed of the connectivity (school and or home) and the time available for personal professional development.

A recent Australian survey of teachers and the Internet (Schoolsnet, 2000) suggests that the most likely point of school access to the Internet is still the school library rather than classrooms. Administration areas and staffrooms were found to be the next likely points of access. While this lack of access is changing rapidly in Australia, as networking within schools becomes a priority, it does show that we have still not reached a point where teachers have reliable personal access to the Internet. Indeed teachers in this particular demographic are some of the least likely to have ready access to technology.

Is school technology adequate to support teacher involvement in on-line activities? Surveys suggest that in Australia 61% of teachers have Internet access in their homes. It is yet to be established definitively whether teachers are more likely to access professional development from school or home, but early evidence from the StageStruck site logins suggests that most access to the Internet outside school hours. In 2002 this study will report on how access to technology affects patterns of involvement and contribution and whether school and/or home technology can adequately support teacher involvement. Teachers in the community will be surveyed and individual access to technology mapped against community involvement. The issue of how much individual contact is required to maintain involvement will also be monitored. Technical and time management guidelines are being developed January 2002 to assist teachers to effectively and efficiently communicate on-line.

Readiness
Teacher readiness issues surround community as an untraditional and less formal professional development structure. Unfamiliarity coupled with the newness of on-line learning itself and teacher preparedness, or lack there of, for open communication, sharing and collaboration will all be factors in teacher readiness for participation in an on-line community of practice.

In 1998 the New South Wales Department of School Education offered an on-line course in information skills. When advertised across the state the response from teachers wanting to be involved was overwhelming. Completion rates in the first cohorts were heartening and the feedback from participants was very positive. However this was a predetermined formal on-line training event held over five weeks. How prepared and motivated are teachers for less formal and more self-directed and multi-directional on-line involvement?

It is the impact each of these readiness issues, and more probably the combination of them, that stands to confound the outcome of this research. It is planned to include questions related to past experience and motivation in the mid-year and final semistructured interviews to determine how level and type of previous on-line experience relates to member contribution and learning. There is some clear anecdotal evidence from experience in previous on-line projects that, upon completion of student projects and after some reflection, teachers find project activity to have been very effective informal personal professional development. Teachers report on the skills and confidence they themselves have developed through supporting the student involvement and being able to learn along with their students. In February 2002 structured projects are being offered for students to engage in. It is envisaged that these projects will motivate further involvement from the teachers and draw them to other teacher-specific areas of the site.

Culture
Cultural issues of the teaching profession surround a depressed professional status; a need for incentives, recognition and accreditation for self initiated professional development and the teacher conception of the Internet as a consumer technology.

The Schoolsnet survey suggests that teacher at-school use of the Internet is largely for research (86%) and email (73%). At home use is primarily email, Web and research. Teachers perceive the Internet as a consumer and sometimes publishing technology. Teaching and professional development programs have largely supported this perception through a continual focus on resource retrieval. Teachers need to be supported to overcome a resistance to new ways of using the Internet and commit to communicating, collaborating and contributing in order for on-line community to even have a chance of delivering effective professional development. Focus group discussions with teachers have indicated that they are
concerned about recognition and accreditation for time spent in activities on-line. In early 2002 it is
intended that the StageStruck site will offer certificates for hours of on-line activity, whether seeking or
answering, linking or mentoring, joining discussion or leading activity. To this end we are currently
investigating precedents for equating on-line time and contributions with hours of professional
development. As part of this investigation insights are been sought from similar face-to-face teacher
professional associations and groups to see what parallels can be drawn between their development and
the planned growth of this community.

As of December 2001 the StageStruck Online Community hosts a network that had not yet developed the
hallmarks of community (Stuckey et al., 2001b). Facilitator/researcher focus for 2002 is on the member
uptake of opportunities to contribute and the adoption of roles and development of strong ties, which will
allow it to be labeled a community. It remains to be seen whether it will show signs of developing into a
true community or whether while operating as a network it might still ably meet teacher professional
development needs.

Abstract:
Institutions like Webster University (St. Louis, MO) are increasing the number of 100% online (Internet-based) courses and programs in teacher education. How does online teaching affect instructors’ view of themselves, their teaching, their students, and the learning environment? This paper summarizes the individual emotional and cognitive changes that instructors reported after receiving training for teaching online and developing and teaching at least one 100% online course. Common themes include: improved understanding of course content and design; raised expectations for student autonomy and quality of student work, and increased professionalism and formality. Changes in instructors’ views carried over to the on-campus classes. The implications for program development, faculty development, and the possible development of new norms and sub-cultures are examined.

Paper Summary

Introduction
Like many teacher education institutions, the School of Education at Webster University (St. Louis, MO) has been increasing the number of 100% online (Internet-based) courses and programs. Currently (Spring 2002 Semester), the School of Education offers 20 online courses, and two Master of Arts in Teaching (MAT) degree majors that may be completed entirely online. Faculty who teach online courses receive training to work with the online teaching tools, and they develop or redesign their courses for online delivery. Do instructors’ experiences in preparing and teaching online courses change their views of themselves, of their teaching, of their students, or of the learning environment? This paper reviews the individual emotional and cognitive changes that instructors reported after receiving training for teaching online and developing and teaching five 100% online courses in the last three years.

Procedures
As part of the evaluation of new online initiatives, the School of Education’s online instructors who received training for online teaching and who had developed and taught at least one 100% online course were invited address the following questions on a written questionnaire:
1. Has the online teaching experience changed or influenced your teaching? If so, How?
2. Has the online teaching experience changed how you relate to others, including students, other faculty, family, friends? If so, How?
3. Has the online teaching experience changed your thinking or your perception of reality? If so, How?

The responses as well as oral elaborations were discussed at department and School-wide faculty meetings.

Results and Discussion
Among the 23 instructors who met the qualifications, 16 instructors (7 full-time, 9 adjunct) completed the questionnaire. Preliminary results include the following:
• All instructors report a notable change in their teaching. (Question 1) Examples of types of changes described are: “I learned how to teach online;” “After teaching online, I had to reorganize my face-to-face courses too.” “I learned a new way of thinking about course design and instruction.” “I found teaching online to be so much more focused and effective—I might want to do all of my teaching online.”

• Four instructors reported that the online teaching experience changed how they related to others. (Question 2) The other 12 instructors reported no change in their relationships. Changes described include: “I feel like I have a window into the students’ mind;” “I learned that there are some students whose personalities or learning styles are not suited for online courses. There are also some instructors who should not use this media.” “Because I get much deeper level discussions online, I think I now expect a higher standard of my students in both online and on-campus classes.”

• Two instructors reported that the online teaching experience changed their view of reality. (Question 3) The other 14 instructors did not comment on this. One instructor elaborated on how online courses places students and instructors alike in a new social and academic environment and culture. The norms and expectations for what occurs in an online course are defined anew when compared to the norms of a campus course. The other instructor described how online teaching was part of a “transformation of academia” in which technology mediates and permeates all activities in higher education, from keeping appointments on PDAs and conducting advising by email, to teaching and conducting research entirely online.

Learning to teach online, in particular 100% online courses, involved more than adding to one’s repertoire of teaching techniques. For all instructors, it was a significant professional development experience that expanded their understanding of curriculum design, and instructional principles. Every instructor devoted many more hours per week preparing and implementing the online course compared to the preparation and delivery of other new campus-based courses. The extensive preparation time was generally viewed as negative, but counterbalanced by the professional growth and gratification from valuable learning. Instructors described applicability of their new learning to curricular or instructional designs of the their campus courses.

The second and third questions aimed to elicit more personal reflections. The responses to these items may have been limited because personal information is still considered taboo for open discussion. Most instructors did not attribute profound personal change resulting from the online teaching experience. The impact of the online teaching experience upon oneself may be subtle and difficulty to observe. Or, one may resist acknowledging a personal transformation in an academic community that would probably eschew such a reaction as less than rational.

The wide range of responses combined with the already divided views among the faculty about the desirability of online courses and programs, may be reinforcing the divide in the School community between faculty who teach online courses and those who do not. If the interpersonal relationship changes that faculty reported were to extend into the School community, we may expect emerging norms such as increased personal autonomy and responsibility, more formal relationships, and lowered tolerance for unfocused expression. It is possible that these and other norms that emerge among the online faculty and students will begin to define a distinct sub-culture or counter-culture within the School of Education.

###
Collaborative Learning and the Online Learner: Do Those Who Choose Online Delivery Want Collaborative Learning?

Gary R. Tucker, PhD
Northern Arizona University
Flagstaff, AZ – Gary.Tucker@nau.edu

Michael Blocher, PhD
Northern Arizona University
Flagstaff, AZ – Michael.Blocher@nau.edu

Abstract: When the courses were designed for the online Masters Degree in Educational Technology at Northern Arizona University, they were designed with various approaches that require collaboration among the students. This approach in online course design was based on research in designing effective online learning environments and on constructivist learning philosophies of the faculty. This need for collaboration that seems to be so vital for online environments and the general inclusion of this technique in the courses for this degree brings up two very key questions: Do online learners have certain profiles that would make collaborative learning a less desirable technique for them? Are we forcing them into an instructional technique that they find exceptional difficult and undesirable? This paper reports on a initial research project that begins to shed light on these two questions.

Introduction

In the Spring of 1999, The Center for Excellence in Education at Northern Arizona University (NAU) began an online Masters Degree in Educational Technology (M.Ed. in Ed. Tech.). In designing the courses for this online degree, the faculty, with knowledge of the need for collaborative learning in online environments, designed the courses with various approaches that require collaboration among the students. This need for collaboration that seems to be so vital for online environments and the general inclusion of this technique in the courses for this degree brings up a very key question: Do online learners have certain profiles that would make collaborative learning a less desirable technique for them? Due to our limited knowledge of the dynamics of this instructional technique are we placing the students into an environment that is too difficult and problematic for them to be successful?

The California Distance Learning Project (1997) reviews some of the research on successful students in distance education programs and suggests that students who are attracted to this form of education share certain characteristics. They

- Are voluntarily seeking further education
- Are motivated, have higher expectations, and are more self-disciplined
- Tend to be older than the average student
- Tend to possess a more serious attitude toward their courses.

Pratt (1996) research indicted that an introverted person would probably become more successful online, given the absence of social pressures that exist in face-to-face situations. Conversely, extroverted people may have more difficulty establishing their presence in an online environment, something that is easier for them to do face-to-face (Pratt, 1996). Palloff and Pratt (1999) state that online learning can provide an educational experience that helps motivate students who appear to be unmotivated because they are quieter than their peers and less likely to enter into a classroom discussion.

Although these data provide baseline information on the type of students that are attracted to online learning environments, the authors of this study and faculty in the M.Ed. in Ed. Tech believe that greater information is needed to understand the learning preferences and characteristics of engaged students. For example, what are these students motivated by, what are their higher expectations, and how do they use or manage their self-discipline?
New Student Perceptions Of The Online Learning Environment

Students entering the Online M.Ed. in Educational Technology at NAU submit a battery of self-report instruments to help the faculty better understand their perceptions and expectations for learning in this new environment. One such instrument is the Motivated Strategies Learning Questionnaire (MSLQ: Pintrich, Smith, Garcia, & McKeachie, 1991). The MSLQ is a self-report instrument where learners rate their motivation and cognitive and metacognitive strategy use for a specific course. This instrument was administered to students enrolling in the M.Ed. in Ed. Tech. degree program to gain insights into students’ feelings about motivation and strategies for that specific course. The MSLQ has fifteen different scales that can be administered individually or together with modular design to fit the needs of the researcher. Analysis by the author of the MSLQ scales reported only moderate correlation with participants’ final grade. However, the Cronbach’s alphas or p-values ranging from .52 to .93 suggesting that they have reasonable between factor validity.

To gain a better understanding of students’ expectations regarding peer collaboration as they entered the program, individual items from two scales where analyzed, peer collaboration and help seeking – as it relates to peer collaboration. The results in Table 1 provide some interesting findings. For example, students reported below the median of 4 in the 7-point likert scale that they would try to work on their own even if having trouble. However, when seeking help the means seem to indicate that if they did seek help, it would probably be first from the instructor and then individual peers. When examining student means concerning peer collaboration the means for all three items where noticeably lower than the help seeking means. This would give some indication that students, even though they would seek help if needed, may be less apt to engage in peer collaboration upon entering the online degree program.

Rationale For Building Collaborative Learning Activities

Nipper (1989), a relatively early writer in the area of computer mediated distance learning discussed the need to create a sense of “synchronous presence” and reduce the social distance between all participants. Nipper notes that the need for social connection is a goal that almost supersedes the content-oriented goals for the course. Nipper suggests that it is important to somehow create the sense that a group is working together in real time. Many online instructors, seeking to create this sense of “working together in real time,” have incorporated active learning techniques such as working collaboratively (Myers and Jones, 1993). Palloff & Pratt (1999) go as far to state that the
ability to collaborate and create knowledge and meaning communally is clear indicator that a virtual learning community has successfully coalesced.

In the online classroom, it is the relationship and interactions among people through which knowledge is primarily generated. (Palloff & Pratt, 1999). P15

This research combined with the fact that modern learning theories indicate that there is a very important social aspect involved in one's learning process gives a profound foundation for building collaborative learning activities in online environments.

... ideas can be collaboratively developed as the course progresses, creating the socially constructed meaning that is the hallmark of constructivist classroom in which an active learning process is taking place. This ability to collaborate and create knowledge and meaning communally is clear indicator that a virtual learning community has successfully coalesced. (Palloff & Pratt, 1999). P32

Lev Vygotsky “believed that it is our need to interact and communicate in the sociocultural context that makes human cognitive development intellectual” He also believed that “all higher mental functions” develop from social interactions (Kafai & Resnick, p. 178).

Even though the social distance of the online environment calls for some type of community building and our knowledge of modern learning theories show the need for social interaction there seems to be an indication that learners themselves are entering online learning environments with reservations about collaborative learning. In addition, educational practitioners may not have a very good understanding of the dynamics of collaborative learning (Burton, Brna, & Treasure-Jones, 1997). This could result in creating problematic situations when collaborative learning activities are included in online learning environments.

**Purpose of Paper**

This brings us back to the original questions that this effort is attempting to shed light on: (1) Do online learners have certain profiles that would make collaborative learning a less desirable technique for them, and (2) due to our limited knowledge of the dynamics of this instructional technique are we placing the students into an environment that is too difficult and problematic for them to be successful?

As mentioned earlier, the MSLQ provides some insight as to how students feel upon enter the program regarding peer collaboration. However, it cannot provide information on students’ perceptions of specific courses where they are required to interact with peers and engage in collaborative learning activities.

This paper reports on an ongoing study that surveys students who have completed a particular course in the M.Ed. in Ed. Tech. that has a heavy emphasis on collaborative learning. The study inquires about students’ perceptions concerning the required collaborative learning activities. Specially, they were asked to report on their likes, difficulties, successes, and perception of their learning as it compared to other online courses.

**ETC 567**

The collaborative learning or cooperative learning activities of the course that the survey queried focused on working together to come to a shared understanding or view. The students were assigned different roles of involvement and the roles rotated so that each member experienced all roles. The collaborative groups were designed so that in order for the students to come to this shared understanding or view required them to engage with one another using asynchronous communication systems such as, e-mail, bulletin boards, as well as synchronous chats.

Table 2: Means and Standard Deviations for specific items of the Collaborative Learning Survey for ETC 567

The Student Perceived Difficulties of Online Collaborative Learning Activities

When asked to respond to the difficulties they experienced in the collaborative learning activities, the difficulty most often mentioned centered around the complexity of coordinating a synchronous time when they all could meet in the chat—especially when many were located in different time zones.

Coordination and time are the most difficult aspects—also people who don't or can't open their email everyday—or several times a day. During the summer last year I was in a group that had people in every time zone. I was in Michigan and twice I joined a chat at 1 AM my time because 10 PM Arizona time was the only time everyone else could get together. I understand that real life is like this, but it is a pain nonetheless.

Even though students reported that they were successful in dealing with peer group dynamics, they also reported that it created difficulties.

People that did not do their part. Difficulty in coordinating times to get together, people not showing up. Group work is great, but online has the same drawbacks as in person.

I have a hard time with the collaborative activities. First, two of my group members didn't show up to any scheduled chats at all. Another team member and myself had to complete the assignment tasks for all four people. We were eventually put in another group. The whole thing takes a lot of time and effort. I am in different time zones than everyone else and it is difficult to schedule chat times.

Successes of the Online Collaborative Learning Activities

As Table 2 indicates, the students who responded to this survey reported a mean of 2.864 (just below the median), which would indicate that they did not feel extremely successful nor exceptionally unsuccessful in their collaborative learning experiences in this course. However, when asked to describe the successes they experienced in the collaborative learning activities 76% responded with specific examples. When their comments were examined one area of success they experienced seemed to center around mastering the technical issues, such as chat. For example this student mentioned a success in dealing with her frustrations with technical issues: “I learned to deal with my frustrations better, and I got more proficient at email and chatting!” Another mentioned, “The successes I experienced were directly related to the technology and the team work with my colleagues. Negotiating the web, learning how to chat, and understanding the processes involved in the discussion performance were valuable.”

Another area where the students mentioned a feeling of success, dealt with overcoming some of the problems of group dynamics. They mentioned such issues as learning how to share with unseen and unknown individuals, leaning how to manage people, overcoming the issues of coordination of schedules and developing leadership skills. For example this student describes it best:

Managing people by long-distance and responding to the needs of a group when you don't know the group are challenging to say the least. The first time I had to do this, the whole group crashed and burned... In subsequent classes I and everyone else felt the responsibility stronger and...
performed better. I think this is an important part of the learning process and I am sure that the future for professionals in all areas will call for more work like this—long-distance group participation. So, although I hated it, I am glad I had to do it and I don't think you should drop it.

Conclusions

Data from the MSLQ suggests that students entering the M.Ed. may only slightly employ peer collaboration as part of their learning strategies. Although they reported several difficulties that hampered their collaborations, not all were related specifically to online or technology mediated collaborations. Indeed, some reported difficulties are inherent to any kind of collaborative learning activities—regardless of delivery method. Interestingly, they reported that they didn’t feel successful in the online collaborative learning activities, but 76% identified and reported specific successes that they experienced. While many expressed difficulty with the group dynamic complexities and even their dislike for the collaborative learning activities, they also reported they were glad they did it and that it shouldn’t be removed from the class design. Perhaps the most interesting finding is that they reported that they learned more than other online courses that they had taken.

To answer the questions; Do online learners have certain profiles that would make collaborative learning a less desirable technique for them? It would appear that students enrolled in our M.Ed. Ed. Tech. Degree program might come to online courses expecting to interact more with the faculty than with their peers. This may indicate that their expectations are built upon a more “correspondence model” of distance learning. However, the degree program is built upon a more constructivist, learner-centered model where peer collaboration is a central component. This certainly can create some misconception of expectations but it appears that over the span of the course, students became aware of the importance of peer collaboration. This brings up the second question; Due to our limited knowledge of the dynamics of this instructional technique are we placing the students into an environment that is too difficult and problematic for them to be successful? Although students reported specific difficulties, some in the area of the technology and some in the area of the group dynamics, they also reported how they overcame them. Certainly this information can be used to help us become more mindful of our students’ needs as we design our online courses. Indeed, more inquiry may be helpful in determining how they would modify the collaborative activities. But most importantly, their reports tell us that they came to learn and be successful in spite of the difficulties and felt the collaborations should not be removed.

Bringing Inservice and Preservice Teachers Together In an Online Learning Community

Abstract: One of the implications of the information age is the massive information load. To keep up with the skills and knowledge of the information age, teachers can support each other and learn collaboratively in an online learning community. In this paper, we introduce such a community in which every teacher can learn from other teachers. We introduce the ICQ active list, the Internet tool we used for creating the online learning community.

Introduction

Teachers of the information age are required to have more diverse skills and knowledge. Besides, these skills and knowledge are increasing day by day. Layman & Varian (2000) estimated that roughly 250 megabytes of unique information is produced in the world per year for every person. Teachers might be supported with various resources, services, tools, and specialized staff to close the gap in their skills and knowledge. However, a lot of inservice and preservice teachers lack this support on a timely and consistent basis. In order to address these needs, teachers can collaborate in an online learning community.

An Online Learning Community (OLC) is a community in which all of the members share control and everybody learns (Wilson & Ryder, 1996). The characteristics of the OLC are distributed control, commitment to the generation and sharing of new knowledge, flexible learning activities, autonomous community membership, and high levels of collaboration. Wilson & Ryder (1996) presented three scenarios in which learning communities could be formed. One of these scenarios used Internet discussion groups to form an OLC.

Many other Internet tools can be utilized to form an OLC. Examples are a web site, e-mail, e-mail list, threaded discussion group, chat, instant messaging, audio conferencing, and video conferencing (Harrison, 1997; Madjidi et. al., 1999; Pattison, 1999). Harrison (1997) found the problems with tools that support OLCs as finding appropriate software for members, access control to keep outsiders from disrupting communication, training members in the use of various software packages, and cost of acquisition of appropriate tools. This paper describes ICQ Active List (ICQ AL), an Internet tool which can support an OLC for inservice and preservice teachers while eliminating almost all of the problems mentioned above.

ICQ and ICQ Active List

New forms of Web tools are becoming available everyday. ICQ (I Seek You) is one of them, which is an integrated set of Internet tools. Although it first came out as an instant messaging tool with limited capabilities, users of ICQ can also chat, and send files and URL's to others. All these functions are within one easy to use client software. Version 99b of ICQ client comes with a new feature, the ICQ Active List (ICQ AL). Users can create or join ICQ communities based on a common interest and easily access them from their ICQ client software. Once users join an AL, they can broadcast messages to all of the members of the list, receive events from other list members, chat in a virtual room, post and view messages in a threaded discussion group, and e-mail each other. Users can also become an AL owner, which gives them total control over the AL.
order to run an AL, Active List server software needs to be run. As long as the AL server software is running, the AL will be accessible by all ICQ clients.

**Our Use of ICQ Active List to Bring Teachers Together in an Online Learning Community**

In our learning community, we adapted the learning model identified by Wilson & Ryder (1996). This linear model has seven components which are articulating the learning need, seeking help, engaging in the help consultation, assessing the learning, sharing the solution with the OLC, archiving the solution to the problem, and the repetition of the process.

When a member of the OLC needs help, he/she may seek help in a variety of ways. The member might broadcast an instant message to other members of the OLC, who are online at that time. Or, the member can open the threaded discussion forum, and create a new thread by posting the problem. For example, one of the preservice teachers in our OLC asked for sample lesson plans for science education by sending an instant message to the group and by posting a message in the threaded discussion group.

After the problem is stated, OLC members may help to the member who has a problem. Helping might be implemented in a variety of ways, like giving instruction in the chat room, sending an instant message to the member, sending a Web address (URL) that will explain a solution to the problem, posting a solution to the threaded discussion group, or sending a document. In our example, one of the OLC members sent a lesson plan in the word processing format to the member in need of help. Another member posted a message in the threaded discussion group, which contained web addresses for sample lesson plans.

At the assessment stage, the member who asked for help evaluates the solutions offered through different channels. If these solutions are not enough or complete, he/she can seek for help again. In our case, the preservice teacher was satisfied with the lesson plan sent to him by another member; however he indicated that the Web addresses posted in the threaded discussion group didn’t contain lesson plans for science education.

When a solution to a problem is found, this solution might be shared with other OLC members. Threaded discussion group is a convenient place for sharing the solution with the OLC, since every posted message stays there as long as it is not deleted by the administrator of the AL. In our example, the preservice teacher posted a message in the threaded discussion group, explaining how he found solution to his problem.

Interactions in the OLC should be archived for future reference. Current or future members of the OLC might seek help for a problem that was already solved in the past. In such cases, the archive of the OLC might serve as an EPSS (Electronic Performance Support System) or as an FAQ (Frequently Asked Questions). In our OLC, we created a thread in the threaded discussion group called ‘Solutions to past problems’. There are also sub-threads under this general thread for such domains as ‘Science’, ‘Computers’, ‘Mathematics’, and etc. Such a categorization allows members to browse the solutions easily in a timely manner.

**Conclusions**

With the help of ICQ active list, an Internet tool, we have created an online learning community for teachers, in which every member can learn from each other. We have observed that such a learning community can be utilized by teachers successfully to close the gaps in their skills and knowledge. Since this is an ongoing research, our future research agenda includes nurturing the learning community, fostering communication in the learning community, and examining interactions in the learning community.

A Technology Based School/University Partnership

Peter West, Northern Illinois University, US
Donna Wiseman, University of Maryland, US
Moses Mutuku, Northern Illinois University, US

This presentation will describe an initiative designed to better prepare teachers for the rapidly changing demands that technological and sociological changes are imposing on how they teach and how students learn. It goes without saying that few technologies have grown as explosively as telecommunications over the last decade. By simply connecting a computer to a phone line, anyone can access untold worlds of information. One of the biggest challenges facing education today is harnessing the tremendous opportunities created by those advancements and putting them to work in the classroom.

This session will describe this program and outline how a partnership between schools, universities and businesses have been working together to create solutions to technology integration.
Nuts and Bolts: Authentic Educational Web Project Development

Harrison Yang, State University of New York at Oswego, US

World Wide Web is a rich learning environment that can be used for designing direct instruction, learner oriented learning activity, and professional development. To design any kind of educational Web project, it is necessary to understand how teachers' experience and the insights of researchers can be linked together. This paper synthesizes both action and reflection of pre- and in-service teachers' ideas on four different kinds of educational Web projects: Internet educational resource book, inquiry-based learning activity, class Web, and Web-based portfolio. Descriptions of distinctive characteristics, benefits, and challenges on each education Web projects are included.
Telecommunications and education – the two are becoming increasingly intertwined in our classrooms and programs at all levels, especially in teacher education programs that are preparing educators to effectively use these technologies in their classrooms. The range of applicable technologies is growing as new ones are emerging and current ones are expanding. The number of schools with Internet-connected computers in libraries, labs, and classrooms continues to grow, providing potential opportunities for students and teachers to participate in global learning communities, and to both retrieve and produce educational resources. Teachers must learn to use and feel comfortable with these technologies, as tools to enhance teaching and learning. So where and how does this take place? The papers in this section demonstrate the wide range of approaches, for both preservice and inservice teachers, in university, field-based, and alternative programs, with delivery sites being online (Internet), videoconferencing, university classrooms, or K-12 schools – either individually or in combination.

Both video-conferencing and online Internet-based courses are described, as are uses of these technologies as integral components of classroom-based courses and/or faculty development. Also discussed are general support and community resources that are not course-connected, and that speak to the concept of lifelong learning. Taken as a whole, these papers provide a snapshot of ways that telecommunications can be used to support and promote effective teaching and learning in today's educational settings. Accounts of both successes and lessons-learned, as well as discussion of methods of assessment of the use and/or effectiveness of various technologies provide guidance for current and future educators.

The Internet may be a veritable goldmine of resources, or it can be an endless maze through which educators wander in a fruitless quest for those resources. Growing numbers of portals and other methods of organizing Internet resources are appearing. Levin and Grotto introduce one such effort – discussing how resources are selected and evaluated for inclusion in a database, and how teachers can become a part of that process. In addition to finding resources, the Internet also provides a forum in which educators can share resources they have created, thus contributing to others in their profession. Repman, Carlson, and Downs describe and provide links to a number of web-based tools that they have found helpful for productivity and instruction. Gersh, also explores web-based tools, discussing those that facilitate “Internetized” lessons and internet-based projects. Specialized applications provide opportunities such as the use of remote scientific instrumentation technology in K-12 and teacher education classrooms, as described by Thakkar, et al. This use of Internet-based activities is basic to the world of telecommunications for classroom instruction, and opportunities to learn more are often available at universities and colleges, as well as at school districts.

E-mail has become almost as common, if not more so, than the postal service it sometimes seems, and is but one of the methods of communication enabled by telecommunications. Several papers explore the communication and community building aspect of the Internet and related tools. Thomeczek examined electronic communication in an undergraduate teacher education course, and compared an e-mail discussion list with a web-based discussion board. Collier and Yoder suggest techniques, based on existing literature, for conducting successful online discussions and collaboration. Tuzun and Yılmaz describe an online learning community of inservice and preservice teachers, communicating via ICQ Active List. Leh and Winograd present some moderating strategies for instructors who are managing online computer conferences. Online communication forums may promote life-long learning, as students continue with these communities after completing their university studies.

Communication is also enhanced by the use of telecommunications to link university classrooms with those in K-12, a practice that has provided unique opportunities for preservice teachers to
observe and interact with schools at a distance. Adcock and Austin discuss their experiences with a preservice observation project that connected the university with public school classrooms via a two-way audio/video conferencing system. Lehman and Razzouk describe a method of observation/interaction using IP-based videoconferencing. Boccia, Fontaine, and Lucas describe a "two-way television teaching, debriefing, and general mentoring" program that led to the development of a CD to help better prepare preservice teachers for observations. Videoconferencing permits students to broaden their perspectives and experiences, as they 'visit' schools, often at a distance.

Online courses also provide experiences 'at a distance,' and studies relating to faculty and students are being conducted to help guide the development of successful educational experiences for all. McKenzie, Waugh, Bennett, and Mims report the findings from their study of what faculty should know about course preparation for online learning. Tucker and Blocher review characteristics of successful distance education students and then describe their study of students and online collaboration. Other papers describe online courses for high school students, and for faculty development.

Integration of technology is one of the 'buzz-words' of the day – teacher preparation programs debate whether to have a stand-alone computer course, or whether to integrate technology throughout the teacher preparation program. What is the best method of introducing preservice teachers to ways to integrate technology into their future classrooms? Redmond and Albion used a newsgroup and a guest 'expert' in communication with preservice teachers to explore that question, and they report the results and explain their choice of methodology. Koro ec, Kumpulainen, and McManus have also addressed the integration issue – they describe a survey they developed to obtain information about technology integration from faculty and students, on an institution-wide basis.

The papers in this section demonstrate a wide range of uses for telecommunications throughout the educational arena. There are full courses offered via video-conferencing, while others are online over the Internet. There are classroom-based courses, with online or video components. The modes of communication vary; as do the uses to which this technology is put, and the authors provide a view into successful implementations, as well as a discussion of lessons learned and some suggestions for improvement. The body of literature is expanding, as are the technologies. These papers provide a snapshot of ways telecommunications technologies are being used in support of teaching and learning.
Abstract: Research has shown the more classroom experience teacher candidates have, the better prepared they will be as teachers. However due to time constraints, liability concerns with on-site visits, and issues of school safety, many teacher preparation programs are seeking alternative observation methods. One such alternative that is being used at the University of Nebraska at Omaha is a two-way audio/video conferencing system. This type of system uses a computer's internet protocol number through the internet for remote viewing of the school site from the university, which enables panning the room to follow teacher-directed large group or small group learning activity. A qualitative study is being conducted to compare the responses of university students who experienced both remote and on-site observations, to determine if there is a significant difference in these two types of observation methods.

Introduction

In the past the only observation experience available to teacher preparation programs was through the student teaching experience. Studies have shown that the more experience in the school classroom, where learning takes place, the better for teacher candidates (Darling-Hammond, 1998). Consequently many teacher preparation programs have teacher candidates in classroom observation visits in every year of the college experience. However considering the time involved, the liability issues of on-site observation visits, and safety management concerns in schools, it is a possibility that visits to community schools from outside institutions such as colleges or universities could be limited or eliminated all together. Therefore, due to the reasons stated above, along with the intrusive nature of observation visits in the school classroom, teacher preparation programs are looking for alternative methods for observation experiences.

Alternative Observation Technology System

At the University of Nebraska at Omaha, federal grant money was secured for a two-way audio/video conferencing system called PictureTel. This two-way conferencing connection is possible through a computer's internet protocol (IP) number that allows for remote viewing of any classroom with ethernet connections to the internet. A port in the firewall, which block incoming and outgoing electronic traffic, must be opened at each site to allow for the two-way connection. A T1 line of a high bandwidth is preferred to handle the high traffic these audio/video presentations generate. One thing to remember is the amount of internet traffic an institution has can make a difference, especially in the video display. This conferencing system allows for two-dimensional viewing of the school classroom through a camera that is very small, only about 8 inches high and 4 inches wide, which is virtually soundless. The microphones are placed strategically around the room to pick up the voices of the teacher and the children. At the university the professor has remote camera controls that permit one to follow the learning activity, whether following...
the teacher in large group learning or zooming in on small group learning activities. The video display also allows for viewing of both classrooms simultaneously with the picture-within-a-picture option. The microphones, cameras, and controls can be connected and used at each of the sites, creating a form of distance learning. The remote video observation can be taped, which gives the university classes flexibility for viewing during class, or at a later time for classes which meet in the evening. This taping feature is also helpful with children's classroom schedules which do not provide quality observation time, such as when a child is engaged in quiet reading time, or when children are away from the classroom for lunch and other activities.

The Study

In Human Growth and Learning class, university students have five observation experiences at the preschool, kindergarten, special education, elementary and secondary levels, which are guided by field competencies. By being a part of these observation experiences, university students can gain an understanding of how children learn, in what type of setting children learn, and how children are different in intellectual development and language acquisition due to the physical, cognitive, and psycho-social domains (Flavell, 1993).

In the pilot study university students observed on-site at the preschool, kindergarten and special education classrooms during the first part of the semester. Later in the semester observations were completed using the two-way conferencing system for observing at the elementary and secondary levels from the university classroom. From this pilot experience, several valuable lessons were learned. The two-dimensional remote video observation is more limiting than three-dimensional on-site visits. Therefore it was determined that the best classroom observations using technology are when there is more interaction between teacher and the children, such as in situations involving younger children, or children with special needs. As a result during the next semester, the remote video observations were scheduled earlier in the semester with the preschool, kindergarten, special education, and the on-site visits by university students, in the elementary and secondary classes were scheduled later in the semester. As a result of this change in the observation schedule, university students felt their experiences via technology were more beneficial

Summary

At the end of the semester a qualitative study using an interview was conducted. Five university students from each of the four classes were randomly selected, of which nineteen students completed the interview. The students were asked to compare the remote and the on-site experiences. In their comparison, the university students were to consider the physical setting of the classroom, the nature of the instruction between the teacher and the children, and the development of an individual child in the physical, cognitive, and psychosocial domains. This study will compare the responses of students having experienced both methods. In consideration of the observation competencies, the faculty will determine if there is a difference in the two forms of observation methods, and if this difference is significant. This study will be used as a guide for future studies of observation methods to determine if these alternative forms are meeting the needs of the university student in their preparation as teacher candidates.

Abstract: (75-100 words) This paper reports on a three year federally funded project that demonstrates the feasibility, effectiveness, and replicability of a technology-mediated classroom observation program for preservice teacher education. The study describes technical, staff and programmatic requirements for the project and some of the challenges likely to be faced during implementation. While not a replacement for in-person school visits, the virtual observation offers groups of preservice teachers the opportunity to watch and discuss high quality, real time teaching. The utility and value added of a carefully constructed technology-mediated classroom observation program for teacher education is evident from this study.

Introduction

Intensive, supervised field experiences are widely accepted as critical components of successful teacher education programs. "Prospective teachers learn just as other students do: by studying, practicing, and reflecting; by collaborating with others, by looking closely at students and their work; and by sharing what they see. For prospective teachers, this kind of learning cannot occur in college classrooms divorced from schools..." (National Commission, 1996, 31) In most teacher education programs, preservice teachers are placed in public schools for a variety of observation and assisting activities linked to academic courses in the teacher preparation curriculum. Debriefing of these field experiences usually occurs in the related courses and not onsite with the classroom teachers. Yet, "access [to] expert teachers' knowledge-in-action" is a powerful source of learning about the connections between theory and practice for preservice teachers (Ethel & McMeniman, 2000, p. 99). All too often, the public school schedule, particularly at the secondary level, provides no time for teachers to talk about their work with preservice observers. At institutions that use public schools as field sites, the quality of preservice teacher education is diminished to the extent that opportunity for dialogue about observed practice is missing or limited. Instead of serving as powerful sources for preservice teacher learning, school based observations become little more than time served in schools.

A related limitation of onsite observation is the narrow range of schools accessible to preservice teachers within most regions. For universities located in suburban or rural areas, access to urban educational settings is severely limited. Yet "prospective teachers need experience in schools in which cultural pluralism is valued, and where talk about racial, ethnic, and social–class diversity is a central item in faculty discussions.” (Holmes,1990, 36) Increasingly, teacher educators are turning to technology to address the limitations of traditional onsite observation experiences, and in some cases to improve upon them. This paper reports on the Looking Into Classrooms project, a three-year, federally funded two-way interactive television classroom observation and dialogue program that linked preservice teachers at a university and public school teachers and students in 8 communities.

Project Overview

Looking Into Classrooms is a technology-mediated observation program for preservice teachers that is designed to expand and enrich their field experiences while simultaneously engaging master teachers in reflection and dialogue about instructional practice. The model uses two-way interactive television technology to provide preservice teachers real time observations and debriefing opportunities with a broad range of high
school classes and teachers. The technology involves simultaneous audio and video communication between university classrooms and high school classrooms, allowing teachers and students in the high school classroom to be seen and heard by preservice teachers and their faculty. The high school students and their teacher can also see and communicate with the preservice teachers as part of a debriefing process. In addition, a web site was established to facilitate master teacher and preservice teacher discussion about the observed classes.

The foundation for the pedagogical model of the project is the Principles of Effective Teaching, developed by the Massachusetts Department of Education. These principles address Currency in the Curriculum, Effective Planning and Assessment of Curriculum and Instruction, Effective Management of Classroom Environment, Effective Instruction, Promotion of High Standards and Expectations for Student Achievement, Promotion of Equity and Appreciation of Diversity, and Fulfillment of Professional Responsibilities. Master teachers for the program were selected in part based on their awareness of and commitment to implement these Principles in their classrooms. Other frameworks of effective teaching could be used for the same purpose, such as the Model Standards for Beginning Teacher Licensing and Development developed by the Interstate New Teacher Assessment and Support Consortium (INTASC Standards).

Project Description

The Looking Into Classrooms project and model have the following components:

- A 2-way television connection that provides simultaneous audio and video broadcast and recording capability between the base site (i.e., the college) and the observationsites (classrooms).
- Technology support personnel to develop, implement, troubleshoot, and manage technology-related aspects of the program.
- Camera persons who know where to set up cameras and microphones in accordance with the goals of the teacher and college supervisor.
- Email accounts for all participants (preservice teachers, college faculty, program coordinators, classroom teachers, technical personnel) for scheduling and communication.
- An electronic forum with interactive dialogue capacity.
- Master teachers who represent a variety of teaching styles and disciplines in as broad an array of structures and settings as possible.
- A sound framework for defining exemplary pedagogy, such as the Massachusetts Principles of Effective Teaching or INTASC standards.
- Courses of study related to instruction to which the 2-way observation is linked. Course should include, but not be limited to, a methods teaching course where practices are embedded, a pre-practicum or clinical observation program, and an onsite observation program that complements the 2-way observations.
- Permission of participating preservice teachers, master teachers, and classroom students to be videotaped.

As part of the evaluation process, a detailed profile of the Looking Into Classrooms model was created based on the “Innovation Configuration and Practice Profile” methodology developed by researchers at the University of Texas at Austin more than 25 years ago. This methodology has been used in countless programs to define the specific requirements for implementing a program faithfully, including Unacceptable, Acceptable, and Ideal levels of fidelity. The Practice Profile for Looking into Classrooms can serve as a guide to further implementation of the program or its components not only at the originating site, University of Massachusetts Lowell, but also at other institutions.

Project Outcomes

In the first year of the project, eight secondary-level classroom practitioners, representing a variety of disciplines, were recruited to serve as master teachers. The master teachers were nominated by their principals or by university teacher education faculty based on their excellent teaching and ability to work with newcomers to the profession. The first master teacher group then served as a mentor team to teachers who joined the project in subsequent years. By the project’s end, twenty-three teachers were involved as master teachers. These experienced teachers (12-35 years teaching) are well educated and have participated extensively in professional...
development related to their subject area, teaching, and/or a specialty area. In addition, their motivation to participate in the program indicates a strong commitment to their own growth (making them excellent role models) as well as to the development of preservice educators.

Over a three-year period, the master teachers conducted a total of 33 two-way television classes and debriefings from eight different communities, including urban and suburban settings, as well as middle, secondary and technical schools. Classes included math, science, English, history, American Studies, special education, bilingual, English as a second language, and a K-16 Life Skills program. In addition, the master teachers participated with preservice teachers and university faculty in an electronic forum for extended discussion of the classes observed and, in the third year, in a student teacher support forum to help novices deal with the myriad issues of the practicum experience. In several instances, the master teachers were selected by preservice teachers to serve as their cooperating teachers in the practicum experience.

Master teachers found the two-way television teaching, debriefing, and general mentoring of preservice teachers a powerful learning experience. For many of these veterans, teaching had become instinctive and they were not easily able to articulate the rationale and purposes for what they did in the classroom. However, in order to respond in the debrief sessions to preservice teacher questions about teaching practice, the veteran teachers began to reflect on and express their professional skills in the pedagogical language used to frame the project. Examples of their reaction to the technology-mediated observation program include the following comments:

"I think the program forces me to look at my own teaching methods - to focus in on discussion and student thinking - not leading."

"I was very interested in interactive teaching. The idea of seeing myself in action as well as talking with teachers about teaching was very appealing."

"This program provides an opportunity for all of us to engage in activities designed to promote better teaching practice."

"I am interested in better education for my students, my colleagues, and myself. This program provides an opportunity for all of us to engage in activities designed to promote better teaching practices."

The 50 preservice teachers who experienced two-way television classroom observations over a three-year period generally agreed that the experience provided a more focused look at teaching than the traditional classroom visit. In addition, sharing the observation and debriefing with classmates enriched the learning experience as preservice teachers compared notes and formed questions about what they had seen in the observation. Finally, the preservice teachers recognized that the quality of teaching provided in the two-way observations was consistently excellent, illustrative of a teaching principle, and varied in methodology, conditions not guaranteed in traditional classroom observations. Another benefit of two-way television observation that preservice teachers listed was the psychological distance afforded by the physical separation of master teacher and observers. This distance empowered preservice teachers to ask hard questions of master teachers, questions that might have seemed too direct or even challenging in a face-to-face encounter. Examples of the preservice teacher comments about the observations and debriefs include:

"2-way observations are very effective. It's very helpful to watch and question real teachers."

"I have enjoyed this portion of the program. This is good quality control because there is too much of a chance students will have bad field observations. The 2-way (observations) are more effective and a better use of time."

"It's especially great to actually see Principles of Effective Teaching in action, which wasn't always happening with onsite observations."

"I thought the teachers used in the 2-way were superlative. It was a very good variety of styles and levels."

"Discussion (live) with peers and master teachers was by far the most valuable aspect of the semester."

"The debriefs were great. Don't change them. Talking to the teachers about their methods was extremely effective."

Although not part of the original project plan, a CD-ROM was created using clips of the first year's two-way classes as a tool to train preservice teachers in classroom observation skills. This component of the project was well received by all participants and led to a supplemental funding application to create a CD using higher quality video and focused questions for observation training in the future.

Preservice teachers also found the observation booklet to be "very useful in organizing thought and a great tool to explain what you should be looking for." The electronic forum was less well received in part because, in its original design, it was cumbersome to access and demanding to use. Subsequent versions of the forum alleviated the initial design problems but preservice teachers continued to resist discussing their
observations after the experience. Only when master teachers joined the forum, and preservice teachers were
required to make weekly postings to the forum, did the participation rates and quality increase. Indeed, from
beginning to end of the third project year, the length, depth and quality of preservice teacher comments,
reflections and questions to master teachers increased substantially. The public and professional nature of the
electronic forum, as well as preservice teachers' experience with the tool and their own emerging identities as
teachers, may explain the marked improvement in the dialogue over time.

Conclusions

The Looking Into Classrooms model has demonstrated substantial viability as a complement to more
traditional methods for providing preservice teachers with opportunities to observe master teachers at work.
The main reason for developing a technology-mediated classroom observation model was to expand the range
and quality of classrooms and teaching styles preservice teachers could observe, and to provide the opportunity
for dialogue about teaching with master teachers; the project achieved these goals. It also achieved a number of
other outcomes that were not anticipated in the original study design, but emerged in the course of project
implementation.

Some of the unanticipated outcomes had positive impact on the project. For example, the need for
preservice teacher observation training that included demonstrations of what to look at in classrooms became
apparent in the first year and led to development of the Beta version of the CD-ROM and eventually to a
purpose-shot CD linked to the national INTASC standards. The dramatic improvement in preservice teacher
questioning and reflection skill as a result of the debrief experiences and electronic forum assignments suggests
the power of group learning and public discourse on practice, learning principles worth extending into other
educational arenas. The unexpected assumption by master teachers of an active, sustained mentoring role led to
them being viewed by preservice teachers as the experts, not only in the classroom but also in the electronic
forum. The uncustomary collaboration of university faculty in planning and viewing classes via two-way
television meant that preservice teachers from a variety of disciplines and grade levels came together to watch
and debrief classes in fields and levels outside their own. These “out-of-field” observations were reported by
preservice teachers to be among the most powerful experiences in their preparation experience. At the school
level, too, there were unlooked-for outcomes. The high school students being observed via two-way television
found the experience exciting and important. Their teachers reported that the students always wanted to know
“how they did” and what the preservice teachers thought of the class. If there were more time in both the high
school and university schedule, conversations between the students and preservice teachers could prove very
informative for both groups.

Not all outcomes, however, were positive. We were surprised to find how many university faculty
were reluctant to give up scheduled class meetings to have their students participate in two-way observations.
The logistics of planning two-way television observations in high schools, with their different and often
changing schedules, was a constant challenge for the technical staff as well as project directors. Even when the
schedules worked, the technology infrastructure in some communities and at the university was not always
reliable. A promised cable connection to one high school did not materialize, the sale of another cable company
resulted in an end of linkage between another community and the university, a snowstorm damaged the
university microwave. Fortunately, rapidly evolving technologies made it possible to connect schools and
university via ISDN lines using compressed video. While not originally considered a quality connection, the
new versions of this equipment provide high quality audio and video signals without dependence on public
access cable channels and all the complex politics that accompany use of these services.

We have learned a host of lessons about school-college collaborative projects, about distance learning
technologies, and teacher education in the course of directing what became a four-year program linking eight
school districts to a university. Our advice to people who might replicate this project, or undertake a similar
one, is to use the simplest and least expensive technology available, a feasible approach given advances in the
Internet and bandwidth size; to involve school people in the planning and guidance of the project from the
outset, especially onsite technicians who understand the infrastructure of the different buildings in their school
districts; to expect higher education faculty resistance to any instructional methodology different from their
prevailing practice, and to create powerful motivators to get faculty onboard; to be flexible in project
implementation so as to accommodate unforeseen challenges and opportunities; and to talk to other people
doing similar projects at other institutions for ideas about solving problems common or endemic to the work.
Finally, we would caution project replicators about the complexity of creating high quality CD-ROMS. Both
pre and post production efforts are far more complicated than we had envisioned based on our Beta CD and may be better done by a professional organization than an in-house staff. These cautions notwithstanding, we would also strongly encourage others to undertake school-university collaborative projects to support preservice and inservice teacher development using technology. The common cause of preparing the next generation of teachers and the challenge of using technology to do so created a powerful, sustained partnership between schools and universities that continues beyond the funding period and has become an integral part of teacher education at the originating university.

Objectives:
Conferees attending this session about a video conference will discover how:
1. Urban schools with limited funding and resources can present otherwise unattainable learning experiences for underprivileged students.
2. To maximize school/university and PT3 partnering and learning through video conferencing.
3. To involve elementary students, preservice and inservice teachers, PT3 teacher educators, and technical assistants to collaboratively provide authentic, virtual classroom learning.
4. To collaboratively work together across educative roles to technologically prepare and implement meaningful learning opportunities for learners at multiple levels.

Presentation Outline and Format:
Beginning this presentation, the technology coordinator and a PT3 inservice participant at the urban elementary school will detail how a video conferencing project moved from idea to actuality. Each representative involved in the grant activity, the technology support director, and the school/university partnership liaison, will describe their role in making the video conference a reality for the third grade students and preservice teachers on site at the urban school and at the secondary university site. Digital photos and video clips inserted into the PowerPoint™ presentation highlight aspects of the descriptive portion of the project and image the realms involved in this collaborative technological effort. The project offered urban students an opportunity that most have not had, that is to virtually travel to the Tennessee Aquarium as a culminating activity to classroom study. Additionally, it provided elementary preservice teachers with a first hand, technological experience that made virtual resources available to field settings with limited resources. Educators at varied levels collaborated in partnership and modeled effective education. The third grade students accomplished literacy standards outlined by the ISTE, especially standards 6 & 7 for grades 3 – 5. The performance indicators for teachers were met in this project. The ISTE professional performance profile was met by preservice teacher involvement. The format for this presentation is a panel, with interactive discussion. Questions and answers will be encouraged.

Research Implications
Because the teaching force will change dramatically over the next decade, and the fact that the nation’s schools will need to hire 2.5 million teachers over the next 10 years (Hussar, 1999), provides an unequalled opportunity to transform the quality of teachers serving our nation’s schools. Researchers’ work led to clear conclusions. Teachers exert a powerful influence on the academic performance of students, and some teachers are consistently more effective than others. The success of teacher education programs ultimately will be judged by how well the K-12 students of our graduates perform. Furthermore, we recognize that to prepare students for success in careers and life within a technologically advanced society, teachers and higher education faculty must be able to model and reinforce effective use of available technology through teacher preparation: disciplinary knowledge, pedagogical practice, and clinical experience.

Technology implementation during teacher preparation is a predictor of whether preservice teachers use technology as inservice teachers. Unfortunately, most do not use it during field experiences, nor do they apprentice with teachers who do (ISTE, 1999). It is our commitment to establish sound pedagogical practice in effective learning environments to better educate youth, while providing model technological conditions for involved educators at every level (Wiseman, Cooner, & Knight, 1999).

Tracing Virtual Travel: Touring, Thinking, and Telling about Video Conferencing, our presentation, is a component of a PT3 grant funded by the U.S. Department of Education. By this activity, we prepare teacher/leaders through infusing technology into curriculum with the collaborative mentorship of inservice and teacher education faculty in clinical and university settings. This presentation features quality, educative, technology methods from a PT3 mentorship initiative. Conferees will see, hear, and discuss a project in which third grade students in an urban school/university partnership learn about animals/insects at the aquarium through a video conference session which was also viewed on the university campus by preservice teachers not yet placed in field settings.

The presenters’ qualifications range from technology coordinator/teacher in the elementary school, associate and assistant professors in teacher education, and a technical support director within the school of education.
Video Conferencing as a Tool to Link Colleges of Education with K-12 Schools: A P3T3 Project Initiative

Abstract: Distance education technologies offer capabilities that can be used to enhance teacher preparation while addressing technology integration issues in teacher preparation programs. Video conferencing allows pre-service teachers to observe and interact with K-12 classrooms at a distance. This can provide needed access to diverse student populations and examples of exemplary technology use that may not be available in nearby schools. As one part of P3T3: Purdue Program for Preparing Tomorrow’s Teachers to use Technology, two-way video conferencing is being used to link college students and classrooms with K-12 students and classrooms. Particularly promising are new IP-based videoconferencing systems, which support high quality video conferencing over the Internet. Initial experiments in the use of this technology suggest that it provides a viable alternative for some types of student observations and interactions with K-12 teachers and students that typically occur through traditional field placements. Advantages include support for directed observations, linkages with diverse settings, and integration of technology. Limitations include issues with school firewalls, classroom audio, and the fact that these are not true field experiences.

Introduction

Distance education technologies can be used to enhance teacher preparation while addressing technology integration issues. Future teachers can use distance education technologies to observe and interact with K-12 classrooms from afar. Experiments involving the use of closed-circuit video technologies to link colleges of education with K-12 classrooms date back many years (e.g., Abel, 1960). In the 1980s, Iowa State University’s Teachers on Television project used microwave-based video connections to link the campus with multiple public school classrooms and teachers. Project results showed that the observation skills of pre-service elementary teachers could be improved through training involving the use of these video connections to classrooms (Hoy & Merkley, 1989). However, these older video technologies were expensive and difficult to set up and maintain. Today's video conferencing technologies offer a flexible and cost-effective option.

P3T3 Project Video Conferencing

Many colleges of education face difficulties placing students in field situations that provide for needed experiences such as access to diverse student populations and examples of exemplary technology use. This problem is particularly acute for Purdue University, which is not located near a major metropolitan center. As one part of its P3T3: Purdue Program for Preparing Tomorrow’s Teachers to use Technology project, two-way video conferencing is being used to link Purdue students and classrooms with K-12 students and classrooms. Particularly promising are new IP-based videoconferencing systems, which support high quality video conferencing over the Internet. These newer technologies are more flexible and less expensive than preceding video technologies.
We use equipment from Polycom (http://www.polycom.com), which makes room-to-room as well as computer-based desktop video conferencing units. Viewstation SP or Viewstation FX units are used for room-to-room conferencing. The Viewstation SP connects two sites at data rates up to 768 Kbps. The Polycom Viewstation FX is a high-end room-to-room unit that has a built-in Multiple Control Unit (MCU), a device that bridges together multiple inputs so that up to four sites can participate in a video conference. Computer-based desktop video conferencing is done with Polycom's ViaVideo, which offers video and audio of high quality at connection speeds of up to 384 Kbps. ViaVideo, which is available for Windows-based PCs, supports file sharing, whiteboard, chat, and file transfer along with video conferencing.

A year-and-a-half experience with IP-based video conferencing technology suggests that it provides a viable alternative to traditional field placements for some types of student observations and for interactions with K-12 teachers and student. The technology offers several advantages. (1) Beginning pre-service teachers are poor classroom observers. Using video conferencing, pre-service teachers can make observations under the direction of a faculty member and so improve their observational skills. (2) Students cannot observe a full range of school settings in close proximity to the college campus. This technology supports linkages with schools at remote sites that can provide access to diversity, technology use, etc. (3) The technology is relatively inexpensive, easy to use, and flexible. Because it requires only a fast Internet connection, it can reach places that other technologies cannot easily reach.

However, as with any new technology, there are also shortcomings. (1) IP-based video conferencing equipment requires access through the school's Internet firewall. School technicians must make the necessary arrangements, which can be time-consuming and difficult if the school's technical support staff is not fully knowledgeable about firewalls. (2) Video conferencing over the Internet requires high bandwidth (typically 128 Kbps or better) to insure a stable connection of acceptable quality. Network traffic can lead to degradation or even interruption of the connection. (3) This is a new way of communicating for most people. Participants have to take time in the beginning to get used to the technology and become comfortable in using it. (4) Audio problems can limit observations and interactions. Typical classroom noise makes it difficult for pre-service teachers to listen to particular conversations in a busy classroom. This is not usually a technical problem per se, but it can cause problems. For more information, visit our website at: http://p3t3.soe.purdue.edu.

In Their Own Words: Pre-service Teachers’ Perceptions of ICT Integration

Petrea Redmond
Department of Education, University of Southern Queensland, Australia, redmond@usq.edu.au

Peter Albion
Department of Curriculum and Instruction, Purdue University, USA, palbion@purdue.edu

Abstract: Pre-service teachers participated in an online discussion that included a guest who facilitated conversation about integration of ICTs. Students mostly agreed that integration of ICTs was desirable but differed in their views about specific practices. They demonstrated awareness of the challenges facing teachers and schools in integrating ICTs but appeared to have had little personal experience of ICT integration during field experience.

Prologue

One of us is old enough to have taught in the 1970s, when the other was a child in primary school and the place of information and communication technologies (ICTs) in education was very different from today. The terminology of ICTs had not been invented; hand-held four-function calculators were new technology; and a few pioneers were beginning to use computers in schools. Where computers figured in the curriculum, they were objects of study in “computer awareness” or “computer literacy”. Most often these topics were the province of teachers of mathematics or science and they frequently involved consideration of binary notation, boolean algebra, half- and full-adder circuits and programming in BASIC. In the late 1980s, there was an expansion of ICTs from mathematics into business education with a focus on teaching skills for generic software such as word processors and spreadsheets in an office environment. The focus throughout those decades was on teaching about computers.

Now, over 25 years later, personal computers have been available long enough that one of us has an adult daughter who cannot remember home without computers. Personal computers are common and easy enough to use that his grandchildren regard email as a basic form of communication with extended family and one grandson had digested his knowledge of dinosaurs, gained largely from independent use of CD-ROMs, into a personal web site before beginning school. The other of us has owned a computer since the beginning of her teaching career and her son, considers the use of an eyeball camera and computer as a normal method of communicating with his godfather who lives 1500 kilometers away. Our grandchildren and children consider technology as part of their every day life. For them, ICTs are thoroughly integrated. Our task is to prepare teachers to integrated ICTs in their teaching.

Context

Recent Australian reports have referred to the “information economy”, the “knowledge society” (DETYA, 2000) or “knowledge nation” (Jones, 2001). Regardless of terminology, it is clear that the impact of ICTs requires changed approaches to education. It is no longer sufficient, or even, perhaps, necessary to teach about computers as in the 1970s. It is necessary to teach with and through ICTs to prepare students for life in a rapidly changing world.

Queensland policy on computers in education began in 1983 (Galligan, Buchanan, & Muller, 1999). Its focus was on computer awareness, basic skills, computer assisted learning and vocational programs. In 1991 the effect of rapid technological change on learning and teaching was identified as one of eleven key issues for Queensland education and the integration of information technology for learning and teaching was listed as one of four goals for schooling (Queensland Department of Education, 1991). In 1994 a revised policy document, emphasized the use of computers to support learning across the curriculum at all year levels, while still acknowledging the importance of computer skills for future employment (Queensland Department of Education, 1994). Schooling 2001 (Education Queensland, 1998b) set system-wide targets to be achieved by 2001. These included the provision of one computer for every 7.5 students, the connection of every classroom to the Internet, and the use of computers “in all key learning areas, P-
Minimum standards for teachers in the use of learning technology were set (Education Queensland, 1998a). More recently the New Basics project has shifted the focus to the application of ICTs within rich tasks, which span multiple curriculum areas. Examples include the construction of multimedia profiles and web pages by children in their third year of schooling (Education Queensland, 2000).

Australian education has two goals for ICTs in education (Toomey, 2001). They are that students leave school as “confident, creative and productive users of new technologies” and that schools integrate ICTs to “improve teaching and learning”. These same themes have emerged through the development of Queensland policy. As ICTs become more deeply embedded in society, the focus on teaching ICT skills as distinct from the use of ICTs for teaching and learning blurs and the two goals merge. Although teacher education programs will need to adapt to these changes, there is, as yet, no mandatory requirement for teacher preparation programs in Queensland to ensure that graduates meet the minimum standards in learning technology nor even to address the issues of technology integration. However, most programs have responded. A previous paper described some approaches being adopted at the University of Southern Queensland (Albion, 2000) including modeling of ICT integration within classes and the design of a course (85045) focused on preparing graduates to meet the minimum standards and to integrate ICTs. This study was situated within that course which is described in more detail elsewhere (Redmond, 2002).

Method

Both authors and a colleague taught in the 85045 course in first semester of 2001. In the belief that computer mediated communication (CMC) was an important tool for teachers and that there was value in learning through practical experience, students were required to complete minor group projects using CMC in the form of mailing lists and newsgroups. The activities provided a context for CMC experience but, given that the tasks could have been completed in face to face meetings, were somewhat contrived. In reviewing the course, a less contrived CMC activity was sought. Previous studies have demonstrated the value of an “online guest” in providing a “focus for dialogue” and directing conversation (Williams & Bowes, 2000). It was thought that an online guest would provide purposeful focus for the CMC activities in the 85045 course and be less contrived than the original activity.

In second semester of 2001 one of us (Albion) was working in the USA. This provided an opportunity to engage students from the 85045 course in a CMC activity involving a member of the course team as an online guest. The proposed activity would allow the absent team member to maintain contact with the course and enable students to experience, by modeling, a teaching approach which might be applied in their own future classes. Experience with students in previous offers of the 85045 course had suggested that many found difficulty in grasping important concepts associated with integration of ICTs into teaching and learning. Hence integration of ICTs into teaching and learning was selected as the topic of discussion with the online guest. As it happened the “guest” was concurrently teaching two sections of a course discussing technology integration with teacher education students in the USA.

To allow time for introductory work, the activity was scheduled for a block of six weeks in the middle of the course which, allowing for a two week recess, corresponded to four weeks of scheduled classes. The activity was announced early in the semester when the classes were introduced to the use of CMC. Because students in this group had some prior experience of electronic mail including listservs and personal mailing lists, a newsgroup was selected as the CMC venue for this activity in order to provide students with experience of threaded discussion. The newsgroup was created two weeks prior to the date set for introduction of the guest who was to join the group on Monday, September 7. The first author posted a message introducing the guest four days prior to the scheduled start of the activity. By that time one student had already posted an anticipatory message and three others did so before the guest made his first posting.

Results

Figure 1 shows the distribution of postings over time. The recess is visible as a period of reduced activity. Most postings occurred on days when classes met in computer laboratories and tutors were able to prompt activity.
Table 1 provides the distribution of frequency of posting by individual students. Most students posted just once and relatively few posted more than twice. Several of those who posted twice appeared to have done so in error, possibly because the repeated the process when their first attempt was not immediately visible in the list of messages. Assessment credit was available for posting, so many of those who posted once did so for that reason although their posts were typically no less relevant than those of the more frequent correspondents.

Table 1: Distribution of postings among students

In his introductory posting the guest commented on the value of having a sense of direction in daily life and invited students to comment on the need for teachers in a school to have a common understanding or sense of direction in regard to ICT integration. Students were also invited to explain why they thought a common view was or was not necessary. The first responses tended to agree that some common view was necessary although it was not long before ambivalent and contrary opinions surfaced. The earliest responses suggested that the common view:

- "should be couched in plain language, simple, ... that can accommodate people from disparate backgrounds" 
- "serves as a direction for how the school functions with technology, (having different understandings) may result in conflict among teachers".

Most students agreed with the proposition that a common view was desirable. Their reasons for thinking so varied:

- "(communication among teachers is possible) only ... if all parties are coming from the 'common view'"
- "(a mutual decision is needed) about the importance of children learning, understanding and interacting with technology in the classroom."
- "If teachers don't know what they are talking about, or have a different understanding of what technology integration is, then the students we are teaching will be even more confused than they already are."
- "so that students don't miss out regardless of a teachers perception of information technology"
- "in order to benefit children’s learning and also to share a common school goal and understanding"

Some thought that an effort to develop a coherent shared view of technology integration might be doomed to failure:

- "How can you possibly get a bunch of diverse adults with different ideas on what technology should be used, then get them to agree on what technology integration means? I foresee a turbulent time."
- "Since there are so many divergent views on what education is, and how it should be approached, I doubt that teachers will ever agree on what technology integration is and how it should be approached"
- "I think it would be very difficult for all teachers to agree on technology integration within classrooms. For one, the broad range of abilities of teachers gives a large range in classrooms with regards to the amount of technology being integrated."

There were others who expressed ambivalence or, perhaps, an appreciation of the complexity of the issue:

- "... do they need to have a common view? Well... yes and no. Yes they do need to have a basic understanding or platform, but every teacher will interpret technology integration as appropriate for their curriculum area"
and age group. It will be different and so it should be. Teachers are individuals with varying abilities, experiences and personalities. Their approach to technology integration will reflect this. If teachers integrated technology in the same way for all subjects, what a boring place!"

"Common views improve communication and make the use of time more efficient. They can however exclude new ideas or perceptions which could make education an easier more productive experience"

"The common understanding is important as this will provide continuity throughout the grades and between classes. However some diverse views may stimulate some discussion, critical reflection and evaluation that makes the curriculum integration plan better. Thus I think it is important to have a common understanding but one that is open to discussion and change"

Although few threads developed beyond two levels — message and response — it was evident from the references to other postings, mostly agreement, that students were actively reading the postings. At the end of the first week it was one of the mature age students who anticipated the guest's intention by writing

"Most agree that Yes most teachers should have a common understanding of Technology Integration. But most also agree that the task may be quite impossible with the current abilities of teachers ... (for this discussion) we should at least have a common understanding of the meaning ... I would like everyone to give their definition."

Acknowledging this response, at the beginning of the second week the guest briefly summarized the postings to that point, expressed an interest in having students define "technology integration" and drew some parallels between ICTs and literacy education. He then invited responses to two new questions. The first was to provide a definition and the second to make a comparison between the position of ICTs in education and that of basic literacy or reading and writing. Some students appeared to agree that there were parallels and developed the idea further:

" 'integrating technology' into the classroom is about being able to use technology as a tool in the classroom to enhance learning, just like any other tools such as books ... Books opened up the world to people from the time of the first printing press ... just as technology of another sort, computers, can open up the world for people. As always though, equity is a problem"

"If you regard IT as a Literacy, just as English is, then it obviously needs to be deeply integrated into school activities, as well as being explicitly taught. But don't mathematicians and scientists (for example) also believe that mathematical and scientific thinking should permeate all areas? Don't you think it could get a bit too heavy if all learning areas are regarded as a dominant discourse?"

"When I think about the concept, I see it as a teaching tool - a way of teaching the skills and knowledges within the (curriculum). It seems to be closer to ... principles of teaching and learning, than a specific subject area ... The problem is that IT as a 'subject area' within schools is not the same as 'IT integration' across the curriculum - a bit like the difference between teaching literacy as a specific subject, and using literacy techniques within teaching of other subjects ... while individual teachers may hold a common understanding of exactly what that is, the way they use it within the classroom is going to be different"

As early as the second day of discussion there had been comments about resources and teacher preparation for ICT integration. One student had commented that some teachers are "dead scared of computers" and "ignorant of the ways they can be used". He called for additional funding for resources and trained support personnel in schools and others offered similar comments. Continuing this line of practical comments, students wrote:

"... there are millions in this country (who are not computer literate) and many hundreds of millions who are struggling to become literate in any sense ... ICTs would have to be all pervasive for the need of another 'literacy', that is when all of us have access to these technologies all of the time ... in a typical high school classroom there isn't any access to these technologies!!!!"

As might be expected in a conversation of more than 50 voices, albeit each only briefly, many ideas were expressed in no particular sequence. Some students waited until the end of the activity to express their thoughts, which were as likely to be linked to the first postings as the later ones. Despite that there did appear to be some development in ideas as the conversation progressed although there were dissenting opinions even in the closing stages:

"I think there is too much emphasis on technology. Children cannot spell any more ... Even though I don't mind computers, children should not be exposed to them at such a young age. ... Why can't we teach younger to type on typewriters and then at a later stage - high school - put them on computers. I also had given an assignment ... one of the tasks was to write the assignment out by hand. A lot of children were complaining. What does this say about our emphasis on technology?"
"I too think there is too much emphasis on technology especially in primary schools. Within a high school computers become more important in the publication of assignments and important for future employment or university studies."

During the second week of discussion, the guest had recounted an example of a teacher integrating ICTs and invited students to contribute their own examples. Few chose to do so, which was, perhaps, a reflection of the paucity of examples they had seen during field experiences. There were some comments in response to the invitation:

"I am quite concerned to say that I cannot think of a specific example!! This worries me a little. All I can say is that we are the new fresh faces going out to teach and we need to integrate technology into our lessons and provide variety."

"I think it is quite unfortunate that we have so few positive experiences to contribute to the group of how to integrate technology into the classroom. ... I saw some examples where IT was used satisfactorily, such as researching assignments and preparing either the essay or the presentation, and some examples where the teacher stopped teaching and just expected the IT to do the job for her without effective monitoring."

"From what I have seen out there the students know more than a lot of the teachers and have better facilities at home."

Conclusions

Possibly without exception these pre-service teachers saw ICTs and their integration as important issues in their future careers as teachers. However, some seemed to experience some difficulty in articulating a view of what ICT integration might mean in practice and others appeared skeptical about what they saw as an emphasis on ICTs rather than the more traditional values of education. Both of these findings are perhaps related to the relative paucity of good examples of integration encountered during field experience. It is inevitably difficult for them to imagine how they might engage in behaviors for which they have few models. There is a clear need to continue developing university programs which model ICT integration and to develop stronger partnerships with schools where appropriate models are in practice.

There seemed to be a substantial level of awareness of the challenges faced by schools and teachers seeking to integrate ICTs. Among those referred to in the discussion were curriculum pressure, lack of ICT resources, inadequate technical support and a continuing need for teachers to receive appropriate professional development. As a group they appear to harbor few illusions about the challenges they will face after graduation.

Helping Students Pass PRAXIS I

Karen Smith-Gratto, North Carolina A & T State University, US

North Carolina Agricultural and Technical State University and Winston-Salem State University were awarded an eLearning grant from the state of North Carolina to develop computer based resources for helping students prepare for PRAXIS Exams. The resource for the Elementary Education PRAXIS II was developed by a team of content experts and an instructional designer. The PRAXIS I was developed by the instructional designer.

First the general areas of the test were examined and the initial design broken down into the three major sections found on the test. These three major sections became the main menu which also informed students how long each portion of the test is and the type of items on the test. From the main menu students are linked to Reading, Writing, and Mathematics sections. These sections are further divided into submenus.

One submenu contains the basic areas that are addressed in Reading. This section is divided into a section that provides vocabulary-building tips, different ways to determine the meaning of unfamiliar words, and steps that can be used to help interpret passages and answer questions about those passages. In addition to the information contained in each of these sections, there are links to websites that address vocabulary development.

Another submenu deals with writing. There are three major areas represented on this menu: sentence correction; writing essays; and links to web sites that can be used to help improve writing skills. The sentence correction menu provides information about parts of speech, mechanics, homonyms, and sentence structure. The section on writing essays gives a basic procedure for writing an essay. The links to web sites include sites that explore and teach about a variety of writing related information such as, grammar and graphic organizers.

The last section of the resource deals with the areas of mathematics that are addressed on the PRAXIS I. The areas covered through information and links are whole numbers, exponents and square roots, order of operations, decimals, fractions, number theory, ratio and proportion, percents, probability, statistics, logic, permutations, scientific notation, equations, geometry, coordinate grids, formulas, graphs, and problem solving.

This study resource is not meant to initially teach or tutor students. The function is to provide an organized resource that students can access and use to review areas where they are experiencing difficulty. Students at North Carolina A & T State University are given practice tests and the areas of the test where they show weakness are identified. It is hoped that the study resource will help students review their weak areas and be better prepared to take the exam.
Improving Experiment Project Evaluation through Web-based Self- and Peer Assessment

Yao-Ting Sung  Chen-Shan Lin
Department of Educational Psychology and Counseling
National Taiwan Normal University, Taiwan
sungtc@cc.ntnu.edu.tw
Chee-Lung Lee  Kuo-En Chang
Department of Information and Computer Education
National Taiwan Normal University, Taiwan

Abstract: This study attempts to incorporate the Web technology into the self- and peer assessment procedure, and then to make it a part of the instruction activity. The results of this study indicate that the Web-based self- and peer assessing activities could be successfully incorporated into classroom instruction of experiential psychology. Moreover, the discussion among peers over their opinions and feelings about the observation and assessment results helps consensus-building among participants in evaluation and improves the objectiveness of their assessment.

Introduction

The study on learning in the last decade can be generally described as being dominated by the situative/interactive perspective (McCaslin & Hickey, 2001; Greeno, Collins & Resnick, 1996). The situative/interactive view of learning has not only created major impact on curriculum design and teaching methods in recent years (Palinscar, 1998), it has also greatly promoted the reform of learning assessment (Cizek, 1997; Gipps, 1999; Shepard, 2000). To sum up the opinions of the scholars advocating this new culture of learning, they share some common views on the new learning assessment: 1. Students should actively participate in the process of assessment. 2. The assessment should reflect the process and results of learning at the same time. 3. Assessment should be effectively combined with instruction. 4. The subject of evaluation should be extended from the cognitive aspect to cover the student's social interaction and practical participation in the community. 5. Increased attention to evaluation for high level thinking and complex operations.

In recent years, some classroom evaluation methods that conformed to the new expectations for instructional assessment began to emerge. For example, self- and peer assessments are enjoying growing prestige. From the perspective of learning, these two evaluation methods are not only special in letting students actively participate in the evaluation. They also allow the students to reflect on the amount of their effort invested in the process by observing their own products, and to decide whether the standards they set are appropriate. This can be very beneficial for the students' self-monitoring and adjustment. Furthermore, self- and peer assessment can be combined with performance assessment and portfolio assessment. The combination may generate even better evaluation effects (Paris & Paris, 2001). Because they have those evaluative characteristics that conform to the new learning culture, quite a number of scholars have advocated the adoption of these methods as one of the effective methods of class evaluation (Boud, 1995; Falchikov & Goldfinch, 2000; Shepard, 2000).

The first objective of this study is to explore whether there is a decrease of over-marking or under-marking in self assessment results under the situation where self assessment and peer assessment are integrated. The second objective of this study is to explore the observation among group members on the scoring results and the discussion process. Is it possible to make the scoring behavior of team members more consistent, thus improving the inter-rater reliability? And is it possible to make the evaluation standards more consistent with those of the experts, thus decreasing the over-marking and under-marking in self- and peer assessment and improving the correctness of the results? As evaluation activities, self- and peer assessments are also fit to be embedded in the instruction activities as part of the instruction. The third objective of this study is to attempt to design self- and peer assessment activities based on the World Wide Web environment that are more suited for application in the instruction situation as the extension of class instruction activities. Meanwhile, we try to observe through computer records the changes in the evaluation behavior of self- and peer assessment under peer interaction.

Method

Participants: the participants in this study are 34 sophomore students in the Experimental Psychology class.

Tools/materials:

Web-based Self- and Peer Assessment System: the tool used in this study is Web-based Self- and Peer Assessment System (Web-SPA), developed by the researchers. The system contains several modules: setting evaluation standards, observation of products, observation of evaluation results, discussion, self assessing, and peer assessing and is capable of synchronous and asynchronous assessment on the Web.

Evaluation scales for the experiment projects: Eight Likert five-point scales for evaluating the quality of experiment plans. The contents of the eight scales are the evaluation of the following aspects of the plan: theoretical basis, criticalness, innovativeness, logical coherence of thinking, and appropriate hypothesis verification method.

Experiment project: the five teams chose their own topic for the five projects before writing them down. The projects must contain the following elements: motives and objectives, literature review, research hypothesis and research method.

Procedure: In the first week of experiment evaluation, the groups uploaded their products to an assigned Website and made self-assessment according to the eight scales in class. After that, the participants may go online to conduct observation and peer
assessment at the time of their choosing. Self-assessment can also be revised as the peer assessment proceeds. The participants may leave messages in the guest book on the Website. In the 110-minute class lecturing session in the second week, the following activities were performed in five stages: (1) reenacting the observation, peer assessment and self assessment activities. (2) the system compiled the results of the scores given to the groups by their own members, and showed them to the group members along with rankings and comments. Discussions were conducted within the groups, and re-scoring was allowed after the discussion. (3) The system compiled the scores and ranking of the groups by other groups, and the total ranking was made according to the scoring of the whole class. The participants were asked to conduct discussion on the merits and flaws of the works by their own group and those by other groups, the basis on which they scored (ranked) the groups as well as their degree of satisfaction with how other groups scored (ranked) the works by their group and other groups. (4) Each group then sends a representative to present oral report and defense of 5 to 8 minutes about the conclusions reached in the discussion in stage (3). (5) The teacher made comments for about ten minutes.

Results

This study collects the results of the self assessment before observing the projects of others, the first self- and peer assessment after the observation and before peer interaction, and the results of the last self- and peer assessment after peer interaction (reading the scoring results within and among groups and discussing the results). The average scores of each group (Table 1) are calculated by summing the scores in the eight five-point scales of group members (the scales 3, 6, and 8 are reverse marking), and then divided by scale number and the number of members in each group. Numbers closer to 1 means low score, and numbers closer to 5 means high score.

This study calculates the Kendall's coefficient of concordance (W) of the last assessment results by group members before the observation/discussion and the last assessment results after the observation/discussion (Table 2). The outcome shows that the Kendall's coefficient of concordance increases in all five groups when the materials for assessment include their own products. In groups 4 and 5, the results change from lack of significant consistency to significantly consistent (W changed from .342 and .101 to .491 and .355, respectively). When the rating data from one's own group are deleted from the assessment material, calculation is only done on the data of peer assessment. The results show that except for group 1, whose coefficient of concordance lowers slightly, all four other groups show the trend of increase. Groups 3 and 4 changed from lack of significant consistency to significantly consistent (W changed from .336 and .303 to .428 and .445, respectively). The results above indicate that through the sharing and discussion of assessment results with each other, the participants indeed managed to build better consensus about the substance of the products and gain better understanding of each other's viewpoint. As a consequence, the consistency of scoring behavior is improved. It is certain that the process of sharing and discussion helps improve the consensus-building among group members, but would this kind of consensus lead to even more inflated (over-marked) or self-deprecating (under-marked) scoring, thus deviates from the expert scoring even more? Or would it make the results clearer and more correct, bringing them closer to the expert results? To clarify this problem, this study makes a comparison of the expert rating with the assessment data before the discussion and after the discussion. The Spearman's ? were calculated (Table 3). The result shows that except for groups 1 and 3, the Spearman's ? of the expert data and the data of all three other groups shows inclination of increase. Groups 2 and 4 changed from the opposite direction of the experts (? is -.20 and -.70 respectively) to the direction consistent with the experts (? is .80 and .30 respectively). The reason why the Spearman's ? for group 1 changed from positive value to negative is that the group started with a view quite consistent with the experts' before the discussion, but dramatically elevated the ranking of their group product to number one after the discussion. The excessive deviation from the expert assessment data changed the Spearman's ? from positive to negative value. We can see from the information above that the sharing of opinions about assessment and products through peer interaction not only helps to build the consensus among group members regarding the rating of products, it also helps to improve the correctness of their assessment to a certain degree, thus improving the criteria-relevant validity.

From the process of group discussion and concluding report, one can observe a participant's view of his own product, his criticism of the products of others, his response to other people's criticism in defending the substance and value of his product, and his decision-making process of whether to revise his ratings after reading the rating results of his own and other people's works. The discourse data help to give a clearer insight of the influence of peer interaction on self assessment and peer assessment.

This study finds that in the process of self- and peer assessment, the students can indeed have more direct application and discussion about the evaluations standards for experiment projects they have learned. They have more reflection and reexamination of their own products and other people's products. They have more direct feelings and response for the comments of others. This study also shows that using the World Wide Web to be a potential device for classroom instruction, the data of self- and peer assessment—such as the materials for evaluation (experiment projects) and the results of assessment—can be recorded and shared through the mechanisms of Web-based systems. Therefore, they can be conveniently used in real classroom instruction situations, making the combination of evaluation activities and instruction more feasible.

A Comparison of Two Types of Electronic Communication in an Undergraduate Teacher Education Course.

Melissa A Thomeczek
School of Education
Indiana State University
csthome@isugw.indstate.edu

Abstract: In education, teachers face the dilemma of increasing job requirements and decreasing time available to students. This leaves faculty with a dilemma of how to be available to their students for questions and concerns as well as how to provide feedback to their students in a timely manner. This research study looks at the use of two different electronic discussion forums in an undergraduate teacher education course. The amount of student use and student attitude toward the two different types of communication are examined.

Purpose

The goal of this research study was to better understand the role computer-mediated communication (CMC) plays in the classroom. Two common types of CMC were selected for comparison. The first is communication through an organized email discussion group (often called a listserv), and the second is online discussion utilizing a web-based discussion group. This study examined if differences exist between email-based and web-based discussion groups as determined by: (1) total number of messages posted and (2) user attitude.

Introduction

Electronic communication may benefit the learner beyond traditional classroom communication. In a traditional classroom, when class time has ended, discussion ceases. However, with electronic communication, the conversation can continue. The instructor can pose questions or make comments on the discussion to further provoke the student's thought processes. CMC can also be used to increase participation. Zahn et. al. (1999) supported the use of electronic communication, stating that the engaging nature of computer technology enhances communication. Further support of electronic communication is offered by Garner and Gillingham (1999) who followed a high school literature teacher in California. The teacher encouraged his students to use the Internet to tell stories about themselves to age-mates in geographically dispersed classrooms. As one might expect, the "A" students were highly productive, but more importantly, the authors found that six of the students in the most productive group were labeled "at-risk". These students were failing, in danger of failing, disengaged in the classroom, or did not complete written assignments. This finding lends strong support to the idea that electronic communication can not only be used to communicate, but that it might also enhance communication by including those students who would not participate in traditional settings.

While research supports the learning benefit of CMC, a more practical consideration of using CMC is time constraint. With the increasing amount of content being placed on faculty and teacher education students (Handler & Strudler, 1997, ISTE, 2000, NCATE, 1999) the amount of material that needs to be covered cannot always be addressed in the available class time. The use of CMC in conjunction with a traditional classroom setting allows an instructor to introduce a subject or an idea briefly and then discuss the topic in detail outside of class time. Additionally, the instructor can provide guest speakers in an online discussion, which allows students to have access to experts in the field that may allow further student development. Students who utilize a type of CMC in conjunction with an education course are generally satisfied with the results (Johnson & Huff, 2000). Johnson and Huff also reported overall student satisfaction with the discussion group used in their study. The authors found that the use of the discussion group allowed the instructors a means to exchange information with the students and thereby preserve class time for instruction. As a result, the authors strongly recommended CMC as a tool for communication.
Methods

Thirty students from the Elementary and Early Childhood Education (ELED) 259 class at Indiana State University served as participants for the study. This class was selected due to the already existing requirement of electronic communication within the course and the willingness of the professor to involve her students in this research project. As a requirement of the class, students participated in both forms of communication. Students were required to participate in the electronic communication as a part of their course grade, but were given the option of not participating in the survey. Students were randomly assigned into two groups. One group communicated using the email discussion list for six weeks followed by web-based discussion board for six weeks while the second group did the reverse. Following each six-week segment, students completed the Messaging System Survey developed for this study. This survey contained 19 questions regarding user attitude toward CMC. Items were set up in a forced choice Likert-type rating system. The survey also contained demographic questions. Data was analyzed using a repeated measures t-test.

Findings

Results indicate that, when using an email based CMC (M=3.18, SD=.36), students had a significantly more positive attitude about CMC than when they were using a web based CMC (M=2.57, SD=.29), t(29)=7.16, p<.001. Results further indicate that students will post a significantly greater number of messages when using an email based CMC (M=3.61, SD=2.84) than when using a web-based CMC (M=1.03, SD=.87).

Conclusions

Based on the survey questions, it is clear that students found the email-based discussion to be more convenient, more organized, less time consuming, easier to sort through unwanted mail, and easier to read, respond to, and post messages. Students also indicated on the survey that they were more comfortable using the email based discussion forum. From this study, it is clear that a distinct difference exists between using email-based and web-based CMC. Students definitely have a preference when it comes to CMC and that preference results in more posted messages and a more positive attitude toward CMC. While there was a significant difference between the standard deviation of email-based and web-based CMC, with regard to number of messages posted, a repeated measures t-test is robust to violations of the assumptions when there is a large N.

The research has been unclear regarding if one method of communication is more beneficial than another and if a difference exists, what the contributing factors might be. Clearly, this study has identified that the functional differences between various types of communication, such as method of grouping messages or method of accessing messages, can cause preference of one type of CMC over another.

The Collaboratory in Your Program

Bonnie Thurber, Northwestern University, US
Bob Davis, Northwestern University, US

Abstract:
Learn how to participate in the Collaboratory, a web-based environment educators use to build Internet collaborations, create and engaged learning projects, and communicate. Session participants will also view student contributions to the Collaboratory. Practitioners and future teachers use the Collaboratory to create collaborative classroom projects online.

The Collaboratory Project, http://collaboratory.nunet.net, is a Northwestern University initiative that provides consulting, training, technical support, and information services to K-12 teachers and their students who are interested in using Internet technologies to advance education.

The Collaboratory is an easy-to-use web-based collaborative environment that enables teachers to develop innovative curricular projects in a framework for engaged learning that is activity-based, linked to Illinois Learning Standards, and provides for assessment. It provides a supportive and secure environment that teachers use to meet their specific curricular needs. By removing technical barriers to accomplishing objectives and delivering services, the Collaboratory is making it possible for teachers to successfully carry out significant and meaningful educational activities.

Collaboratory Communication Services include messaging, conferencing, discussion forums, invitations, announcements, instant messaging, and calendars to support collaboration among teachers and students. Automatic alerts and notifications keep participants up-to-date about activities, new projects, and events. Search capabilities enable participants to easily find other people and projects.

Collaboratory Resources provide the scaffolding teachers use to develop innovative curricular projects. These resources include:

- THE CYBRARY, customized, curriculum-specific virtual libraries of Internet resources;
- MEDIASPACE, "electronic multimedia postcards" containing text, graphics, sound, and/or video are used to share projects and information;
- THE INTERNET BOOK CLUB, students share book reviews, compositions and poetry;
  - THE SURVEY STUDIO, online surveys, questionnaires, and data collection forms.

Prerequisite participant skills/knowledge required for Collaboratory participants include:

1. Participants must have Internet experience including using email and the internet/web.
2. Participants should have an Internet-connected computer access either in their classroom or sufficient access to their school's computer lab to support the project.

The Collaboratory in Your Classroom eCourse is a no cost online course for educators who want to use the Collaboratory to develop technology enriched, project based learning activities for their students that meet Illinois Learning Standards and Goals. Librarians, media specialists, and technology facilitators who are collaborating with classroom teachers attending the Collaboratory Online Class are encouraged to participate.

Examples of Teacher Created Projects in the Collaboratory

100 Ways to Count the Days (Grade K-2)
This project will provide first grade students with a variety of learning experiences related to counting to one hundred using traditional and technological resources to complete language arts and math activities.
A House Divided - The Election of 1860 (Grade 8)

Students will gather information and report on the presidential election of 1860 and its importance in American History. Their reports may be presented in many different mediums.

Air Quality Chicago (Grade 6-8)

You will investigate the history of environmental laws from 1938 to the present that pertain to air quality and propose new city/state legislation in hopes of curbing air pollution.

Costa Rica through "El Ojo de Agua" (Grade 9-12)

After having read the book "El Ojo de Agua" in class, the Spanish level III students of Warren Township High School will investigate and report on various cultural and geographical aspects of Costa Rica.

Creating A Butterfly Garden (Grade 3-5)

Students will research the butterflies of the Chicagoland region and find out what plants and other needs a garden would require to support a butterfly of their choosing.

Dinosaurs Part 1: Discovering (Grade K-2)

Imagine discovering the bones of a dinosaur that lived millions of years ago! You probably won't make that kind of discovery, but there are other ways of discovering wonderful things.

Kid-made Toys from Around the World (Grade K-6)

Join us as we celebrate children's creativity through the toys they make all over the world! In this project, students will research, recycle, design, and explain a new toy.

Shape Up Third Grade Geometry (Grade 2-4)

Students will identify and describe plane and solid shapes by their attributes (number of sides, number of edges, corners/vertices).

Steps to Success (Creating Great Science Fair Projects) (Grade 7-8)

This project enables 7th-8th grade students at Jordan Community and Norwood Park Schools to create meaningful science fair projects.

Strike for Bread and Roses - Lawrence Textile Strike of 1912 (Grade 8)

Students will use the story "Strike for Three Loaves" to enhance the study of U.S. Labor History of the early 20th Century. The story involves the issues of labor unions, immigration, child labor, and strikes.

The Rise and Fall of the Aztec Empire (Grade 4-5)

Our 5th-grade students will research the Aztec Empire and create hands-on materials that depict the culture, history, economy and present-day aspects of the Aztec way of life.

Thermodynamics and Heat (Grade 7-12)

Students working in groups of two or three students, third student must me a member of another class, students will explore the concepts associated with heat. Topics to be included in this exploration are, gas laws, specific heat, calorimetry, heat transfer and, the laws of thermodynamics.

WTHS Roadkill Study (Grade 7-12)

The Warren Township High School Roadkill Project involves the monitoring by 11th and 12th grade Environmental Science students of a one mile stretch of roadway for roadkills during several two week periods throughout the school year. Monitoring sessions will occur in the Fall, Winter, and Spring.
More specifics about several projects include:

- **Shape Up with Third Grade Geometry (3rd grade)**
  In the Shape Up with Third Grade Geometry project, teachers and students use the Cybrary to provide web-based math resources for students and teachers. Students learn about geometric shapes by looking at images other students have selected. They identify geometric shapes on their school playground, at the local zoo, and in the nearby community. They post their information about shapes in MediaSpace, a place where participants share information through images, text, sounds, and short movies.

- **Immigration Studies and Oral History**
  In the Immigration Studies and Oral History fourth grade students from around the USA learn about each other by interviewing family members and using real-time conferencing and messaging to exchange information about each other. They use a discussion forum to develop group poetry. Students use the Survey Studio to create surveys for collecting family facts and information about social happenings so they can better understand the cultures and customs of their ancestors. They use The Cybrary that their teachers created for Web research. As part of a culminating project, fourth graders recreate or create family shields and do presentations about what the art in the shields represents. The artwork is posted in the MediaSpace, a community for the sharing of information electronically.

- **Creating a Butterfly Garden**
  The Creating a Butterfly Garden project is designed to teach students about using the Internet, conducting research on the Internet, posting information on the Internet, and working in teams while planning a garden to attract local butterflies. They study these butterflies and post information about them on the Collaboratory to share with their peers. This shared information is in the form of poetry, short stories, pictures, text, sounds, and short movies.

**Prerequisite participant skills/knowledge required for Collaboratory participants include:**

3. Participants must have Internet experience including using email and the internet/web.
4. Participants should have an Internet-connected computer access either in their classroom or sufficient access to their school’s computer lab to support the project.

**About the lead presenter:**
Bonnie Thurber has worked for The Collaboratory Project, Northwestern University for the past four years. At the Collaboratory she develops programs, facilitates workshops and presents sessions about using the Collaboratory to collaborate and integrate Internet technologies in to the Classroom to educators.

Collaboratory eCourses have been facilitated Winter 2001, Summer 2001, Fall 2001, and Winter 2002. Recent Collaboratory workshops and presentations include:

Presentation at Chicago Learning Technology Center’s TLCF Grant Recipient Workshop, Fall 2001. Chicago, IL.

Presentation at World Conference for Computers in Education, Summer 2001. Copenhagen, DK.

The Collaboratory Project Networking Session for eCourse Participants, Northwestern University, Summer 2001. Northwestern University, Evanston, IL.

The Collaboratory Project’s Symposium, Spring 2001. Northwestern University, Evanston, IL.

The Collaboratory Project Networking Day for eCourse Participants, Northwestern University, Winter 2001. Northwestern University, Evanston, IL.
We are bringing the world to the classroom and the classroom to the world with the aid of computer networks, hardware and software. Educational telecommunications systems include one-way and interactive television, one-way and interactive video teleconferencing, computer-based learning, and most recently, interactive web-based learning. Almost all the papers in this section address web-based learning that has caused the explosion in distance education across all grades and around the globe. There are many papers within this annual that could have been included herein but the authors determined that their focus was not on the technology but on what was being accomplished with it. See, for example, the papers in Distance Education.

In order to achieve our collective goal of improved teaching and learning with technology, we require reliable, cost-effective, and secure telecommunications systems and services with access for all. In this new century, we are realizing the dream of computer as pencil (Papert, 1980) or ubiquitous computing (Weiser & Brown, 1997). The hot topic in hardware is wireless networks and in software, learning management systems.

**Wireless Network Systems**

Wireless telecommunications systems are beginning to establish themselves as the system of choice in higher and lower education. From the network administrator perspective, wireless networks eliminate the costs of cabling and wiring existing buildings and make it possible to add new users instantly (Charp, 2002). From the user perspective, the computer becomes as portable and ubiquitous as the cell phone and the ballpoint pen.

At the university level, major investments in campus-wide, wireless networks have been made by Cornell (http://wnl.ece.cornell.edu/) Carnegie Mellon (http://www.cmu.edu/computing/wireless/), and Tulane (http://www.tulane.edu/~tis/new_site/wireless/wireless_home.shtml). At the K-12 level, wireless networks are cropping up everywhere. Proxim, a wireless technology provider, (http://www.proxim.com/products/enterprise/solutions/k-12.html) offers case studies of school systems that have implemented wireless systems. Some of these schools are Hayt School in Chicago, IL, Edison Elementary in Alameda, CA, Baltimore (MD) County Public Schools, Campbell Union High School District in San Jose, CA, and Camp Hill School District in Harrisburg, PA.

In January, 2002, The Maine Department of Education signed a four-year, $37.2 million contract with Apple to supply the technology, training, and support to Maine’s groundbreaking initiative that will equip all the State’s 7th and 8th grade students and teachers with one-to-one access to wireless notebook computers and the Internet. The contract is believed to be the largest single purchase ever of personal educational technology (http://www.state.me.us/mlt/newsrelease1_7_02.htm). Closer to home, one of my doctoral students, Bruce Curry, is working with the implementation of wireless systems at St. Paul’s Christian Academy in Nashville, TN (http://www.stpaulchristianacademy.org/ne/news/newsitem.asp?id=63).

**Learning Management Systems (LMSs)**

The need and desire to use telecommunications systems and services literally exploded. The number of schools and universities interested in getting aboard the Internet far exceeded the number of people able to create their own solutions. To accommodate the need, companies developed template programs into which teachers could upload their content and become distant educators. Some of the more popular providers are Blackboard (http://www.blackboard.com/), eCollege (http://ecollege.com/) and WebCT (http://webct.com). These systems are representatives of a class of software that provide learner tools and support tools. Some of the learner tools include web browsing, e-mail, bulletin boards, synchronous chat, white board and application sharing. Some of the support or teacher tools include course planning, managing and monitoring, presenting instruction and curriculum management. All providers work with higher and lower education.
Conclusion

Because ours is a conference of teacher educators, the papers in this section relate to applications of telecommunications systems and services. Each offers a unique perspective. If you are new to this area, read them all and investigate the links provided in this introduction.

Using the Web to Provide Parent Progress Reports on Standards for All Students: Developing the System

Kevin M. Anderson, Ed.D.
Interim Assistant Superintendent of Instruction
Kenosha Unified School District
United States
kevander@kusd.edu

Cindy L. Anderson, Ph.D.
National College of Education
National-Louis University
United States
clanderson@wi.rr.com

Abstract: Reporting for students and parents of progress on academic standards is becoming a necessity in most school districts. Kenosha Unified School District is developing a comprehensive program to provide this for parents of students in both general and special education. A pilot project to use digital video with this system is being developed with plans to integrate selected videos into teacher education as training tools for future educators. This presentation will demonstrate the Kenosha system being developed and its pilot project for pre-service teachers.

Background

This presentation shares the progress made by the Kenosha Unified School District in southeastern Wisconsin to translate learning standards from theory into practice and to assess and report student achievement using these standards. Backed by a School Board mandate stating that "by fall 2003 all teachers will report out using standards and benchmarks", the district has been making plans to convert from a traditional report card format using single grades per subject each marking period. Statements from some teachers, such as “Glad I’m retiring by 2003”, have made this a challenging process. Therefore, making informed, research-based decisions about daily assessment and methods of reporting student progress to parents will go a long way toward allaying the fears of teachers related to change in the traditional curricular process.

The Kenosha Unified School District began in 1995 to develop its own standards and benchmarks for academic content and lifelong learning in all grade levels PK-12. Teachers were actively involved throughout the entire process from development through Board adoption. Developed prior to the introduction of the Wisconsin State Standards, Kenosha’s standards and benchmarks are based on the standards recommendations of numerous state and national organizations. When the Wisconsin Standards were released, the Kenosha standards and benchmarks were carefully aligned to ensure coverage of essential elements on the state assessments in grades 4, 8 and 10. With the addition of the Wisconsin State High School Graduation Test (HSGT), the alignment of the standards was extended through grade 12.

Following the production of notebook-based curriculum guides, the Kenosha Schools Department of Instruction contracted with the Technology and Information Educations Services (TIES) group of Roseville, Minnesota, to develop and electronic curriculum notebook using the Filemaker Pro database. While the design of the electronic notebook is not completely finished, the potential of using such an electronic version of the curriculum guide is readily visible to teachers and administrators. Current plans call for producing both a web version of the notebook and a CD-ROM copy for use by teachers without web access at school or home. As they design their lessons and units using the standards and benchmarks, teachers will be able to quickly refer to activities, vocabulary words, exemplary units, web links, and suggestions for teaching about the particular skill.
Then, they will be able to “drag and drop” information from the database into a lesson plan template and create their own customized plans. In addition, the electronic notebook is intended to provide video and audio clips of actual teaching lessons as models for teachers to follow. When the database is finally ready for use on the web, parents and students will also be able to access the district’s standards at home to help with homework and to clarify class/course expectations.

Assessment and Reporting of Student Progress

A small group of middle school teachers began experimenting in 1999 with grading and reporting out to students and parents using a standards-based process. This pilot has now broadened to include all core academic subjects at the middle school level and to select elementary schools and high school departments. Teachers began piloting an electronic grade book for reporting on student success at the standards level during fall 2000. The district purchased Easy Grade Pro for all teachers in the district following a review of grading software. Previously some teachers had used software programs for grade reporting, but various limitations forced the district to look for a more complete reporting program. Easy Grade Pro met this need since it allows more fields for entry of data and a wider variety of options for innovative reporting. District teacher-consultants and classroom teachers have been testing the use of this grading program with the district’s standards and have found it to be very good for current needs. Parents have also expressed satisfaction with the types of information now available to them at report card conferences. However, teachers are still using these reports as supplements to the traditional report card.

During the 2000-01 school year, teacher-consultants began visiting schools to present the overview of the reporting process to all teachers. They utilized a computer slide show, “The Show”, to help teachers begin evaluating what is actually contained in the grades they award. Conversations have been sometimes heated as teachers redefine their philosophies of homework, late assignments, and what it means to reach a standard. Reliability and validity of grades have been discussed throughout the process to get teachers to talk with each other about common (and not so common!) grading practices in the district.

With this slowly growing shift in the thinking about grading, the Kenosha Schools have been working on developing a new grading policy that calls for a separation of the academic and non-academic grades. This shift in grading practice has drawn the most discussion at the district level due to the fact that teachers want to include “penalties” for late work that impact the final grade. The district is trying to move away from this practice so that the academic grade actually reflects what a student has learned and not how well he or she has pleased the instructor or met deadlines that may not appropriate for all students. In other words, the new reporting system is being developed to show what students know in relation to course standards rather than grades being given that don’t always relate to course content. This grading policy change is still in the works and may face several revisions before finally being adopted.

Because of the size of the district (21,000 students and over 1,700 teachers), the Department of Instruction has faced its biggest challenge in affecting widespread change at a rapid pace. In an effort to bring all teachers on board at the same time concerning developing standards-based grading practices, the district is devoting its single district-wide in-service day this year to practicing how to set up a standards-based grade book. Similar in-services will follow during the 2002-03 school year to make sure that all teachers are ready to begin using the reporting system in fall 2003. Since the current district-wide computer network has not yet been set up for full web access of grades by parents, students, and teachers, training is being conducted on how to report to parents on a more limited basis at regularly scheduled conferences. The district is currently reviewing web-based software options, but funding will need to be planned for at least three years into the future to accomplish a switch in reporting systems. Current estimates of the cost to switch to a web-enabled system are running between $500,000 and $1,000,000.

Reporting Progress for All Students

The Individuals with Disabilities in Education Act of 1997 requires schools to provide progress reports to parents in a similar fashion to those of students without disabilities. However, often the activities of students
with disabilities do not lend themselves to traditional evaluation methods. Standards-based reporting processes using electronic means enable teachers to vary their evaluation techniques depending on the needs of the students. Grade book software allows teachers to use multiple grading methods within the same class, while still maintaining the integrity of assessment.

The Kenosha Unified School District, in collaboration with National-Louis University, is undertaking a project to make such standards-based reporting a reality for all parents of the district. A pilot project is also underway to use the Internet to turn the district’s Individualized Education Plans into electronic portfolios for students with disabilities. These electronic portfolios will feature parental progress reports identified by the appropriate standard and linked to the appropriate activity from the regular classroom standards report. In an effort to better demonstrate the progress of some students, digital videos will be used in the portfolio as a method for making these reports more meaningful to parents. A CD-ROM format for parents who do not have access to the Internet is being planned, as well as short videotapes for families without access to a computer.

With parental permission, selected videos of assistive technology being used to meet standards will be integrated into the National-Louis teacher education program. These videos will be used in general education technology courses to meet the requirement of the International Society for Technology in Education (ISTE) for students to become acquainted with technology used by students with disabilities. These videos can also be used to meet new requirements in special education teacher education programs found in the new Common Core requirements that include knowledge of assistive technology.

Summary

This presentation will provide a demonstration of the standards-based reporting program that is being developed for regular and special education students in the Kenosha Schools. Included will be examples of the electronic curriculum notebook, grading software, and plans for developing web-based reporting. This presentation will also demonstrate an example of the pilot portfolios being developed for students with disabilities.

Introduction

With the introduction of open standards and communications over public networks, the need for automated tools for protecting information during transmission, as well as that stored on the computer, became evident. In an enterprise network, the idea that the security of the entire network is only as strong as its weakest part is termed the weakest-link axiom. Computer and network security can be defined as the protection of network-connected resources against unauthorized disclosure, modification, utilization, restriction, incapacitation, or destruction. The generic name of the collection of tools designed to protect stored data is computer security, while network security measures are needed to protect data during its transmission. Network security measures may be implemented at different layers of the OSI model. Security implies safety, including assurance of data integrity, freedom from unauthorized access, freedom from snooping or wiretapping, and freedom from disruption of service. This paper analyzes security threats, and outlines the development of appropriate security policy and measures.

Security Threats

Hundreds of thousands of systems are now connected to the Internet. There is no accurate way of measuring the threat that may be launched by an imimical agent. Security risks vary from uploading files with embedded malicious code onto a network to stealing information. Each time a company deploys a new Internet gateway, LAN, or distributed client/server system, it risks leaving another virtual window open for cyber-prowlers, disgruntled employees, or unethical competitors to work through. Security threats can be divided into two major categories: passive threats and active threats.

Passive threats involve monitoring the transmission data of an organization. The goal of the attacker is to obtain information that is being transmitted. These threats are difficult to detect because they do not involve alteration of the data so the emphasis in dealing with passive threats is on prevention rather than detection. Although they can be directed at communication resources (routers and lines), they generally perpetrate at the host level.

Active threats involve some modification of the data stream or the creation of a false stream. It is difficult to prevent active attacks because this would require physical protection of all communications facilities at all times. Instead, the goal is to detect active attacks, quickly recover from disruption or delays.
caused by the attacks, and possibly pursue legal action against the hackers, all of which have a deterrent effect and may contribute to prevention. These threats are most successful when directed to what could be the weakest link in the overall system, namely, at the host level.

Although the best solution for these threats is prevention, this goal is almost impossible to achieve. The next best approach is to do the following:

- Detect
- Purge
- Recover

**Security Policy**

Before an organization can enforce security, the organization must assess risks and develop an unambiguous policy regarding access to each element of information, the rules an individual must follow in disseminating information, and a statement of how the organization will react to violations. Establishing a security policy and educating employees is critical because humans are usually the most susceptible point in any security scheme.

**Security Measures**

Some of the basic security strategies that can be utilized to combat the threats include:

- Access control
- Encryption
- Authentication

The purpose of access control is to ensure that only authorized users have access to a particular system and/or specific resources, and modification of a particular portion of data is limited to authorized individuals and programs. The most effective way of securing the integrity of electronic data is by the use of encryption, which involves scrambling of data by use of a mathematical algorithm so that the scrambled information is undecipherable and meaningless. This can be done at various levels of the OSI model with software, hardware, or both.

Authentication methodologies include: one-way encryption to validate information transmitted, digital signatures that verify both the information sent and the sender, and digital certificates that are distributed by a Certification Authority (CA), to acknowledge the identity of the user.

**Firewall**

Firewall is a piece of hardware and software, a security device that allows limited access out of and into one’s network from the Internet. It operates at the application layer, or at the network and transport layers of the protocol stack. In essence, it partitions an enterprise network into two areas, informally referred to as the inside and outside. Firewalls are classified into three main categories:

1. Packet filters
2. Application-level gateways
3. Proxy servers

**Security Provisions in a VPN**

VPNs share similar features at varying degrees of sophistication, cost, and ease of implementation. The main components integral to VPNs are: encryption, authentication, and tunneling protocols, where each one provides a different way of ensuring privacy. Combined, they complement and strengthen each other, enhancing the integrity of the transmission and ensuring security. A VPN has three main components:

- Security gateways
- Security policy servers
- Certification Authorities (CAs)

**Summary**

The manager of a network configures the network, monitors its status, reacts to failures and overloads, and plans intelligently for future growth. Security is of vital concern among both users and network managers; it is indicative of a mindset that believes no system is completely unhackable. An ideal network management system is an intelligent self-learning system that learns what and where a problem can arise and tries to resolve it automatically; and at the same time alerts the network manager and calls attention to any special characteristics of the situation.
Abstract: The explosion of information via the World Wide Web has resulted in a large number of educational research related documents being easily available. Finding appropriate, quality materials has become difficult due to the volume of information available. This poster will review the advantages of online publications and provide suggestions as to how the educational research community can identify important works.

Tim Berners-Lee (2001) had a very simple objective when he developed a system for a global hypertext space at the European Particle Physics Laboratory. That objective was to enable the users to share a common information space. What is unclear is whether Berners-Lee had considered how unwieldy this space would become in such a short amount of time. Thus, while access is certainly much easier, the determination of what is worth accessing has become incredibly cumbersome.

Like the physical scientists at that laboratory, educational researchers are also interested in sharing important documents. (The use of documents is a bit of a misnomer since we are truly interested in information in any form, however, in the present state of educational research, the document, or paper, is the standard unit). Currently we share documents in an extremely cumbersome manner—via peer reviewed, hardcopy journals. The problems with this system of distribution are numerous (for a brief review see Glass, 1999) and the movement away from it towards a Web-based distribution system appears inevitable. As we move away, it is important that we recognize what the current system does well and attempt to retain those characteristics while also taking advantage of the new opportunities provided by electronic distribution. One thing that this system does well is to establish the important works in our field. What becomes considered an important work begins with acceptance into, of course, an important journal. Once in the important journal, it is read by the important scholars in the field represented by the journal. These scholars then refer to this important work in their subsequent articles. While on the surface this may seem a bit innocuous, it works quite well.

The key steps in the process outlined above include the peer-review and then the subsequent citation. As we move to the electronic distribution of our work, it is essential that we retain these characteristics in a meaningful, and possibly improved manner. The peer-review can easily be accomplished in a manner that is equivalent to, and possibly superior to, the way it has been done in the past. It may be improved because the distribution of review copies becomes much more efficient and thus more reviews are possible (Glass, 1999). The second component, the citations, can also be completed in a similar manner. It is this second component that, in the world of electronic publishing, can be taken to a much more sophisticated level. To explain why requires a brief digression into the world of Web search engines.

Most Web search engines depend upon matching terms provided by a user with terms found in the Web page (Sullivan, 2001). Simply matching the terms often results in a very large number of results. The search engine will then rank the results based upon some algorithm that looks at the frequency and location of the words in the Web page. The Web search company Google (www.google.com) has quickly become the leader in this field by using a very different, yet effective strategy based a system called PageRank™ (Google, 2001):

PageRank relies on the uniquely democratic nature of the web by using its vast link structure as an indicator of an individual page's value. In essence, Google interprets a link from page A to page B as a vote, by page A, for page B. But, Google looks at more than the sheer volume of votes, or links a page receives; it also analyzes the page that casts the vote. Votes cast by pages that are themselves "important" weigh more heavily and help to make other pages "important." (p. 1)

An interesting comparison can be made between the PageRank™ system and the identification of important works in educational research. The Social Sciences Citation Index (SSCI) is a highly valued resource that provides (albeit indirect) some measure of the importance and quality of an article by listing the number of times an article is referenced by other articles in important journals.

The purpose of this poster session will be to present a Web-based tool that can be used to perform a similar function for online publications relevant to educational technology research.

Abstract: This paper will address a series of issues, problems and solutions, and useful technique tips in designing, implementing, and maintaining a college Web site. The author of this paper is the Web manager and has worked on every single task through the entire development processes of this college Web site. Generally, developing a Web site is all about information and technology—using technology to organize and display information in an appropriate way to meet the purposes of the Web site. This paper will also present some useful strategies dealing with Web design, such as the structure of the site, function of navigation and orientation, the control of page loading speed, use of graphics, screen structures, file management, information collection/selection and administrative problems that a Web manager may be confronted with. These experiences and technique issues/solutions could be useful for those who design or maintain an educational institution Web site, and those who are teaching web design courses.

Introduction

When a student is to decide which university he/she will apply for to continue his education toward an advanced degree, he needs to search for the information of programs, course settings, or application requirements and procedures from different universities. When a new graduate is about to accept a job offer from a school or company, she would like to find out more details about his/her future working environment. When faculty members develop a new course or program, they might need to review what has been done in this field. To obtain the information, obviously, the Web is the first information resource they would choose. In this digital age, people depend more and more on the Web for information related to almost any aspects in their life. The question is to what extent the Web sites could provide valid information people need, which is one of the most important issues addressed to the Web developers. This paper will, from a Web manager and developer’s view, introduce the processes of redesigning an informative college Web site, and discuss a series of issues, problems and solutions, and useful technique tips in designing, implementing, and maintaining the site.

Purposes of the Site

The Web site introduced in this paper is the site of our College of Education. It had an old version that was developed years ago. The purposes of redesigning it were: First, we intended to use it to provide more information for students who want to apply for our programs, and for people who want to know more about our faculty, resources, technology facilities and so on. Second, we considered it an efficient way to show the mission/vision and the conceptual framework of the college, to show the strength of our programs, advantages of our resources. And the third purpose of redesigning the Web site was to establish a new and fresh image of the college for the NCATE evaluation, and to provide NCATE evaluators an easy path to find the information about the college (The Web site did play a useful and important role for our high scores in the NCATE evaluation).

According to these purposes, the development of the Web site, from the site structure to page/screen details, emphasized on two major principles: (1) valid and adequate information, and (2) clear and easy navigation, which are the basics to ensure an effective information resource.
Structure of the Site

After reviewed the purposes of the Web site, the next issue was to determine the structure of the information, and the structure of the Web. The structure of the information indicated the way to organize original information such as text files, data files, html files, graphic files, and other Web resources; this was an issue of file management. The information should be organized by category so that any future Web manager or current co-manager can easily find the files to edit or update. Therefore, the structure the information was redesigned in three fashions: (1) by administrative structure, that is, administrative divisions, departments, and centers; (2) by program, including all undergraduate, certificate, masters, the doctor programs; and (3) by faculty, including faculty contact information, courses taught, research areas, and publications. Figure 1 is an example of the file structure:

![File Structure of the Web Site](image)

Figure 1. File Structure of the Web Site

The structure of the Web was the way to navigate the information. The navigation should provide all possible paths to all information. One technique issue was how to merge the three structures smoothly into one site so that people could find information easily by departments, divisions, programs, courses, faculty, or other categories. Figure 2 shows an example of the Web structure, which is different from the file structure. Another technique issue was that during the redesign and restructuring process, we need to maintain certain consistence of the paths, file names, links from the old site, because they had been used for many external Web sites and quoted as references by instructors.

![Example of Web Structure](image)

Figure 2. Example of Web Structure

During the redesign of the Web site, the author found out some useful and practical Web design tips, some which as introduced in the next section could be used as the solutions to these two structure design issues.
Web Design Tips

Navigation and Orientation

In the design of site navigation and orientation, index page, navigation table, and site map were used. In the home page, buttons with links to different information categories were created – to administrative departments, programs, faculty and other categories. However, the links do not directly link to the specific page; they link to the second level pages – index pages. Index pages are the place where we put the links to specific pages that contain the information of the same category. For example, the “Departments” index page includes the links to the four departments in the college; from there, people can go to each department. The index pages should have the same style of screen designs. As in Figure 3, they have the same style of title design; people will easily see where they are.

Figure 3. Examples of Index Pages

Then a navigation table (Figure 4) containing links to all the index pages were included in all the major pages within this Web site, which makes the easy paths to anywhere within the site. Also, a site map that navigates through the entire site is necessary and always helpful; it provides not only the links to all the major pages, but also the structure of the site. Index pages, navigation table and site map are three useful methods to merge information of different categories into the site and make the navigation clear and easy.

Figure 4. Navigation Table

When redesigning the Web site based on certain information from an old site, to certain extent, the old structure still needed to keep. Some folder names, even file names were used as they were. In this way, the URLs to certain important pages did not change, and meanwhile, we added a lot of new information. The index pages were used to organize the site structure, but the file structure kept as less changes as possible from the old site.

Page Screen Design

In the page screen design, to arrange the texts, graphics, buttons, or any other objects to certain position, traditionally, people use frames to separate the page into several areas and hold different objects. For example, title frame at the top of the page, side menu frame on the left or right side of the page, and the main frame to hold the major text or graphic – the three frames are three files when you create the page. One disadvantage of
using frames is that, if the visitor wants to print out the page, he/she might just be able to print out the single
frame (the single file) where the mouse pointer is on. One method that could produce the same or even better
effects is to use table. We may create a table and set the boarder to zero, then set different colors as the
background of the major cells. In this way, the table cells separate the screen into several areas, and all areas are
still within one file. This will also make the file management work simple—one file for one page versus three or
more files for one page.

Currently, pages on the WWW contain the information of the institution name and address, contact person, date
of last updating and some other general information related to the site. Besides, one important thing is the URL
for the current page, especially when the page provides information for visitors to download or print out. They
need the URL as the reference resource for future use. Whether the page URL can be printed out automatically
at the bottom or top of the page depends on the default set up of the browser software (Netscape or Explorer) on
that particular computer. It may or may not automatically print out the URL. Therefore, when we complete one
page, the last thing is to put the URL of that page at the end.

Every page should also include contact information, which can be E-mail link or contact firm. If using contact
form, a clear path is needed to where the input information would be collected. The form input information
could be sent to either the email address of the Web manager or the relevant administrator, or a server database.

Use of Images

Almost all the Web sites have images, pictures, or graphic designs. One issue of using images is the file size.
One useful tip of using images and reducing image file size is that use one single image file instead of multiple
files. For example, when you need to use a set of pictures, you group them all into one file. The file size of this
grouped picture is much less than the sum of all single image file sizes. In Figure 5, the top picture is a grouped
picture file with five pictures, and its file size is 20.1KB; the picture below is a single picture, and its file size is
12.8KB. Obviously, if we use five separate single pictures, the sum of the five files’ sizes would be around
60KB. And, as we know, the smaller the file size, the faster it is loaded to the page.

![Figure 5. Image File Sizes](image)

Using image is a major factor that influences the speed of the site. Especially, when using JavaScripting to load
random images, display rotating images, or produce animations, the loading speed is very much slowed down.
Sometimes, people use these new skills to create fancy effect, which does not always fit the purpose of the Web
site. Therefore, images or special effects should be used only when necessary.

Another issue of putting images on the Web is the copyright issue; do we have the permission to use it?
Especially, when we use real person’s picture, or use the pictures found from the Web. Generally, we do not use
pictures copied from other Web site into our pages. And we need to obtain written permission from the person
to use his/her picture.

Download Option

If we have a document site, text based page, we may use hypertext to organize the sections, subtopics, or even
paragraphs. But, remember that people may want to have the entire document (e.g., the course notes, or
application requirements). Therefore, in a document site, we always provide a download option, or an option to print out the entire document in an easy and direct way, so that people do not have to print out them section by section, and if the site is non-linear hypertext, people may get lost in certain places.

To do this, first we create a link to the word file, and then upload the word file onto the Web. When people click on the link, the browser either launches the word processor for people to open and print the file, or provides an option to save the word file into the disk.

**Tricks of File Name and Folder Name**

There are some other technique tips that the author found useful and effective to enhance the quality of the site. When we work on the pages, one very basic step we may perform hundreds of times is to save the page file into certain folder, and FTP them to the Web. Sometimes, everything works perfectly on the local, but the links are dead after they are uploaded on the Web. One cause of this might be, very often, that when you create the files and folders, if you type the names in a upper-lower keys format, when they are FTPed to the Web, all the file names or folder names become all upper keys – that is, all capital. Sometimes, if the file name or folder name consists of more than one word with space between, after they are FTPed to the Web, the space usually is interpreted as 20%. For example, if we use a file name “project one”, it would be interpreted as “project20%one” after transferring to the Web. Therefore, the hyperlinks can never find the right folder and right file to link with. A simple way to avoid this is that we always use all-lower keys and one word for file names and folder names, with NO spaces in the names.

**Strategies of Duplicating a File or a Site**

There are several ways to duplicate a file such as “Save As”, or copy. Our experiences suggest two best ways to do this: (1) use Windows Explorer to copy the file, and (2) use FTP to download it directly from the Web. The worst way is to use “Save As” (open a file and then save it as a new file in another folder) – this is very likely to change all original link paths on that page to local paths such as C:\foldername\..., when the link paths are uploaded to the Web, again, the hyperlinks can never find the right folders or right files to link with. Because there is NO such a path C:\ foldername\... on the Web.

**Information Collection and Administrative Roles**

The above sections introduced some very practical technique skills to create a Web site as an effective information resource. However, developing a Web site is about “information + technology” and the hard part is the information collection. A Web manager may not have the power to obtain any information effectively from the departments or faculty members. According to the author’s experience, one efficient strategy is to work with the Dean and department chairs, and get all faculty involved. For example, when the author was working on the faculty pages that reflect faculty members’ accomplishments, most faculty were very supportive and provided information for their short vita page.

**Maintaining and Updating Work**

After the Web site was published, the work of maintaining and updating the pages was an every-day work. A plan of updating the pages was developed and implemented for the academic year 2000-2001. Basically, the updating work was cooperated with program directors, administrative managers, and individual faculty members. Program information was updated by semester, and individual faculty page by academic year. Also, individuals were responsible for maintaining and updating the information linked from their pages.

This Web site http://www.towson.edu also was used as an example to demonstrate certain basic Web development skills to a “Web Based Instruction” course taught by the author. It is the author’s hope that these experiences and technique issues/solutions could be useful for those who design or maintain an educational institution Web site, and those who are teaching web design courses.
PhoneChannel: Bridging the Digital Divide with Ubiquitous Technologies

rossj@iaete.org

Abstract: The Institute for the Advancement of Emerging Technologies in Education (IAETE), in cooperation with AT&T Labs, completed a pilot study in Calloway County, Kentucky, to explore the use of ubiquitous technologies (i.e., telephones and televisions) to increase teacher-parent communication. PhoneChannel enables teachers to push visual information from a computer to a family’s home television. Concurrently, the teacher and parent talk by telephone about the items displayed on the screen. This allows the teacher to communicate with underserved families who do not have access to a computer. The pilot study confirmed an increase in communication between school and home, and this unique application has breathed life into two common technologies now poised to become more powerful tools in education.

Many teachers have access to computers that can be used to communicate with parents, but parents without home computers cannot benefit. The Institute for the Advancement of Emerging Technologies in Education (IAETE) and AT&T Labs are using PhoneChannel to explore the use of ubiquitous technologies (i.e., telephones and televisions) to increase teacher-parent communication.

PhoneChannel is a new communication service that allows a teacher with Internet access to display visuals on a family’s television while talking by telephone. For example, a teacher could call a parent, ask him or her to tune to channel 77 on the household television, and display a student’s schedule, projects, or homework. The telephone provides a way to convey socio-emotional information in real time, thereby allowing attunements to establish trust. The television enables the sharing of visual information to establish common ground and increases trust by reducing uncertainty related to task-oriented information.

Originally studied in e-commerce environments (i.e., real estate and catalog shopping), PhoneChannel was recently pilot studied in a school setting. Calloway County, Kentucky, is a large, rural county in the southwest part of the state that has identified increased parental communication as a goal for improvement. Student households are widely distributed across the county, and distance is a significant barrier to successfully engaging parents in school meetings and conferences. In addition, 43 percent of students (10 percent more than the national average) live in a single parent household where involvement is typically minimal.

The pilot study utilized a teacher at each of two elementary schools, one of which is designated Title I. Each teacher used the PhoneChannel application to augment school-to-home communication while maintaining more traditional means, such as written notes, phone calls, and face-to-face meetings. The teachers recorded their school-to-home communications by type and frequency and rated perceived quality and effect.

Several factors encouraged the successful deployment of the PhoneChannel application in Calloway County. Preliminary surveys of target classrooms indicated that all student households had at least one television and all but one had telephone access. All classrooms in the two schools had telephone access, and teachers used computers in their classrooms on a daily basis for instruction, lesson preparation, student management, or communication. The PhoneChannel application required minimal new technology competencies beyond teachers’ existing skills. Also beneficial was Calloway County’s use of student portfolios, easily shared via PhoneChannel.
The Calloway County pilot was a key step in the evolution of a large-scale study in an educational setting. Moving the application from the laboratory to the field, it was important to negotiate and adapt to the realities of delivering secure information over a cable television infrastructure. The realities of cost models and proprietary system protocols were compounded through the need to transmit the PhoneChannel signal over two different cable companies. Representatives from Charter Communications and MediaComm in Calloway County worked with the researchers and developers to establish a working solution to transmit information originating outside the cable network to subscriber homes. Future delivery of PhoneChannel will owe a great deal to this pilot study, regardless of whether it is transmitted via cable television, broadband cable modems, the Internet, or satellite.

The pilot also helped to establish some user perspectives on the types of communication that are effective when using the PhoneChannel application. School personnel reported that if the Internet connection was reliable, the system was very easy to use. In fact, one school technology coordinator who was going to offer technical support during a session discovered that the teacher and parent were already using the system when she arrived. School personnel generally agreed that teachers could run the system on their own and could even use it from home computers.

While the original intent of the educational application was to share artifacts from an electronic portfolio, school personnel involved in the pilot offered several common school-related activities (e.g., discussing assignments, demonstrating progress, delivering reports, sharing discipline referrals, etc.) that could benefit from delivery via PhoneChannel. The District Technology Coordinator named three student populations in which PhoneChannel could make the greatest impact: night class, alternative school, and homebound. In the case of homebound students, teachers work one-on-one and spend much of their time on the road between homes. PhoneChannel could eliminate much of this travel time, which could be spent on instruction.

The greatest difficulty in terms of implementing the system was finding time to accommodate the call. While the physical system worked well, parents simply are not home during the school day when teachers are working, and the existing structure of the school day does not compensate teachers for working outside school hours. Several solutions were provided, including trying to schedule PhoneChannel conferences during teacher planning times, installing the system on teacher home computers or school laptops, and investigating novel scheduling practices. Some schools schedule half-day or part-day parent conference days, which still occur while parents are not commonly at home. In order to contact parents not available during that time, schools could consider giving teachers release time and teachers could log comparable time on the system at night. All use would be logged by the server and would be very easy to corroborate actual time spent.

During the trial, one feature of the system was discovered that had not been discussed earlier. Documents that were pushed to a home were stored in an archive. Home users could view these documents from their television at any time, regardless of whether they were involved in a session. The archive was accessible using the remote control from the set top box. This archive generated further suggestions for solving the difficulty of scheduling. Teachers could push items to the student archive during their planning period and discuss the items at a later time when the parents were home. Another option, parents could view the archived documents at night and discuss the documents with the teachers during the day by telephone only during a prearranged call, such as during the teacher's planning period. Use of the archive feature holds great potential for increasing the effectiveness of the PhoneChannel system and merits further investigation.

While the pilot study relied on cable dissemination, a variety of delivery modes are possible in subsequent applications—including wireless transmission. PhoneChannel also has opened the door to a variety of education-related activities that are not limited solely to traditional classroom support. Based on this preliminary study, it appears that service providers could use PhoneChannel to support adult and family literacy programs, ESL programs, distance-based and distributed learning and training, and services for disabled and underserved users. This unique application has breathed life into two common technologies now poised to become more powerful tools in education.
The Place of Internet-based Architectures in Supporting the Professional Practice of Teaching

Abstract  
This paper describes the varied technologies and on-line architectures that serve to meet the needs of practicing classroom teachers and the ways in which they can meet those needs. The focus of the research is on teacher professional development and online technologies. The symbiosis between education reform and the integration of technology into learning is profound: technology requires the rich learning environments envisioned by reformers; reform demands the power of technology to put people at the centre of their own learning. (Serim, 1996, p.1) Having established that there is value in community development and its potential for ongoing professional support, it is important to examine the circumstances under which the community of practice could effectively go on-line. It is equally necessary to review all the Internet-based architectures and the strength of each in supporting classroom practice. This review and analysis of architectures will help to refine the concept of ‘on-line community’ and to shape and place value on all the current Internet architectures.

Supporting Classroom Practice  
In-service teacher needs in relation to ICT can be summarised into relation to three main issues:  
- Hardware and connectivity - support and maintenance  
- Professional development - recognition and accreditation  
- Equity of access to quality resources  
As hardware and high speed connectivity becomes more readily available in classrooms, educators need to focus on the issues of support, ongoing professional development, recognition of ICT skills and leadership, accreditation for high level skill development, access to high quality resources and equity delivery formats and languages.

The National Foundation for the Improvement of Education report Teachers Take Charge of Their Learning (NFIE, 1996, p.1) asserts that; “to improve student achievement, public schools must weave continuous learning for teachers into the fabric of the teaching job. This work can and should be initiated by the teaching profession itself in partnership with other educators, communities, districts, and states”. There is an imperative for new professional development strategies and for teachers themselves to take control of their personal professional development. For the past ten years it has been recognised that a ‘culture of collegiality’ is required. This can be achieved through an environment where teachers teach teachers in a supportive network of practice. (Little, 1993; Lieberman & Miller, 1991; Warren & Roseberry, 1992). There are no simple remedies, but it does seem understood that communication and collaboration are two of the keys.
Current Internet Architectures

It is important to clearly determine what are on-line communities, as Brown (1999, p.1) cautions “Community is quite possibly the most over-used word in the Net industry. True community – the ability to connect with people who have similar interests – may well be the key to the digital world, but the term has been diluted and debased to describe even the most tenuous connections, the most minimal activity”.

Terms like portal, hub, network and interest group are all used interchangeably with the term community to describe involvement with Web site. These structures or architectures are arguably distinctly different in what value they offer for on-line users. Kanfer et al (1997, p.1) offer a useful distinction between the ways that humans access information and support. Traditionally, there are two different sources from which human beings access information: broadcast or mass media, and interpersonal communications. Building on Kanfer’s distinctions we can map current Internet architectures (Stuckey et al, 2001) and the levels and directions of possible interactions within those architectures. Table 1 maps these architectures and possible interactions against Kanfer’s high-level divisions. All implementations of web architectures can be described as primarily broadcast or interpersonal.

<table>

</tbody>
</table>

Table 1: Mapping Internet Architectures against broadcast and interpersonal delivery models

In order to build a deeper picture of the information contained in the map presented in Table 1, we need to examine in some detail each of these web architectures to define and distinguish each, to explore examples of each and to propose how each can meet the needs of professional teaching practice.

Web Site

A Web site can be defined as a compilation of pages created in programming codes such as HTML, DHTML, XML and ASP produced for display on the World Wide Web. The purpose of a web site is largely informational, promotional and/or marketing. The content can be static or dynamically delivered from a database and offer search options. There is usually neither membership nor access to others interested in this topic. Users who visit the site are usually passive consumers. Data might be trapped about users through cookies and visitor’s books but this is data known only to the site developers. For the owner’s success of the web site might be judged by hits on the site or contacts made with the developers or the visitor’s book. Examples are too numerous to outline but we offer a few popular educational exemplars, which deliver varied media and technologies within the site architecture and are working towards accessible design.

- NASA [http://www.nasa.gov](http://www.nasa.gov)
- Sydney Opera House [http://www.sydneyoperahouse.com](http://www.sydneyoperahouse.com)

Portal

The Oxford Dictionary describes a portal to be a doorway or gate. An Internet portal is a gateway to an aggregation of approved, categorized and/or indexed content, resources and services. The purpose of a portal is to become the first port of call for broadcast of content for users within a topic or domain. The site is often database-driven with some level of automated updating and the design may allow for customisation of the interface or records. The most effective portals offer some level of review and approval of the sites and resources that access if given to. It is this filtration, distillation and annotation of the Internet resources that gives true value to the portal for teachers. The site may offer membership or registration but users will have little or no access to other members. The users are still consumers but may
be able to contribute sites and resources for review. Success for the owners of the portal is measured in numbers of hits on the home page. Examples are resource libraries, link sites, media databases, search engines and intranets (HR). Consider these sites:

- PT3 Digital Equity Portal http://www.digital-equity.org/portal.cgi/
- Texas Public Education Portal http://ritter.tea.state.tx.us/
- Science Education Gateway http://cse.ssl.berkeley.edu/SEGway/
- Education Network of Ontario http://www.enoreo.on.ca/

Network

A network can be defined as people connected by exchange of information. It is useful to also note the television metaphor as a group of broadcasting stations connected for simultaneous broadcast of a programme. The network is largely still a broadcast mode of delivery of content and services delivered from one to many or in one direction. A network may involve database delivery of content through a portal and some leader to member communication. Members will be unable to establish communication with other individual members of the network. Content is administrator controlled and users may contribute through moderated technologies. Success may be measured in numbers of members and hits on areas of the site. Only weak ties may be established while members remain largely anonymous in many on-line networks. For the members the involvement is individualistic and will be a general interest or 'keeping up-to-date' focus. Examples of networks include web and portal sites with added and varied technologies such as listservs, newsletters, discussion boards, forms for limited data collection or member contribution to the site. Consider these sites:

- Learning Network Family Education http://www.familyeducation.com/home/
- Education Network Australia http://www.edna.edu.au
- Idealist.org http://www.ideal.org
- EnviroLink Network http://envirolink.netforchange.com/

Interest Group or Special Interest Group

This is a familiar organisation to most teachers and special interest groups or SIGs often form at face-to-face get-togethers and conferences in order to support specific areas of teaching practice or needs. There is on-line a two-way communication focus and this may one to many or one to one. Focused discussions there may be moderation from leader not necessarily the owner or administrator of the group. Registration and membership is essential and usually under some scrutiny and approval process. Members are rarely anonymous, whether they use real names or nicknames and pseudonyms a real persona is developed over time. On-line the SIG ties will be stronger than on a network and members contribute not only with communication but also with resources, ideas and leadership, an interest group offers communication between members about those specific topics. The communication is more than sharing; it is support for each other’s practice through facilitation, leadership and mentoring. Success might be measured in numbers and types of issues and responses/ratings. Interest groups use technologies such as listservs, discussion spaces and member upload and review of resources along with advanced communication and face-to-face opportunities. Special interest groups include user groups, associations, fan clubs (ezines) and tightly knit demographic groups. Consider these sites:

- iEarn Homepage http://www.ieam.org/
- American Educational Research Association Special Interest Groups http://www.aera.net/sigs/
- Special Education Technology SIG (SETSIG) http://www.iste.org/setsig/community.html

Community

A community of practice is different from a network in the sense that it is “about” something; it is not just a set of relationships. It has an identity as a community, and thus shapes the identities of its members. (Wenger, 1998, p.4) Putting people together in a place real or virtual does not make a community. Loosely bound collections of people in groups on the Web do not make communities and most certainly not communities of practice. People in true communities collaborate, teach and mentor each other, solve problems and build solutions together; they do so much more than just communicate with a site
administrator, leader or each other. In a community members are producers, consumers and builders. The communication is multi-dimensional and there is strong reciprocity. Real names are more likely to be used and even insisted on. The members share team projects/activities and develop joint artifacts. Communities are not built they grow through personalisation, member participation, contribution and most importantly ownership (van der Kuyl, 2001). They can effectively be used to leverage tacit knowledge from and between members of the group. Designers can establish frameworks, architectures and spaces to promote or facilitate certain activities and interactivity but it is the members who build the sense and value of community. As Preece (1999, p.3) explains "communities develop and continuously evolve. Only the software that supports them is designed".

Wellman & Gulia (1997) have used the terms ‘social networks’ and ‘community’ interchangeably and the Howard Rheingold has adopted ‘on-line social networks’ (Kimball & Rheingold, 2001) to describe organisational groups. These blended terms represent attempts to clarify and distinguish the Internet communications that have arisen and to give due separation to the quite rare true community. What distinguishes a true on-line community from an interest group is when the collaborative projects and activities arise from the sharing and support within the group. When members take up the varied roles offered to them and work with others in the community to develop new resources, projects, form consortia, apply for grants, then we can truly say that we have established community. Communities evaluate their performance through more qualitative measures than do most other interactive structures. While numbers of members and resources might still be important to a community, it is the quality of interactivity and collaboration and the rate of adoption of leadership, mentoring and facilitation roles that is its true measure of success. Consider these community sites some not fully fledged but burgeoning:

- Tapped In http://tappedin.org (Community of communities)
- StageStruck http://www.stagestruck.uow.edu.au (Interest group aiming to build community)
- SITE Community Forum – Learning Communities http://www.aace.org/site/forum/categories.cfm?catid=17 (International collaboration for SITE02)
- MirandaNet http://www.mirandanet.ac.uk/

The Value Of Internet Architectures to Classroom Practice

These architectures, while as suggested are not mutually exclusive, represent a shift in focus and in the dimensions of interpersonal communication and interactivity. This increased development is shown in Diagram 1 but it is worth noting that there is at present conversely a decrease in the proliferation and use of such architectures as we move towards interest groups and communities.

Diagram 1: The development of interpersonal ties through the respective Internet architectures.

A community has collaboration as its focus and offers experts and novices varying roles and ways to communicate, contribute, initiate ideas and devise joint projects. A community can develop from one of the Web-based communication architectures if greater levels of functionality, input, responsiveness and group task development are made available to the members and if this is what the members require. An intended community can become an interest group or a network if the members do not take up active involvement and leadership roles. Networks and Interest groups are interactive on-line structures in their own right, structures of merit and value to the membership. Each is also a possible developmental stage in the building of a community. You can design and build a network or an interest group but you can only enable the members to grow a community.
Groups and institutions planning to employ on-line architectures need to know what it is that teachers need, resources, communication, collaboration or a combination of all of these to decide which architecture will best meet their needs. The lower cost and more automated nature of a portal makes it an attractive option yet in another context the dynamic supportive nature of the interest group makes it most attractive. It is the needs of the teachers that must be understood before the technology is chosen.

Educational Internet product and service developers need to ask themselves whether teacher needs will be met by access to resources or to each other and at what level and intensity.

Abstract: Taiwanese government has emphasized education reform in the past few decades and has focused particularly on distance education. Several legislative initiatives involving distance education have recently implemented new policies governing distance education. These new policies are in opposition to the results of research accomplished in foreign countries regarding distance education and underscore an urgent need to examine the feelings and attitudes of students, instructors, administrators, policy makers, and related employees about the new policies for distance education in Taiwan. The purpose of this study is to determine the attitudes of students and teachers regarding the new policies controlling asynchronous distance education and distance education degree programs in Taiwan. The outcome of this study will improve the effectiveness of distance education teaching and learning, and will support appropriate academic standards for distance education in the Taiwanese learning community.

Introduction

Taiwan has experienced an economic miracle over the past two decades and her computer industry has been an integral piece of this economic success. The country's burgeoning gross national product has allowed the government to infuse large amounts of money into educational reforms, particularly into distance education. Several policies regulating distance education have been implemented under the aegis of the Asynchronous Distance Education Regulation (MOE, 1999).

Current Status

Distance education (DE) plays an important role in the history of educational technology in Taiwan. The purpose of DE in Taiwan is to promote societal education to fulfill lifelong learning goals. It is intended to achieve the goal of equal education. Confucius' philosophy, "to provide education for all people without discrimination," has greatly influenced DE. One of principles of DE in Taiwan is "school admission is open; evaluation is solid; and graduation is rigid." The intention is that "everyone has chances to get education; everywhere is a classroom."

School entrance examinations limit the opportunities to pursue a higher education. Each year more than 100,000 high school graduates take the examination. About 60% will pass and get admitted to colleges. The establishment of National Open University in Taiwan (NOU) provides a different venue for citizens to pursue higher education.

NOU students are typically married, middle class, and with incomes slightly below the national average (NOU, 1999). The specific reasons given for participating in NOU's programs include augmenting knowledge and skills, pursuing personal interests, raising personal educational levels, enjoying the social aspects associated with university, and increasing the chances for job promotion.
Three important periods of development of DE are identified (Chu, 1999): (a) Broadcast radio & television instruction, (b) Broadcast television instruction, and (c) Computer-based instruction.

The development of DE in Taiwan began in 1966 with the establishment of an educational radio station and began with a trial of the “School Over the Air.” In 1971, the first open learning institution in Taiwan the “High School Over the Air” was established, and in 1973 teachers' college courses were offered over the radio to meet the vital need for elementary school teachers. In 1977, the “Junior College Over the Air” was established to provide alternative schooling and continuing education to adults and broadcast television became the main medium.

During the period between the 1960’s and mid 1980’s broadcast radio and broadcast television were the major media of instruction with the latter becoming dominant in the 1980’s. Such televised instruction is supplemented with correspondence education and a limited number of face-to-face (FTF) instruction sessions as well as other technological and instructional support to provide feedback and interaction. The focus of this period was at first aimed at providing an alternative for the general public to receive education beyond the compulsory secondary education. As the education level of the general public moved beyond secondary education the focus switched to provide avenues of continuing education to adults with an emphasis on providing college and university level courses and to promote the idea of lifelong learning.

NOU in Taiwan was established in 1986, offering humanities, social sciences, business, public administration, living science, and management and information.

In the early 1990s, the third generation of DE, which utilized advanced CMC technology to provide interactive instruction evolved. NII (National Information Infrastructure) Project, one of the major educational technology plans, identified/categorized DE into three different modes: (a) Real-time multicast systems (RTM); and (b) Virtual classroom system (VC); and (c) Curriculum-on-demand (COD) system utilizing technology. Under the NII Project, seven national universities are initiating interactive DE courses. The focus was the establishment of instructional systems on different communication carriers, computer-based virtual classroom systems, and developing multimedia course materials (Wei & Su, 1997).

This interactive DE project utilizes a multimedia teaching environment through the use of audio/video and computer technologies, such as A/V facilities, video processing, echo handling, CAI, room design, and related setups, to create an excellent educational activity. Educational activities focus on two main issues, teaching techniques and production of computer-based teaching material.

Although RTM has become a popular mode, MOE (1999) announced a regulation for planning asynchronous instruction that includes three requirements: instruction design, delivering methods, and production of course materials. Methods of delivery that are allowed are videotapes, video CD, the Internet, cable, or satellite broadcasting, and videodiscs. Interestingly, regardless of the type of medium “teachers’ images and voices must be shown, suggesting that the favored mode of delivering instruction is through lectures. Additionally, instructors must post their office addresses and allow students meet with them either in FTF or through real-time online communication to increase course interaction. Clearly, the authority transfers traditional instruction design to DE.

Attitude toward to DE

Taiwanese education developed in a traditional Confucian way: rigorous examinations, creation of elite higher education institutions, and teacher-centered learning. This belief leads the development of DE in Taiwan to be more conservative while the Open University in Hong Kong demonstrates a more student-centered belief (Sherritt, 1999) although both schools share similar/same Chinese cultures. In fact, Huang (1997) argued that in Taiwan older learners are not attracted to and do not learn effectively in a traditional environment. Additionally, NOU has been categorized as a supplemental education system, which implies a somewhat marginal position in the whole education system. Data indicate that NOU graduates enjoy enhanced quality of life but seldom use their educational attainment for conational advantage. Hsieh (1996) found that DE had positive influence on labor force skills development and economic growth.
Tu (2001) concluded that Taiwanese students have positive responses to CMC in distance learning environments. Hsiung and Tan (1999) found similar results and concluded that Taiwanese perceived computer Internet systems as interactive and effective communication media in the distance-learning environment.

**Difficulties and Challenges**

Challenges are identified in the DE system in Taiwan that must be resolved to advance the system, but the prospects for DE in Taiwan are promising (Tu & Twu, in press). Effective reforms require thorough cooperative efforts from students, faculty, staff, administrators, institutions, policy makers, governments, and all others.

**Need driven rather technology driven**

Current DE development has put more weight on the attributes of delivery technology than the needs of students. Certainly, obtaining hardware and technologies is necessary to the initiation of the reform process; however, it is necessary to examine what students need to learn, how they would like to learn, and how their learning experiences can be enhanced.

**Course design**

Effective course designs are the key to the successful enhancement of learning. Clearly course designs have been transferred from traditional instruction to the DE environment. Standard lecture transmission has become the major instruction design; but, it is doubtful that the lecture mode works well in computer based DE environments (Tu & Corry, 2001).

It is important that course design must be tailored to the cultural mores of local learners. Many institutions have failed to consider the cultures of the learners in instructional design (McIsaac, 1993). Foreign DE models should be referenced but the course design must reflect the Taiwanese culture and the learning styles of Taiwanese students.

Adult instruction design should be taken into account. Most adult learners perceive their learning process as more self-directive; experiential learning techniques have more meaning; learning should be able to apply to practice; and learning should lead to increased competencies (Knowles, 1976). It is a challenge to integrate adult instruction design into current DE instruction because of the educational foundations of school systems and the passive learning of the culture. DE may exert limitations on independence, critical thinking, and intellectual inquiry. Therefore, there is need for students to be trained to be independent and utilize critical thinking skills that will benefit them at their workplace and in their lifelong learning experiences.

Effective evaluations will provide students feedback and serve functions of directing their learning experiences. Current evaluations adopt traditional test styles, such as true and false, multiple choice, essay, etc. It is recommend that various assessment strategies be applied to monitor student learning progress and should mix systematic, summative, and formative methods.

**The needs of theoretical foundation**

DE in Taiwan has a short history; therefore, well-grounded and solid theoretical constructs are still evolving. Urgent need exists for more research to form a theoretical framework to project direction, to guide practice, and to serve as leadership.

**Effective teacher training**
Distance teaching differs significantly from traditional teaching. In fact, many DE teachers have been applying their traditional teaching styles to distance environments, which result in many frustrations, ineffective teaching, and retardation of student learning. Therefore, prior to becoming involved in distance teaching DE teachers should receive training in distance instruction. "Ongoing" training is more effective than one-time training.

Curriculum integration

Current DE graduates did not change their careers or use their degree to obtain a job. The purposes of DE are to provide various learning processes to suit the needs of the students. Therefore, curriculum integration should be flexible to provide various programs, certificates, and trainings to assist students to achieve their individual lifelong learning goals.

Insufficient resources

The government and their institutions do not adequately support distance teachers. The teacher and student ratio is fairly high (1:21). In fact, distance teaching normally demands more of the teachers’ time and a greater amount of effort for course preparation, course delivery, student support, and course management etc. (Tu, 2000) because of the diversity of the students’ ages, cultural backgrounds, learning experiences, and technology experiences. Therefore, continuing support for DE teachers is imperative.

Role of DE and Perception

Although Taiwanese society has developed a room to face DE and the schools have developed rigorous adherence to high standards, most Taiwanese are still skeptical about the quality of this learning process, grumbling that it’s not seemly to get a degree without going to school or by just watching TV. This misconception resulted from the fact that the government initiated DE as supplement to traditional education. Therefore, it has been seen as "alternative," "second best," and non-mainstream education. Particularly, it is wrongfully perceived that DE is for one who fails the college entrance examination to pursue his/her higher education and “Superior students go to traditional colleges.” How society will perceive DE is a serious hurdle to cross in the process of development. It has been shown that DE students can learn as effectively as can students in traditional instruction (Hiltz, 1998). The authority should take the leadership to correct this misconception of DE.

Insufficient financial support

There were insufficient funds dedicated to DE. Each year the government assigns US$3,125 to $9,375 for a traditional university student, while the expenditure for a DE student is US$625. This differential in financial support limits distance students from obtaining a start-of-the-art quality instruction through distance learning technology when compared to students in traditional universities.

Conclusions

Moving Taiwan towards a learning community is an ideal and ultimate goal. The technology-based learning serves a vital tool to enhance learning. Learning and knowledge are the goals students need assistance to attain. Content, hardware, and software do not equal knowledge. The utilization of various learning technologies will allow Taiwanese to select their ideal learning methods to achieve their lifelong learning goals and to reach the definitive goal: “life is learning; learning is life.”

Infusing Wireless Technology into Teacher Education

David Zandvliet, Simon Fraser University, CA
Laura Buker, Simon Fraser University, CA

Abstract

The brightest promise of technology in education is as a support for new, innovative, and creative forms of teaching and learning. The Centre for Educational Technology at Simon Fraser University has established a wireless network throughout the instructional areas in the Faculty of Education. This network is used in conjunction with a 'portable lab' of laptop computers and allows us to infuse technology into our work with the Professional Program (Pre-Service Teacher Education) in a variety of classroom settings. This infrastructure currently satisfies many of our current and future instructional and technological needs while providing a rich venue for the project and further and continuing research and evaluation associated with it.

Introduction/Background

Educational reform initiatives aimed at integrating technology into the curriculum are well at work in institutions of higher education such as Simon Fraser University. As more and more K-12 teachers are required to change their teaching methods and teaching styles to include technology, educators within teacher education programs are being asked to alter their methods and styles of preparing teachers, specifically to include teaching with technology (Edwards, Ahn and Mooney, 1998). To facilitate this change and to structure computer-based activities, many teacher preparation programs in Canada and the U.S. tend to use the International Society for Technology in Education (ISTE) Foundation standards, (ISTE, 1997a; ISTE, 1997b; ISTE, 1997c). However, while teacher education programs may have a short-range need to impart basic computing skills to their students, the real challenge is to teach and to reinforce these skills to pre-service teachers while simultaneously showing them how to integrate the technology into the range of curriculum they will be teaching.

Generally, educational researchers would place schools, colleges, and departments of education (SCDE's) along a continuum in terms of this goal for the integration of technology (eg. Beck and Wynn, 1997). However, comprehensive reports on the subject indicate that the use of technology is not central to teacher preparation and that most technology instruction concerns "teaching about technology" rather than "teaching with technology" across the curriculum (eg. U.S. Congress, Office of Technology Assessment, 1995). A more progressive view of the needs of SCDE's in the U.S. was posed by a report by the National Commission on Teaching & America's Future (1996) which posed the challenge: "Schools of education need to model how to teach for understanding in a multicultural context, how to continually assess and respond to student learning, and how to use new technologies in doing so" (p.77).

In Canada, Faculties of Education need also to pay greater attention to the goal of integrating information and communications technologies (ICTs) into Pre-service teacher education programs. A recent report by the Angus Reid group (Globe and Mail, 2000, September) stated that Canada is near the top of the class globally when it comes to offering Internet access to its students. The report relates that 74 per cent of this country's students had Internet access at school, while 71 per cent had access to it at home (U.S. students were more likely to report Internet use available at home than at school). Further, the Industry Canada project, SchoolNet, claimed last year to have made Canada the first country in the world to connect all its public schools to the Internet. This public infrastructure then forms an important part of the teaching/learning context in public schools. At the very least, this argues the point that pre-service teachers need adequate preparation in its use.

The use of wireless networks and ICT has also the potential to transform learning and teaching. In this, the underlying principles of learning and cognition are the same as for all media and learning environments. Like other technologies, the Internet brings into being the ideas of its early innovators--in this case, ideas about hypertext and universal sharing of documents and texts. The Web can also be a vehicle for realizing the vision of educational thinkers like Dewey, Piaget, and Vygotsky who long ago advocated a constructivist or meaning-centered approach to learning and teaching (Wilson & Lowry, 2000, May). Constructivism, which stands in contrast to mechanical
conceptions of thinking and action, emphasizes the learner's role in constructing meaning—as opposed to simple transmission from teacher to student (Duffy & Cunningham, 1996). Learners do more than process information—they build an understanding through interaction with their environments (and the technology infused into these environments).

**Infusing ICT into Curriculum**

In the context of pre-service teacher education, a number of early attempts have been made to describe the effective and pedagogically meaningful integration of ICT into the curriculum. Omoregie & Coleman (1998) designed a study which investigated the degree to which technology infusion played a significant role in the development of quality instructional materials by pre-service teachers and influenced their academic performance. Their study reported that their integration of ICT into the curriculum enhanced the interactions between students and preservice teachers while also increasing motivation, computing skills and academic performance in pre-service teachers. In addition, the researchers noted that the infusion of ICT encouraged rapid feedback between university faculty and pre-service teachers and that this increased student interaction using electronic mail enhanced their writing skills.

In another study (Persichitte, 1998), case studies were conducted to document and analyze factors (positive and negative) associated with the integrated use of educational technologies within SCDEs and further to develop rich descriptions of best practices use and integration to serve as models for preservice teacher program revision. Among its intentions, the study aimed to document (in a qualitative sense) what characteristics of pre-service teacher faculty, students, curricula, and programs would currently be considered examples of "best practice" in the use and integration of educational technologies for the preparation of teachers. Examples described in the report included the development of problem based learning (PBL) workshops, and a range of student designed 'electronic portfolios'. The study further inferred how the use and integration of educational technologies influences the planning for, and maintenance of existing technology infrastructures and of curriculum frameworks within pre-service teacher education.

Edwards, Ahn and Mooney, (1998) discuss one such problem-based approach which they term 'scenario-based computing'. They relate that these activities incorporate the day-to-day work situations encountered by in-service teachers with the possibilities of effective computer use and so provide pre-service teachers with an opportunity to focus on both the (professional) management and instructional duties faced by in-service teachers and technical integration issues within the classroom. The authors relate that scenario based activities also force students to think about each task in relation to tasks or situations that they might actually face sometime in the future. The use of scenarios in ICT instruction may facilitate students to think about and discuss computer use relative to (a) what needs to be done, (b) why the computer becomes the medium of choice for a specific scenario, and (c) exactly how the computer will be used.

Another approach to ICT infusion is related by Doty and Hillman (1998) who describe their Teacher Technology Portfolio program as one integrating instruction on technology with 'modeling of instruction' with technology throughout the course work in each of the teacher training program. Pre-service teachers begin their portfolio work in their introductory courses with opportunities in later methods courses to build competence; investigate curriculum and technology connections; and to develop and implement activities integrating technology. The portfolios are then finalized during the professional, student teaching semester. Portfolio requirements described included the development of a reflective statement regarding technology and education, the development and implementation of lesson and unit plans (with electronic artifacts), and a documentation of mastery of basic and advanced competencies with a variety of instructional technologies.

Jackson (1998) describes another portfolio approach taken. In this project, pre-service teachers developed computer portfolios as part of their professional program. Included in these portfolios were such items as text casts of philosophical beliefs, voice casts of effective teaching strategies, and digitized videos of actual teaching performance. The author states that portfolios allowed pre-service teachers an opportunity to both self reflect and assess their recent student teaching experiences while providing them with a greater understanding of how technology can be implemented into their future classrooms. Jackson states that the process of pre-service teachers developing their own computer portfolio had many positive outcomes. First, these pre-service teachers benefited by reflecting upon their student teaching experience as they compiled their own effective teaching characteristics. Second, the end product became a very valuable instrument in the student's job search. Third, the opportunity to author their own computer portfolio provided students with and increased technical capacity to infuse technology later in their own classrooms.
Finally, in an approach to teacher education that would be viewed as consistent with the student centred and constructivist models described, Topper (1998) relates a strategy which uses Technology coaches (or mentors) hired to support students learning to use technology and to assess their technological proficiency. The success of this work (and the mentoring model applied) was credited in helping future teachers develop the necessary expertise, dispositions, and attitudes to support their own generative learning around and with technology, and learn to use technology appropriately to serve some useful pedagogical end. With this project, the Centre for Educational Technology applies a similar model in infusing technology into pre-service education through the use of our wireless network and portable lab, the provision of a project facilitator and the development of workshops aimed at generating student designed (web based) instructional resources and the connection of these to their development as professionals through the progressive design of electronic or ‘virtual’ portfolios.

Project Methodology

The development of knowledge and skills related to the use of information and communications technologies (ICT) is an important goal for any teacher education program. In this, it is important to consider technology learning objectives as an integrated part of the development of teacher-professionals and not a separate requirement. In practice, this means subordinating technology-learning to the overarching professional nature of the pre-service curriculum, our intentions with this project are: to explore the possibilities for technology to enhance learning in the pre-service curriculum during on-campus experiences; to consider ways to utilize technology in our approach to subject-specific and integrated curriculum studies in the practicum settings; and to enable an understanding of technology as one of the many aspects of teaching and learning that collectively contribute to effective pedagogy. Further, social, gender and cultural issues that surround the use and possibilities of technology will be addressed and attended to within on-campus and school-based experiences.

This project is also sensitive to the reality that many pre-service teachers have little familiarity with technology. Our primary aim is to provide supportive learning situations that will facilitate both their comfort level and their expertise. There are two components to our current project: construction of ‘virtual portfolios’ throughout the program; and the design and implementation of a technology project during their practicum experiences. The requirements for the virtual portfolio accommodate the potential differences in competency, and on-campus experiences will include specific instruction in the use of technology which will support pre-service teachers’ abilities to utilize technology ___in effective and pedagogically meaningful ways. In addition, pre-service teachers will have opportunities to collaboratively participate in technology-supported inquiries through the self-initiated projects which will also support their technology learning and provide a meaningful context for technology-based inquiry within their practicum experiences.

Perhaps one of the greatest strengths of embedding technology within a pre-service module is that there is no presumption of expertise. In other words, learning about pedagogy, and learning about the possibilities of technology as a supportive pedagogical tool, are embedded within the broader goals of Professional programs. The intent with both is to nurture and encourage pre-service teachers to construct, reflect upon and practice their beliefs about teaching and learning, always attending foremost to the needs and abilities of the children who become their students. Beyond the specific requirements of technology-learning and learning about the unique aspects of middle school theory and practice, our ultimate goal is to create a meaningful, supportive and enabling learning environment for our pre-service teachers that will optimally be a model for their own practice.

Our specific goals related to the development of an ICT strand within pre-service teacher education programs are therefore threefold:
1) To infuse technology into the entire teacher education program. Throughout their teacher education experience, students should learn about, learn with, and learn to incorporate technology into their own teaching.
2) To introduce technology in context. Teaching pre-service students basic computer literacy is not enough. Pre-service students should learn about the many uses of technology because they are integrated into coursework and field experiences.
3) To allow students to experience innovative technology-supported learning environments in their pre-service program. Technology has the potential to transform learning.

The brightest promise of technology in education is as a support for new, innovative, and creative forms of teaching and learning. The Centre for Educational Technology at Simon Fraser University has established a wireless network throughout the instructional areas in the Faculty of Education. This network is used in conjunction with a
'portable lab' of laptop computers and allows us to infuse technology into our work with the Professional Program (Pre-Service Teacher Education) in a variety of classroom settings. This infrastructure currently satisfies many of our current and future instructional and technological needs while providing a rich venue for the project and further and continuing research and evaluation associated with it.

The Wireless LAN technology was introduced gradually over the fall semester (September-December 2000) by developing a mobile computing lab consisting of 16 IBook (Apple Macintosh) computers organized on a portable cart. In addition we began offering 'Wireless Workshops' to Pre-service teacher education modules and working extensively with the Middle School - Learning Community module in Jan.2001. These workshops demonstrate the utility of the wireless network technology (and mobile lab) while also introducing potential applications for its use in teacher education and classroom instruction. The workshops are followed up with consultation and collaboration with faculty associates in the teacher education program to ensure their continued use and connection with the instructional goals of the program. These connections are part of an on-going research and evaluation project that began in January 2001.

Conclusion

Evaluation of our current work is continuing as we monitor the efficacy of our approach and the suitability of the learning environment we have provided for our students. Observation, interview and classroom learning environment surveys assist us to document and compile case studies on a variety of pre-service projects as they relate to teaching experiences designed by our developing teachers. Finally, in documenting the development and implementation of the wireless network in Teacher education we will continue to look for a number of different types of information related to its efficacy. For example, What technical and pedagogical limitations are imposed or removed by the use of ICT in teacher education? How do these differ from those experienced in other other ICT settings? Further, what are students' perceptions of their learning environment when using ICT in this way? Finally, are there qualitative differences in the nature of their technology-learning in the wireless setting? (i.e. Can enhanced connections between ICT and professional practice be described?)

In order to implement and evaluate this process, we have facilitate opportunities for students to critically examine their teaching practices and the assumptions they make about the nature of learning, teaching, and the role of technology - These are the learning goals of the electronic portfolios they create. Further, in building collaborative relationships, and in respecting the students' knowledge and expertise that they bring to these interactions, project staff support student efforts to construct their own practices of teaching with and document this through the design and implementation of web-based pre-service projects implemented during their practica. We believe that these approaches are consistent with the socio-constructivist views of learning we hold in the Middle School Module of Professional Programs and in the Centre for Educational Technology at Simon Fraser University.

Abstract: Collaborative learning systems offer common virtual spaces where different users (i.e. teachers, students, school directors, parents, researchers, and experts) can interact. Participants can share their pedagogical, technical and administrative knowledge. CONEXIONES project, a research group that has been enhancing the learning process in Colombian schools through the use of new technologies, has developed COLEGA, a collaborative and learning tool to support knowledge evolution processes within learning communities. This paper presents COLEGA, a collaborative and learning tool that integrates retrieval document algorithms based on keyphrases, synchronous and asynchronous communication tools, and support for evolving individual and group memory. Results of a usability study are also presented in this paper.

Introduction
CONEXIONES project is part of the R+D Group in Computers in Education at EAFIT University - Colombia. CONEXIONES aims to improve Colombian education by developing and implementing new learning environments in real schools and community centers (Zea et al. 2000). More than one hundred schools (urban and rural, private and public) from five provinces of Colombia form part of CONEXIONES. There are strong cultural differences and social-economic levels among schools. Every month approximately 12,000 users interact in a virtual space. Users are students, teachers, parents, researchers, educational agents, and family members of the community centers.

COLEGA facilitates communication among users. Researchers and technical staff need to be in constant communication with teachers, students and family members within CONEXIONES. COLEGA provides users with synchronous and asynchronous communication tools where they will be able to solve their problems, share ideas, and express their pedagogical and technical doubts about CONEXIONES. COLEGA has been proposed as a new alternative to support communities within CONEXIONES.

Different groups can create their own learning spaces. For example, teachers in COLEGA use a learning space to discuss about topics related to collaborative projects. A teacher can create a learning space to interact with their students and an invited expert. Family members can be also involved on different groups in order to share their ideas with students and teachers. Students and teachers from several schools working on similar collaborative projects are able to share ideas and knowledge. Students from low-income and rural areas have the opportunity to interact with students, teachers, researchers, and experts from different regions and countries. Thus, COLEGA is instrumental in integrating educational communities.

Related Work
Learning communities have been supported using a variety of technologies. From simple electronic mail, multi-user environments (MUDs and MOOs) to collaborative virtual spaces. CSILE - Computer Supported Intentional Learning (Scardamalia and Bereiter 1991 1996 1999), for example, uses new technologies to support decentralized forms of discourse, and knowledge building within a discipline. CSILE is an asynchronous discourse tool that supports knowledge building providing thinking-type labels, scaffolding of notes, and different views of notes. CSILE has demonstrated how such technology produces positive
effects in learning. CaMILE (Guzdial et al. 1995) offers a collaborative environment in which participants can share their ideas through the use of notes. Students in CaMILE can classify their interactions and change accessibility privileges to their notes. The IHMC Concept Mapping Software - CMaps (Cañas et al. 2001) empowers users to construct, navigate, share, and criticize knowledge models represented as Concept Maps. The toolkit allows the users to build, and collaborate during the construction of concept maps, as well as, share and navigate through others' models distributed on servers throughout Internet. COLEGA distinguishes from existing software by its particular use of keyphrases-based technology and participants' annotations to categorize and organize documents and interactions, that makes it possible to manipulate individual and group memories in benefit of the participants.

COLEGA

"In classrooms that adopt the collaborative knowledge building approach, the basic job to be done shifts from learning to the construction of collective knowledge. The nature of the work is essentially the same as that of a professional research group, with the students being the principal doers of the work. Thus, in the ideal case, there is a complete shift from students as clients to students as participants in a learning organization." (Scardamalia and Bereiter 1999).

COLEGA supports users working in a learning activity by offering collaborative learning spaces in which they can learn from each other, solve their problems, learn about collaboration, and learn the appropriate use of this technology in their own context. Fig. 1 presents a general view of COLEGA. Users can interact with synchronous and asynchronous communication tools to create documents and/or interact with other users based on previous documents. Users classify each interaction as a document, an idea, an alert, an attention, a question, an agreement, or a disagreement. Automatic key-phrase techniques are used classify each document with in a list of domain categories. This facilitates organization of documents with in individual and group memories.

![Figure 1: COLEGA Architecture](image)

Participants can maintain their own knowledge space (individual memory) and share it later with their group. Students can decide with whom they want to share their questions and new ideas. Teachers can monitor individual and group memories to be able to guide students with their learning processes. Teachers can generate a list of topics of interest and use this information in their class. In that sense, COLEGA becomes an assessment tool for teachers. Furthermore, students and teachers in COLEGA can make the group memory available for other users to start a discussion based on an existing document or interaction. These users will create their own individual and group memories by including their own questions, ideas, or answers. As individual and group memories evolve, CONEXIONES' project memory evolves. Participants have three different ways to interact within COLEGA: by participating based on an existing document, by participating based on a previous interaction, or by adding a completely new document or interaction. In the first two cases, participants can use synchronous or asynchronous communication tools to add their interaction or document. When participants are not satisfied with the search results or there are not documents or interactions related to a particular keyphrase, users can start their own discussion.
COLEGA will automatically extract keyphrases from the new document and will make it available for others to participate. See Fig 2.

Asynchronous and synchronous communication tools allow users to interact with others in a variety of settings. Participants can use an initial document to work with and generate a final document with the contributions of the group. This process can be done on-line during a face to face meeting (synchronous tools) or it can be based on messages posted by the participants in a group memory (asynchronous tools). Fig 3 shows a screenshot of the asynchronous communication tool in COLEGA. The user can select the user(s) to which the interaction is for, specify to whom a copy should be sent, classify the interaction according to one of the types COLEGA offer, type or import the document/interaction content, and send it. If the user desires to get help about how to classify the interaction, there is a help option available.

A group of participants can witness how their 'group memory' evolves through their interactions. New users can inspect group memories to learn about different topics. In fact, new participants can select an existing document to start a conversation with his/her own group. COLEGA provides methods to create and maintain knowledge spaces.

Moreover, several search facilities have been implemented using automatic keyphrase extraction techniques (Turney, 2000) to automatically extract keyphrases and classify information into categories previously generated based on existing documents. Using automatic extraction of keyphrases, documents can be classified into meaningful categories that will make simple searching processes. This in conjunction with participants' classification of their interactions within COLEGA makes individual and group memories easy to be accessed. COLEGA supports keyphrase based queries, which opens up existing documents to participants interested in a particular topic.
Usability Study

In this study, teachers, students and researchers had the opportunity to use COLEGA to solve some common tasks, such as: searching individual and group memories using keyphrases, searching by using categories from a proposed tree of initial categories, reading existing documents and generating new interactions using asynchronous communication tools mainly. Initial documents were consistent with real CONEXIONES messages (i.e. emails, teachers' and students' reports, and papers and technical documents). Participants solved a final questionnaire and observers were taking note of their reactions towards COLEGA. Each task was carefully designed taking into consideration the participant's language and probable topics according to the type of participants (i.e. student, teacher, researcher, etc.). Some of the initial results are as follows:

- Teachers considered COLEGA to be a helpful tool in their teaching both as a learning and as an assessment tool. Teachers were able to use keyphrase based searching facilities to monitor students' work and to find information about their topics of interest. Teachers liked the idea of been able to keep in touch with researchers, teachers, and students from different places.
  
  "COLEGA is an interesting pedagogical tool because I can keep in touch with other users of CONEXIONES. Besides, it is possible to give your opinions and engage in the construction of knowledge. it provides a great opportunity to generate knowledge and increase the one we already have" Teacher comment.

  "COLEGA provides a searching and interactive method to helps us to solve doubts with students, partners and experts." School director opinion.

  "I think COLEGA is easy to use. I can find answers to the questions I have. I can also ask people who know about my questions." Student comment.

- The Discussion Room – synchronous tool- generated a lot of interest. Participants considered that it will give them another way of interacting and building knowledge collaboratively.
  
  "I think is a great tool that will give a lot of support to the CONEXIONES Project. It will allow us to have more contact with teachers." Researcher comment.
Teachers and students considered COLEGA as an innovative tool, that will increase their confidence in new technologies. COLEGA reduces their fear to computers and encourages interaction among participants.

Participants felt that the instructions were clear and enough to understand the way they were supposed to interact with COLEGA.

"This system (COLEGA) seems to be useful for CONEXIONES' schools. It is a way to share experiences and to search for information related to different topics. It presents an attractive and an easy way to handle information. It motivates the members of CONEXIONES and increases their ability to share experiences." Teacher comment.

According to the initial results and the comments by participants, COLEGA was accepted and considered as a useful tool that supports their learning activities. COLEGA combines collaborative learning tools, group and individual memory, human-computer interaction and document retrieval techniques. COLEGA uses of keyphrase based technology and participants' annotations to facilitate access to individual and group memories. Learning communities can benefit by inspecting and interacting with information maintained by COLEGA.

Conclusions
COLEGA is instrumental in providing a collaborative solution for managing group and individual memories. It promotes the generation of learning communities and learning spaces according to current participants' interests. This collaborative and learning tool aims to support participants of CONEXIONES with learning about a particular topic. In addition, participants can learn about group interaction, leadership, and collaboration while using the system. COLEGA breaks geographic barriers in order to support modern learning communities. COLEGA was accepted by members of CONEXIONES who understood their potential and advantages to support learning in different settings. Future work includes a formal evaluation of the synchronous discussion room and integration of new tools to handle conceptual maps and learner models such as CMaps (Cañas et al. 2001) and ViSMoD (Zapata-Rivera & Greer 2000).

Acknowledgments
We would like to thank Claudia Zea and María del Rosario Atuesta for their support in CONEXIONES Project, COLCIENCIAS – Colombia for partial financial support, Peter Turney for creating some of the automatic keyphrase extraction algorithms used in this project, and the participants of the usability study, especially Irma Urrego and Lucero Rendon for their comments and suggestions.

References
The integration of technology into the classroom is a dynamic process that emphasizes the theoretical constructs related to how learners learn. Primarily, the focus of change in pedagogy, curriculum, and learning experiences is the challenge of the technological classroom. The articles in this section illustrate how theory and research can provide a different conceptualization of the processes of teaching and learning using technology.

Fetherston's article, "Educating teachers for the knowledge economy" proposes the knowledge and methods needed to prepare teachers to incorporate Information and Communication Technology (ICT) into the classroom. The dominance of constructivist pedagogy when using new technologies seems to be most important in training teachers. The knowledge economy, as explained in the article, demands that teachers must be able to assist students in learning how to access and work with information. Teachers can help students learn using technology by understanding and implementing the approaches of guided participation, conceptual change strategies, metacognition, and reflection.

In Bull's article, "Pedagogical Ethnotechnography: A bifocal lens to understand technology in education," readers learn about a research method for gaining insight into how individuals use and experience technology as a pedagogical tool. The author provides definitions, procedures, and benefits regarding Ethnotechnography. This type of research should increase understanding of the changing nature of pedagogy with the advent of technology. In a related manner, Kurubacak and Wiburg's article, "Designing a technology, society and education course" moves from the individual's experience to the impact of technology on society as a whole. Relying on project-based learning and creative activities, students enrolled in the course described in this article, develop an understanding of the relationships between technology and societal and educational change. Seemann's article, "Technology as a developmental influence" also delineates the impact of technology on society. The experience of technology is developmental, requires more abstract thinking skills, and has changed learning related to individual and societal occupational, social, and educational development.

Kayashima's article, "A model of self-regulation skills: penetrable process and not-penetrable process" describes a model of cognitive processing as part of a technological instructional method. The skills of metacognition and self-regulation are developed into a model based on production systems that aid in understanding how individuals construct knowledge.

Mishra and Wallace's article, "Teaching as design: Implications for learning to teach with technology" relies on the metaphor of design in technology as a process of learning to teach with technology. By comparing the complex, creative, and dynamic processes between design and teaching, students learn about the strong parallels between the two, thus developing an understanding of teacher knowledge for teaching with technology.

Cilesiz and Ferdig's article, "The design of electronic learning environments in teacher education: Understanding the importance of representation as a choice in technology production" explains how representation affects cognition and facilitates learning. However, the key point is that representation is of paramount importance in online environments and should be given special consideration in the development of online courses.

Kurubacak and Gonzales' article, "The use of the Internet to teach critical thinking" indicates how the Internet can facilitate learning critical thinking skills. The authors feel that teaching critical thinking should be one of the most important educational goals for students and that technology, especially the Internet, can be used as an educational tool in enhancing critical thinking.

Chih-Hsiung Tu's article, "Research and online social interaction" is concerned with the online learning community. Research has not adequately differentiated computer-mediated communication from face-to-face communication; therefore, relying on sociology, social learning, and self-presentation constructs would enhance research to better understand online social interaction. Additionally, Chih-
Hsiung Tu and Michael Corry's article, "Building eLearning communities" expands on the online social process by providing a conceptual framework for developing an eLearning environment. The impact of eLearning communities on human learning is considered as well as recommendations for future research.

Laferrière, Bracewell, and Breuleux's article, "The emerging ecological contribution of online resources and tools to K-12 classrooms" explains the ecological contribution of online network technologies on student learning. Research based on observation has indicated that a distributed change across all educational activity should provide a new pedagogy in order to take full advantage of information and communication technologies.

In summary, the integration of technology and education has provided change in pedagogy, learning, and social interaction. Future research and refinement of theory should expand the understanding of the dynamic processes regarding teaching and learning using technology.
The Emerging Ecological Contribution of Online Resources and Tools to K-12 Classrooms

Thérèse Laferrière, Laval University, Canada, tla@fse.ulaval.ca
Robert Bracewell, McGill University, Canada, robert.bracewell@mcgill.ca
Alain Breuleux, McGill University, Canada, Breuleux@Education.McGill.ca

Abstract: This paper presents the emerging ecological contribution of online network technologies on student learning. Significant effects of the use of ICTs were gathered from documentary reviews. An organizing framework was developed in order to make sense of preliminary observations, in combination with raising scientific discourse on the teaching-learning process. The framework was further validated through the research team's extensive participant observation in networked classrooms. Twelve observations are formulated out of the research literature. They regard process over product. Both the organizing framework and the observations form the basis of an ecological perspective on the contribution of online resources and tools to K-12 classrooms.

Introduction

Learning with online tools and resources is emerging in the brick-and-mortar primary and secondary school of North America. Meanwhile, an increasing number of researchers, including cognitive scientists and teacher educators, recognize that the teaching-learning process must evolve. It is advocated that teacher-talk and rote knowledge (addition and retention of facts, principles, and procedures) on the part of the learner must give way to higher-thinking skills acquisition for all (Resnick, 1998), and teaching for understanding (Bereiter, in press).

The contribution of new technologies to K-12 classroom learning and teaching will not obviously be well known for many years to come. As its title suggests, this paper focuses on the physical classroom, not the virtual one. The network capacity of classrooms and schools is emphasized, and not only the simple fact that resources and tools are online. A theoretical approach to the ecology of the networked classroom is presented, one grounded in three documentary reviews on the contribution of new technologies to teaching and learning (1996, 1998, 2001), and in our ongoing participant observation of networked classroom processes and products (1995-2002). A comprehensive framework emphasizing extreme circumstances of use is brought forward, followed by propositions that organize results found in scholarly works and other highly relevant studies, pointing to emerging observations in the process.

The method

The online search dealt with the contribution of new information technologies to learning and teaching in elementary and secondary schools for the 1998-2000 period. The search was exhaustive and emphasized articles, reports, papers and book chapters meeting the criteria for scholarly publications. Proceedings were judged to be of an exploratory nature which usually do not present final conclusions and findings, but some papers presented at conferences were included to support specific trends. Finally, a search using Internet search engines such as Alta Vista or Excite was also excluded since the volume of information retrieved would have been too large, many of the articles would not meet scholarly criteria and it would have been difficult to evaluate and authenticate the studies. However, online articles, reports, and papers meeting scholarly criteria were included.

The organization framework

The past five years have seen a radical change in what researchers sees as being important when considering the contribution of online resources and tools to teaching and learning in the classroom. Prior to this period, much of the research in this area can be described as implementing a rather simplistic horse-race model, in that the studies were designed to compare whether or by what amount the use of a particular...
technology was more successful in promoting learning than another technology or a traditional instructional practice (Zhao, Byers, Pugh & Sheldon, 2001). In contrast, more recent perspectives are grappling with the complexities of integrating online resources and tools with learners, teachers, administrators, and instruction. In a heartfelt and accessible call for a more encompassing treatment of online technologies in education, Nardi and O'Day (1999) apply the metaphor of *ecology* to the use of these technologies in the classroom, thereby highlighting the systematic relationships among participants and resources, the diversity found in educational settings, and the potential for evolution of instructional practices.

This ecological (as opposed to horse-race perspective) can be seen in the theoretical tools now being deployed in studies and analyses. Researchers are developing and applying both existing and new theoretical constructs to understand conditions for the effective use of online technologies. These include learner characteristics such as *metacognitive abilities* and *epistemological belief* (Hartley & Bedixen, 2001) and contextual variables such as the *distance* of new practices using online technologies from existing instructional practices and the degree of *dependence* of teachers using online technologies on non-traditional resources and personnel (Zhao et al, 2001). Researchers are also turning to and applying more comprehensive theoretical frameworks in investigating online technologies and resources in the classroom. These frameworks include *communities of practice* (Barab & Duffy, 2000), *problem solving* (Jonassen, 2000b), *cultural psychology* (Brown & Cole, 2000), and *activity systems theory* (Jonassen, 2000a). Application of these frameworks both provides a more adequate description of what is required for effective integration of online resources (and ICTs generally) and also brings this research and its application into the mainstream of educational research and professional practice.

Our ecological perspective relies on a number of constructs to organize the findings of the documentary reviews. The first of these has to do with the nature of change in educational practices involving online technology. Change can be characterized as being either incremental or transformative: *Incremental change* refers to the use of technology to carry out already existing instructional tasks in more effective and efficient ways; *transformational change* refers to the use of technology to instruct in new ways (Maddux, Johnson, & Willis, 1997). In addition, the implementation of change can be characterized as either isolated or distributed—it is clear from the research findings that effective use of online technologies in education requires *distributed change* involving all the constituents of educational activity. The second set of constructs has to do with the educational constituents, which are characterized in terms of Schwab's (1973), four commonplaces (or dimensions) of the educational situation: The *teacher*, the *content*, the *learner*, and the *context* (see Figure 1). With respect to the use and effect of online resources, the four constructs vary in the following ways:

- The *teacher*, who, at one extreme, may be primarily concerned with delivering content information to the learner using online technology while, at the other extreme, may be concerned primarily with facilitating network activities of the learner that result in learning;
- The *content*, which, at one extreme, may be a fact or already existing body of knowledge and, at the other extreme, may be a theme or project that is being built up by the learner(s);
- The *learner*, who at one extreme, may have only limited access to online technology and network capabilities through a school-based lab and, at the other extreme, may have full access via laptop and modem;
- The *context*, which, at one extreme, would provide minimal support with respect to leadership and knowledge for the use of online resources and, at the other extreme, would involve participation and support from all stakeholders (teachers, administration, and parents).
Figure 1: The four constituents of the educational situation in networked classrooms and their variations.

Most current classrooms would lie toward the left end of each continuum: 1) the teacher is a transmitter of knowledge rather than a facilitator of learning, 2) the content is pre-organized by the teacher or 'canned' on a CD-ROM or a web site, rather than constructed by the learner; 3) the learners have low rather than high access to online resources and tools; and 4) the context offers the teacher and his or her classroom a limited rather than a high level of support for new initiatives and resources. This model of use, called (TCLC - ), which stands for each of the first letters of the four basic constituents, is being given here the notation minus (-) in order to point to low levels of interaction between the teacher and the learners, pre-organized content if any, low access to online resources and tools, and limited support from the external context.

The TCLC - model of use or any of the three other variations in which one of the four constituents is at a low level is still by far the most frequent situation at this point in time. However, we believe that the educational situation is evolving in that learners' access is less limited, and that the context has offered some technical support and opportunities for professional development to teachers. In contrast, the overwhelming thrust of research initiatives within the socio-cognitive psychological perspective would seem to be directed towards the opposite ends of each continuum: teacher/facilitator, content/constructed, learners/high access, context/extensive support (TCLC + Model of use). Here, the teacher primarily facilitates student learning, the curriculum content is largely constructed by the learners, the learners have free access to online resources, and the context supports the use and expansion of the resources.

Emerging observations in the networked classroom

First, with respect to the learner:

Observation 1: Higher levels of control by learners are called for as classrooms are getting more online. The student is found to play a more active role in the networked classroom.

Observation 2: Online resources boost student interest and motivation in the classroom through a greater diversity of learning goals, projects, and outcomes. Student motivation is increased, and this is consistently found across diverse groups of learners.

Observation 3: Learners' thinking becomes more visible. Computer applications facilitate the construction of knowledge representations that can be seen by the teacher and classmates.

Second, with respect to the content:

Observation 4: Internet and learning projects are broadening the curriculum. An increasing number of educational services are being offered online, and these include drill-and-practice
learning activities as well as more open-ended activities such as telecommunication exchange.

Observation 5: **There is a greater range of construction of content by school learners.** In the networked classroom where the teacher has a powerful repertoire of pedagogical strategies, the content is more diverse and there is more student input. More advanced topics are studied.

Third, with respect to the teacher:

Observation 6: **Learning situations become more realistic and authentic as classrooms are getting online.** Both access to online resources and learners' increasing engagement in the construction of content is conducive to better and more authentic learning situations in the classroom.

Observation 7: The successful online classroom combines information technology with appropriate pedagogy. The more engaged teachers have students do more collaboration and communication, carry out more and longer work on projects and have students tackle more open-ended problems.

Observation 8: New online practices by educators are adopted through adaptation. The dissemination and implementation of effective uses of online technologies in classrooms take account of local contexts of instruction.

Fourth, with respect to the context:

Observation 9: **Cooperative and collaborative classroom processes are increased online.** Small group learning with computer technology has positive effects on group task performance, individual achievement, and attitudes toward collaborative learning.

Observation 10: The education of educators is broadened to include just-in-time or collaborative learning. Teachers have had the opportunity to join virtual interest groups and learning communities for nearly a decade, but teachers are far from taking full advantage of such opportunities.

Observation 11: The online classroom challenges the locally-established curriculum. Transmission of the curriculum by the teacher gives way to more approaches where the learner interacts more directly with online content.

Observation 12: Educators use online learning as a key enabler of educational reform. Evidence has been building on the mutual dependency between the use of online tools for learning and school renewal efforts.

**Discussion**

Information and communication technologies (ICTs) present us with a unique opportunity and challenge, to reach for a more human approach to teaching and learning with the purpose of preparing knowledgeable, democratic and socially responsible citizens. Therefore, to downplay the role of the teacher in the education of the knowledge worker of tomorrow – the formation and cultivation of understanding (episteme, knowing-that) and practical judgment (phronesis, knowing-why) – and to overplay that of the skillful production of artifacts as well as that of the expert mastery of objectified tasks (techne, knowing-how), would be here ill-advised. The new pedagogy put forward by the above observations constitutes not only a model of improved human relations but of sociocognitive processes in the classroom.

Teachers' creative integration of ICTs in the curriculum is likely to bring significant changes in the way schools carry out their educational mission. The school culture is bound to open up and to become more collaborative for the teachers and learners to face the inherent changes called for by the wide acceptance of the networked computer. On-line discussions conducted on a small group, on a school basis or on a broader scale, may greatly contribute to the development of such an expectation.

Network-enabled learning communities appear to provide most benefits: on-time access to resources, including best available practice on various subjects being studied, joint exploration of topics and issues, reflective analysis of educational situations, etc. Teacher learning communities that contribute to the intellectual life of the teacher outside the classroom (face-to-face and on-line discussions), and support his or her professional practice are key.
Conclusion

It is important to remember that the classroom is a place where order prevails. The infusion of information and communication technologies (ICTs) creates a zone of uncertainty for both teachers and learners, one that will engage them in a process of risk and exploration for some time to come. This uncertainty may be reduced by a better understanding of the sociotechnical framework needed to take full advantage of available ICTs. Research on one or the other of the four basic constituents (learner, content, teacher, context), while neglecting the others, is bound to lead to partial and confusing results that tend to raise superficial questions and unproductive debates. The interdependence of the four constituents that this review takes into account (and highly recommends for consideration in all further inquiry) should be progressively documented with respect to the impact of online technologies on teaching and learning in the classroom. More recent conceptual developments occurring in other fields such as the learning organization framework and the new domain of knowledge management, seem to point in the same direction.

Pedagogical Ethnotechnography: A bifocal lens to understand technology in Education.

Prince Hycy Bull, North Carolina State University, US

Pedagogical Ethnotechnography

In an attempt to understand curriculum as a technological text, I developed the concept of pedagogical ethnotechnography as a research method. Ethnotechnography has its root words in Greek origins; *ethnos* from the noun nation, tribe or people, "*techne*" is translated as art, craft or skill and "*graphy*" from the verb to write. Aristotle defines "*techne*" as the systematic knowledge for intelligent human action. Ely (1983) defines technology as "any systematized practical knowledge, based on experimentation and/or scientific theory, which enhances the capacity of society to produce goods and services, and which is embodied in productive skills, organization, or machinery." The term ethnotechnography simply means writing about technology as experience by people within a defined boundary.

Understanding Curriculum as an Ethnotechnography Text

Ethnotechnography as envisaged has several branches from which lived technological experiences can be study. Ethnotechnography can be viewed as "cultural ethnotechnography," "business ethnotechnography," "medical ethnotechnography," and "Pedagogical ethnotechnography."

Cultural ethnotechnography can be viewed on how members of a given group or community use or perceive technology within their culture. One major area that this may cover is the study of the "digital divide" from a cultural diversity perspective. One can also study cultural ethnotechnography from an ethnic perspective within society. Business ethnotechnography would focus on how technology is used in the business world. Medical ethnotechnography would focus on the use of technology in the medical field. Pedagogical ethnotechnography is a study of technology as a pedagogical tool as experienced by stakeholders - students, teachers, or school administrators - within an educational realm with an empirical analytic paradigm within a defined boundary set by the empirical analytic paradigm. The educational realm of pedagogical ethnotechnography spans the spectrum of educational delivery from preschool to higher education to educational policy makers. The emphasis in pedagogical ethnotechnography is the rich description of the lived experience as experienced by the participants - teachers, students, parents, administrators and policy makers.

Boundaries within pedagogical Ethnotechnography

The boundary that is set in pedagogical ethnotechnography is not a physical or geographical one, rather it is a scientific boundary to determine entry points in terms of skill level, perception or attitude, or usage before the lived experience and the exit point in terms of skill level, attitudes and usage after the lived experience.

Procedures to conduct a pedagogical ethnotechnography

1. Identify a pedagogical ethnotechnographical issue as it is lived by participants.
2. Prior to investigation, design an empirical analytic paradigm to determine the boundary of the lived experience. By boundary I mean, entry and exit points or pre and posttests of the experiences as lived within defined parameters.
3. Investigate the pedagogical ethnotechnographical issue as it is lived by participants
4. Reflect upon the issues, essential themes or structures that occurred within the defined boundary physically or virtually.
5. Describe the lived pedagogical ethnotechnographical issue using the art of writing supported by empirical analytic paradigm.

Pedagogical Ethnotechnography and Collaborative Autobiography

Ethnotechnography can be studied using collaborative autobiography of participants lived experiences with technology. Richard Butt and Danielle Raymond advocate the use of shared autobiographical works to help teachers understand their 'lived experiences'. The concept of "collective biography" is formulated to point to the appropriateness of reporting and analyzing teachers shared or common experiences. Butt and Richard gives credence to the ethnotechnographical research methodology when they state that in the
process of interpreting individual and collective biographies, one might blend qualitative and quantitative aspects of educational experiences.

**Pedagogical Ethnotechnography and Phenomenology**

Phenomenology is that form of inquiry, which focuses on human perception and experience. As one can see from the definitions, phenomenology and pedagogical ethnotechnography share similarities but there are stark differences between the two.

- Both theories study the world as it is lived. Phenomenology seeks to produce knowledge of what it means to be human. Ethnotechnography seeks to understand what it means to be human in using technology as a pedagogical tool. Also, with ethnotechnography, lived experience means both physical and virtual. Virtual in the sense of what is observed via e-mail, listserv, forums, teleconferencing and e-chat databases.
- Phenomenology theory seeks to ask the “what” instead of “how” questions. Pedagogical ethnotechnography asks both the “what” and the “how” questions.
- Van Manen states that phenomenology is a conscious practice of thoughtfulness and always embodies a poetic quality. I also envisage ethnotechnography as a conscious practice of thoughtfulness but not limited to poetic quality. I envisage a blissful harmony between empirical-analytic paradigm and poetic quality. One in which poetic articulation becomes the lead singer and empirical-analysis the backup singer.
- Phenomenology theory begins with a single case, moves to the universal, and returns to the single instance. Once ethnotechnographical theory takes off with a single case, it simultaneously develops universal and single tentacles to support both single and universal instances.

**Some Benefits of Pedagogical Ethnotechnography**

1. The qualitative and quantitative aspects compliment and validate each other in terms of the data collected and analyzed.
2. The disparities between qualitative and quantitative issues, if apparent are easily identified within the same study rather than in future studies.
3. The findings of pedagogical ethnotechnography are easily generalized to the target population.
The Design of Electronic Learning Environments in Teacher Education:
Understanding the Importance of Representation as a Choice in Technology
Production

Sebnem Cilesiz
Ph.D. Student
Educational Technology Program
University of Florida
USA
cilesiz@gove.ufl.edu

Richard E. Ferdig
Assistant Professor
Educational Technology Program
University of Florida
USA
rferdig@coe.ufl.edu

Abstract: We use representations and abstractions in every aspect of our lives. Designing and choosing the right representation is very important as Norman (1993) states “because representations allow us to work with events and things absent in space and time, or for that matter, events and things that never existed – imaginary objects and concepts” (p.49). In distance education environments, teachers and learners face representations rather than real entities. Thus, correct representation becomes essential in designing electronic learning environments. The authors draw on the importance of representation in cognition in, specifically when designing electronic learning environments. The authors also reflect on related topics and suggest that further studies be done.

Don Norman (1993), in his famous book “Things That Make Us Smart”, makes the argument that representations are important “because they allow us to work with events and things absent in space and time, or for that matter, events and things that never existed – imaginary objects and concepts” (p.49). He also says that the “trick is to get the abstractions right, to represent the important aspect and not the unimportant” (p.49). In other words, the user of the representation is expected to understand the idea or concept without the existence of the original—by looking at and making inferences about the representation.

His statements about representation are important because of the ubiquity of representations in our life. The Oxford English Dictionary (2001) defines representation as:
1. A material image or figure; a reproduction in some material or tangible form
2. The fact of expressing or denoting by means of a figure or symbol; symbolic action or exhibition
3. The action of presenting to the mind or imagination; an image thus presented; a clearly conceived idea or concept.

These definitions point to the fact that representations are things we use in our everyday lives. They include such things as numbers, alphabet, attire, graphs, imagery, tables, and even language. Norman (1993) even argues that the powers of cognition come from abstraction and representation: “the ability to represent perceptions, experiences, and thoughts in some medium other than in which they have occurred, abstracted away from irrelevant details” (p.47).

His statements about representation are also timely, though, as we begin to work with and through technology. As we begin to teach and learn with technology, we create cognitive artifacts that are, in and of themselves, representations. (for that matter, Donald (1991) would argue that human cognitive evolution itself has been greatly affected by our representational abilities.) Norman (1993) had foreshadowed this aspect in his writing, arguing that the future of human evolution would be through technology. Shaffer & Kaput (1999) follow Norman and state that “computational media make it possible to externalize not only information, but also the processing of information” (p.102, italics in the original). Thus, one of the most important affordances of computational media is their ability to allow for conversion of multiple representations, which eases many cognitive tasks. In some sense,
we now continue to create representations as we have always done. However, we are also beginning to create meta-representations to better serve our cognitive needs because of the tools we have available.

Since representation affects cognition, it has a vital role in education and learning technologies. Distance education in specific requires focused attention on representations, because these environments lack many supplementary features of human communication, namely interaction. In other words, these electronic environs use representations as major substitutes for missing elements in non-face-to-face interactions (Muirhead, 2000). In traditional learning environments we can back up false or missing representations by additional features to convey the intended message, however we do not have the same luxury in online environments.

Representation is further important in education because it affects not only the way teachers perceive the designer’s intentions but also the way they design their teaching, thus affecting their students’ perception. Norman (1993) implies that teaching is a skill of understanding “how a topic has to be presented” so that the learner can “acquire it most readily and successfully” (p.121). For example, Suzanne Nyrop (2001) utilizes representation very well in the online environment Tappedln. (Tappedln is an online teacher professional development environment enabling teachers to discuss and share ideas. It is available at http://www.tappedin.org/) She says that she likes to combine play and work in her virtual office “Susanne’s Virtual Playground”. She continues “Here, I keep my notes and records for later retrieval. I also enjoy my virtual pets. Virtual food and beverages are available to offer to my virtual guests” (http://www.tappedin.org/info/perspectives/sn.html). As all other users and designers, Nyrop has made a decision to represent herself. Embedded in all representation is decisions and assumptions – decisions on how we want others to perceive us and assumptions on how they see us. [This reflects the theory of Symbolic Interactionism]. Nyrop chose to represent her office as a playground. This increases the likelihood that people interested in combining work and play will visit her office and meet her. Thus, in some sense, her representation has succeeded.

As representations are important, they should be considered as such for designing electronic learning environments for teacher education. The discussions have many implications for designing online teacher education environments. We suggest that further studies that (i) provides a more complete history of representation and cognition drawing on the works of Donald and Shaffer & Kaput, (ii) describes how to become cognizant of representations (iii) using Mead’s Theory of Symbolic Interactionism, presents information about the self and ways to design representations. (iv) concludes with implications for design and future study needs be conducted.

Several decades ago there was a movement in curriculum for a humanistic education. In part it represented a reaction of educators against the behavioral theories that of learning that were then dominating curriculum and educational policy making. This paper explores the apparent failure of the humanistic education movement and the part that contemporary information technologies play in its revitalization.
Abstract: Driven by common international trends and the acceptance of such constructs as the knowledge economy, pre service teacher education institutions are forced to conceptualise how to integrate ICT into their curriculum. In this paper the author proposes that Habermas's three domains of human interest are an excellent beginning in organizing the curriculum to include ICT. Using these domains he proposes possible curriculum content under headings of What should they be able to do, What should they actually do (in the classroom) and What knowledge empowers them.

Education systems in Australia at all levels increasingly have to respond to the challenge of incorporating Information and Communications Technology (ICT) into curricula. Like many other countries, Government policies mostly drive this movement. Recent Australian National reports such as: Teachers for the 21st Century: Making the Difference (DETYA 2000a); Learning for the Knowledge Society (EdNA 2000); and Models of Teacher Professional Development for the Integration of ICT into Classroom Practice (DETYA 2000b) all highlight the importance of teachers being able to integrate ICT into normal classroom practice. As pre service teacher educators, need to revisit what and how we teach this group of students.

Another factor, which forces us to examine practice at all levels in regard to ICT in Australia, is that Australian State governments are rapidly equipping schools with computers and Internet access. This access is occurring concurrently with a national initiative designed to develop a wide array of on-line learning resources. All these elements focus attention on the preparation of our pre service teacher education students for the rapidly changing context in which they will eventually work. We, as pre service teacher educators, need to revisit what and how we teach these students.

Deciding on what we should teach our pre service teachers is essentially a curriculum design task. This is a task as Grundy (1987) describes, of "constructing" or "designing" a curriculum (p27). Approaches that are dynamic and interactive appear to hold the most promise. These approaches usually start from the premises that planning involves making decisions about the learning experiences of students (content and process), that it will involve many groups, that it will take place at many levels and that it is a continuous process (Beane, Toepfer & Alessi 1991).

It appears that a useful beginning point might be to accept that planning curriculum involves making decisions about the learning experiences of students (content and process). So what follows then is just one personal conceptualisation of what we should be teaching our preservice teachers. It is accepted that other processes would need to follow this beginning. What is proposed below would have to be subjected to some kind of systematic process before it was adopted and these processes.

In my thinking about learning experiences of pre service students, it occurred to me that Habermas's views about the three domains of human interest in learning might be useful. These areas define cognitive interests and are grounded in different aspects of social existence that include work, interaction and power. In regard to pre service teachers, this grouping can be put very simply. At the end of their course What should they be able to do, What should they actually do (in the classroom) and What knowledge empowers them? In the remainder of this paper I would like to use this scheme to propose some answers to the main question of what we should teach.

What should they be able to do?
It is difficult to define exactly what teacher's technical skills should be, as we all know that the history of the ICT industry shows us that technical advances are inexorable and rapid. Nonetheless it is possible to define some generic areas in which they should have enabling skills. Enabling skills are those that I define as those that enable a graduating teacher to use ICT for learning purposes. In other words they are generic skills that become transferable and ubiquitous but allow the user to accomplish much more in learning terms than if they didn't have the skill.

A good example of an enabling skill is word processing. Teachers should be able to use a word processor to enter text, format text, check spelling and print and this skill should be at mastery level. These skills should be transferable to word processing programs other than the program on which they were learnt. These skills would also be able to be used to advantage in other programs. Teachers should have similar kinds of basic skills in the use of a spreadsheet, database and presentation software. They should be able to use a web browser and search engine to locate information efficiently on the Internet. Every teacher should be able to receive and send an email, know how to subscribe to a list server and conduct an on-line chat session.

I think it is also reasonable to expect teachers to be adept at transferring digital information to, from and around a computer. Teachers need to be skilled in these transfer procedures in regard to still pictures and in regard to video and sound files. I believe also that all teachers should be able to construct a simple Web page and mount it on a server.

Should all teachers be required to know how to configure a computer so that it can act as a server or know how to maintain a network? Should they all have a passing familiarity with IP addresses? I don't think so but they should have a conceptual overview of what a network is. Such an overview would enable teachers to make good judgments about the use of emerging technologies like Wireless Application Protocol (WAP) devices.

Should they have knowledge of programming? Programming I would regard as a specialist curriculum subject not applicable to all preservice teachers but with a place in a preservice course for some specialist teachers. Similarly I believe that not all teachers need to know how to upgrade a computer or install a card or memory even though these skills are reasonably straightforward. Anyone aspiring towards a coordinating position in a school should be able to perform these tasks and so courses like this should be available as part of teacher training for those aspiring to specialist coordination positions.

What should they actually do?

How teachers should act in a classroom is essentially a pedagogical question. The answer depends on the individual teacher who takes into account many, often conflicting factors such as the learners' characteristics, their own curriculum knowledge, management issues, outcomes desired and the general social setting in which the learning occurs. The additional factor, which now has to be taken into account in many settings, is ICT. The key pedagogical question facing the teacher is how to best use these technologies to assist the learning process. The dominant learning theory today is constructivism. Constructivist pedagogy acknowledges that students construct meanings that are individual, that students interpret classroom events in individual ways and that social processes are important in learning. This means that for example, when using new technologies like the Internet in the classroom, teachers should regard the Internet as not just a delivery medium but a potentially rich teaching and learning tool (Fetherston 2000). They would then use the Web to address student's own ideas, to allow students to become active participants in their learning and to attend to conceptual change.

Authentic approaches like situated cognition (Brown, Collins & Duguid 1989) are essentially constructivist approaches and the Web has enormous potential to assist with these approaches as they allow explicit links to be drawn between knowledge encountered and its conditions of use. For example, through communications technology students are well able to contact practitioners within their field of interest, to work collaboratively on real world problems and to compare their growing concepts with the expert's and other's conceptions.

Guided participation (Rogoff 1990) offers a sound theoretical framework to guide learning in this way. The Web can potentially allow a "...formal, instruction-oriented apprenticeship model in which novices are systematically coached, guided and supported by expert practitioners" (Hodson and Hodson 1998, p17) to be established. Participation in joint activities with more knowledgeable others is congruent with a social constructivist approach to learning and establishes an environment in which scaffolding can take place. Scaffolding in most settings is mostly a language-based activity that allows cognitive processes that occur first in this social plane to become shared processes and eventually to be internalised by a student. This Vygotskian (1978) process is deserving of much research in the on-line environment (and indeed in all classrooms).
Any pedagogy that embraces the use of ICT would recognise that when students use the Web they can potentially join a community. This community can be like-minded “surfers” or the community could be founded around a common topic and utilise communication technologies. By constructing and posting a web page students immediately have an audience for their work even if they do not know who and how many constitute this audience. For this to be meaningful in learning terms, students need good models to enable them to participate successfully in this environment and to be able to evaluate the quality of information available. Pre service teachers need to develop these models as part of their training. They need to also to be able to eventually implement them in their classes.

The knowledge economy has rapidly become a well-worn phrase. It refers to an economy that recognises that the generation and exploitation of knowledge play a dominant part in the creation of wealth. The rise of the knowledge economy is closely coupled to the globalisation of capital where capital continually circulates economies in search of maximum investment opportunities. Information technology has not just accelerated this process and made it more successful but is the key factor that underpins the existence of the knowledge economy. The key attribute of knowledge workers in the knowledge economy is that they are symbol handlers and that they know how to access and work with information, using ICT. Romer sees knowledge as the third factor of production in leading economies (Romer 1990). Romer views knowledge as the basic form of capital, and economic growth as being driven by the accumulation of knowledge.

Metacognition and reflection are regarded almost universally as important elements that affect learning. As part of a pedagogy that embraces the use of ICT in schools, these elements need to be encouraged and developed. In addition students in schools increasingly need access to tools which enable them to track the progress of their own knowledge: not just by using tools like concept maps nor by working with data bases, but by using personal tools that track their own ideas and the influences upon them. They need tools which answer the metacognitive question “what was I thinking”, tools that enable them to reify their ideas, to link these ideas to other ideas, to link them to what they know already, and allow them to also present these ideas in various forms to others. Allowing students to draw upon existing textual material, graphic images, video or web pages in order to present their ideas should facilitate this and accords with a constructivist framework. Unfortunately such cognitive tools that can do all this do not exist at present. However even presentation software like PowerPoint can assist with new ideas in creative ways.

Innovation, intelligence, concepts, symbol manipulators, information massagers would seem the essential “right stuff” for a successful knowledge worker. In the same way as machines were the stuff of the industrial revolution and people become wealthy by inventing new machines or new applications for existing machines, concepts are the stuff of the knowledge economy. People will become wealthy by coming up with new ideas or by applying new ideas in creative ways.

This means that in terms of pedagogy our graduating teachers must have ways of assisting students so that they can turn information available on the world’s biggest library into meaningful concepts. Of course before this can occur students need to know how to locate such information in the Internet environment and this ability is now I believe a critical literacy. Once having found the information, it is not the information itself but the effect of that information on students’ own ideas that is important and teachers must know how to develop each student’s individual understandings. Much research accords with the view of Becker (2000):

“that teachers were three times more likely to have their students use the Internet if they held more constructivist beliefs about teaching in general—that is, they believed in devoting attention to student interest rather than curriculum coverage, focusing on critical thinking and real-world applications, and using complex problem solving in small groups to help students learn, compared with teachers with more traditional beliefs and practices” (p54).

For students entering the competitive knowledge economy it is their own ideas that they bring that are important as well as their ability to apply these concepts in new and interesting ways.

For students entering the competitive knowledge economy it is their own ideas that they bring that are important as well as their ability to apply these concepts in new and interesting ways. Metacognition and reflection are regarded almost universally as important elements that affect learning. As part of a pedagogy that embraces the use of ICT in schools, these elements need to be encouraged and developed. In addition students in schools increasingly need access to tools which enable them to track the progress of their own knowledge: not just by using tools like concept maps nor by working with data bases, but by using personal tools that track their own ideas and the influences upon them. They need tools which answer the metacognitive question “what was I thinking”, tools that enable them to reify their ideas, to link these ideas to other ideas, to link them to what they know already, and allow them to also present these ideas in various forms to others.

Allowing students to draw upon existing textual material, graphic images, video or web pages in order to present their ideas should facilitate this and accords with a constructivist framework. Unfortunately such cognitive tools that can do all this do not exist at present. However even presentation software like PowerPoint can assist with the process and pre service teachers need to know how to use these tools to accomplish as much of the above as possible.

So what does the existence of the knowledge economy mean for pre-service teachers? Firstly it means that these teachers must know how to develop conceptual understanding in students. Teachers need understanding of broad-based, conceptual change strategies generic through a range of units of study and across many learning areas. Teachers would probably need at least to become familiar with Posner, Strike, Hewson and Hewson’s (1981) four conditions for conceptual change or Hewson, Be eth, & Thorley’s later views that conceptual change can be seen through a change of status attributed to a particular conception (1998).

If we wished preservice teachers to adopt particular approaches to teaching in their classrooms, then teacher training organisations should model these approaches. These organisations also need to re-examine some of the
assumptions about what constitutes core content and what it means to be a teacher.

Deakin University (Victoria, Aust.) and Microsoft have entered into an agreement to implement a degree built around the philosophy of "learn while you work". Students complete 12 months study in traditional manner at university they will then complete the rest of their qualification while working and learning within the IT industry with a guaranteed job. They emerge with a bachelors degree, an industry qualification and two years of work experience.

We must construct similar innovative training for our pre service teachers as the people who teach the future knowledge workers need direct experience in the knowledge economy and this should be a national priority. Benefits would flow onto the students they teach. Perhaps it could be argued that pre service teachers are the group more than any other that need good knowledge of this industry.

**What knowledge empowers?**

What are students' values and perceptions of technology and how are they affected through interaction with ICT? Our pre service teachers need heightened awareness of the possible effects the use of these technologies have on the acceptance or not of individualistic values. Our teachers need to be able to critique the use of ICT in schools and to assist students to develop values that enable them to use these technologies in socially useful ways that enhance the human condition. They need an understanding of the social impacts of such technologies.

ICT technologies have the potential to alter our understanding of what is important, "which is another way of saying that embedded in every tool is an ideological bias, a predisposition to construct the world as one thing rather than another" (Postman 1990). Does the use of ICT in schools help construct a Technopoly where "the primary, if not the only, goal of human labor and thought is efficiency, that technical calculation is in all respects superior to human judgment ... and that the affairs of citizens are best guided and conducted by experts" (Postman 1993). Implicit in this statement is the realisation of such a society is based on the assumption that science is supreme and that ICT technologies support and make possible such a society. The knowledge society seems already disturbingly like this.

**Conclusion**

This paper started with the recognition of the importance of newly graduating teachers being able to develop learning environments that utilise ICT and which contribute to the realisation of a wide variety of learning outcomes. We need to examine what we teach our pre service teachers in regard to ICT and such an examination I regard as essentially a curriculum design task. After examining traditional approaches to design, I decided that a Habermasian view of knowledge centered on what this group should be able to do, what should they actually and what empowers was useful. I then suggested content that could be addressed under these headings in a pre service course. In conclusion I recognize that all the above attends mostly to scope and content: what has to follow are more systematic curriculum design processes in solving sequence, articulation and continuity.

An Model of Self-Regulation Skills
-penetrable process and not-penetrable process -

Michiko KAYASHIMA
Faculty of Art
Tamagawa University
Japan
kayasima@lit.tamagawa.ac.jp

Abstract: ITS (Intelligent Tutoring Systems) researchers consider how ITS assists a user in the
construction of knowledge. The formulation of an answer to this question examines a new
instructional methodology. Additionally, it is observed that metacognition is involved with a
new instructional methodology. In further exploration of these relationships, a metacognitive
architecture, based on a production system as a cognitive architecture, is proposed.

Introduction
While learning theory maintains that learning is the successful transmission of knowledge, the central
issue for traditional ITS (Intelligent Tutoring Systems) is finding efficient ways of transferring this knowledge.
However learning theory has shifted to social constructivism or situated cognition. This has further shifted the
view of learning from instruction to construction [Koschmann, 1996]. The new learning theory forces ITS
researchers to explore new ways to help learners in their acquisition of knowledge such as coaching
self-explanation [Conati and Vanlehn, 2000].

We deem the successful acquisition of self-regulation skills as a new and helpful way to help learners to
acquire knowledge. Self-regulation skills, that are parts of metacognition, allow one to monitor and control one’s
cognition by oneself [Brown, 1987]. Supporting to acquire self-regulation skills allows learners to apply their
knowledge to wider variety problems.
The new learning theory takes a nonabsolutist, fallibilist view of knowledge as constructed, and views this
construction to be essentially a social process [Ernest, 1995]. According to this theory, knowledge is closely
connected with a social situation on which knowledge is constructed. Despite of this view of knowledge, human
experts can use their knowledge in multiple ways according to context. Their flexibility depends on not their
general knowledge but their strategy to use cognitive resource efficiently. We believe that a learner’s
self-regulation skills could cause the learner to apply their knowledge to the problem solving in different
situations. The purpose of this study is to help learners acquire self-regulation skills.

The acquisition of self-regulation skills helps learners to make their knowledge plastic. Discovery
learning requires learners to reflect upon procedures used in solving tasks and to explore which procedures must
be improved [Collins and Brown, 1988]. However, solely utilizing a discovery learning system such as LOGO
does not require the learner to directly monitor and control cognitive activities by himself. Adding them to a
function to help learners to monitor and control their cognitive activities by themselves augments the weak point
of these systems. In this study, we utilize production systems to represent a model of self-regulation skills.
Production systems are adequate for this study, because they represent human cognitive architecture, and they
are constructed by a set of condition-act pairs called productions. The separation between acts and conditions
have the possibility to apply actions to different conditions.

In this paper, we propose a model for self-regulation skills, which are based on production systems. We
will first describe production systems. Next, we will categorize cognitive process into “penetrable processes”
and “not-penetrable processes”. This distinction can be viewed as the difference of inferential mechanism at production systems. Continuing, we will propose a model of self-regulation skill.

**Production systems**

Here we wish to describe production systems, which are known as cognitive computational architectures.

There are a number of candidates for general computational architectures for achieving a mental system, including general problem solvers [Newell and Simon, 1972], general schema systems [Minsky, 1975, Shank and Abelson, 1977], ACT' (Adaptive Control of Thought Star) [Anderson, 1982], SOAR(State Operator and Result). ACT’ and SOAR have been predicated on the hypothesis that production systems provide the right kind of general computational architecture.

A production system consists of two memories: working memory, and long-term memory. Working memory contains the information that system can currently access, consisting of facts retrieved from long-term memory as well as temporary structures deposited by encoding processes and the action of productions. Long-term memory contains facts and productions. The basic claim of production systems is that underlying human cognition is a set of condition-action pairs called productions. The condition specifies some data patterns, and if elements matching these patterns are in working memory, then the production can apply. The basic action is to add new data elements to working memory.

According to ACT’, all knowledge initially acquired declaratively through instruction must be interpreted and reorganized into general procedures through experience. However, by performing a task, proceduralization gradually replaces interpretive application with productions that perform the behavior directly. This mechanism is a learning mechanism. It is referred to as knowledge compilation on ACT’ and called chunking by SOAR, creating task-specific productions through practice. Knowledge compilation is the means by which new productions enter the system.

The knowledge compilation processes in ACT’ can be divided into two sub processes. One, which is called composition, takes a sequence of productions that follow each other in solving a particular problem and collapses them into a single production that has the effect of the sequence. A composed production still requires that the information be retrieved from long-term memory, held in working memory, and matched to second and subsequent clauses. The second process, proceduralization, builds new productions. These productions no longer require the domain-specific information to be retrieved into working memory. Rather, the essential products of these retrieval operations are built into the new productions [Anderson, 1982].

**Penetrable processes and not penetrable processes**

Here, we will categorize productions into penetrable processes and not penetrable processes. This distinction implies the difference of inferential mechanism within production systems.

**Penetrable processes and not penetrable processes**

According to one of cognitive psychology’s recurrent hypotheses, there are two modes of cognitive processing. One is automatic, less capacity-limited, possibly parallel, invoked directly by stimulus input. The second requires conscious control, has severe capacity limitations, is possibly serial, and is invoked in response to internal goals [Anderson, 1996]. Also, a process can be considered as semantically penetrable or not. A penetrable process is a process that can be affected by specific instructions or by giving some explicit information [Pylyshyn, 1998].

Here, we wish to distinguish the above-mentioned productions between penetrable processes and not penetrable processes. Proceduralized productions and composed productions are not-penetrable, a sequence of general productions is penetrable.

First, we consider that the process of a sequence of general productions is penetrable. The process of combining one general production with other general productions can be affected by data in working memory retrieved from long term memory, data encoded from the outside world, data deposited by executing production,
or conflict resolution. Here, we describe the process to decide a general production which should be executed. These data in working memory and conflict resolution decide the production to be combined as a sequence of productions to solve a problem as in the following. In the match process, data in working memory are put into correspondence with the conditions of productions, and then a conflict set of productions is selected. Then only one production that will be executed is chosen by a conflict resolution principle (Fig. 1). Therefore, the execution of a sequence of general productions is penetrable. From this process, a sequence of general productions for solving a problem can be shown in Fig. 2.

However, although the execution of composed production involves the match process, data in working memory are put into correspondence with the conditions of productions, the match process cannot affect the choice of a production. The process of composed production is a non-penetrable process (Fig. 3). Also, the process of proceduralized productions no longer invokes the match process and then is a non-penetrable process (Fig. 4). Therefore, both processes of composed productions and proceduralized productions are not-penetrable processes.

The distinction between penetrable process and not-penetrable process indicates the difference of inferential rule in production systems. Although penetrable process is affected by data in the working memory that production appended immediately, not-penetrable process is not. Furthermore, the distinction between composed productions and proceduralized productions can be viewed as the difference of the extent of knowledge compilation.

A model of self-regulation skills

Here, we propose a model of self-regulation skills.

The architecture for both cognitive and metacognitive process is same

The same architecture must be responsible for both cognitive and metacognitive processes simultaneously [Lories, Darsenne and Yzerbyt, 1998]. This idea leads to the following cognitive process and metacognitive process. Cognitive process is the processing of the information, which is retrieved from long-term memory or the outside world and held in working memory by standard cognitive architecture. Metacognitive process is considered as processing the information that is held in working memory as a product of cognitive process by the same cognitive architecture.

A model of self-regulation skills

As self-regulation skills rely on cognitive process, self-regulation skills on penetrable processes may be different from those of not-penetrable processes. Self-regulation skills which rely on penetrable process result in
the monitoring and control of the inferential process. But self-regulation skills which rely on not-penetrable process result in monitoring and control of the composed process. Although the process of self-regulation skills is different, both of them process information in working memory. The contents of working memory included actions of production that were executed immediately.

**Penetrable process**

As Self-regulation skills are employed to monitor and control inferential processes which were executed for achieving a goal, they can be viewed as exploring a set of productions that have been executed. The trace chaining is shown in the following.

1. A production in which actions correspond with data that is set as a goal, is chosen.
2. If conditions of the productions correspond with data in working memory, go to step 3.
3. A production in which actions correspond with conditions of the chosen production is selected. If there are no productions to which actions correspond with conditions of the chosen production, the process will stop. If a suitable option may be chosen, go to the step 2.

The trace chaining will separate composed production into a sequence of productions. Next, this separation must be evaluated as to whether it is justified.

The relationship between the actions of the productions that were chosen at the last and the conditions of the productions that were chosen next to last in the sequence is evaluated as to whether it is cause and effect. If it is cause and effect, the sequence is justifiable. If not, the sequence must be improved. This process indicates self-regulation skills.

**Not-penetrable process**

Here, we propose to divide composed productions and proceduralized productions into a sequence of general productions as self-regulation skills. As not-penetrable process doesn’t involve the choice of appropriate production, we must evaluate and regulate the process of knowledge compilation as self-regulation skills. This idea is seen in NEOMYCINE’s decompilation. Decomposition is the separation of strategic knowledge from domain facts and rules. This was an attempt to recognize the performance of human experts who can access their knowledge in multiple attempts according to context [Wenger, 1987].

To divide composed productions and proceduralized productions into a sequence of general productions make the composition and proceduralization explicit, providing them warrants. The process of unpacking the complexity of these productions is to articulate knowledge, including justifications in both causal and teleological terms. From this, we propose to isolate composed productions and proceduralized productions by a sequence of original productions as self-regulation skills.

Additionally, proceduralized productions can be viewed as a part of composed productions. In other words, proceduralized productions are a specific form of composed productions. Thus, we describe a model of self-regulation skills of only composed productions.

The process of separating into a sequence of general productions is trace chaining without memory access. Consider the following productions which were demonstrated by Siegler [Siegler and Klahr, 1982].

- **P1:** IF weight is the same THEN say “balance”.
- **P2:** IF side X has more weight THEN say “X down”.
- **P3:** IF weight is the same AND side X has more distance THEN say “X down”.
- **P4:** IF side X has more weight AND side X has less distance THEN compute torques: \( t_1 = w_1 x d_1 \); \( t_2 = w_2 x d_2 \).
- **P5:** IF side X has more weight AND side X has more distance THEN say “X down”.
- **P6:** IF the torques are equal THEN say “balance”.
- **P7:** IF side X has more torques THEN say “balance”.

Applied to the sequence of production P4 above followed by P6, composition create P4&P6.

- **P4&P6:** IF side X has more weight AND side X has less distance AND compute torques: \( t_1 = w_1 x d_1 \); \( t_2 = w_2 x d_2 \). AND the torques are equal THEN say “balance”.

After composed production P4&P6 is executed, data “balance” might be appended into working memory. Self-regulation skills on P4&P6 are described as the following.
The candidates of general production; P1, P6, and P7; the actions of which correspond with data “balance”, are chosen. From these candidates, a sequence of general productions will be combined. We describe two cases; the candidates of general production P1 and P6.

The case of P1:
There are no productions, the actions of which correspond with conditions of production P1, “weight is the same”. Then, a candidate sequence of general productions is P1.

The case of P6:
There is no production, the actions of which correspond with conditions of production P6 “the torques are equal”. But the relation between the actions of the production P4 “compute torques” and the conditions of the productions P6 “the torques are equal” is of cause and effect, and consequently this connection may be evaluated as being justifiable. Next, the production, the actions of which correspond with conditions of production P4 “side X has more weight” and “side X has less distance” was chosen. But, there are no productions, the actions of which correspond with conditions of production P4; “side X has more weight”. Then, a candidate sequence of general productions is P4 and P6.

There are two candidates of separation as a conflict set. As the condition of P1 “weight is the same” doesn’t satisfy the criteria, a sequence of P4 and P6 is a candidate of separation.

Summary
We propose a model of self-regulation skills based on penetrable processes and one on not-penetrable processes.

Reflecting on the not-penetrable process, compiled knowledge has become so specialized toward a specific use as to have lost transparency and generality. The state of being compiled is independent from the process by which the state was reached [Wenger, 1987]. Therefore it is necessary to warrant compiled knowledge through the process by which the state was reached. Kitcher (1983) defines intellectual knowledge as warranted belief, where the “warrant” for a belief is a set of specific experimental episodes that have given rise to the belief and that justify it to a particular person. In other words, the actual warrant is a process.

The process of separating compiled knowledge into a sequence of general productions is also to justify it to oneself. Therefore the process of separating compiled knowledge into a sequence of general productions is one of self-regulation skills.

Abstract: A distance education professor from Turkey and a professor of Learning Technologies in the United States have collaborated on the design of a graduate course for studying the dynamics of change in an era of electronic technologies. They will describe the perspectives used to examine the impact of technology on society and thus on the pedagogical tools developed to enhance eventual online delivery. The course provides an opportunity for students of learning technologies to look at the field from broader perspectives through historical, sociological, political/economic, cultural and personal perspective on how technology has changed human activity. Through short writings, reaction papers to the books and research syntheses in an area of interest, students develop a personal change model and revisit that model. Students, also, wrote a science-fiction story that shows what they think education might be like in the future. Readings are from fields other than education.

Introduction

This graduate course titled “Society, Education & Technology” in the College of Education at New Mexico State University covered a lot of different aspects of how technology affects society and education. It began with the larger historical perspective offered by Toffler of how technology has changed world history during three distinct phases or waves of technological change moving from the agricultural to the industrial to the current information/communication age. We looked briefly at how technology and specifically computers have changed in the last 50 years and what that means for education. Our model of the changing functions of computers involved moving from computers as number crunchers to data processing machines to communication devices and finally to seeing computers and the networks they are connected to as a knowledge creation environment. Then we considered briefly how technological innovations have influenced education or not influenced it and finally we looked at some of the stages of technology use in education.

To explore the dynamic relationship between changes in technology, society, and education and their influence on human interactions and learning, students in this class collected information from a variety of perspectives, historical and philosophical, sociological and cultural, political and economic, and psychological and personal, and create their own knowledge environments related to technology, society, and education. They tried to find an answer to how technology affects society and thus education and technology and its relationship to societal change. They found these answers not only through reading widely in books outside of education but also by interviewing young students who were involved in using the web.

During the second week students received an invitation from the instructors to participate in a research symposium to be held toward the end of the class on the subject of technology, society and change. The students refined their questions and formed question research groups. The intention was for the class to formulate a number of powerful essential questions that can drive the investigations into the relationships between technology, society and education. An essential question must be meaningful and deep enough to lead to fruitful research and consideration of big ideas. The research groups developed questions about technology, society, and education, which are answered through interactive multimedia presentations, which will be presented at the (Society for Information Technology and Teacher Education (SITE) conference 2002.
The main objectives for the students were:

- To discover technology and its relationships to societal and educational change.
- To work in a project-based team to investigate a technology, society and education question deeply.
- To make assumptions based on their coursework and write a narrative on the future.

**Background of the Class**

In the words of Buffalo Springfield, *Something's happening here... what it is ain't exactly clear...* or as Dylan suggested *The times they are a-changing.* The world is not the same place in which we grew up or in which our parents and grandparents lived. We live in what Margaret Mead called a *post-figurative culture,* in other words a culture in which our children experience a whole different reality from what was experienced by older generations. The effect is that much of the knowledge we gained growing up may not be especially relevant or useful in today's world.

Yet, there are historical parallels to this period and common to these parallels are how society often reacts to fundamentally new technology. The course begins with a story from Socrates about the fears educators had about student learning when the alphabet was introduced. When the printing press was first invented no one envisioned the profound effect it would have on human activity. Books were still seen as something only for the elite. Language and literacy are crucial technologies influencing human events. History has many examples of how writing and reading was forbidden in different cultures including the slaves in early U.S. History. From 1066 to the late 1300's in England all official transactions were done in Latin or French. At one time English was only an oral language spoken by the peasants. By 1400 the people's English began to blend with French and Latin into Chaucer's Middle English and eventually modern English.

Now we have the personal computer. Where once only computer gurus in data processing departments could control the information to which people had access, an elementary student today can quickly access the Web and soon know more than his or her teacher about a specific subject. Scary. And then there is the more recent history of technological innovations in schools, so well articulated by Larry Cuban in *Teachers and Machines* (1986). In each era from films to radio to instructional television great claims have been made by researchers and technologists about how this new innovation will change education. In fact, very little has changed. Is there something fundamentally different this time? Is the web more like the printing press than just a faster engine? This class is about all of these issues. It asks the essential question: "How is technology changing the world and what does that mean for education?"

The historical perspective in this class was investigated by studying Toffler’s three distinct waves of technological change from the agricultural to the industrial to the current information/communication age. Students also read *The Victorian Internet* (Standage, 1999) and compared this innovation to current web development. They were amazed at the similarities between the development of the telegraph and the web today. We looked at the long view of history using writers like Alvin Toffler and his book *The Third Wave.* We also began scanning current media to detect the hottest issues in society today in relationship to technology following the lead of Naisbitt’s *Megatrends* (1991) a book he wrote based on column inches dedicated to current news. As part of the historical perspective students developed their own interactive timeline in relationship to the Question/Research group they join.

A sociological perspective included reading *Growing Up Digital* (Tapscott, 1999) and doing student interviews with *Netgeneration* students. Technology has always had a profound effect on human activity. Small communities were formed when the technology of farming was invented. The invention of the wheel made it possible to move goods and people easily from place to place and contributed to the creation of commerce. The class investigated models of the change process, examined speculations related to the directions and dynamics of change in an era of electronic technologies, explored shifts in the cultural and personal activities and relations of humans, and speculated on concomitant educational implications. Each student developed a personal model of change and shared it in class.

We also discussed the importance of tools. Technology is not neutral, but affords different kinds of activities (Norman, 1994). As computer capacity has grown and network resources increased exponentially the power of computers have changed from what were at first glorified typing and teaching machines to systems in which it is now possible to create as well as distribute education. High levels of access allow teachers and students to participate with others in the community and to generate new community knowledge environments. One of the
important potentials for today's interactive multimedia technology is to help students who are English Language Learners. Technology can also afford community building or individualistic types of learning.

In the year in which the Berlin Wall fell (November 9, 1989), Francis Fukuyama (1993) believed that the end of the cold war signaled the end of a long ideological evolution from feudal times through republics, communistic approaches, to the final form of government - a universalization of liberal democracy. In contrast, Samuel Huntington (2001) highlighted that the world was entering a new period in which there would be a Clash of Civilizations. He issued a much more ominous forecast and suggested that the passing of the cold war had brought an end to competition among nation-states, but it had also launched an era of growing competition among the world's major civilizations. These questions were pressing after the September 11th terrorist activity and the class turned to books like Jihad vs. McWorld (Barber & Schulz, 1996) to help understand the current crisis and its relationship to society and technology. Political and economic explorations were also grounded in the economic history of Hegel and Marx and expanded to include cultural perspectives through reading C.A. Bower’s Let them Eat Data (2000). We abandoned the regular syllabus after September 11 and spent three weeks on questions related to this event including time spent exploring alternative world media. Especially interesting was how different countries used media to explain their point of view on this event. We returned frequently to a very professional web site developed underground by professional women in Afghanistan (http://rawa.fancymarketing.net).

Project-Based Learning

If teachers are going to change the way they teach they need to be in classes that model constructivist, project-based learning. This class was designed to involve students in researching, organizing, evaluating, and presenting information that they felt illustrated relationships between technology, society and education. We are to thinking as the Victorians were to sex, writes Papert (1980), everyone does it, but no one knows how to talk about it. As we create new electronic learning milieus, we have the potential to create environments that scaffold and enhance higher-level thinking. Anchored Instruction is one way to think about a constructivist design for learning. The term was introduced by the Cognition and Technology Group at Vanderbilt (1990) to describe situated learning. Norton and Wiburg (1998) describe this type of instruction, Anchored instruction creates environments that permit sustained exploration by students and teachers and enables them to understand the kinds of problems and opportunities that experts in various areas encounter and the knowledge that these experts use as tools. (p.103) It is this type of constructivist learning that we aimed to model in our course on Technology, Society and Education.

Students built their research presentations around problems and questions that were both meaningful for them and rich in opportunities to understand how technology affects society. The culmination of the course was the research symposium presentations. During the class, findings from the readings were explicitly tied by the students to their larger research questions. The topics were extremely diverse and quite interesting. The groups in this class choose the following topics:

- Environmental Racism - What impact have computers had on the quality of life from an economic, health, and consumer perspective?
- Virtual Learning & Real Benefits - As the need for education increases and time for pursuing and education decreases, can the combination of high-quality instruction and current technology assist specialized groups of learners to obtain their objectives and does gender play a significant part in this learning progress?
- Influence of Technology on Human Health - How has the growth of technology has an effect on individual’s quality of life and health across socioeconomic boundaries?
- Technology & Multicultural Diversity - How does an individual’s socioeconomic, gender and racial background affect their learning with technology?
- The Influence of Technology on Educational Delivery - How have new technological media influenced distance education opportunities for woman?

Each presentation took almost an hour in spite of the assignment, which was to do a 30-minute presentation. However, students had created extensive time lines, web connections, and interactive multimedia components to their presentations and we did not want to limit their time. The student presentations will be available via the web on the New Mexico State University Learning Technologies web site (http://mathstar.nmsu.edu/EDL610.htm).
Creative Activities

Piaget once wrote, To understand is to create. To provide students with a truly constructivist environment we asked them to build creative products as part of this class. The first product was their personal theory of change in which they developed both a visual metaphor and a narrative related to their theory of how things changed. We did not limit their product to education but allowed them to think about change in the world. This reflected the class in general, for which we had decided that graduate students need to think outside of the paradigm of education. Metaphors included different types of swimmers in a race, a peeling onion, a train going downhill, types of eaters, and spirals without beginning or end.

The final project in the class and the one the instructors felt best evaluated the ability of students to think about the future was an assignment to create a science fiction story about education and life in the future. Graduate students who were now well trained in writing research papers protested loudly against having to write fiction. However, the instructions understood the value of transforming information from one form to another (expository to narrative) as well as the value of showing via narrative what things mean (Brunner, 1966). The resulting stories were uniformly very, very good and showed, often in a very moving way, the potential relationships between technology and society. The stories reflected the two-sided sword of technology. Some were very scary and portrayed an Orwellian future in which technology controlled all human interactions to make them efficient and non-messy. All babies had to perfect in order to enter society and all jobs were designed for each individual’s skills and interests. A character who was curious about the what other people did or the possibility of changing jobs had to be eliminated. Other stories reflected the liberatory potential of technology to serve rather than destroy diversity. In one educational system a student and his grandmother used the web as well as electronic time travel to study an area of historical interest.

Conclusion

This course covered many different aspects of how technology affects society and education. It began with the historical perspective offered by Toffler of how technology has changed world history and then explored parallels between an earlier revolution caused by the telephone and the impact of the web today on society and education.

As with any new technology computers were first used to do more efficiently things that teachers have always done. During the 1960’s and the 1970’s the computer was used for “drill-and-practice” or “tutorial” programs with students. This was known as computer-assisted instruction (CAI) or computer assisted learning (CAL). Students would type in answers and the machine would indicate whether the answer was right or wrong. If it were wrong then the computer would indicate that the answer was wrong and then present a new question at the same level of difficulty. If the answer were correct then the computer would present a progressively more difficult question. It was believed that students could learn more in a shorter period of time using this type of technology. In many cases CAI has been useful in improving student achievement. However, Cuban notes a study by Levin, Glass and Meister (1984) that noted that peer tutoring was actually more cost effective in terms of learning gains that the use of computers. Hativa, N. (1988) did an extensive meta-analysis of the use of computer-based drill and practice in arithmetic and suggested it was widening the gap between high-achieving and low-achieving students. CAI is often least effective with English Language Learners since their problem may not come from not understanding language rather than content (Wetzel, K & Chisholm, I., 1998; Butler-Pascoe & Wiburg, in press). In a 2000 study, A recent large-scale study by Wenlingsky (2001) found that those children whose teachers used computers in constructivist ways to teach mathematics (simulations, spreadsheets) scored significantly higher in mathematics achievement than those who used the computers as tutorial and drill and practice machines

Most current leaders in the field of learning and technology suggest that it is only by tying the use of computers to new forms of instruction such as constructivism and socioconstructivism that the power of the computer for learning can be tapped (Bereiter, 1994; Dede, 1998; Norton and Wiburg, 1998; Rodriguez & Berryman, 2000). There is emerging a powerful synthesis between new theories of how students learn by constructing and sharing knowledge and the capacity of new computer-based technologies to support these types of learning strategies. However, access to these best uses will not occur until teacher educators embrace and model these deeper uses of technology.

It was important in this class to think critically about the notion of change. Each new innovation is introduced with strong words from the developers as to how this new device will fundamentally change education.
In reality, many of these innovations have had very little impact on teacher practice. The final book we read in the class, Leadership and the New Sciences, reinforced for the students the nature of systems and the potential impact of the larger system on efforts to make change. As a result of studying changes in society and education in relationship to technology, students became more reflective and critical about what kind of change is possible in the world of education today. Is the computer such a fundamentally different machine that its integration into school practice is likely to alter practice in fundamental ways as suggested by Norman (1994) or Dede (1998)? Or is the institution and culture of K-12 education fundamentally in conflict with the potential of computers to create changes in educational practice? What are the limitations of the current educational structure in the United States and how does this limit what is possible in terms technology and learning? Taking a variety of perspectives and a global view of change helped students to think about how to answer these questions and to become the leaders we need in the field of information, communication, and learning technology.

Abstract: The world is rapidly becoming more technologically complex. As a result, students need to be taught differently than they have been in the past. Schools must prepare students to become active members of this changing society, and to adapt to these transformations as they occur. The Internet can be a strong partner in enhancing a student's ability to think and solve problems critically. However, without teachers who understand how to integrate technology meaningfully into their teaching, the desired student outcomes may not occur. This paper discusses ways that the Internet can be used to teach critical thinking in a classroom.

Introduction

Critical thinking and problem solving have become increasingly important in the educational development of students. Critical thinking helps students to better read, listen to, understand, and remember information (Smith, Knudsvig, & Walter, 1998). Moreover, engaging in critical thinking requires students to be active participants in the construction of knowledge, rather than passive receptacles for information delivered by a teacher or instructional medium (Jonassen, 2000).

Critical thinking can be easily incorporated into a constructivist classroom that supports students in being producers of their own knowledge. In a constructivist environment, students work on complex projects, synthesize information to build their own understandings, learn skills and concepts, and use them to solve real-world problems. These projects, often done in groups, follow from a theory of learning that suggests subject matter becomes meaningful, and therefore understandable, when it is used in context-rich activities (Fosnot, 1996; Norton & Wiburg, 1998).

The availability of technology and access to the Internet has allowed educators to bring real-world problems into the classroom for students to explore and solve. In addition, students are often more engaged in problem solving when using such external vehicles as the Internet, because they encourage comparing one's ideas with others, an important component of the critical thinking process. Students in today's world have other possibilities than learning face-to-face from a teacher. They can also learn by discussing problems, ideas, and beliefs with peers and experts throughout the world by using the Internet. According to Bransford, Brown, and Cocking (1999), "Technology can help to create an active environment in which students not only solve problems, but also find their own problems" (p. 195).

The Internet as an Enhanced Critical Thinking Tool

The Internet is the world's largest computer-based communication network. It contains many resources that educators can access to create enriched learning environments, and it has the potential to offer up-to-date information for teachers, and learning activities for students. It also can expand the boundaries of a school far outside its walls, and change the roles of teachers and students in the educational process.

Learning on the Internet can help make education more meaningful for some students than learning by traditional methods, because they can acquire knowledge using a variety of modalities, including visual, audio, and text. They can also gain a great deal of information about any topic in a very short period of time, and have
access to original sources and experts throughout the world. Numerous databases found on the Internet can help teachers guide students to access, analyze, and evaluate information. With appropriate instructional strategies that teach critical thinking, students can then learn to construct their own meanings from this information.

According to Harris (1994), the use of the Internet as an enhanced critical thinking tool in the classroom can include independent learning, one-on-one coaching, and large group projects, with both independent and assisted practice. For example, retrieving research information can be done alone or as a member of a group. Email is a useful medium for collaborative writing activities, and can also be used for communication among groups of students from various cultural and socio-economic backgrounds. Bulletin boards and Usenet newsgroups provide individuals the opportunity to read, reply and reflect on messages focusing on specific areas of interest. Web sites also allow users to store documents and multimedia resources. In addition, the Internet allows for computer conferencing and virtual classrooms. Internet Relay Chat (IRC) lets users see what is typed on other users' screens; and, video conferencing permits users to send and receive video images from people throughout the world. One of the newest learning environments is virtual reality, which gives users the impression of three-dimensional interaction.

Although there are many advantages to using the Internet in the classroom to enhance critical thinking, learners may become overloaded with information. Harris (1994) found that students are more successful when they consciously apply specific strategies to learning tasks. The learning tasks then direct their thinking, and encourage them to monitor and evaluate their progress. Thus, it is crucial for teachers to assist learners in developing strategies for best accessing and evaluating online information. In addition, educational activities should include offline resources, such as video, books, and other available resources.

If educators hope to use the Internet effectively to enhance the teaching of critical thinking, all schools and teachers must have access to technology and the Internet. However, they also need to have professional development opportunities that teach them to meaningfully integrate the Internet into their curricula. Without such staff development programs, delivering web-based courses to teach critical thinking may be a time-consuming and frustrating educational activity for both teachers and learners.

Conclusion

Teaching critical thinking should be one of the most important educational goals in today's society. When thinking critically, we become active, productive, hopeful, and psychologically healthier people. However, teaching students to become critical thinkers is often difficult. With today's emphasis on test scores, a teacher must make an extra effort to integrate problem solving and critical thinking into her daily routine. When done correctly, this may have the additional benefit of higher test performance.

We need educational environments with high levels of communication, interaction, and collaboration. The Internet can be a valuable tool in an instructional strategy, because it enhances active, cooperative learning through communication with people, both nearby and around the world (Smith, 1996). Today's educators are beginning to use technology to support students in critical thinking activities, because they provide learning environments that are more interactive and engaging. Teachers will continue to have a very important role in the development of Internet applications for their classrooms.

It has become quite clear that the Internet is breaking down the walls of the traditional classroom, and allowing students to gain worldwide communication and information online. Moreover, instead of teaching and learning only in the conventional educational environment, we can now do so at a distance with our own computers. We are just beginning to understand the potential of the Internet as an educational tool that can be integrated into the classroom in a meaningful way.

Abstract: Teachers, particularly those working with technology, have to deal with the issue of design. However, it is often hard to describe what design means. This paper offers an analytic framework for better understanding the process of design and comparing it to the kinds of activities that are involved in teaching. We do this by looking at case studies of design as instantiated in a Master's seminar in Educational Technology. Participants in this class were expected not only to learn interactive web-based technology but also to generate abstract knowledge (about designing educational technology) through working on authentic design projects. In this paper we look closely at the design process and compare it to the process of teaching. Our analysis is guided by prior work on the analysis of design conducted by Mishra et al. (1999). We believe that a better understanding of design can enrich our understanding of both teaching and technology taken individually, as well as offer us new ways of teaching with and about technology.

Introduction

This paper grew out of a conversation about teaching with technology, a conversation between two researchers who focus on educational technology, teaching, and teacher education—though with slightly different backgrounds and interests. The first author is a designer, researcher and educational technologist with a keen interest in the nature and process of design while the second is a former school-teacher and researcher in teacher education. Clearly we approached these topics (of designing technology, teaching with technology, and teaching about teaching with technology) from different perspectives but with fundamentally similar concerns, (a) to better understand the manner in which teachers use technology in their classrooms; and (b) to use this understanding to develop better strategies for assisting this complex process. As we continued to talk it seemed that certain themes began to emerge, themes that tied together teaching and design in interesting and insightful ways.

Underlying our conversations was a concern with teacher’s attitudes towards technology or more appropriately people’s perceptions of teacher’s attitudes towards technology. Too often it seemed to us teachers were being represented as Luddities or people resistant to the incorporation of technology into their classrooms. Moreover teachers also report feeling ill prepared to teach with technology, and research suggests that for the most part, teachers are not making the kinds of transformative uses of technology that seem likely to have a positive impact on education (Becker, 1999). However, this is where we faced a paradox. Through our conversations we came to realize that at some level, teachers should be the ones most comfortable with technology. They are accustomed to complexity; they design complex environments and solve ill-defined problems day in and day out (Leinhardt, 1994; Lampert, 2001). On the face of it, they have some of the most important characteristics needed to be effective technology users.

This seeming contradiction between perceptions of teachers towards technology and our belief that teachers should be the most comfortable with it is the basis this paper. To understand the problem, we use
the metaphors of teaching as design, and design as teaching. Through these lenses, we explore ways that
teachers can understand the work of learning to teach with technology as an extension of what they already
know and can do. We begin by talking about design, what it is, and what it is not. At each and every point
we contrast it with teaching. What we find is that both design and teaching share many important
characteristics. Specifically we shall focus on a series of themes about design and look at each theme as it
plays out in the case of design and of teaching.

Why these particular metaphors?

Recent research projects on learning environments have been described as design experiments,
and the metaphor of designing for teaching has been extended by some to teaching as design. Educational
technology researchers work at the interface between design and teaching. We help teachers learn to design
technologies, and to design their teaching to take advantage of the affordances of those technologies. We
help them learn to teach with designed artifacts. The link seems natural because our work is focused on
both design and teaching.

From time to time, both teaching and design have been conceived as being formulaic—a series of
predetermined steps that must be accomplished in order to achieve a particular goal. Both programmed
learning and standard design methodology courses suffer from this misconception. At the heart of
misconception is what Donald Schon calls the "model of technical rationality" (Schon, 1983, p. 21). This
model assumes that both design and teaching consist of "instrumental problem solving made rigorous by
the application of scientific theory and technique" (Schon, 1983, p. 21). Just as too often technology is seen
to be "merely the application of the relevant basic sciences to the making of artifacts" (Dasgupta, 1996, p.
4), teaching has been seen as the application of psychological principles to the process of student learning.

For instance, looking more specifically at design, it has been argued that design is more than the
application of scientific knowledge to a given real world problem (Dasgupta, 1996; Geiermete, 1999;
Mishra, Zhao & Tan, 1999; Schon, 1983; Winograd, Bennett, De Young & Hartfield, 1996).

As Mishra, Zhao, & Tan (1999) say:
Design is a creative activity that cannot be fully reduced to standard steps, and should not be
thought of as mere problem solving. A designer lacks the comforting restraints of a well-organized
discipline because designing is inherently a messy endeavor. It includes, but goes beyond, the
ability to be creative in solving problems. A host of techniques and skills come into play during
design. Many of the techniques and skills are explicit and publicly available, while others may be
tacit and unspoken. According to Smith and Tabor (1996), design is as much an art as it is a
science—spontaneous, unpredictable, and hard to define. (p. 221)

It is enlightening to read the above quotation once again, though this time replacing the words
"design", and "designer" with the words "teaching", and "teacher". The new quote would echo a
perspective that is valued by many teachers and teacher educators.

Similarly, both teaching and design require a balancing act among a variety of factors that often
work against each other. It requires the application of a wide array of knowledge, from algorithms to rules
of thumb. This inherent "messiness" of both these professions is further complicated when we consider the
very abstract nature of their respective goals—be it learning for understanding or the design of an after-
school program (Vyas & Mishra, in press) or an online course.

Both design and teaching are inherently teleological. Both are concerned with the invention of
artifactual forms—an activity that aims to satisfy human goals and aspirations. Often, particularly in the
case of design These goals can be quite concrete as in the case of building a bridge or or writing a poem. In
the case of teaching, however, these goals can be more abstract: developing student understanding, learning
content and so on.

In addition, both design and teaching are dependent on dialogue or interplay. As the individual
acts on the environment, the environment also acts upon the individual. Design and learning are not simply
about understanding and assembling materials. It is fundamentally about ideas and transforming oneself
and the world through the process of working with those ideas. This process of "acting on" an idea happens
in two ways: intellectually and physically. Intellectually, the designer or the learner engages with the ideas
and concepts and attempts to learn more. Physically the designer works with the artifact, modifying,
manipulating objects to fit the desired ends. This is essentially a dialogue between ideas and world, between theory and its application, a concept and its realization, tools and goals. We see this dialogue as being at the heart of true inquiry, involving as it does the construction of meaning and the evolution of understanding through a dialogic, transactional process.

We begin with a framework for thinking about design developed by the first author (Mishra, Zhao & Tan, 1999). In this paper we attempt to “unpack the black box of design” by closely studying the theoretical, technical, social and cognitive issues surrounding the design of two different computer programs. This analysis (1999) builds on previous empirical and theoretical work by other scholars (Dasgupta, 1996; Schon, 1983; Winograd and Flores 1986; Winograd et al, 1996), and led to the outlining of twelve general themes that underlie the design process.

We extend this discussion about the similarities and differences between design and teaching through a deeper analysis of the 12 themes of design as offered by Mishra et al (1999). These are:

1. Design/Teaching is purposeful, intentional, and conscious
2. Design/Teaching keeps human concerns at the center
3. Design/Teaching is knowledge intensive
4. Design/Teaching is historical and path-dependent
5. Design/Teaching is selective
6. Design/Teaching is aesthetic
7. Design/Teaching is communication
8. Design/Teaching is a social activity
9. Design/Teaching is creative
10. Design/Teaching is emotional
11. Design/Teaching is an ongoing conversation
12. Design/Teaching requires closure

Limitations of space prohibit us from delving into each of these themes in greater detail. Clearly some of these themes will not be new to teachers and educators. However there are others that may not be as obvious. The fact that design is aesthetic brings to the forefront the fact that teaching is also an intensely aesthetic activity. However, this is not an issue that is raised often during discussions on teaching. Similarly both design and teaching require immense emotional commitment, once again not something discussed often. Finally the fact that design requires closure allows us to think about the ebb and flow of teaching (be it a single class or a school year) very differently. Thus what this metaphor does is allow us to think about teaching with a new perspective.

Applying our ideas

The similarities between teaching and design can also be seen in discussions about how both are to be taught. Schon (1987) lists a range of reasons arguing that design cannot be “taught” in conventional ways. Once again it is instructive to see how appropriate these reasons for why teaching cannot be taught in conventional ways. Schon argues that: (a) Designing is a holistic skill. It must be grasped as a whole, by experiencing it in action; (b) Design depends a great deal on recognition of design qualities. This recognition is not something that can be described but rather must be learned by doing; (c) Designing is a creative process in which a designer comes to see and do things in new ways. Therefore, no prior description of it can take the place of learning by doing; (d) Descriptions of designing are likely to be perceived initially as confusing, vague, ambiguous, or incomplete; their clarification depends on a dialogue in which understandings and misunderstandings are revealed through action; and finally (e) The gap between a description of designing and the knowing-in-action that corresponds to it must be filled by reflection-in-action.

Over the years we have been applying our ideas about design and teaching in a series of master’s courses taught by the first author. The emphasis in these courses has been on learning about design by “doing” design. Most participants in these courses are practicing k-12 teachers who bring their rich professional knowledge of teaching and learning to the classroom. Participants in this class were expected not only to learn interactive web-based technology but also to generate abstract knowledge (about designing educational technology) through working on authentic design projects. In the learning process, each member of the communities is engaged in activities that compel them to seriously study technology,
education, the interface between the two, and the social dynamics of working with others. They participate in various learning activities such as group projects, whole class discussion, group collaboration, project presentation and critique, asynchronous on-line discussion, journals and final group reflection on design process. Through learning about and through authentic design focused on genuine problems of practice, participants use technology creatively in various educational contexts.

One of the key arguments developed over the duration of the semester is that of the similarities between design and teaching. This is not something that is explicitly pointed out at the beginning of the course. Rather in the beginning they are told this course is just about learning technology through design. As the semester progresses, these similarities between teaching and design are allowed to emerge. This culminates in a formal presentation by the instructor towards the end of the semester that describes the similarities between design and teaching. Finally the students are asked to write a paper on the design and teaching process connecting them to the 12 themes of design/teaching.

Design and teaching are not things that can be taught by lectures and demonstrations. They are best learned through the active process of creating and doing. That said, both are hard to learn. Both can be extremely motivating and enjoyable though frustrating as well. The fact that there are no magic solutions, and even the solutions that emerge are compromises at best is often a difficult message to swallow. By involving teachers in these design projects we offered them an opportunity to explore and play within the relatively “consequence-free” zone of a classroom. In some sense the classroom became a laboratory for teachers to experiment and try out different concepts, to experiment with technologies and ideas.

Bringing ideas of design into the realm of teaching allows teachers to think about what they do on an everyday basis in a new light. As one of the students in the class wrote in a journal posted to the class listserv: “I buy into the strong parallels between teaching and design. We design lesson plans. We design strategies to hopefully interest children in learning, discovering, and developing an interest to learn more. Early on I tried to design lessons to get them to learn the correct information they needed. Correct information is important, but now I try so much harder to just get them interested in learning and develop an interest to learn more. I work at designing an environment that is appealing not only for the information, but for the aesthetics. Over the years that I have taught (~20) I agree … that teaching is spontaneous, unpredictable, MESSY, and creative. So much more is involved than just me. How much the students know already and what the students are like just from one class to the next.” He continued “The problem is design cannot be taught. It is a holistic skill - it must be experienced… I was so unprepared for what I found in the classroom, because there was so much more going on than what my college classes covered. I needed college for the knowledge of my field, but I needed more input from teachers than I had when I started… If I had not been under contract the first 2-3 months I think I would have quit.”

The course became a site where students thought about the complexities inherent in both design and teaching. As one of the students in the class said: “Ultimately, I think one of the things I’ve learned from this is how complex and dynamic the process of design can be. We have brainstormed, gotten ideas from and been influenced by other people, our audience, our surroundings, and by the object of our design itself. By listening to opinions, taking the advice of others, and considering our own vision we are creating something unique and exciting.”

Conclusion

We believe that bringing these two worlds (that of design and that of teaching) together adds to our understanding of teacher knowledge for teaching with technology. It allows us to explore aspects of what teachers already know, albeit tacitly, and how that knowledge can be called on in support of new skills and competencies. Finally we believe that the metaphor of “teaching as design” allows us to think of both teaching and design in interesting ways. As we know, metaphors serve as filters for our perceptions, providing a kind of framework within which we interpret our experiences and assign meaning to them. Metaphor is deeply embedded in our language, culture, and the way we think, and hence affects how we experience and interact with the world and other people. We believe that bringing the metaphor of design into teaching with technology allows teachers to step out of the “paradigm of technical rationality” and to become better and more flexible users of technology.

Abstract: As a prominent environmental feature, the availability of advanced technology likely has a pronounced developmental influence on those who encounter it. As technology becomes more integrated into society, and as society becomes more technology dependent, an individual without even basic technology skills may face the same challenges as one who lacked basic literacy twenty years ago. Exposure to technology likely has other benefits, such as facilitating the development of advanced cognitive and conceptual skills. A problem exists, however; not all individuals have adequate exposure to technology or adequate opportunity to develop technology-related skills.

Human development is largely dependent on the environment. A compromise accepted by many in the seminal nature-nurture debate is that the environment determines how heredity expresses itself. Society has changed much in the last eighty years, and the degree of change within the last thirty years has been more rapid than in any other period of human history. Basic skills sets have always changed based on the availability of technology and the dynamics of social convention. The advent of the computer age has changed human occupational, social, and educational development significantly in a very short period of time. The computer is likely responsible for the single largest developmental shift across many areas of learning and performance; this is especially true of not only what children, adolescents, and young adults are expected to be able to do, but how they conceptualize problem solving and the degree to which abstract reasoning is important in concept formation.

The workplace has changed significantly due to the automatization of many formerly manual jobs. Education has changed on several fronts as well; not only do computers (and other sophisticated electronic devices) require special skills to use, they are also now part of standardized education in many areas and will only become further ingrained in education service delivery at all levels. Occupations formerly considered to be non- or low skill vocations now require at least some degree of technological sophistication. This level of knowledge is considered minimal compared with other, more technology dependent occupations, but for the unskilled person trying to learn a new job, these basic skills can pose a significant obstacle.

Because the changes in available technology have occurred so rapidly over the last three decades, the more glacial pace of social change is having difficulty keeping up. Standard developmental influences, such as modeling work behavior from a parent or a role model, acquiring training in a traditional vocational or elementary classroom, and hands-on exploration of one’s immediate surroundings will likely not be sufficient to teach fundamental skills necessary to later acquire more advanced abstract concepts and hands-on technology skills. There is a significant impetus to put computers in elementary and college classrooms, but not all classrooms have them and many do not have a sufficient number of machines for the number of students served; many learners on all levels have
The importance of learning technology skills from the job performance/occupational requirement perspective requires some examination of the evolution of most common occupations with respect to the availability, reliability, and capacity of computer and electronic technology. Computers and computer-controlled technologies are readily available to business and industry, companies, service providers, and manufacturers. Those who integrated these advances early on found themselves at an initial competitive advantage over the competition. With the widespread integration of technology into the workplace, this advantage seemed to normalize across employers, leaving those who either failed to integrate advanced technology or failed to fully incorporate and update technology on hand at a competitive disadvantage. Advanced technology is no longer an advantage, it is requirement. Simple paper and pencil functions, such as signing for a parcel or filling out a room reservation in a hotel have been almost entirely replaced by computers and portable data units. Many organizations keep few paper copies (unless required by law) and store most of their data and documents electronically. Any business or service provider that attempts to operate without at least a minimal level of technological integration is almost certain to fall short in their respective market. The integration of technology into our lives has come both as a massive rush of change and as subtle changes to everyday life. The computer revolution suddenly reinvented mass communication, giving us an entirely new medium in the Internet. Just as revolutionary but with greater subtlety came debit and credit card purchases in supermarkets, on-line shopping, computer controlled ignitions in vehicles of all sorts, cellular phones, and so many other changes. Skill in the use of advanced technology, even in its most basic form, is now a fundamental skill set as important as literacy. Twenty years ago an illiterate adult entering the workplace found his or her options decidedly limited. Lack of literacy skills is less common of a problem than twenty years ago, but the lack of basic technology skills is fast replacing illiteracy as a fundamental skills deficit.

The social and educational environments have changed as well due to the infusion of technology into every aspect of our lives. Technology has become a developmental experience and is no longer a set of supplemental skills. Children socialize by playing games. Many of the games children play involve computer technology, and the skill to use such game stations are relatively easy to acquire, especially if there is another child to act as a model. Internet use and skill with the more advanced functions of a personal computer are more difficult. Children who lack these skills may withdrawal from the settings in which they are used. Such early skills development and the development of patterns of approach/avoidance behavior to technology will influence the learner for the rest of his/her life. Technology serves not only an occupational function, but is increasingly a social medium and catalyst as well. Potentially, the lack of education and availability of developmental experiences with technology could create an "out group" of people who not only have difficulty maintaining adequate employment, but who also find themselves at a distinct social disadvantage.

Not only have the tools of the trades changed, and not only have the media of the social environment followed the evolution of technology, but basic conceptualization and cognitive mediation have changed as well. People with exposure to technology as a key feature of their environment likely develop advanced thinking skills earlier than those without such experiences. Those for whom technology has been consistently available likely think in more abstract, representational terms, as opposed to a more concrete style involving more realistic references and less abstract interpretation. Advanced concept formation and problem solving are likely the benefits of exposure to technology across many settings over a sustained period of time.

Potential solutions must include increased exposure to appropriate technology and fundamental skills acquisition. The main problem is not inability to learn these skills, but the insufficiency of learning opportunities for many learners. Within the economic structure of the United States a series of broad solutions, based on collaboration, is possible. Because of the rapid nature of technology-driven change, and the correspondingly ponderous rate at which various social engines adapt to that change, these solutions must include a higher level of collaboration between private coronations, educational institutions, and government bodies than has been present to this point. Advanced technology likely has an impact on individual development second only to heredity. The children of today who are consistently exposed to a technology-rich environment will undoubtedly develop advanced conceptual and synthesis skills when they become the adults of tomorrow. Integrated cooperation from all sectors will be necessary to ensure such development.
Building eLearning Communities

Abstract: Effective eLearning communities play an important role in the technology-based learning environment. An eLearning community has been misrepresented as a place where learners only learn together. This thesis is discussed, reviewed, and examined by considering effective eLearning communities, the impact of eLearning communities on human learning, different frameworks for eLearning communities, and proposes a refined theoretical framework for future research and development of eLearning communities. In this thesis, eLearning community is referred to a place where learners learn together and, in addition a community that learns. A refined theoretical framework for eLearning communities is proposed that encompasses three major constructs "Instruction," "Social Interaction," and "Knowledge Construction Technology." It is recommended that eLearning communities should be implemented with looser structure but with effective systemic strategies.

Introduction

Active approaches to effective learning present learning as a social process that takes place through communication with others (Hiltz, 1998) in communities (Hiltz, Turoff, & Benbunan-Fich, 2000). The importance of online learning communities has been emphasized by recent studies (Gordin, Gomez, Pea, & Fishman, 1996; Haythornthwaite, Kazmer, & Robins, 2000). In fact, students and faculty were yearning for a deeper sense of community. From a social learning aspect, learning community is defined as a common place where people learn using group activity to define problems affecting them, to decide upon a solution, and to act to achieve the solution. As they progress, they gain new knowledge and skills (MacNeil, 1997). It is a process much more profound than merely appreciating one another. Little conceptual framework has been developed regarding this new learning environment. ELearning community is the term widely applied in electronic education. Researchers (Schlager et al., 2000) are aiming and advancing toward a community that learns/evolves in addition to being a community for learning. How learners gather information and apply appropriate information to knowledge construction is more critical than simply obtaining information, making it necessary to examine knowledge construction in an eLearning community and advance to the level of a community that learns, rather than just information sharing and learning together.

Learning Impacts

Before exploring eLearning communities, it is necessary to understand what impact an eLearning community has on learning. Studies of virtual teams have shown that issues of interdependence, leadership, social communication, and project management are critical in forming successful teams (Jarvenpaa et al., 1998).
Research has demonstrated that electronic collaboration as an effective instruction design for an eLearning community. Ocker and Yaverbaum (1999) found that asynchronous electronic collaboration is as effective as face-to-face (FTF) collaboration in terms of learning, quality of solution, solution content, and satisfaction with the solution quality. Additionally, Hiltz (1998) argued that eLearning with a collaborative design is more effective than working individually.

Collaboration mechanisms directly affect cognitive processes by three functions (Dillenbourg & Schneider, 1995). First, conflict/disagreement. Second, Internalization. Third, Self-explanation. The more advanced members also benefit because providing an explanation improves the knowledge of the explainer (self-explanation effect).

Equal Access

An eLearning community has the potential to equalize economic and learning opportunity. OECD (1996) has identified eLearning as an effective means by which disadvantaged communities and individuals can acquire and improve their skills and knowledge. Although this argument is strong there is little evidence to define the impact that online technology exerts on equality and a particular digital divide may be created (Gladieux & Swail, 1999). Graham basically agreed with the value of an eLearning community; however, in the construction of the ideal eLearning community network model equality should be optimized and the impact of technologies should not be the main focus.

Social Presence

Learning in an eLearning community occurs as an active social process. Online Social presence, the degree of feeling, perception and reaction of being connected by online to another intellectual entity through a text-based encounter, is required to insure the interaction necessary to sustain community activity (Hiltz, 1998). Social presence is a critical factor that affects the eLearning community. Gunawardena and Zittle (1997) found that the degree of social presence is predictive of the satisfaction of online learners with their learning. Social presence, online learners' social relationships, tasks being engaged in, communication styles and personal characteristics impact online learning (Tu & McIsaac, 2001). Therefore, it is concluded that to foster an ideal eLearning community, one should increase and idealize the level of social presence.

Technology as Learning Tools

Technology has been seen as a tool to sustain and enrich an eLearning community. Office of Learning Technologies (1998) argued that computerized commuting technology has been viewed as a revolutionary tool to build eLearning communities, strengthen relationships, and mobilize joint planning and community action. In the past two decades, research has shown that "The No Significant Difference Phenomenon" exists between technology-based instruction and traditional instruction (Russell, 1999). However, technology can be applied as a tool to enhance learning and as a means where learners can approach the learning experiences of their choosing at their own pace.

Resources

Resources available through technology provide the greatest advantage to its use. Current technology is capable of delivering many resources, particularly resources that can trigger and reflect on knowledge. These resources are likely to enhance learning in an eLearning community. Technology brings participants together to generate online interaction. An ideal eLearning community should be able to provide its members with multiple perspectives in their learning experiences (Tu, 2000). These rich perspectives will be able to enhance the online interaction and to stimulate a higher level of thinking and learning. A cumulative sharing of learning, knowledge, and experience can result in the development of a community.

Blurred Boundaries

Electronic communication democratizes the eLearning environment (Rheingold, 1993). Computer-mediated communication (CMC) has been described as a venue where participants can contribute equally in communications (Rheingold, 1993). Democratic openness, the absence of nonverbal status cues, teacher-student role reversal, and learner-to-learner interaction within a CMC environment provide an opportunity for a more equal
platform for communication and more stimulus for action than does a traditional classroom and more peer interactions were concluded. This phenomenon obscures the boundary between learners and teachers.

Learner Driven

Because of the blurred roles of students and teachers more weight is placed on the learning process/experience than upon roles and “teaching” processes. In other words, both students and teachers are learners and share their responsibilities in an eLearning community. Morrison (1995) argued that the learning process is unbounded by time (when one learns), space (where one learns), mode (how one learns), pace (the rate at which one learns), level (the depth of learning) and role (with whom one learns). Therefore, it is not merely learner-centered; in fact, an eLearning community is a learner-driven process.

Lifelong Learning

Since the learning paradigm is shifting to community-centered learning, lifelong learning is gaining in importance. Lifelong learning is what individuals learn over the course of their lifetimes and in a multitude of contexts. Galbraith (1995) defined it more precisely as: “those changes in consciousness that take place throughout the life span which result in an active and progressive process to comprehend the intellectual, societal, and personal changes that confront each individual human being.” Clearly, this definition has given weight to community-centered learning.

Theoretical Framework

A new theoretical framework for eLearning communities is proposed in this thesis. It is a preliminary model that provides an appropriate direction for future research in eLearning community. In this framework, “Instruction,” “Social Interaction,” and “Knowledge Construction Technology” are major three dimensions of eLearning communities. To develop an ideal eLearning community, these three dimensions should be consistently maximized. Somewhat lopsided development may result in different learning experiences in the process. However, the balanced development is not a static force. This framework represents a theoretical framework for eLearning communities that are dynamic, not static, flexible, not fixed, and negotiable, not pre-set.

Instruction

One should engage their community members in an authentic and an interactive design of activities. Community members that are more experienced, or experts, should function as mentors to stimulate members in processing knowledge internationalization. Material and information should be presented in a fashion that stimulates and indicates to members what is to be understood. Coaching processes allow novice members to receive appropriate feedback and to be aware of how they deviate from mastery and how can they modify their processes to be closer to the model.

Community learning is not only active but is also interactive. Community of Practice (CoP) serves as an appropriate concept for an eLearning community. Several factors identified in a recent study (Tu & McIsaac, 2001) should serve as a model for building a CoP for education reform: determine knowledge; build important topics/issues; gain members’ background context; and design pull technology.

Collaboration enhances the active exchange of ideas within small groups and increases interest among the participants but also promotes critical thinking (Garrison, 1999). The community of collaborative learning, the grouping and pairing of learners for the purpose of achieving an academic goal, has been widely examined and is advocated throughout the professional literature.

Recent publications (Berge & Collins, 2000) have emphasized the importance of moderation in an eLearning community, a necessity that has often been ignored in online instruction. Knowable use of strategic moderation can enrich and deepen the dialogue and foster learning in this emerging venue.

Social Interaction

Social context is constructed from the community members’ characteristics and their perception of the eLearning environment. Less attention is being paid to other components, affective and social, as well as cognitive.
Bauman (1997) argues that social factors can be as powerfully motivating (Lowell & Persichitte, 2000) as intellectual ones in keeping learners on task. Research should focus on the relationships of community members and their perception of the eLearning community.

Ideal eLearning engages community members in deep thinking, provides multiple viewpoints, supports reflection, and offers frequent feedback and guidance toward higher standards. Kearsley (1998) contends that but the most important overall impact of the eLearning environment is the emphasis they place on critical thinking and discourse. The one thing that happens in eLearning, is that community members communicate a lot more with each other (novice and experts).

Knowledge Construction Technology

Knowledge construction technology contains attributes of electronic technology and technology that assist learners conduct knowledge construction. The latter is more important than the first. Electronic computing and telecommunications technologies are converging into knowledge construction tools. Technology not only delivers content (information) and it has the capability to trigger and stimulate chances for knowledge construction. In fact, contents, bits, learning, and cognitive science are converging to “knowledge Media (Eisenstadt, 1995).”

Unlike a traditional FTF communication, knowledge construction technologies have the capability to deliver single or multiple channels either asynchronously or synchronously. When a new communication medium becomes available, one often applies a FTF communication style to this new communication environment, which often generates misunderstanding between the two communicators. Appropriate selection and use of communication media is very critical.

Conclusion

ELearning community is an important concept in technology-based learning. An effective eLearning community reaches beyond the point that community members learn together and should be perceived as a community that learns. The concept of an eLearning community implements the generation of social interaction and learning processes to generate dynamic and effective knowledge rather than “fixed” information. An eLearning community never dies after it is born. Instead, it grows and learns; and it may mature into a different character as a community. Therefore, community learning is endless and translates to knowledge construction and gaining information that is infinite.

References

As Barry Sponder and others who submitted papers for this section indicate, one of the more vexing issues in teacher education is the difficulty of bridging the gap between the theories of teaching and learning that credential candidates are exposed to while preparing to teach, and the complex realities these teachers encounter when they are employed and engaged in their teaching practice. Among the many techniques frequently used to address this issue is the use of text-based case studies. Shulman's research clearly indicates that these text-based cases, when used by instructors who are skilled in facilitating reflective dialogue, can improve teaching practice by helping credential candidates develop reflective skills. But Wasserman also points out that learning to teach is difficult when credential candidates have little time to observe teachers handling daily problems in their classrooms. Miriam Sherin points out in her paper in this section that learning to notice key components of a teaching situation and “connecting those components to broader concepts and principles of teaching and learning” is critical. The papers in this section indicate some ways that video, combined with newer CD-ROM technology and/or the World Wide Web, is helping to provide credential candidates not only with more opportunities to observe teaching practice but to observe practice in ways that may be more effective than classroom observations alone.

Benefits of Video

Several of the papers in this section point to similar benefits found in using video cases as part of preservice education. One of these benefits of the use of video is that it allows the credential candidates the ability to review a classroom teaching situation many times. This is substantially different than the normally limited ability of a candidate to do observations in the classroom itself. This is pointed to both by Sherin and myself in our papers. This is also implied by the nature of the video databases created by InTime at the University of Northern Iowa and the video database at Arizona State University. These databases can be accessed by different instructors for different purposes as needed.

Many researchers have pointed to the complexity of the classroom and the failure of schools of education to prepare candidates to deal with this complexity. The affordances of digital video, in particular, allow candidates to observe a single video through many different lenses. Haydek, from the InTime project, emphasizes that their video databases can be searched through the lenses of the Technology as Facilitator of Quality Education Model. This model includes the following elements: a) technology, b) students at the center of their own learning, c) content standards, d) teacher knowledge and behavior, e) information processing, f) principles of learning, and g) tenets of democracy. Thompson from the University of Houston indicates “much more can be learned from these video segments than how to teach a single skill.”

Using video cases also gives candidates a common forum for discussion. As Lynda Ginsburg says about the Captured Wisdom videotapes, they are “useful for stimulating teachers to think about and question the approaches of other teachers and the ways that they might adapt what they see and hear for their own local education contexts…. “ This observation, reflection, and dialogue process, just as with text-based cases, appears to be a key component of the video cases. Sherin, in particular, describes this dialogue and how continuation of this cycle over time changes the teacher’s reflective practice.

Another benefit of digital video, especially when used in combination with the web or a CD technology, is the ability to add teacher and expert commentary. This enables the candidate to “see” the video through the eyes of other, more expert, viewers. Savenye at ASU includes these commentaries as do we at Pepperdine. Yusko describes the process of having the mentor teacher watch the tape and comment on his own teaching. As Yusko says, “We found that the ‘stimulated recall’ nature of this interview allowed [the mentor teacher] to speak in rich detail about his thinking…”

PT3 Convergence

As a PT3 Project Director I was intrigued by the common elements being included by many of the PT3 projects that are creating video case studies. One of these elements is the Pre / Post Teacher Interview portion of the video case study. This is included in the InTime cases, the Pepperdine cases, the ASU cases, and in Yusko’s work. As discussed above, this commentary appears to guide the candidate to focus on critical elements in the video.

Some of the projects have commentaries by others as well. Both ASU and Pepperdine include commentaries by content experts and by a technology expert. As Sherin and van Es point out, teachers “need to find ways to focus their attention on new aspects of classroom interactions.” It appears that these commentaries, along with the commentaries of the teacher, might scaffold this “noticing” process.
Sponder points out that lesson planning and classroom management are classic conundrums for the new teacher. Many of the video cases include elements designed to address this. The ASU cases include a portfolio of the lesson plan, materials developed by the teacher, and links or resources for the technology used. The InTime cases include a lesson overview and information about the content standards covered. In the Pepperdine cases, a resources section includes links to related research, state frameworks or standards, additional reading, as well as samples of student work. Classroom Management is specifically addressed in the video cases developed by the University of Houston and as I point out, Peppernine’s experience is that viewing case studies from different perspectives leads to use in new areas. For example, [video cases] can be used in an Instructional Strategies class where preservice educators may be discussing possible classroom management strategies. They might also be used in an Educational Psychology course where preservice teachers might develop their observation and reflection skills.

Analysis and Reflection

Sherin and van Es discuss in their paper how the use of video seems to change the course of discussion over time from a focus on the “how of teaching” to the “why of student learning”. They raise a very important concept for all involved with the use of video cases about the need to scaffold to ability to “learn to notice” and then to link this noticing to key theories and prior knowledge.

Yusko points out that there is a great value in the process of editing the videos because that process itself is a key analytical tool. In fact, that realization is what led Jim Stigler to create the LessonLab software used by Pepperdine. Stigler came to this realization after his experiences with analyzing the videotape captured during the TIMSS project. The analysis gained through thinking about what is important in the video is key. Following this with reflection and dialogue leads to a much richer experience, according to the preliminary results of the work of many who submitted papers in this section.

This concept that editing a video leads to greater analysis has led some creating video cases to have teachers and students create their own digital videos that they then edit and on which they reflect and comment. This concept is highlighted in the TLC – Teachers as Students Project from the Department of Defense Dependents’ Schools. David Georgi from California State University at Bakersfield has also been experimenting with this concept. We have begun work with this at Pepperdine as part of our work on electronic portfolios.

Video Production: Lights, Camera, Action

Yusko, while candidly sharing his journey into creating video cases, describes the experience of many of us as we entered this world. He says, “We quickly began to realize the complexity of capturing high quality classroom video footage. Even when we carried the camera around the classroom, we realized that we needed guidelines to accommodate different classroom formats, such as whole group discussions, small group work or individual work. We needed to know where to focus the camera, on who, and for how long. To make sure that we had high-quality sound, we experimented using two remote transmitters with different types of microphones.” During our panel discussion, Redmond, Georgi, and I also propose to answer questions about what we have encountered in this area.

One of the key elements that no one specifically refers to in their papers but that I am sure will be quite obvious in the demonstrations is the fact that this newer technology makes it much easier to scan the video and to jump backwards or forwards to places where the analysis, reflection or discussion might be focused.

Unique Purposes

Several of the video projects included in this section had purposes very different than the typical case study used in preservice education. For example, Eastern Washington University and Cheney School District created a 17 minute video to “tell” teachers of the value of participating in the partnership between these two institutions as part of their PT3 grant. Stephen Ransom from Ball State University uses video cases to help teachers better understand how to evaluate software. After learning the limitations of checklist evaluations, he experimented with showing the software being used in a classroom, thus situating its use. His paper highlights the reactions of the teachers to this use of video and this new form of software evaluation. His ending note is particularly interesting because, as others here noted, the use of the video can frequently extend well beyond its original purpose. The University of Minnesota uses case studies to document how technology integration is successfully sustained. Finally, swinging full circle back to Sponder’s comments about the difficulty of bridging theory and teaching experience, Sponder created a CD-ROM that includes not only video cases designed to help preservice teacher prepare for student teaching, but also includes answers to Frequently Asked Questions and interviews with key personnel. This CD-ROM is designed to be given to every candidate prior to their student teaching experience.

Conclusion

Miriam Sherin and Elizabeth van Es summarize best much of what is written in the papers in the Video Cases section. Research indicates that video can help us to help teachers to learn what to do in the classroom. The newer video cases, using newer technology, extend this to helping teachers to notice what is happening in a classroom. With guidance, this ability to notice can lead to improved teaching practice and the ability to adopt new teaching interactions and processes as well as to integrate new content or materials.
Developing Digital Video Resources to Improve Teaching with Technology:  
The PT3 - "Best Practices" Project

Introduction

The Preparing Tomorrow's Teachers to use Technology (PT3) program is an initiative of the U.S. Department of Education designed to improve teacher preparation programs to allow educators to more effectively integrate technology into their teaching. The foundation of the PT3 program is that schools increasingly have access to network resources and the Internet; their goal now is to improve teachers' and students' use of technology to improve learning. For instance, Base and Meek (1998) report that 78% of K-12 schools have access to network resources. School district leaders believe their students must have access to and use technology (Brush, 1999; Brush & Bannon, 1998.) Although most institutions that prepare teachers offer some type of technology course, research continues to show that teachers do not feel prepared to effectively integrate technology into their instruction (Schrum, 1999; Strudler & Wetzel, 1999; Topp, Mortensen, & Grandgenett, 1995.)

In August, 2000, Arizona State University was awarded a 3-year, $1.15 million PT3 Implementation Grant. This award is being used to fund a project entitled "A Field-Based Model for Integrating Technology into Pre-Service Teacher Education." The technology skills and processes the preservice teachers are learning are based upon state recommendations and the ISTE (2000) standards.

This field-based project involves a collaboration among schools, three university campuses, and the Arizona K-12 Center. During the first year educational technology and methods faculty teamed with educational technology graduate students to develop and present hands-on workshops at five elementary schools where students take most of their methods courses. Mentor-teachers at the schools work with the preservice teachers and also participate in the technology workshops. During the summer of 2001, a Teacher Institute was held for the mentor-teachers at these schools and three more are participating during the second year.

The primary goals of the ASU PT3 project are that that the preservice teachers, along with their methods faculty and their field-based mentor-teachers will demonstrate a significant increase in both the quality and frequency of technology integrated into their teaching.

As part of the field-based PT3 project a set of prototypes of a www multimedia database of materials and best practices has been developed.

In the proposed SITE Video Festival demonstration we will focus on presenting samples of all components of the database, a software tool designed to aid preservice, but also inservice, teachers in integrating best practices of technology into their teaching. We will present an example of one full "lesson" from one of our participating teachers, along with sample video clips of several others of the teachers. In addition, in our discussions with SITE members, we may also discuss aspects of the development of the video-based "best practices" project.

The "Best Practices" Digital Video Database

Arizona State University, the Arizona K-12 Center, and Northern Arizona University are partnering to provide the preservice teachers with access to databases of instructional materials and methods for utilizing these materials. The K-12 Center is hosting the database, so that it is accessible not only to project teachers, but to teachers throughout the state. Preservice teachers will be expected to access these materials via the www, evaluate appropriate methods for using these materials, and integrate these materials into their instructional activities.

"Best Practices" Videos to be Demonstrated at SITE

Our prototype series includes several recognized "best practices" teachers. A sample of the materials, each set of which will include a pre-instruction interview with the teacher, a video of the teacher delivering the technology-based lesson, and a post-instruction reflective interview with the teacher, will be demonstrated. A portfolio consisting of the systematically-designed lesson plan (cf. Dick & Carey, 2000; Sullivan & Higgins, 1983) and materials developed by the teacher, links or resources for the technology used, and a sample of a commentary by an educational technology or methods expert will also be presented to SITE audience members.

The Video Lessons

Each lesson is built along a "model" or "timeline" of a lesson, which allows for all types of teaching styles and philosophies. Preservice teachers can access the lessons and lesson materials by clicking on components along a timeline that serves as a metaphor for the lessons. The lessons consist of:

Lesson Interviews and Commentaries. Each lesson includes extensive reflective interviews and commentaries. Teachers were interviewed prior to teaching the videotaped lesson and immediately after they taught their students.
follow-up commentary is also included; the teacher reviews his or her edited lesson and then comments upon his or her teaching practices.

For each lesson one subject-matter expert or peer-expert teacher, and one technology expert have also provided a reflective commentary while viewing the edited tape. Preservice teachers may then choose to view each lesson several times, reviewing the teacher or various other experts’ perspectives each time.

**Timeline Components.** A flexible framework was developed for the lessons. For each lesson the videos include an Introduction, Presentation, Activities and Wrap-up. Preservice teachers can access any or all components of each lesson and can review any sections they wish.

**Example Lessons to be Demonstrated**

One lesson will be shown in full, followed by illustrative excerpts from several other lessons.

*Fifth-sixth grade mathematics.* It is planned that this lesson will be shown in full. A fifth-sixth grade teacher prepared a lesson on Archimedes Spiral for her class of higher-achieving middle school students. The students had previously learned about natural spirals. She began her lesson with an inquiry-based introduction, in which she questioned students extensively to help them recall what they learned in the prior lesson. In this introduction, as the students actively built upon this knowledge base, she wove new instruction into the inquiry. She used a Powerpoint presentation with many photographs and drawings, and an animated illustration of Archimedes Screw to show students historical and current uses of this spiral in technology. She then showed students a Quicktime movie she had prepared to show students in close-up views the tools and techniques they would be using to build their own Archimedes-type spirals. She gave students several challenges for their participation in the lesson, including to test what happens when they vary the size of the peg used to make their spirals. Also during the active participation part of the lesson students were challenged to search the web on one of their classroom computers to answer questions about the spiral and further uses. Students worked in cooperative groups to build the spirals and to answer the internet-based challenge questions.

In pre-and post-interviews the teacher described the purposes to which she put technology in this science and math lesson, what she hoped students would learn, state criteria being met in the lesson, how she will assess student learning and advice for new teachers who wish to use this lesson.

**Examples of Excerpted Lessons to be Demonstrated:**

- **High-School Language Arts.** A high-school teacher used technology to motivate lower-level students in an English class. She has found that building challenging lessons using the web has helped her increase these lower-achieving students’ successful completion of this English class. This teacher used PowerPoint, Inspirations software and a Web-Quest, followed by student presentations, to allow students to “build their case” for who King Arthur might have been, and where Camelot might have been.

- **High School Physical Science.** Another teacher is using SimCalc to help his students learn to analyze and interpret data from their physical science experiments.

**Implications**

We anticipate that access to the “Best Practices” videos, lesson materials, reflective interviews and commentaries, both by PT3 teachers and all teachers in the state, will enhance teachers’ success in integrating technology into their classrooms. Their use of technology will go beyond using computers as tools to allowing their students to learn in innovative ways using a full range of technologies.

Portraits of Three Schools from the U.S.A. Exemplary Technology-Supported Schooling Case Studies Project

Sara Dexter,  
sdexter@umn.edu  
Center for Applied Research and Educational Improvement  

Ronald E. Anderson,  
rea@umn.edu  
Department of Sociology  
University of Minnesota  
U.S.A.

Abstract: This presentation features video footage from three schools with innovative classroom teaching using technology. The results were obtained as part of 11 case studies in USA schools and were selected to be part of two international studies, one by OECD and the other by IEA. Innovative roles of both teachers and student were evident and improvements were sustained by professional communities and by emphasizing both technical and instructional support.

Background

New conceptual and methodological models are needed to cope with the changes that result from integration of information technology into education. Rapid changes in technology and the ways that schools adapt to them mean that qualitative methods are needed to identify key factors, uncover hidden meanings, and explore alternative conceptual models. The “Exemplary Technology-Supported-Schooling Case Studies” project (funded by OERI of the US Department of Education) was part of the United States participation in two international projects, one by OECD and the other by IEA.

The methodology was designed to study sites successful in dealing with rapid changes due to technology. In the USA, sites selected also had to be committed to meeting high content standards; have students drawn from diverse backgrounds with some low income students; implementing reform efforts that appeared to be sustainable and transferable; and have compelling evidence that the reform efforts were resulting in educationally significant student outcomes. An extensive procedure of solicitation of nominations from numerous experts and organizations was followed to obtain candidate school sites around the country.

Overview of the Schools

From the eleven case studies we completed, we selected three schools to feature in video portraits. One was a senior high with only 240 students. However, the other two schools, a middle school and an elementary school, were average in size with two-thirds of the students from low-income families. These three schools and their innovative programs are summarized briefly:

(1) The New Tech High School has an underlying philosophy of educating students in capabilities most essential to the 21st century, especially problem-solving, project construction, knowledge management, and teamwork. Most classes are interdisciplinary and team-taught, and students’ work often requires they serve as a team member on a project. Students spend a major part of every day using computers, as most of their assignments are projects requiring educational technology applications. Nearly ninety-five percent of the students attend college within two years of graduation. New Tech High has established a reputation for innovation and high productivity with frequent visitors from all over the world.
(2) The Lemon Grove Middle School focuses upon academic performance emphasizing professional development and extensive technology support made more feasible by a relatively high density of "thin clients," network PCs lacking local diskette or CD-ROM storage devices. The district also provides these thin client computers free or at low cost to parents without home computers. Essential to the success of the program is a strong professional development program providing every teacher in the school with a minimum of 120 hours related to technology during the first year. Equally critical to the program is a very extensive technology support system. While the program encourages and supports all types of pedagogical approaches including inquiry and project learning, a major emphasis is on remedial activities and other technology applications that help to improve student achievement. Test score gains for the school are consistent with their program goals.

(3) At Newsome Park Elementary, laptop computers are linked wirelessly to hubs for shared activities and Internet access at a 5:1 student to computer ratio. The wireless laptops support flexible distributions to classrooms so small groups of students can use networked computers on a fairly regular basis. A central tenant of their reform effort is to utilize student interests and discussion to drive the direction and character of projects, which are usually long-term and interdisciplinary. An essential feature of their school-wide program is for every teacher to participate in a school-based, intensive, forty five hour, technology-focused professional development experience. This kind of instructional technology support has made it possible for some teachers to implement some advanced techniques such as concept maps with young children.

Overview of the Findings

New Teacher and Student Roles in the Technology-Supported Classroom

The use of educational technology is part of a shift toward new instructional approaches within a context of school improvement or reform. A range of technologies are supporting teacher and student practices and contributing to a transformation in their traditional roles. Students are more often serving as knowledge managers, team members, and self-regulated learners. Teachers are more often serving as instructional designers, collaborative team members and coordinators of teams, as advisors to students, and as assessment specialists.

Contributions Professional Community Makes to Exemplary Technology Use

The commitment to teachers' individual learning about technology as a support to instruction was very strong at these schools, as evidenced by the support staff and professional development programming dedicated towards this end. The technology leadership at the sites contributed further to the supportive conditions and need for teacher learning that was required to implement technology-enhanced pedagogy in exemplary ways. It appears that the presence of this need to learn and the supportive conditions to do so was reciprocal, or mutually supportive, of the development of professional community around technology use. The professional community deepened and refined the shared vision related to the purposes of instructional technology, and the technology support. Our tentative supposition is that effective use of technology and professional community are mutually supportive—that increases in one create conditions for increases in the other.

Implications for the Future

Regarding the sustainability and transferability of these innovations: the teachers who practice the innovations consistently report that they expect to continue the instructional practice in the future. The systemic factors such as school culture, district support, and state policies influence the sustainability and transferability of these innovations. Systemic factors that were most mentioned included: funding and shared vision; strong leadership that is shared with teachers; public and private sector partnerships; professional development that is institutionalized and extensive; high quality technical and instructional support; climate that is supportive of reform efforts; and commitment to exploiting technological resources.
Incorporating Technology into Early Childhood Pre-Service Field Experiences

Ruth Gannon-Cook, UH-Clear Lake, US
Michael Joseph Bell, West Chester University, US

Preparing early childhood pre-service teachers is very challenging due to the national and state mandates to diversify experiences among settings that range from infant and toddler rooms up through the primary grades of elementary school. Within these experiences pre-service teachers will have opportunities to work with experienced and qualified individuals who are dedicated to serving families and nurturing the development and education of young children. However, due to the lack of program continuity and well-integrated curriculum across program boundaries, pre-service teachers will encounter a wide range of classroom practices and program policies.

Within university and college-based teacher education programs, faculty and staff are striving to understand and incorporate technology into teaching practices and pre-service teacher learning activities. Incorporating technology into teacher preparation programs is driven by goals that include: (1) broadening young professionals understanding the electronic communication, professional development and professional research, (2) nurturing pre-service teachers’ skills in using technology to promote young children’s understandings and broaden the scope of classroom learning activities, and (3) developing pre-service teachers’ understanding of the appropriate and effective applications of technology in early childhood curricula.

Preparing early childhood pre-service teachers through field-based courses and field-based internships presents challenges regarding the acceptance, development and implementation of technology as a fully integrated component of early childhood classrooms. Most early childhood programs promote the development of young children across several developmental domains. A growing number of programs are focusing on basic skills and pre-academic activities that may or may not be deemed appropriate for young children. The use of technologies as a viable means of promoting young children’s development and learning has largely been attributed to those programs that focus on “academics,” rather than developmental approaches.

This paper suggests that early childhood teacher educators could enhance the development of pre-service teachers and neighboring early childhood programs by identifying classroom strategies and curricular constructs that would promote the use of technology in early childhood settings. Further, teacher educators should broaden their view of technology to include materials and objects that promote children’s abilities to understand (1) parts to whole relationships, (2) systems that function and “work,” (3) computer and electronic hardware that promotes the use of touch and grasping as a means of input, and (4) multimedia as a means of individual creative expression. This paper suggests that developmental early childhood programs should view the use of technologies as an on-going process of learning and interactivity, rather than the widely held belief that technology is a simple input/output relationship. Field-based early childhood programs should model, promote and facilitate the integration of technologies into training sites within their surrounding communities. Due to the diverse needs and program differences found in childcare, federal preschool programs, public school early childhood programs and early childhood special education programs, the challenges are great, but not insurmountable.
Captured Wisdom
by Lynda Ginsburg, Ph.D.
National Center on Adult Literacy
University of Pennsylvania/Graduate School of Education
3910 Chestnut Street
Philadelphia, PA 19104-3111

The two videotape set of Captured Wisdom is a resource that is designed to help inform educators of successful practices of integrating technology into adult education instruction. Innovative, replicable activities are shown, described, and discussed by front-line classroom educators and learners so that other teachers feel that they have had an opportunity to actually visit the class and chat directly with the learners and teacher about their work together.

Captured Wisdom documents the ways educators and learners actually use technology in their classrooms as a tool to support instruction and learning in a variety of content areas. When used as a vehicle for professional development, Captured Wisdom is especially useful for stimulating teachers to think about and question the approaches of other teachers and the ways that they might adapt what they see and hear for their own local education contexts, learners, equipment, and curricular and instructional goals and plans.

The two videotapes contain seven 10-14 minute videos of authentic adult education classrooms. The classrooms were located at Brooklyn Public Library, Linn Benton Community College in Oregon, and Rend Lake College in Illinois among others places. The locations were chosen for the diversity of their student populations and programming. Teachers and adult learners comment on what they are doing and why. There is a short booklet that accompanies the videotapes and provides ideas for how they can be used for teacher education.
This poster session will focus on case studies of students and teachers from several of the Department of Defense Dependents Schools throughout Europe who are currently offering a new course, entitled "Technology Leadership Community" or "TLC".

TLC Course Description

The course is about teaching, learning, and learning to teach. The domain of information is technology and technology skills.

Technology Leadership Community (TLC)

Grade Level: 7-12

Length Of Course: 18-36 Weeks

Recommendations:

Experience with PCs, strong working knowledge of applications used in school and capacity to learn newest technologies, interest in education and teaching. Students must be self-motivated and have a high level of personal responsibility.

Major Concepts/Content:

The TLC class merges learning the newest computer technologies with learning how to effectively teach others those technologies. Students collaboratively study and learn new software packages and computer skills while learning how to become effective trainers and educators. In addition to raising the technological knowledge of the school community, TLC students examine their own roles as teachers and learners, increasing their learning abilities in all other classes.

Major Instructional Activities:

This course is designed to train students to become effective teachers and learners by complementing the technology support in their school community.

Technology study includes Internet navigation and searching, web page creation, server management, desktop publishing and graphics applications, GIS, CAD, and other specialized software. Pedagogical study includes methodology of teaching, materials preparation, presentation strategies, evaluation techniques, and formalized self-reflection activities such as log-keeping and using videotape to observe, analyze, and improve their own teaching efforts.

Teaching activities include weekly one-on-one mentoring sessions with faculty, staff, students or community members; teaching in larger group situations (such as another classroom learning a single application); and preparing manuals and other instructional materials for their "clients." Other activities include regularly assessing the school's technology learning needs and developing strategies to effectively meet those needs.

Major Evaluative Techniques:

Students will create their own assessment rubrics and goals. Doing so enables them to set learning objectives and have a clear understanding of what is expected of them. They do this individually with the teacher. The students will also be graded on completion of tasks and participation and there will be several take-home essays that reflect what the student has learned at different points in the semester.

Assessment Will Be Based On:
How well they learned to identify, analyze, and improve their teaching abilities through their video and writing work. This will be based on survey and writing assignments, comparison of pre/post surveys, and essay writing.

How well their mentees learned the technology material. Teachers and other mentees are asked in survey form to assess their experiences with the TLC students. The TLC student assesses himself and a combination of this data describes how the student performed.

The degree in which a student’s technological knowledge improved. The TLC teacher, along with the student, will examine the pre/post surveys and determine how much of the technological knowledge the student learned. Students are expected to attain a high level of competence in one or two applications, rather than learning only a little about as many applications as possible.

Essential Objectives:

Upon completion of the course, students should be able to

Demonstrate how teaching others enhance one’s own learning abilities and styles, in any subject.

Demonstrate technological competency on at least one application. Competency is defined as thorough knowledge of the program, fluency with operation, and ability to explore with the tool.

Design a teaching unit or activity, including an assessment piece about a specific software or technological application.

Demonstrate growth in communicative, developmental and social areas. For example, students learn how to become articulate, develop confidence to communicate clearly with adults and youngsters, become methodical in their learning styles, attain a very high degree of responsibility.

Help the school use the complex technologies already in place, working with and complementing the training tasks of the Education Technologist, and also develop new training programs to meet changing demands.

Demonstrate that work of this nature is directly tied to real-world workplace skills.

This is a course that engages the student in the learning process. The content and activities serve to get students to think of themselves as learners, identify their own learning patterns and styles, and improve as learners. They do this by studying how to teach, by teaching others, and by reflecting upon themselves as teachers and learners.

The topic they teach is technology. This is not a technology learning class per se; it is not a computer education, application, or programming course. Those topics may be included, but it is primarily about learning how to teach technological information to others.

This is also not a “students-as-techies” course or program. While students in the TLC may learn how to service an LCD projector or a printer, their job is not to visit a classroom and change a printer cartridge, but rather demonstrate to the faculty in one-session maintenance procedures on a range of common technological equipment. TLC students are the leaders of the school, and presumably the leaders of tomorrow; therefore it wouldn’t make sense to exploit their knowledge by having them tasked to fix problems everywhere.

The TLC course contains rigorous academic activities as well as demanding technological experiences.
InTime: A Video Archive for Integrating Best Practice Technology into Classroom Curriculum

Doreen Hayek, University of Northern Iowa, US

Purpose

This presentation will demonstrate the INTIME (Integrating New Technologies Into the Methods of Education) video materials that were developed as part of a $2.4 million PT3 Catalyst Grant at the University of Northern Iowa. (http://www.uni.edu)

The purpose of this session is to show how to utilize online video vignettes of Pre K-12 teachers using technology in a robust educational environment in preparing tomorrow's teachers to use technology.

Abstract:

The purpose of INTIME (A Video Archive for Integrating Technology into Classroom) is to provide the necessary resources for methods faculty to revise their courses, model technology integration, and require preservice teachers to integrate technology, along with components of quality education, in their lessons and units. INTIME features over 300 video scenarios of PreK-12 teachers effectively using technology in the classroom. The participants will view and critique online video vignettes of technology integration and quality education in a PreK-12 setting via video streaming technology.

Description of the presentation:

During the session the audience will experience an online video developed at the University of Northern Iowa as part of the INTIME project, applied to the educational environment. The purpose of the project is to provide the necessary resources for methods faculty to revise their courses, model technology integration, and require preservice teachers to integrate technology, along with components of quality education, in their lessons and units.

INTIME provides a wealth of learning resources by featuring video scenarios of PreK-12 teachers effectively using technology in the classroom. The INTIME server hosts over 300 web-based video vignettes of teachers integrating technology in the curriculum. Real Player software may need to be downloaded to view the video vignettes. Classroom activities are analyzed through the lenses of Technology as Facilitator of Quality Education Model. TFQE Model includes the following elements: Technology, Students at the Center of Their Own Learning, Content Standards, Teacher Knowledge and Behavior, Information Processing, Principles of Learning, and Tenets of Democracy.

TFQE Model

The video clips of about 5 minutes in length are searchable at the project website not only by elements of quality education but also by grade level, content area, teacher name, state, video title video code, software, and hardware.

During the session, the audience will have the chance to view one of the videos and its nine versions: an interview with the teacher, a lesson overview, content standards, technology, teacher knowledge, information processing, democracy, principles of learning, and teacher behavior. The video tracks appear on the left side of the screen with a scrolling text narration at the bottom of the screen. The scrolling text has terms that are hyper linked to the summaries of the model. On the right side of the screen the audience will see a complete lesson plan that includes the teacher’s name, school, state, grade, curriculum area, full description of the classroom activities, content standards identified for each activity,
tools and resources, assessment, timeline, and teacher's personal comments on the implementation of this particular activity.

Participant Involvement and Outcomes:

The participants will understand the structure and the purpose of the “Technology as Facilitator of Quality Education Model” as well as view and critique online video vignettes of curriculum technology integration and quality education in a Pre-K-12 setting via video streaming technology.

This session will show how the project is intended to produce change in teacher training programs in three ways: 1) The project provides web-based learning resources to support new teaching and learning processes in teacher training courses; 2) Teacher trainers can model technology integration in their classes and use the video scenarios and online discussion forum to discuss the technology-based learning process; and 3) INTIME provides a Faculty Online Discussion Forum through which teacher trainers can share strategies for integrating technology with other trainers.
Viewing Successful Partnerships: Teachers and Teacher Candidates Working Together

Linda Kieffer, Eastern Washington University, US
Nancy Todd, Eastern Washington University, US

The Eastern Washington University and Cheney School District PT3 partnership provides opportunities for EWU teacher candidates to jointly plan and carry out, with classroom teachers, a lesson incorporating technology. Such projects included WebQuests, classroom newspapers, daily school news "broadcasts," and story writing and illustrating.

A professional video (17 minutes) was produced that shows scenes of teacher candidates working with children to help them use computers in school district classrooms for a variety of technology based projects. Also included are interviews with Cheney teachers and pupils. The video portrays successful projects that were facilitated by teachers and teacher candidates working together.

The video was used in October 2001 at faculty meetings in each of the district schools to sell PT3 partnerships with teachers who had not yet participated with EWU candidates helping with technology in their classrooms. Hearing testimonials of fellow teachers, who admitted on tape to being initial technophobes, many teachers responded, "If so and so can do that with an extra set of hands, I might be able, too." Seeing local success was inspirational to teachers and encouraged them to give technology a try. It was well worth the production cost of the video.
Using Video to Support Teachers' Ability to Interpret Classroom Interactions

Miriam Gamoran Sherin
School of Education and Social Policy
Northwestern University
United States
msherin@northwestern.edu

Elizabeth A. van Es
School of Education and Social Policy
Northwestern University
United States
van-es@northwestern.edu

Abstract: This paper examines how video can be used to help pre-service and in-service teachers learn to notice what is happening in their classrooms. Data from two related studies are presented. In the first study, middle-school mathematics teachers met monthly in a video club in which they shared and discussed excerpts of videos from their classrooms. In the second study, a group of pre-service high-school mathematics and science teachers used a new video analysis support tool called VAST to examine excerpts of video from their own and others' classrooms. In both cases, we found changes over time in what the teachers noticed and in how they interpreted these events. This research adds to our theoretical understanding of the role of video in teacher education and also provides direction for the development of new forms of video-based professional development activities.

Introduction

Video has become an important tool for working with both novice and veteran teachers. This is particularly true in mathematics and science education, where many new video-based and multimedia programs have recently been developed. In some cases, video is used to demonstrate new ways that teachers can explore specific content areas with students (e.g., Hatfield & Bitter, 1994)). In other cases, video is used to illustrate particular classroom processes such as discourse or problem-solving (e.g., Corwin, Price, & Storeygard, 1996). Common to both of these approaches is an emphasis on helping teachers learn what to do in the classroom.

In contrast, we are examining how video can help teachers learn to notice, that is, to develop new ways of seeing what is happening in their classrooms. We claim that this ability to notice is critical in the context of current reforms that require teachers to make pedagogical decisions in the midst of instruction. For example, teachers are supposed to pay close attention to the ideas that students raise and then use these ideas as the basis for the lesson-in-progress. This adaptive style of instruction calls for teachers to be skilled at noticing and interpreting classroom interactions. Even veteran teachers who may already be experienced at seeing what is happening in their classrooms need to find ways to focus their attention on new aspects of classroom interactions.

In this paper, we report on two related studies that used video to support teachers' ability to notice and interpret classroom interactions. In both cases, we found changes in what the teachers noticed and in how they interpreted these events. This research adds to our theoretical understanding of the role of video in teacher education and also provides direction for the development of new forms of video-based professional development activities.

Theoretical Perspectives
A great deal of research has explored experts’ ability to recognize the complexities within the situations that they examine (e.g., Goodwin, 1994). In van Es and Sherin (2002) we synthesize such work and propose three key components of teachers’ ability to notice. First, noticing involves identifying what is important in a teaching situation (Frederiksen, 1992; Leinhardt, Putnam, Stein, & Baxter, 1991). The classroom is a complex environment with multiple interactions occurring at the same time. A teacher cannot possibly pay attention to all that is happening. Instead, teachers must be selective in determining where to focus their attention.

Second, noticing involves making connections between specific classroom interactions and the broader concepts and principles of teaching and learning that they represent. Experts in many different fields, from chess to physics have been found to represent complex problems in terms of the larger principles that are at stake (e.g., Chi, Glaser, & Farr, 1988). Similarly, we claim that teachers should not only recognize, as described above, that “This is important.” In addition, noticing involves considering “What is this a case of?” (Shulman, 1996). Doing so can help teachers to recognize important relationships among events that occur.

Third, noticing involves teachers using what they know about the context to reason about a given situation. Prior research has found that as individuals gain expertise within a domain, they become more adept as making sense of situations that occur within that domain (Chi et al., 1988). For teachers, this means that noticing classroom interactions is tied to the specific context in which one teaches — the particular subject matter, school environment, grade level, and more.

In exploring how to support the development of teachers’ ability to notice classroom interactions, prior research suggests that video can be an effective tool (Sherin, 2001). Video offers a permanent record of classroom interactions. Thus teachers do not have to rely only on their memory of what occurred. Instead they can view a video, multiple times if they wish, examining what took place from different perspectives. In addition, researchers have argued that teachers are often constrained by their familiar classroom routines (e.g., Putnam & Borko, 2000). Viewing video, however, provides teachers with a very different kind of experience, one in which the goal is reflection rather than action. By allowing teachers to remove themselves from the demands of the classroom, viewing video may prompt teachers to develop new ways to examine what happens in their classrooms.

Methods

Data for this paper come from two related studies. In the first study, four middle-school mathematics teachers participated in a year-long series of video club meetings. In these meetings, the teachers met monthly for one hour to watch and discuss excerpts of videos from each other’s classrooms. A researcher facilitated the meetings using open-ended questions. For example, after the group watched a video excerpt, the facilitator would ask, “What did you notice?” A total of 10 meetings occurred across the year. Each meeting was videotaped.

In the second study, six pre-service teachers working towards certification in secondary mathematics or science participated in three hour-long sessions in which they used VAST (Sherin & van Es, 2001), a Video Analysis Support Tool, to examine video of their own and others’ teaching. VAST allows teachers to import digitized video from their own classroom and provides a series of scaffolds to foster teachers’ analysis of this video. Specifically, teachers are prompted to analyze three aspects of their videos: student thinking, the teacher’s roles, and classroom discourse. Furthermore, within each of these areas, teachers are asked to respond to a series of questions, the first of which is “What do you notice?” Prior to and following participation in these sessions, the pre-service teachers wrote narrative essays in which they discussed videotaped lessons from their classrooms. (See van Es & Sherin, 2002, for a more detailed description of the VAST software.)

The data were analyzed using an iterative and grounded approach. Fine-grained analyses of videotapes (Schoenfeld, Smith, & Arcavi, 1993) formed the basis for much of the work. Furthermore, we used techniques designed by the Video Portfolio Project (Frederiksen, Sipusic, Sherin, & Wolfe, 1998) to analyze the ways that the teachers discussed and reviewed video excerpts in both the video club and VAST sessions. The narrative essays were analyzed for the extent to which the pre-service teachers (a) highlighted particular events that occurred, (b) paid attention to specific or general evidence from the video, and (c) took a descriptive, evaluative, or interpretive stance toward discussing what had occurred. In addition, changes in the essays were compared with changes in the essays of six other teachers in the same teacher education program but who did not participate in the VAST sessions. Together, these two contexts allowed
us to examine different but related ways that video can support teachers’ ability to notice and interpret classroom interactions. Furthermore, they compliment each other by differing in the grade level of the participating teachers as well as in their years of prior teaching experience.

Results and Conclusions

Teachers in both studies developed new ways of noticing and interpreting classroom interactions. In particular, two kinds of changes took place. There were changes in what the teachers noticed as they discussed the video excerpts, and there were changes in how the teachers discussed these events.

There was a shift in what the teachers noticed.

Changes occurred in what the teachers noticed as they examined videos from their classrooms over time. These changes, however, were somewhat different between the two groups. The teachers in the video club began the year by focusing on what the teacher in the video was doing. For example, in the first video club, the teachers initiated a discussion concerning the mathematical topic that the teacher in the video had decided to pursue. “You know, as teachers [we] make decisions right on the spot about explore it or don’t explore it.” Similarly, the group discussed the ways that the teacher had responded to a group of students that were working together. “I wanted them to discuss it...I wasn’t going to answer him. I wanted his group to do it.” With time, however, the focus of their attention shifted from the teacher to the student, and, more specifically, to the mathematical thinking of students. For example, in one of the later video club meetings, the teachers compared two different methods that students offered for estimating the number of people in an aerial photograph of a crowd. “[Julie’s idea] was kind of the opposite of what [Robert] said, and that is that all dots are uniformly placed. So taking a small sample...wouldn’t make you any less accurate than the larger [sample].” This approach to viewing video became quite common for the teachers and they regularly discussed in detail how students talked about and worked with mathematical ideas. In discussing her experiences in the video club, one teacher explicitly commented on this shift. She explained, “[At first I was thinking] ‘Oh, I think I should have said that or done this.’ As I was watching though, I thought a lot about... just following the ideas of different kids.” This shift is particularly important in light of reform recommendations that encourage teachers to pay close attention to the ideas that students raise (NCTM, 2000). Moreover, researchers have shown that examining student thinking can lead to valuable changes in teachers’ instruction and can help teachers to effectively implement the goals of reform (Franke, Fenemma, & Carpenter, 1997).

In the VAST study, a different kind of shift occurred in what the teachers noticed. Rather than a change in topic, there was a change in the range of events that were noticed and discussed by the teachers. Specifically, the pre-service teachers’ initial analyses consisted largely of describing events as they unfolded in the video. For instance, one essay started as follows, “The morning began with a test and after a 10-minute break, we began to set up for the discussion of ‘number families.’” Another essay chronicled a class discussion by listing the order in which members of the class participated and the comments that were made. “I called on a particular student, Ian, instead of waiting for someone to volunteer. I asked Ian what graph his group chose, and he answered that they had chosen Graph D. I asked him why they chose that graph. After a pause and some giggles from his other group members, they admitted that they had not formed their reasons. At that point, a student from another group, Kenny, raised his hand and said that he picked Graph C...” In contrast, later in the year, the teachers’ analyses became more organized around particular events that they identified as noteworthy. No longer were their analyses simply chronological. Instead, the pre-service teachers were now able to identify significant features of instruction and focus their analyses in that area. This shift represents the development of a key component of noticing and has been identified by researchers as an important aspect of teaching expertise (Berliner, 1994).

There was a shift in how the teachers discussed what they noticed.

Changes occurred not only in the topic of the teachers’ comments but also in the ways in which they discussed these ideas. First, in both studies, the teachers began with an evaluative stance toward events that occurred during instruction. In the video clubs, for example, it was common for teachers to ask “What
should I have done?" or to suggest an alternative pedagogical approach that the teacher on the video might have used. Similarly, in the VAST study, early in the year when the pre-service teachers discussed videos from their classes, they focused on what had and had not "worked" and on what they might want to do differently next time. In one essay a teacher wrote "I wish I had handled much of this discussion differently," and another noted, "I could have ... done a better job of enforcing rules about talking in turn and listening to others." Later in the year, both groups of teachers focused more on interpreting what occurred rather than simply evaluating the teaching and learning that was evident in the video. Thus, for example, instead of focusing immediately on the effectiveness of a particular pedagogical approach, the teachers tried to understand the influence of that approach on the learning that occurred. And when evaluation of a particular situation did take place, it was preceded by careful interpretation of what had happened. We believe that this is a valuable shift and one that is closely tied to the goals of reform. As other researchers have stated as well, a focus on interpretation allows teachers to understand what has happened and to then use these understandings to inform their decisions of how to proceed (Hammer, 2000; Putnam & Borko, 2000; Sherin, 2001).

In addition to adopting an interpretive stance, the teachers also came to base their interpretations of what had occurred in evidence from the video. Teachers in both studies moved from talking generally about their practice to using specific events in the video as a resource for discussing particular ideas. For example, in the later video clubs, it was not uncommon for a teacher to ask to replay a segment of video so that he or she could more precisely discuss what a student had said. Similarly, the pre-service teachers initially talked broadly about what they saw happening in the classroom, stating, for example, "The students are really thinking in this lesson," without being explicit about what in the video indicated "thinking" on the part of the students. Over time, however, they began to refer to specific student actions and comments in the video as representing "student thinking" and as illustrations of their claims. This use of evidence is important for several reasons, two of which we mention here. First, as they use evidence, teachers make connections between the events that they see and key ideas of teaching and learning. For example, teachers in the video club found that watching video helped them to develop a concrete vision of what a "community of learners" can look like in practice. "I got to see this culture of kids knowing that you expect them to interact and bounce off each other's ideas and they aren't going to just look at you for the answer all the time. That's a community of learners." Similarly, teachers in the VAST study developed more explicit definitions of discourse and inquiry. Second, basing one's comments in evidence from the video allows other teachers to offer different interpretations of the same events and can raise the level of discussion and debate among the group. This is particularly valuable as teachers work together to examine and reflect on their teaching practices.

Implications

The results of this paper illustrate different ways that video-based professional development can provide teachers with opportunities to learn. While video has played an important role in teacher education for over three decades, more research is needed to understand the affordances of video for teacher education and those aspects of teacher cognition that are influenced by the viewing of video. In our research, we take an important step in that direction by examining how video can help teachers learn to notice — learn to notice new aspects of classroom interactions and learn to develop new techniques for making sense of these interactions. We found that both the video clubs and the use of VAST helped teachers to develop ways of noticing and interpreting classroom events that are in line with goals of mathematics and science education reform efforts. Furthermore, we believe that the types of changes that were observed in these studies have the potential to influence teachers' classroom instruction. In ongoing work, we are currently examining the influence of teachers' ability to notice on their classroom instruction and subsequently on students' learning.

Online Video Case Studies: What Have We Learned about their Value in Preservice Education?

David Georgi, California State University, Bakersfield
Pam Redmond, University of San Francisco
Sue Talley, Pepperdine University
Terence Cannings, Pepperdine University

Online video cases have the potential to provide real-world examples and dilemmas of classroom teaching to our teacher candidates in ways that text-based cases often cannot. In this presentation the panelists will demonstrate the video cases they have created and will share the results of the use of these cases in their respective teacher education programs. They will also discuss tips that they have learned about the production process. Finally, they will discuss the pros and cons of using text-based cases versus online video cases.

Shulman's (1992) research indicates that the use of text-based cases is very effective in teacher preparation, especially when discussion of the case is led by a skilled moderator who can help students develop the reflective skills necessary to improve their teaching practice. But text-based cases cannot address the need for preservice teachers to observe teachers handling daily problems in their classrooms. Learning to teach is difficult when students often have little time to observe effective teaching in a variety of situations, to practice their own teaching, and to reflect on this experience with others (Wasserman, 1994).

Online video case studies offer promise in addressing these challenges. Online video cases allow teacher candidates and instructors to view the cases many times, whether on campus or at home. These cases can be linked to a rich set of contextual resources to expand what can be understood directly from observation. These resources might include state frameworks or standards, the lesson plans underlying the video case, papers on relevant theoretical research, the rubrics or assessment tools used, and other web-based resources. The Internet also offers the opportunity for online discussion of the cases, creating the opportunity for students to reflect on these cases beyond just face to face class time, thus moving into a 24/7 environment. In addition, the Internet allows discussion to occur between geographically dispersed educators, creating the possibility for teachers to develop the habit of dialogue with others in their community of practice.

Low cost digital video cameras also enable preservice teachers to create their own video cases. They can videotape their own practice, for example, and then add reflective commentary. Easy to use video editors have made this a readily accessible option for teacher educators.

The presenters have all created online video cases as part of their Preparing Tomorrow's Teachers to Use Technology grants.

David Georgi has used Learning Circles consisting of professors, K-12 teachers, future teachers and others to produce streamed videos to illustrate instruction that can be accessed by anyone with an Internet connection. David will share two products, one in Special Education and the other in Physical Fitness.

Pam Redmond has worked with Apple Computer, Inc. to develop online video resources for educators. The project began as the California Learning Interchange and now is expanding into the Teacher's Learning Interchange (TLI). Pam will show some of these resources and discuss their evolution. In addition, she is the evaluator for the work being done at CSU, Bakersfield and will share some of those results.

Sue Talley and Terence Cannings have worked at Pepperdine University on a series of online video case studies. These cases use the tools created by LessonLab, a company founded by Dr. James Stigler. The tools have been developed based on lessons learned from the Third International Mathematics and Science Study. The series includes lessons showing the use of the Language Experience Approach in elementary classrooms, a Climatology lesson in upper elementary using Palm Pilots, and techniques for teaching English Language Learners. Sue and Terry will demonstrate how these videos are used in courses in the Pepperdine teacher credentialing course sequence and discuss the evaluation results to date.
After the demonstrations, the panel members will interact with the audience, answering questions about the value of online video cases and the advantages they have found in using this type of case. They will also discuss times when text-based cases may still be preferable. The panel will also answer questions about production of these online video cases. Finally, they will invite feedback about the elements included in their cases and will discuss the relative merits of these elements based on their use at their respective universities.

Pepperdine Presents: An Online Video Case Studies Series to Use Throughout a Teacher Education Program

Sue Talley, Pepperdine University, PT3 Project Director

Pepperdine University has developed a series of online video case studies to use as part of its fifth year teacher education program. These online video cases use the software tools developed by LessonLab. Three cases from the series will be demonstrated. The first case, from a lower elementary classroom, includes four segments from a reading lesson that uses the Language Experience Approach. The follow-up to this case demonstrates how these same techniques can be adapted for use in a secondary level classroom. The second case includes four segments from a unit on Climatology, covering both science and math concepts and highlighting the use of Palm Pilots as part of the unit. The third case demonstrates a variety of techniques used to teach English Language Learners.

The LessonLab tools are based on Dr. James Stigler's findings from the Third International Mathematics and Science Study. These findings were documented in his book The Teaching Gap. Stigler & Hiebert (1999) write there that they believe that the teaching profession does not have enough knowledge about what constitutes effective teaching and that there is a lack of a system for developing professional knowledge and for giving teachers the opportunity to learn about teaching.

The cases developed by Pepperdine University using the LessonLab tools include a variety of elements that research indicates are valuable when using cases to better understand teaching. By adding other elements to the video, a richer context for the video case is developed. These elements include commentaries designed to guide the preservice educators while viewing the video. These commentaries may be from the teacher or from other experts in the pedagogy being used or in the technology being infused into the lesson. There are also resources such as the lesson plan used, state frameworks or standards, samples of student work, and the rubrics or assessment tools used as part of the lesson. Because these resources are online, students may also be directed to web-based resources that will be important to them in their teaching practice. In addition to video of the lesson, there is video of the teacher indicating, prior to the lesson, what he or she believes is their intent in the lesson. There is also video of the teacher being interviewed after the lesson, indicating areas that he or she feels could be improved and why. In addition, there is usually commentary from the students about what they understood about the lesson.

While the original intent for these online video cases was to supplement materials used in methods courses, our experience at Pepperdine indicates that the cases have much wider applicability. For example, they can be used in an Instructional Strategies class where preservice educators may be discussing possible classroom management strategies. They might also be used in an Educational Psychology course where preservice teachers might develop their observation and reflection skills. As instructors in the Pepperdine teacher education program use the online video cases, they continue to find new and different ways to take advantage of the rich resources inherent in the video case.

Although the content of these online video cases is important, even more important perhaps are some of the ways that these cases are actually used in preservice instruction. Moving cases from text to online allows preservice educators to watch the video many more times than they might within the context of their face to face classroom time. Preservice educators may also participate in online discussions about the cases, not only with their peers but also with a larger community of educators. Perhaps most important, preservice educators, using the LessonLab tools, can interact with the video in a way that lets them identify key points where they observe certain activities occurring in the video and to reflect on why they believe this is happening.

Finally, these professionally developed online video cases have led faculty to use digital video in even more ways in their classrooms. The availability of low cost digital video cameras and easy to use video editors have led faculty to combine the use of the prepared cases with student-developed cases.

Educational Applications of Video: Creating Educational Video with Pre-service Teachers to Demonstrate Classroom Management Strategies

Mary Thompson
Curriculum and Instruction
University of Houston
mthompson@pioneer.coe.uh.edu

This paper will describe a joint project between PT3 grant team members, an Instructional Technology graduate course, a pre-service teacher core course, and pre-service teachers which resulted in video clips that are currently being used to supplement the curriculum of a classroom management course at the College of Education, University of Houston.

The following paper discusses the design and development of a collaborative video project at the University of Houston through the roles of the multiple participants: Dr. Bernard Robin, the video course instructor; Dr. Philip Ruthstrom, PT3 grant coordinator; Dr. Will Weber, the classroom management course instructor; Mary Thompson, PT3 grant technology fellow and videographer, and students of classroom management who participated in the creation of the videos. The purpose of this paper is to describe the video project from the inception of the idea through its completion including the current status of the project.

Course Concept—Dr. Bernard Robin, course instructor
CUIN 7346, Educational Applications of Interactive Video, is a graduate-level course in the Instructional Technology program of the department of Curriculum and Instruction at the University of Houston. It is also the course for which the video project to be described in this paper was the final project. Beginning in the early 1990s, CUI 7346 was a course in which educators learned how to take existing video and edit it for their own use in the classroom. The focus of that time was on taking educational materials such as laserdiscs and videotapes and using them to support the classroom goals of the enrolled students. As video technology both increased in sophistication and decreased in cost, the course objectives changed to the creation of video resources rather than the retooling of pre-existing resources. Graduate students enrolled in the course were taught the basics of videography so that they could create their own video resources for personal use. As the course evolved, however, the need for a focus, a central guiding project, whose goal was more permanent and far-reaching, became apparent. Students needed a goal, in the form of real projects for real clients who intended to use the completed video projects, to give them the impetus for greater creativity. The inauguration of a project-based focus for the digital video course led to greater room for creativity and better implementation of resources which were, by then, more accessible than ever. This new project-based goal required that groups of students work with a client to create video for actual distribution and use. The final step in the process which led to the creation of the classroom management video project was the collaboration between the students and instructor of CUI 7346 and the PT3 grant awarded to the University of Houston in Fall 2000. As a result of the PT3 grant, instructors of pre-service teacher courses within the College of Education became clients for the spring semester of Educational Applications of Digital Video.

Collaboration—Dr. Phil Ruthstrom, PT3 grant coordinator
One of the stated goals, among many, of the PT3 grant team at the University of Houston, was to increase the infusion of technology into the education courses for pre-service, pre-certification teachers. The idea for collaboration between the students and instructor of the Education Applications of Interactive Video and the instructors of these courses grew from the stated goals of the PT3 grant. A stated goal of the PT3 grant at the University of Houston is to create opportunities for pre-service teachers to be exposed to authentic uses of technology in their education courses. The personalized video resources proposed for this project, it was hoped, would become integral components of the pre-service teacher courses for which they were created and thereby expose students to a new and innovative use of technology. As a result, instructors of pre-service education courses, the main focal point of the PT3 grant, became clients for the students enrolled in CUI 7346. The needs of the clients and the matching of video students to those needs were facilitated by the course instructor and the PT3 grant coordinator. Specifications for videos required that they be short, "mini-case" products, between thirty seconds to one and one-half minutes long, which could be incorporated into a class discussion, and would not require the entirety of a class to view. The goal of the finished videos was to be twofold; that these videos would act as curriculum enhancers for the pre-service teacher courses and that they would serve as a resource for many semesters beyond the time of their actual creation. The pre-service teacher instructors/clients for CUI 7346 were informed of and in agreement with the stated goals for the video projects.
Client Experience—Dr. Will Weber, Classroom Management Course Instructor

Dr. Weber’s classroom management course, CUIN 4375-6375, is a required component of the teacher certification program at the University of Houston. Students in the course are encouraged to look at a number of accepted approaches to classroom management and to choose those strategies which they feel will best suit their needs as teachers and their goals for their future classrooms. Dr. Weber often uses the analogy of a classroom management toolbox, enabling students to understand that the more strategies for classroom management that they have in their toolboxes, the better their chances for a successful managerial intervention to address inappropriate behavior, monitor possible problems, and maintain appropriate behaviors. Dr. Weber frequently employs case studies to help students to better grasp the nature of classroom management strategies. The idea of creating mini-video cases for use in his teaching, therefore, was a perfect fit. Dr. Weber offered his students the opportunity to participate in the video project as an alternative to the standard paper project. In return, students agreed to work closely with the video crew, students of the Educational Applications of Video course, to complete the steps necessary to the creation of good classroom management examples.

Coordination—Mary Thompson, PT3 Grant Technology Fellow and student enrolled in Educational Applications of Video

After Dr. Weber announced the project, interest in the classroom management video project was extremely high. The role of video project coordination fell to a PT3 Grant Technology Fellow who was also enrolled in the Educational Applications of Interactive Video course. Management of materials such as video equipment and permission slips, communication between video crew and the pre-service teachers, and an understanding of concepts being taught in the classroom management course were crucial elements to the development of usable video resources. Knowledge acquired as a student of Educational Applications of Interactive Video played a major role in the successful translation of raw footage filmed at the schools into usable mini-clips which accurately and succinctly demonstrated the classroom management objectives. The first semester of the video project encompassed 12 pre-service teacher volunteers and took place in six school districts in the Houston area. Completing such a large project in a single semester required the cooperation and hard work of all involved.

Creation—Preservice Teachers enrolled in Classroom Management (CUIN 4375-6375)

As participants in the classroom management video project, students were required to make arrangements to provide a real classroom setting for filming. They had to obtain permission to use a classroom from school administration and to film actual students from their parents. Once appropriate permissions had been received, the students created scripts which demonstrated the classroom management strategies recommended in Dr. Weber’s course. Students then rehearsed those scenes with their students so that they would be ready for filming. While the amount of work involved in the video project certainly equaled and, in some cases, surpassed the amount of work required by the traditional paper assignment, student evaluation of the process was resoundingly positive. Feedback from two pre-service teacher video project participants follows:

I used strategies and created scenarios that I felt would demonstrate a teacher-student encounter with management strategies in a classroom environment. My video took place at Stephens Elementary in the Gym; I had a total of ten participants from third and fourth grade...I tried to create realistic scenarios such as following directions, proximity control, and "I" messages. Best of all, I enjoyed the making of the video we created in collaboration to create memorable experiences that can be useful for pre-service teachers or any individual who is interested in classroom management. As an undergraduate student, I will always remember the classroom management video that I invested time in creating. I may not remember the titles of papers that I have written for other classes but my video participation is a valuable resource to retain.

Evette Silva, 4th grade pre-service teacher, Video Project Participant, Spring 2001

I believe it is simple to put in theory what one should think a classroom setting should be like. It is very easy to write down on paper what a smooth transition between one lesson and the next should be like but it is not always easy to do it in the real world. Theory and applied theory are two completely different ballgames but without a doubt the video project gave me great experience in applying what I had learned in theory. To be able to write adequate skits I not only had to do my research but, I had to go to observe a class to see what classroom management strategies stood out. Many of the things I observed impressed me so much I decided to incorporate them in my own toolbox of strategies. Once the skits were ready the actors had to be chosen and the skits needed to be rehearsed. The funny thing
is that classroom management needed to be utilized to have successful practice sessions which further
built on my experience with its implementation. What I had learned was needed every two seconds
with at least one of the little bodies we were trying to control. After days of practice, the final day
comes when it was time to film. The effort from the children and the smile on their faces was the
greatest treat of all. No essay can give you that kind of satisfaction. I had a great experience with the
video and if I could do it again, I would do it again without a doubt. It is not only great experience
with the children, but a great chance to see experts doing everyday things that you read about. It is
amazing how you understand some theory when you read it, but it is not until you experience it that
you completely come to understand and internalize what is written in your textbook. This video
project gave me the opportunity to assimilate and internalize my knowledge of classroom
management into something a lot more whole and rewarding.
Betty Garcia, 1st grade pre-service teacher, Video Project Participant, Fall 2001

Along with the educational benefit provided to pre-service teachers by the video project, a positive result has
been the knowledge gained by participants in the creation process. Above all, the decision to use real teachers and real
students has proven to be a valuable one. Using authentic classroom conditions, even in scripted situations, provides a
naturalistic insight into teacher/student interactions within the classroom. In addition, it has become readily apparent
from viewing the completed videos, that much more can be learned from these video segments than how to teach a
single skill. In some cases, the strategy captured on film is not necessarily the exact one that the teacher had planned.
In such cases, the natural interaction between teacher and students, again, plays a strong role in producing practical
classroom materials. Another unforeseen benefit to filming in a real classroom setting with real students is the pleasure
the majority take in participating. Not only do students like the moments when they are the center of attention, they also
like the idea that they are helping their own teachers in a project for their coursework. Additionally, reflection on the
video creation process led to the discovery that educational videos, while needing to be professional and cleanly edited,
do not have to be filled with glamour; the purpose of these videos is to highlight the skills of the teacher not the
videographer. Therefore, fireworks and special effects are not necessary and, indeed, would have distracted from the
established goal.

Current Status—Continued Collaboration
The collaborative nature of this project, involving representatives from all levels of the College, enabled the
success of the venture. The strength of this project lies in the concerted effort of so many participants throughout the
College of Education. Each stakeholder in the video project brought the resources without which the videos could not
have been made. Results are such that the project has been extended and is now in its third semester. The continuing
goal is to create a library of classroom management examples that future students can draw on both in class and in a
projected online component.
The events of 2001 have left an indelible mark on us all and have placed our humanity at the forefront of our lives. This is interesting because for those of us work with information and communication technologies (ICT), it reinforces the need for humans to be in control of machines and to use them to complete our own needs and desires. This process begins in the early childhood years when young children appropriate technologies to make sense of the world in which they live and also to communicate with others. There are those who wish to isolate young children from ICT and they suggest that children need to play only with three dimensional materials in order to understand the environments that they inhabit. Such people ignore the fact that technologies are an integral part of young children's lives and to dismiss them is to become like the ostrich who submerges his head in the sand. I recently met a teacher who proudly told me that her preschool was a "technology free zone". She justified this in terms of developmental theory that required active engagement with materials and stated that young children "had too much technology in their lives". This assertion, based on no evidence at all, was, for me, patronizing, and naive in the extreme. To ignore the role that technologies play in our lives is bizarre. We need to appropriate the power of information and communication technologies so that they can help children to learn in new and dynamic ways. To ignore them, and their potential for learning and expression, is to further isolate early childhood education. How can you ignore a resource that is such an essential part of our lives?

The papers in this section have, as their focus, the use of computers with young children. Buldu interrogates early childhood teachers and discusses the findings of interviews which have, as a focus, children's views of computers and the ways in which they can be used in educational contexts. Buldu suggests that we should pay attention to the results of the study since they impact on the lives of the children that we teach.

Hall considers using technology in the primary grades of schooling. He considers the digital divide in a collaborative project that observed student achievement through the primary grades. Yost looks beyond "drill and kill" software to examine ways in which technologies can be incorporated into early childhood curriculum. She suggests ways in which teachers can use generic software to create learning opportunities that are exciting and innovative. Hirschier describes ways in which technologies can support preschool teachers professional development. She worked with 42 Head Start teachers and discovered that they needed professional development in the area of literacy that incorporated the use of ICT. Hirschier worked with teachers, showing them ways of using ICT effectively and discussed the findings of their work in the context of the provision of quality early childhood experiences. This work links closely with the paper by Crawford which focussed on children in preschool contexts and considered a particular cohort, that is those with a disability. The study is interesting as it highlighted the diverse ways in which computers can be used with this group in exciting and innovative ways.

The papers in this section are examples of the ways in which children and their teachers have appropriated ICT in varying contexts. It is evident that the use of ICT afford opportunities for young children to explore ideas in new and dynamic ways that were not possible without the technologies and additionally that new technologies engage children so that they are motivated to learn. Early childhood curricula have almost been stuck in a time warp that was the 19th century. Young children today are curious and excited and use ICT to explore concepts and communicate with others as a natural part of their everyday lives. Teachers and administrators should embrace new ways of thinking and learning. To dismiss ICT for young children is to ignore an essential element of their existence and further isolate education from the current and contemporary lives of children who inhabit our schools.
Abstract:
What early childhood teacher educators know about and think about computers and computer use for young children will likely affect what future early childhood teachers implement in early childhood settings. In this study, the researcher wished to find out the possible perspectives of early childhood teacher educators on computer use of young children. Three early childhood teacher educators teaching at two Midwestern universities in the US were interviewed for the study. The findings categorized into four categories—knowledge, experience, beliefs about the value of computers, and beliefs about practice. When sorting out the data, the researcher first examined the similarities among the subjects' responses, and then analyzed the differences. The author concludes that it is critical we pay attention to the results of this study and others that examine the teacher educators. It is the first window through which we see what future teachers may implement in early childhood programs.

Introduction
Since computers have been introduced to early childhood education, there has been a wide debate among early childhood professionals about both the developmental appropriateness and the effectiveness of computer use for young children. Classroom and policy decisions made as a result of these debates will have significant impact on young children's development and learning. Therefore, it is important to examine the perspectives of early childhood education professionals, find out where they stand on the issue of computer use with young children. In particular, this researcher examined early childhood education teacher educators' opinions and values.

Conceptual Framework and Rationale
Computers are very important parts of our lives and will probably be more important in the future. Since the last two decades, they have been increasingly present in early childhood education settings. As Clements (1999) states, toward the end of the 1980s, only one-fourth of licensed preschools had computers, and he continues that today almost every preschool has a computer, with the ratio of computers to students changing from 1:25 in 1984 to 1:22 in 1990 to 1:10 in 1997 (Clements 1999). This last ratio shows us that computers became a part of early childhood education settings; therefore, teachers of early childhood education need to be familiar with the latest computer technology in order to make use of its advantages for young children.

In their position statement “Technology and Young children - Ages Three through Eight” (National Association for the Education of Young Children 1996), the National Association for the Education of Young Children (NAEYC) states that “As early childhood educators become active participants in a technological world, they need in-depth training and ongoing support to be adequately prepared to make decisions about technology and to support its effective use in learning environments for children.” In this statement, NAEYC also mentions that institutions of higher education have a responsibility to provide training for future teachers of early childhood education on how to integrate
computer technology into early childhood curriculum. Here the biggest responsibility belongs to early childhood teacher educators.

What early childhood teacher educators know about and think about computers and computer use for young children will likely affect what future early childhood teachers implement in early childhood settings. In this study, the researcher wished to find out the possible perspectives of early childhood education scholars on computer use of young children—their knowledge, their experiences, their opinions about value, and their opinions about practice.

Research Questions

Specifically, this researcher was guided in this study by the following questions: “What is the perceived knowledge, experience, opinion and values of early childhood education instructors?” and “What is the relationship between knowledge, experience, opinions and values of early childhood instructors and implementations for future early childhood teachers?”

Methodology

Convenience samples of three early childhood teacher educators were interviewed for the study. Interviews were audiotaped, and notes were taken during the sessions.

Participants were early childhood education instructors who have been teaching at two different Midwestern universities in the U.S. Early Childhood Teacher Educator A has 14 years teaching experience, and has worked in early childhood education programs at two different universities since 1986. Early Childhood Teacher Educator B has 10 years teaching experience and has been working in early childhood education programs for 6 years. Prior to this she taught two years in Psychology, and one year in Child Development and Family Studies. Finally, Early Childhood Teacher Educator C had 4 years of teaching experience in early childhood education programs at two different colleges as an instructor and associate instructor.

Each subject was interviewed in an-hour-long, and semi-structured interview session. Although interviews were organized into predetermined questions, questions were used only as a flexible guide. Based upon the responses of the subjects, the researcher found he needed to adapt the order and phrasing of the questions from one interview to the next.

During the interviews, four types of questions were asked. These were as follows: (a) background questions, (b) knowledge questions, (c) experience questions, and (d) opinion and value questions. The purpose of these interview questions was to discover the relationship between instructors’ knowledge, experience, beliefs about the value of computers, and beliefs about the practice and how future early childhood education teachers may implement what they learned from their instructors.

Are teacher educators, especially those who have been in the field many years, aware of the issues being debated about computer use and young children? Do they have well-informed opinions and beliefs about this issue? This information is important because what early childhood teacher educators know, believe, and are able to do in terms of computer-use and its value will impact what future teachers learn from their instructors at college level about young children and computers.

Analysis and Interpretation

Based on the framework provided by the questions and results of the interviews, the findings can be categorized into four categories—knowledge, experience, beliefs about the value of computers, and beliefs about practice. When sorting out the data, the researcher first examined the similarities among the subjects’ responses, and then analyzed the differences.

[1] All samples were informed about the purpose of the interviews.
Knowledge:

When subjects were asked about their computer literacy and the amount of knowledge they used in their teaching, Instructor A and B defined themselves as fairly computer literate. They stated that they could do word processing, accessed the web frequently, used e-mail daily, did statistical analyses on the computer, and in general, they felt that they were able to do anything they needed to do on the computer. Instructor C, however, told the researcher that she felt she was not as well prepared to use the available technology effectively. One thing that was common across the three participants was that they all searched the web for information that they can share with their classes. They also each indicated that they were using e-mail for discussion groups and to facilitate communication. In addition, Instructor A and B mentioned that they were using power point for lecturing purposes.

The subjects were also asked about their familiarity with programs and software for young children. Interview results indicated they were all somewhat familiar with the programs and software for young children. In particular, they were familiar with problem solving kinds of software, drill or practice software, and reading, writing, and painting programs.

Experience:

When participants were asked about their teaching experience at the college level about computers and software for young children, results show that the instructors, to date, do not have much experience teaching about computers and software for young children. Instructor B, however, talked about a new early childhood teacher education program that is about to begin at her university.

"... In the new program, technology is one of the three things we want to hit on from the beginning of the program to the end. In this program technology is defined broadly; we want students be prepared to teach in the real world, discussing its value, its dangers, who should have it, should it be in every class; we want students, 21-year-olds, going out at least ready to critically examine technology, and be critical consumers of it. Be ready to know how to access the world wide web, and how to search it, how to use computers as information sources..." (Interview with Instructor B)

Moreover, based on the results of interviews, the researcher found that they did not talk about computers and software for young children very much as something they used as in-class activities in their college learning environments. But, they do take their college students on field trips to early childhood education programs in which they talk to the teachers of these programs, and observe young children using computers. According to the instructors’ reflections about these field trips, most of the programs they have visited have one or two computers, but children do not use them much. "...There were some exceptions to that, where computers are used for painting, writing, sound and letter learning, etc..." said Instructor C.

Beliefs about the Value of Computers:
(a) Physical and Cognitive Readiness of Young Children to Use Computers

Findings from the interviews show that the instructors had different perspectives about the physical and cognitive readiness of young children to use computers. The participating instructors agreed that young children were very capable of using computers. According to instructors A and C, the question was not that, the question was when they should begin to use them, and whether it was good for them or not.

"I think some kids are able to use them, I think some of the software is ok. But, I do not think they are learning anything different. I am not sure what benefits they are getting from it, and what function it serves in the classroom. I do not think it is the primary means for them to get instruction or information; they can get this stuff later. They can learn what they need to do with computers when they are a little bit older, may be in 2nd grade or 3rd grade it would be helpful..." (Interview with Instructor A)

Unlike Instructor A and C, Instructor B had a different perspective. According to her, it depends on a couple things. First, it depends on what we define as young child who varies from birth through age 8, and it depends on what kind of program they, the teachers, are using.
“I feel very differently if we are talking about a primary age child then I do a three or four year old. I am always nervous about the word readiness. I think kids are ready for many different things, whether they are good for them or not. I think I prefer to think about whether it, a computer program, promotes their healthy socio-emotional, intellectual, language, and overall cognitive growth and development rather than if they are ready or not.” (Interview with Instructor B)

Instructor C believes that kids need to be doing other things at ages 2 through 5, such as reading or being read to, writing or having them write their words written down, they need to play, need to be exploring, etc. But, when they get into 1st and 2nd grade she believes that computer access is critical. Her reason for this belief was that we use computers everywhere in our life, whatever level we achieve; we have to know how to use computer technology as a tool, for example communication and record keeping. Those who come from homes in which computer usage is not a part of daily life, for instance children in poverty, may be put at further disadvantage if this tool is not available to them in the classroom. So, Instructor C believes children in elementary school need to learn about computer technology.

(b) Possible Pros and Cons

When asked potential advantages and disadvantages of computers, participating instructors were in nearly total agreement, stating that they see computers as communication tools; a way for children to learn about the whole world through internet, and that computers can be engaging, and entertaining. They also agreed, on the other hand, that computers are addictive, isolating, they replace other activities, and may keep kids from doing real things if used too much. Moreover, Instructor B added: “... maybe depends on the teacher, what he choose for children, how much he knows about computers, how much time he lets children work with computers, whether he supports group work or not”

Beliefs about Practice:

(a) What Would Instructors Like to See in Early Childhood Settings?

Examining the interview data about instructors’ beliefs about the value of computers, it was found that they had different beliefs about computer in early childhood education settings. This is revealed in the following sample of quotes:

“... I would like to see that every 1st and 2nd grade classrooms have may be three or four computers that are also internet ready. ... I would like to see teachers have sufficient knowledge about computers and computer programs, and also teachers walking around the class interacting with different groups of children. ...” (Interview with Instructor B)

“... I would like to see teachers really take the ability of computers seriously to individualized different kinds of instructions, and have the ability to demonstrate to the children how they can use computers as a source of information. ...” (Interview with Instructor C)

“... Teachers who want to use them and know how to do it well can use them, but equally teachers who do not want to use them can do a good a job without them. You can be a good teacher with them or without them. It is just a tool like anything else. ...” (Interview with Instructor A)

The most interesting thing in these findings is that each of the instructors emphasizes the importance of the teacher’s role facilitating of computer use in the classrooms. How they differ is in what they want or require of the teacher. Instructors B and C want the teachers to be knowledgeable and strong facilitators, individualizing instruction as needed, interacting with children who are using the computers as a tool in groups. Instructor A mirrors part of the sentiment expressed by Instructor B, stated earlier, that the computer is a tool. He differs from Instructor B, however, in that she feels that those teachers who do not use this tool can do their jobs as well as those who do; i.e., she does not feel computers are essential.

(b) What Would Instructors Like to See Taught in Early Childhood Teacher Education at the College Level?

Unlike their beliefs about practice in early childhood education settings all three of the instructors were very similar in their wishes about what they would like to see taught in early childhood education at
the college level. They all wanted early childhood education college students to have some experiences in using whatever the current programs are, in searching the world wide web for information, and they want students to know how to use certain kinds of software, and to be prepared to critically examine its usefulness. They want them prepared to be able to select appropriate technology tools for the children in their classrooms, and to understand the importance of staying current — knowing what is the newest and latest and what experts have said about its value. But, on the other hand, Instructor A mentioned that early childhood education college students should decide themselves how much they need to know and learn according to their own teaching style.

Conclusions

This researcher confirmed the findings of Haugland and Wright (1997), who examined the beliefs about the potential dangers and benefits of computers. Haugland and Wright found that some of the early childhood education professionals that they studied fear that computers will replace other activities and may lead to social isolation; while, on the other hand, computers may provide children a wide world to explore, experiment and discover. These findings echo those of the beliefs expressed by Instructors A, B, and C in this study.

It is widely accepted philosophy in the early childhood field, that through active participation, children acquire and construct knowledge. Therefore, before using computers with young children it is important to address the potential effects of computer use on children’s development and learning. There have been many debates regarding the potential dangers and benefits of computers in early childhood classrooms, but too few scholars have actually examined prevailing attitudes and beliefs of teachers in the classroom and of those who prepare teachers.

We need to research what new early childhood teachers, recent graduates from college, implement in their early childhood classrooms. Ultimately, we then must examine how the perspectives affect development and learning outcomes with young children. As pointed out by Davis and Shade (1994), despite revolutionary advances in the field of educational computing, technology remains simply a tool, and potentially powerful and stimulating, the computer is only an inert object that can never be a substitute for the personal touch of the classroom teacher. The critical thing is how teachers implement computer use in their school.

It is critical that we pay attention to the results of this study and others that examine the teacher educators. It is the first window through which we see what future teachers may implement in early childhood programs.

Using Technology in the Primary Grades: An Innovative Educational Pocket PC Project

Grey Hall, East Carolina University, US
Renee Gilpin, Newport Elementary School, US

The playing field in our nation’s public schools is not level and East Carolina University (ECU) and Newport Elementary are collaborating to change that. All students need access, at home and at school, to the tools necessary to allow them the freedom to academically compete with their classmates, regardless of race or socioeconomic background. School leaders need new technological, pedagogical and financial models to make the field as level as possible. Parents and teachers must be part of a communications team to support student achievement. All children must be given an equal chance. The fact that some have more financial resources does not mean they should have a monopoly on essential learning tools.

Many students lacking financial resources do not have necessary technology in their homes. Small and rural schools do not have proper digital equipment in their classrooms. Students negatively affected by this lack of resources are part of America’s rapidly developing digital divide. Their work is often inferior to those who have access to tools supporting content mastery. Without innovative, knowledgeable intervention by school leaders this situation will manifest itself as low scores on local and national standardized tests intended to measure student progress and academic accountability.

Methodology will be both quantitative and qualitative. Standard instruments will be used to quantitatively measure student progress in mastery of technology and curriculum content. Technological, pedagogical and financial models will be constructed before the study begins and modified as necessary. More subjective qualitative measurements will be used for parental assessment of the pilot.

A grant has been procured to purchase the necessary technology. The teacher, her assistant and selected school leaders have been given Jornadas and are being trained to use them. Kick-off meetings have been held with central office, school personnel, university officials, students and their parents/guardians.

In October, 2001 each student will be given a Jornada equipped with electronic reader, software for word processing, spreadsheet application, email, Internet access capability, a calculator and scheduling/tasking packages for homework and communication with parents. Students will be tested at that time for knowledge of the technology and content related to the North Carolina Standard Course of Study in the areas of reading and writing.

In November, or whenever the teacher believes a pre-determined level of mastery has been met, students will be retested on their knowledge of the technology, and on their mastery of reading and writing. This testing, intervention and retesting will repeat throughout the school year, moving to different content areas once a pre-selected level of mastery is achieved.

Parents will be expected to nightly review a folder on the Pocket PC reserved for them and to stay informed of students’ progress. They will also be required to assess the project. The second graders in this study will be measured against norms established by all second graders in the school. Data will be gathered and analyzed in the late spring and early summer of 2002 and a final report will be produced.
Using Technology to Support Preschool Teachers' Professional Development

Julie Hirschler, Education Development Center, Inc, US
Carol Darcy, Education Development Center, Inc., US

Background and Educational Importance

The recent National Research Council's report, Preventing Reading Difficulties, highlights the urgent need for more effective literacy education for preschool programs that serve low-income children. Indeed, our own research has provided deeper insight into the source and extent of the problem. In our study of 42 Head Start classrooms, we found that teachers are minimally knowledgeable about using books correctly, in supporting early writing, and in engaging in intellectually stimulating conversations with children. When teachers are trained in these areas, they do show marked improvements in the quality of programs and in outcomes for children. However, typical professional development is characterized by episodic workshops or lectures that do not reflect research-based knowledge. In addition, early childhood educators have constraints on their time and resources that are not alleviated by traditional professional development opportunities.

Education Development Center, Inc, Newton, MA, a non-profit international research and development, has piloted and is implementing an technologically-enhanced in-service course for early childhood educators that is constituted of 1) two-way television, 2) web participation, and 3) face-to-face facilitated group discussions. In its first operational year, we are offering two sections of the course from the University of Massachusetts, Lowell to six sites in Massachusetts, Connecticut, North Carolina.

This presentation will explore the results of implementing this multi-technology inservice course for teachers. In doing so, it will attempt to answer the following questions:

1. Do participants stay focused and engaged throughout the interactive television sessions?
2. Do participants feel as comfortable contributing to the interactive television discussion as they would during a typical large class?
3. Do participants use the web to help them communicate with other class participants?
4. Do participants use the web to help them learn the class material?
5. Do participants use the web to get new resources or ideas to use their classroom?

Description of the Project

The project, the Technologically-Enhanced Learning Environments Enrichment Program (T-LEEP), includes both course delivery and a research study that examines how preschool teachers and supervisors respond to the use of technology to support their professional growth. The project is being supported by a grant from an interagency consortium of the National Science Foundation, the United States Department of Education, and the National Institutes of Health. Their goal is to develop the knowledge and experimental methods that will allow for the implementation and evaluation of large-scale educational interventions, which will, in turn, inform education policy and practice.

We believe that the integration of technologies adds to the value of professional development for our early childhood teacher participants. Through our course design, we are able to:

- Reach practitioners in geographically diverse locations, minimizing transportation and tie costs.
- Offer opportunities to view model classroom via CD/web augmentation and analyze pedagogy with practitioners during ITV sessions.
- Provide online discussion of course content and online assistance.
• Introduce practitioners to interactive instruction and web-based technologies that can strengthen and widen their communities of practice.

To most effectively support our participant teachers, we have created a new model: the Instructional Videoconference. This consists of 1) a one hour face-to-face professional conversation among participants at each local site. During this conversation, participants share information about classroom assignments and are introduced to the content of the ITV session to follow 2) the two-hour ITV session and 3) a shorter face-to-face session that follows ITV during which participants expand on questions from the ITV and discuss the classroom assignments for the following weeks. These three modes of instruction have been modeled into a whole whose pieces fit together in the interest of making positive changes in child learning outcomes and teacher practices in early childhood classrooms.

Instructors have developed new Power Point presentations with imbedded videos of model classrooms for analysis during the ITV classes. Several interactional techniques are employed by ITV instructors to increase the cross-site interactions during ITV sessions.

The T-LEEP website complements the ITV portion of instruction and interaction by allowing teachers to do more in-depth literacy work around case studies. Part of each participant’s weekly assignment is to log in and post to the discussion board on our website. Because we want to have ITV instructors accessible to students, we have created an Instructor Office Hours section of the website in which students may pose questions directly to the teachers.

Data Collection

Participants complete a survey after each of the ten sessions of the course. After half of the sessions, this is limited to a six-question survey. An extended questionnaire is completed after other sessions in order to collect data on cumulative perceptions of the course and pedagogical practices it is supporting. At the final session, participants complete a much more extensive standardized questionnaire that gauges their perception of the teaching environment. In including such an evaluation instrument, we hope to compare participants’ perceptions of the classroom environment in a technologically-enhanced classroom setting to that in a more traditional classroom.

Web activity will be monitored throughout the course as well to allow us to analyze participants’ use of the various layers of our website and to follow the discussion strands based on course content.

We will conduct telephone interviews with a subsample of participants and with the site facilitators to gain qualitative data. These individual interviews will be designed, conducted, and recorded in order to create a format in which stakeholders can be free to explore the meaning of events in this course. Questionnaire and interview analyses will then be conducted to allow for new and fuller understanding of the use of technology in inservice education.
Computer Use Within Learning Environments:
Early Childhood Case Study

Abstract: This exploratory study investigated a seeming disparity between availability and types of computer use within childcare settings and preschool programs for children with disabilities as reported by families of young children with disabilities. Investigators surveyed a random sample of special education teachers and child care administrators. Results indicate: (a) child care setting environments may provide more and varied opportunity for computer use by preschool children, and (b) the availability and implementation of technology within the learning environments for young children warrants further investigation.

Introduction

The benefits of technology use in special education and young child education is well documented in reviews of the literature (Edyburn, 2001; Blackhurst & Edyburn, 2000; Woodward & Reith, 1997; Okolo, Bahr, & Reith, 1993). Although there is an assumption that early childhood special education teachers have computers in their classroom or access to computers, anecdotal reports from teachers indicated a lack of technologically enhanced learning environment opportunities for children with disabilities. The disparity between the education the teachers receive at the university level and the lack of technology available at the early childhood level leads towards a lack of educational tools at an important stage of development (Crawford & Martin, 2001). Anecdotal reports by families of young children with disabilities commented on the lack of technology in their child's classrooms and the availability of technology in after school childcare programs. This study investigated a seeming disparity between the availability and types of use of computers within the child care settings and preschool programs for children with disabilities.

Method

Data for this exploratory pilot study were collected by phone survey. Special education teachers were selected randomly from graduates of the university teacher preparation program and administrators of child care centers were selected randomly from the phone directory yellow pages. Interviewees were surveyed until a pool of ten special education teachers and ten child care administrators met the following qualifications: Children with and without disabilities aged 3-5 years were present in the setting and computers were available for child use. Interviewees were then asked six questions:

1. Do you have computers for the children to use?
2. Do the children use computers with adult assistance?
3. Do the children use computers with peers/friend?
4. Do the children use computers independently?
5. Do you have software you consider to be for play?
6. Do you have software you consider to be for drill and practice of skills?

In total fourteen teachers of young children with disabilities were contacted. Four were excluded because of lack of computer access for the children. Two childcare settings were also excluded because computers were for the use of staff only. In total twelve childcare centers were contacted and two were eliminated for lack of computer access for the children.

Findings

Findings of this exploratory study to determine a possible disparity between preschool instructional environments for children with disabilities and child care center environments support anecdotal evidence that child care settings provide more and varied opportunity for computer use by young children. Results are presented in Table 1. Implications of this study are limited by sample size, convenience sample of teachers, and self report data. However, findings indicate a need for future studies on the availability of computers and actual computer use by young children in child care and in classroom settings.

Using Technology to Support Student Learning

Staci Noecker
School of Education
Box 1249
St. Bonaventure University
St. Bonaventure, NY 14778
noeckesl@sbu.edu

Abstract: This poster/demo session will present plans and outcomes from a variety of technology-enhanced learning experiences in elementary classrooms. I will provide examples of how technology can be used within all different subject areas and how technology can be used to meet the needs of diverse learners. My demonstrations would include lessons, student and teacher reflections, and student and teacher artifacts of some of the many ways to use technology in the classroom.

To demonstrate my application of technology in the classroom as a learning tool for students during internships and student teaching, I plan to display a variety of examples of what my students and I have been working on. I will provide examples of how technology can be used within all different subject areas and how technology can be used to meet the needs of diverse learners. My demonstrations would include lessons, student and teacher reflections, and student and teacher artifacts of some of the many ways to use technology in the classroom.

I have many ideas in which I would demonstrate incorporating technology into all subject areas. I would show how the software programs Inspiration, Kidspiration, Easy Book Deluxe, and Hyperstudio could be incorporated into lessons for every subject area. I would also demonstrate how a digital microscope brings science alive for students. The program Timeliner would also be presented as a wonderful learning tool with many options for students and teachers. I would show the digital slide show that I created using Timeliner and the class yearbook that I created using Kidspiration and a digital camera. I would also present my electronic portfolio and a HyperStudio stack on ladybugs.

For each example that I present, I would show how the teacher and students are able to use this technology to support their work. I would also present ways in which every student could benefit from this form of technology. This poster/demonstration I would allow me to present my knowledge of how to incorporate technology into student learning and it would allow me to learn great ideas of how other educators inspire children through this new and exciting way of teaching.
Abstract: This paper looks at additional ways to incorporate technology into an early childhood classroom beyond drill and practice software. Several peripherals are examined giving purchasing information, an overview of the basic mechanics of the item, plus examples of how the item can be incorporated into an early childhood classroom. The IntelPlay microscope and desktop cameras are discussed. The paper also looks at incorporating appropriately software like Kidspiration, websites, digital cameras, and PowerPoint.

The pros and cons of the appropriate use of technology with young children is still debated. In my mind the issues lie around how the technology is being utilized with the children. There are so many items available it is becoming easier and easier to look at appropriate, hands-on ways to utilize the technologies with children. This paper will look at several options utilizing peripherals, software, websites, and additional technologies.

Over the last three years, Intel and Mattel have partnered to create new technologies specifically for children. The new venture, IntelPlay (http://www.intelplay.com), currently has four products:
- QX3 Microscope
- Movie Creator
- Sound Morpher
- Me2Cam

I have had personal experience with three of the four products. I am sold on the use of two of them for classrooms. The microscope and movie camera are excellent tools for young children to explore and utilize. The microscope allows the children to examine specimens at three magnification levels. The children can take snapshots of the specimens or create movies of the specimen. The microscope comes with a camera that allows the children to further manipulate the specimen with a paint program. Any activity that involves a microscope can be carried out with this tool. One of the benefits I have found is that it allows multiple viewers of the image, since it displays on the computer monitor.

The second item, Movie Creator, allows the children to explore using a movie camera that is scaled to their size. The children look through an eyepiece to see the actual image being photographed. The use of an eyepiece, instead of an LTD, actually assists in the steadying of the camera for the young hands. Again, excellent software allows the child to manipulate the image further. This camera allows even kindergarten children to operate it successfully. Both are relatively inexpensive at around $100 each.

Another tool that I have found beneficial is the “Flip-Chart” from Mimio (http://www.mimio.com). This hardware plugs in to a USB port and attaches to the standard flip chart. This allows teachers to save the chart work to a graphic that can be altered or shared with parents in a newsletter. This can be a great timesaver for an early childhood teacher. You can save all the chart work to a smaller, readable size without taking up the wall space that a chart paper will. This allowed me to keep work and revisit it when desired, or to print the work to send home to parents. Mimio has text conversion software that I have not invested in at this time, but intend to soon. I believe that this will further increase the desirability of this peripheral.

I have used an inexpensive desktop videoconference camera that can be incorporated in to centers for the children to interact with and explore. The children have used the camera in a dramatic play center as they
explored being meteorologists in a television studio. The software with my Kodak camera is easy for the children to manipulate. They have been successful at creating both still and video pictures. The still images can be inserted into printed documents to share with family and friends. Both file formats can be emailed to others. The videos from this camera have been used in several PowerPoint books created with the children. The camera has held up well to classroom use, the current camera has been used for three school years. A little word of advice is to attach the camera to a tripod for better stability, fewer falls seem to occur this way.

I have used digital cameras for several years for a variety of activities. I have had reservations over allowing the children to operate the $800 Sony with out close supervision. However, a low-end Polaroid digital camera, less than $50, has been effective. Yes, I did sacrifice the quality of the pictures some, but the ease of mind is better. The pictures are a little more cumbersome for the children to retrieve also. But the children can be more autonomous in the use of the camera. They take pictures of their finished block structures and manipulative projects to print and take home.

Software like Kidspiration has gone a long way to encourage children to interact with computers as a tool. This program assist teachers in creating activities for the children to interact with that relate to the current topics of discussion in the classroom. Kidspiration will read the directions to the children, assisting them in recalling what they are to do. Story maps can be created, or whole stories can be written and read back to the children.

An old stand by, but little used in the United States, is the Roamer. This round dish like robot allows children to begin exploring programming. The children use the touch pad on the top and tell the Roamer what direction to go, for how long, and even play music as it goes. The children can create roads for the Roamer, or insert a pen to have the Roamer write their names. While the Roamer is an excellent tool, it is rather expensive at $300 for a basic start up.

Websites need to be explored in advance of using them with children but can be a great addition to the early childhood programs. When discussing dinosaurs and how scientists dig for the fossils, a documentary website on a dinosaur dig was very helpful. The children were able to see photographs of an actual dig, increasing their understanding of what is involved and what a site looks like. During this same unit, children researched individual dinosaurs using information from ZoomDinosaurs.com. Weather cam websites provide the children with a look at what the world outside our small community. During a unit on castles, websites were located that allowed the children to see castles in different locations. Frequently children think of castles as being only the British versions found in fairytales. Because of a high level of diversity in the classroom, we located sites to look at castles in the countries that the children had come from. It was interesting for everyone to learn about castles in Thailand, Korea, China, India, and Egypt. This certainly added a new level to our study.

Monarch Watch was beneficial during our fall monarch study. The information on the site helped the children understand about the migration of the butterflies and the importance of the milkweed to the caterpillar development.

Using image search engines at AltaVista and Google provide the children with the visual images that are frequently missing. It is potential to answer questions immediately thanks to these engines. When reading dinosaur stories and a new dinosaur is named, we search for a picture to learn what it looked like. A child wanted to study mailboxes was able to see a large variety of them through these searches.

Authors' websites allow the children to get to know more about authors and their work. Some authors have activities for the children to explore or printables for them to work with. Jan Brett, probably has one of the richest websites to support her work. Most of the sites have email contact for the author also.

I have used PowerPoint with kindergarten children for 5 years. We have made many multimedia books and projects. These are done as extensions of projects currently going on in the classroom. The books frequently include drawings done by the children, video clips or audio clips. In addition to supporting emergent readers
and writers, I have used it as a tool to evaluate students' knowledge at the end of a study.

These are just a sampling of the many items available to support appropriate, hands-on ways to utilize the technologies with children. The quality of items and types of activities have improved every year and will continue to increase young children's ability to use technology in appropriate ways.

Society for Information Technology and Teacher Education (SITE)

Mission

The Society for Information Technology and Teacher Education is an international association of individual teacher educators, and affiliated organizations of teacher educators in all disciplines, who are interested in the creation and dissemination of knowledge about the use of information technology in teacher education and faculty/staff development.

The Society seeks to promote research, scholarship, collaboration, exchange, and support among its membership, and to actively foster the development of new national organizations where a need emerges. SITE is the only organization that has as its sole focus the integration of instructional technologies into teacher education programs.

SITE promotes the development and dissemination of theoretical knowledge, conceptual research, and professional practice knowledge through the SITE conference, books, collaborative projects with other organizations, and the Journal of Technology and Teacher Education.

SITE (founded in 1990) is a society of the Association for the Advancement of Computing in Education (AACE). AACE (founded in 1981) is an international, educational, and professional organization dedicated to the advancement of the knowledge, theory, and quality of learning and teaching at all levels with information technology.

Executive Committee
President: Niki Davis
Past President: Ann Thompson
Founders: Jerry Willis & Dee Anna Willis
Journal Editor: Debra Sprague
Executive Director: Gary Marks
Global Liaison: Michelle Selinger

www.aace.org/site
This official journal of SITE serves as a forum for the exchange of knowledge about the use of information technology in teacher education. Journal content covers:

- preservice and inservice teacher education,
- graduate programs in areas such as curriculum and instruction,
- educational administration,
- instructional technology, and
- educational computing.

Content categories include:

- Research Papers,
- Evaluations,
- Experimental Studies,
- Tutorials,
- Case Studies,
- Courseware Experiences,
- Opinions, and
- Qualitative Studies.

A quarterly subscription to JTATE is included with SITE membership.

**SITE Electronic Journal**

Contemporary Issues in Technology and Teacher Education (CITE) is an electronic publication of the Society for Information Technology and Teacher Education (SITE), established as a multimedia, interactive electronic counterpart of the Journal of Technology and Teacher Education. Funded by a U.S. Department of Education Preparing Tomorrow’s Teachers to Use Technology (PT3) catalyst grant, CITE makes possible the inclusion of sound, animated images, and simulation, as well as allowing for ongoing, immediate dialog about theoretical issues.

Subscriptions are at no cost due to a PT3 grant from the U.S.A. Department of Education

CITE includes three major categories of articles

- **Current Issues** include more theoretical discussions of technology and teacher preparation.
- **Current Practices** provide shorter, up-to-the-minute snapshots of technology in practice.
- **Seminal Articles** include previously published "classic" articles that have advanced the discussion of technology and teacher education.

Articles address technology and teacher education, assessment, attitudes, beliefs, curriculum, equity, research, translating research into practice, learning theory, alternative conceptions, sociocultural issues, special populations, and integration of subjects.

**Current Issues Articles**

The respective professional societies for each of the following disciplines have sole responsibility for editorial review of Current Issues articles in their discipline:

- **Science Education** - Association for the Education of Teachers in Science (AETS)
- **Mathematics Education** - Association of Mathematics Teacher Educators (AMTE)
- **English Education** - Conference on English Education (CEE)
- **Social Studies Education** - National Council of Social Studies College and University Faculty Assembly (CUFA)
- **General** - Society for Information Technology and Teacher Education (SITE)
You are invited to attend and participate in this annual international forum to share your ideas, explore the research, development, and applications, and to network with the leaders in this important field of teacher education and technology. There are over 1000 presentations in 31 major topic areas!

**Scope**

The SITE Conference includes Keynote & Invited Speakers, Paper and Panel presentations, Tutorials/Workshops, Posters/Demonstrations, Institutional and Interactive Sessions, Mentor Meetings, a Video Festival, Corporate Demos, and Roundtables from the introductory through advanced levels on all topics related to:

1. the use of information technology in teacher education, and
2. instruction about information technology in
   - Preservice
   - Inservice
   - Graduate Teacher Education
   - Faculty & Staff Development

**The SITE International Conference is designed for:**

- Teacher educators in ALL disciplines
- Computer technology coordinators
- K-12 Administrators
- Teachers
- Curriculum developers
- Higher education leaders
- IT service providers to teacher education
- All interested in improving education through technology

---

**Join Us at Next Year’s SITE Conference**

**March 24-30, 2003 • Albuquerque, New Mexico USA**

www.aace.org/conf

---

**JOIN SITE TODAY!**

You are invited to join SITE and receive the following benefits of professional membership. And, as a member of SITE, you automatically become a member of the Association for the Advancement of Computing in Education (AACE).

**Benefits of SITE/AACE membership:**

- Subscription to the *Journal of Technology and Teacher Education*
- Subscription to the member periodical, *Educational Technology Review*
- SITE Conference registration discounts
- Early announcements on Calls for Papers and CITE electronic journal issues
- Discounts on all other AACE journals and conference proceedings
- Opportunities to work and collaborate with members on activities in areas of common interest and concern

**Professional Membership:** $85 (US); $100 (non-US)

**Student Membership:** $45 (US); $60 (non-US)

To join SITE/AACE, see

www.aace.org/membership/join.htm

**International Headquarters:**

SITE/AACE
PO Box 3728
Norfolk, VA 23514-3728 USA
Tel: 757-623-7588
Fax: 703-997-8760
E-mail: info@aace.org
SITE Conference Proceedings
The SITE conference proceedings are published annually and each contains over 800 papers presented at the SITE conference. These volumes serve as major source documents for research work and indicate the current state of teacher education and information technology. Proceedings for several years are available on CD as well as online at:

www.aace.org/conf/site

The SITE Position Paper known as the "Ames White Paper" was developed at Iowa State Univ. in response to a request from Linda Roberts, and presented at the "White House Conference on Technology Training for Teachers" in Washington, D.C. on April 24, 1998. The recommendations flowing from this conference provided the impetus for the subsequent "Preparing Tomorrow's Teachers to Use Technology" initiative.

Publications
- Journal of Technology and Teacher Education
- International Journal on E-Learning
- Journal of Computers in Mathematics and Science Teaching
- Journal of Interactive Learning Research
- Journal of Educational Multimedia and Hypermedia
- Information Technology in Childhood Education Annual
- Educational Technology Review (electronic)
- Contemporary Issues in Technology and Teacher Education (electronic)

Conferences
SITE – Society for Information Technology & Teacher Education International Conference
March 24-30, 2003; Albuquerque, NM USA

ED-MEDIA – World Conference on Educational Multimedia and Hypermedia & Telecommunications
June 24-29, 2002; Denver, Colorado USA
June 23-28, 2003; Honolulu, Hawaii USA

E-Learn – World Conference on E-Learning in Corporate, Healthcare, Government, and Higher Education
October 15-19, 2002; Montréal, Canada

ICCE – International Conference on Computers in Education (Asia-Pacific Chapter)
December 3-6, 2002; Auckland, New Zealand
Invitation to Join
The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with information technology. This purpose is accomplished through the encouragement of scholarly inquiry related to technology in education and the dissemination of research results and their applications through AACE sponsored publications, conferences, and other opportunities for professional growth.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high quality peer-reviewed publications, and conferences.

Join with fellow professionals from around the world to share knowledge and ideas on research, development, and applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government with an interest in advancing knowledge and learning with information technology in education.

Membership Benefit Highlights
- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review [electronic]
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs

Association for the Advancement of Computing in Education
www.aace.org

Advancing Knowledge and Learning with Information Technology
### AACE Journals

Abstracts for all journal issues are available at www.aace.org/pubs

#### Educational Technology Review – Electronic Journal

**Educational Technology Review**

*International Forum on Educational Technology*  
*Issues & Applications*

AACE's member journal is the focal point to exchange information between disciplines, educational levels, and information technologies. Its purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology.

#### International Journal on E-Learning

(formerly WebNet Journal & International Journal of Educational Telecommunications)

*IJEL*  
ISSN# 1537-2456  
Quarterly

IJEL serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of E-Learning in education and training. This journal is designed for researchers, developers and practitioners in schools, colleges, and universities, administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

#### Journal of Computers in Mathematics & Science Teaching

*JCMST*  
ISSN# 0731-9258  
Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The journal offers an in-depth forum for the exchange of information in the fields of science, mathematics, and computer science.

#### Journal of Educational Multimedia & Hypermedia

*JEMH*  
ISSN# 1055-8896  
Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the journal is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

#### Journal of Interactive Learning Research

*JILR*  
ISSN# 1093-023X  
Quarterly

The journal's published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro-worlds, and virtual reality based learning systems.

#### Journal of Technology and Teacher Education

*JTATE*  
ISSN# 1059-7069  
Quarterly

A forum for the exchange of knowledge about the use of information technology in teacher education. Journal content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

#### Information Technology in Childhood Education Annual

*ITCE*  
ISSN# 1522-8185

A primary information source and forum to report the research and applications for using information technology in the education of children – early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.
The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields, have an opportunity to participate in papers, panels, poster/demonstrations and workshops, and meet invited speakers.

ED-MEDIA 2002
World Conference on Educational Multimedia, Hypermedia & Telecommunications
JUNE 24-29, 2002
DENVER, CO USA
JUNE 23-28, 2003
HONOLULU, HI USA

ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications
This annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

E-Learn 2002
World Conference on E-Learning in Corporate, Government, Healthcare, & Higher Education
OCTOBER 14-19, 2002
MONTREAL, CANADA

E-Learn 2002 - World Conference on E-Learning in Corporate, Government, Healthcare, & Higher Education
E-Learn is a respected, international conference enabling E-Learning researchers and practitioners in corporate, government, healthcare, and higher education to exchange information on research, development, and applications. This interdisciplinary dialogue is further supported by satellite events such as by the WebNet Symposium on the WWW and Internet.

SITE - Society for Information Technology and Teacher Education International Conference
March 24-30, 2003
ALBUQUERQUE, NM USA

SITE - Society for Information Technology and Teacher Education International Conference
This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

Co-Sponsored Conferences

ICCE—International Conference on Computers in Education
ICCE is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

DECEMBER 3-6, 2002
AUCKLAND, NEW ZEALAND

AACE Journals

Please check below the journal(s) you wish to receive:

☐ International Journal on E-Learning (IJEL) (formerly WebNet Journal & International Journal of Educational Telecommunications (IJET)
☐ Jrl. of Educational Multimedia and Hypermedia (JEMH)
☐ Jrl. of Computers in Math and Science Teaching (JCMST)
☐ Jrl. of Interactive Learning Research (JILR)
☐ Jrl. of Technology and Teacher Education (JTATE)
☐ Information Technology in Childhood Education Annual (ITCE)

Includes membership in Society for Information Technology and Teacher Education (SITE)

Professional & Student Memberships

Annual membership includes a choice of AACE-sponsored journals, a subscription to Educational Technology Review (member electronic journal), discounts for conferences, proceedings books & CD-Roms and more.

Please check below the Journal(s)/membership(s) you wish to receive:

Professional Membership Student Membership

1 Journal $ 85 $ 45
2 journals $140 $ 80
3 journals $195 $115
4 journals $250 $150
5 journals $305 $185
All 6 journals $360 $220

*If you selected a Student Membership rate above, you must be registered full-time in an accredited educational institution and you must provide the following information:

Expected graduation date: ____________________________
Educational Institution: _______________________________________________________

Non-U.S. postage: add $15 for shipping EACH Journal outside the U.S. $ ______
TOTAL $ ______

Library/Institutional Subscriptions

☐ Int’l Jrl. on e-Learning (IJEL) $120
☐ Jrl. of Educational Multimedia and Hypermedia (JEMH) $120
☐ Jrl. of Computers in Math and Science Teaching (JCMST) $120
☐ Jrl. of Interactive Learning Research (JILR) $120
☐ Jrl. of Technology and Teacher Education (JTATE) $120
☐ Information Technology in Childhood Education Annual (ITCE) $85

Non-U.S. postage: add $15 for shipping EACH Journal outside the U.S. $ ______
TOTAL $ ______

Method of Payment (US Dollars)

Membership extends for 1 year from the approximate date of application. Please allow 6-8 weeks for delivery.

Enclosed: □ Check (U.S. funds & bank, payable to AACE)
☐ Purchase Order (PO must be included)

Credit Card: □ MasterCard □ VISA □ AMEX □ Discover

Card #: __________________________________________ Card Exp. Date __________ / __________

Signature: ________________________________

Total: $ ______

Return to: AACE, PO Box 3728, Norfolk, VA 23514-3728 USA

SOCIETY FOR
INFORMATION
TECHNOLOGY
& TEACHER
EDUCATION

2003
14TH INTERNATIONAL
CONFERENCE

March 24-30, 2003
Albuquerque, New Mexico USA

Proposal deadline:
October 25, 2002

Authors notified:
November 19, 2002

Proceedings file due:
December 19, 2002

Early registration
deadline:
February 13, 2003

- Keynote & Invited Speakers
- Papers • Panels
- Tutorials & Workshops
- Institutional Sessions • Interactive Sessions
- Video Festival • Roundtables
- Posters/Demonstrations
- Corporate Showcases & Demonstrations
- PT3 Special Strand

A CONFERENCE OF
AACE & SITE
SITE 2003 is the 14th annual conference of the Society for Information Technology and Teacher Education. This society represents individual teacher educators and affiliated organizations of teacher educators in all disciplines, who are interested in the creation and dissemination of knowledge about the use of information technology in teacher education and faculty/staff development. SITE is a society of the Association for the Advancement of Computing in Education (AACE).

SITE is unique as the only organization which has as its sole focus the integration of instructional technologies into teacher education programs. SITE promotes the development and dissemination of theoretical knowledge, conceptual research, and professional practice knowledge through conferences, books, projects, and the Journal of Technology and Teacher Education.

You are invited to attend and participate in this annual international forum to share your ideas, explore the research, development, applications, and to network with the leaders in this important field of teacher education and technology. There are over 1,000 presentations in 31 major topic areas!

The SITE 2003 Conference is designed for:

- Teacher educators in ALL disciplines
- Computer technology coordinators
- K-12 administrators
- Teachers
- Curriculum developers
- Principals
- All interested in improving education through technology

Scope

SITE 2003 includes the following:

- Keynote & Invited Speakers
- Pre-Conference Tutorials/Workshops
- Papers & Panels
- Posters/Demonstrations
- Roundtable Discussions
- Institutional Sessions
- Video Festivals
- Interactive Sessions
- Corporate Demos
- SIG Discussions

From introductory through advanced level on all topics related to:

1. the use of information technology in teacher education, and
2. instruction about information technology in
   - Preservice
   - Inservice
   - Graduate Teacher Education
   - Faculty & Staff Development

Information for Presenters

- All communication will be with the principal presenter who is responsible for communicating with co-presenters of that session.
- The conference will attempt to secure basic equipment needs for presenters, with the exception of poster/demonstration presenters. However, when equipment cannot be obtained, presenters will need to bring or rent equipment. The name of a rental firm can be provided.
- Presenters must pay the registration fee. Early registration fee will be approximately $295 (AACE members); $305 (non-members).

Proceedings

The Proceedings will be published by AACE in the Technology and Teacher Education Annual series. Proceedings in this series serve as major source documents indicating the current state of teacher education and information technology. The Annual will be available as a searchable electronic CD-ROM (Macintosh, IBM, and ISO 9660 formats) included in each conference registrant’s packet. Proceedings papers will also be stored and available in the Technology and Teacher Education Digital Scholarship Portal. The Annual also may be purchased in hard copy book form.

Paper & Presentation Awards

All presented papers will be considered for Best Paper Awards within several categories. Award-winning papers will be invited to submit for publication in the Journal of Technology and Teacher Education and will be highlighted in the AACE online periodical Educational Technology Review. Outstanding presentations will be selected for awards in a variety of categories.

Hotel & Travel Arrangements

Conference special hotel room rates will be available to attendees. Special discount airfares will be available from a designated airline carrier.

Topics

- Concepts & Procedures
- Corporate
- Distance Education
- Diversity
- The Educational Computing Course
- Educational Leadership
- Electronic Portfolios
- Faculty Development
- Fine Arts
- Graduate & Inservice Education
- Instructional Design
- International
- Mathematics
- New Media
- Partnerships across Organizations
- Preservice Teacher Education
- Preparing Tomorrow’s Teachers to Use Technology
- Research
- Reading, Language Arts & Literacy
- Science
- Simulations
- Simultaneous Renewal of Organizations
- Social Studies
- Special Needs
- Technology Diffusion
- Theory
- Telecommunications: Graduate, Inservice & Faculty Use
- Telecommunications: Preservice Applications
- Telecommunications: Systems & Services
- Video Cases
- Young Child

Highlighted:

PT3 (Preparing Tomorrow’s Teachers to Use Technology) Strand

PT3 will showcase invited presentations and sessions of all types describing PT3 activities demonstrating and discussing research, development and applications in progress, to gain feedback and to establish connections with those engaged in similar activities.
Submission Information

FULL PAPERS (25 min.)
Papers on all aspects of information technology and teacher education are invited. Accepted paper presentations will be published in the SITE Conference Proceedings.

BRIEF PAPERS (15 min.)
Brief Papers are more condensed presentations or work-in-progress projects and will be published as 2 pages in the Proceedings volume. There will be an award for Best Brief Paper.

TUTORIALS & WORKSHOPS (half-day)
Tutorials and Workshops are intended to enhance the skills and broaden the perspective of their attendees. They should be designed for learning a new area or to provide advanced training in an area. Note that few workshops are selected because a lab of equipment is required for each. If you submit a workshop proposal, please indicate if your proposal is also appropriate for presentation as a non-hands on tutorial.

PANELS (1 hr.)
Panels will consist of at least four members presenting different aspects of a relevant issue and interacting with the audience to broaden the discussion.

INSTITUTIONAL SESSIONS (90 min.)
We invite teacher education programs and institutions to submit proposals for "Institutional Sessions." These 90-minute sessions will give you an opportunity to present innovative teacher education programs. Institutional sessions are informal presentations held in a poster/demo format with other institutional sessions. They should be more in the "show and tell" tradition with active participation by faculty and students. You may, however, submit a formal paper for institutional sessions that will be published in the Proceedings. Presenters will be required to provide their own software and hardware. Table, poster board, and electricity will be supplied.

INTERACTIVE SESSIONS (1 hr.)
This 1 hour will be shared time with 3 other interactive sessions in the same room. If you have mastered a new piece of software (or a new version) that others would be interested in learning about, submit a proposal for an interactive session. In that informal session you would demonstrate the software, illustrate the process of using it, show participants some of the complexities and tricks about it, and give them an opportunity to play with it themselves. These sessions are also appropriate for instructional strategies, procedures, and evaluation procedures such as portfolios. The idea is not to give a definitive workshop on the topic but to provide participants with enough information to help them decide whether their needs can be met with the program or procedure. Interactive Sessions can be supported by a paper published in the Proceedings.

VIDEO FESTIVAL (1 hr.)
The field has matured to the point that we have a growing number of video resources — cases, classroom video clips, and many other forms. Proposals for video festival entrants will be given 1 hour in the conference program. Presenters should have a short handout on the video and take most of the time showing the video. A prize for "Best Teacher Education Video" will be awarded at the end of the conference.

ROUNDTABLES (30 min.)
These sessions allow maximum interaction in informal, small-group discussions on a single topic. The format is appropriate for papers, projects, or work-in-progress that encourage discussion.

POSTERS/Demonstrations (2 hrs.)
These sessions enable presenters to demonstrate and discuss research, development and applications in progress to gain feedback and to establish contacts. Presenters will be required to provide their own software and hardware. Table, poster board, and electricity will be supplied.

CORPORATE SHOWCASES 30 min.) & DEMONSTRATIONS (2 hrs.)
Demonstrate and discuss your company’s products, services, developments, applications and research, inform the audience of your future directions, gain feedback, and establish contacts. Not included in the Proceedings.

Demonstration Format: 2 hours; scheduled with Posters/Demonstrations grouped together in open exhibition-style, usually all in one hall. This is an informal event with a circulating audience. Sales are permitted: You may stock and sell your product at your table.

Corporate proposals must include a brief description (1 paragraph) of what you intend to present.

Submission Requirements

Submit all proposals by following the submission guidelines and completing the form at:
www.aace.org/conf/site

Preparing Tomorrow's Teachers to Use Technology (PT3)

The major USA initiative in our field is one of the conference’s highlighted strands.

Preparing future teachers to use technology effectively to improve learning is a major challenge facing our nation’s schools of education. Over the next decade about 2.2 million teachers must be recruited to replace retiring teachers and to accommodate student population increases. If our information technology investments are to pay off in improved education, these future teachers must be technology-proficient educators who know how to use these modern learning tools to help students meet high standards.

To meet this urgent need for technology-proficient teachers, the Preparing Tomorrow’s Teachers to Use Technology (PT3) initiative is providing $75 million in grant support to 225 teacher education programs and consortia. Consult the PT3 web site at www.ed.gov/teachtech for more information about this grant program.

The Society for Information Technology and Teacher Education (SITE) is working closely with the U.S. Department of Education and with the teacher education professional associations in core subject areas such as Mathematics Education, Science Education, English Education, and Social Studies Education.
Albuquerque is a place where the views go on forever. From the Sandia Mountains you can look out over 15,000 square miles of magical landscape. And to the west, the Rio Grande snakes its way through the cottonwood-lined valley, silhouetting dormant volcanoes against fiery red sunsets.

Albuquerque's beguiling balance of big city convenience and rural charm has something of lasting value for everyone. Here the Old West meets the new frontier. Sip a malt on Route 66, try on some cowboy boots, watch an unforgettable sunset, take a tram ride, hike the Sandias, revisit the great atomic past or tour the silicon future. Delight in the dizzying blend of shops, industry, culture, arts and entertainment.

From the Sandias in the east to the dormant volcanoes out west, up and down the river, you'll be seduced by Albuquerque's rich character, mild weather, and unique place in history. In a city that's unpretentious and accessible, friendly and easy to negotiate, you'll enjoy our beautiful mountains, spiritual history, cultural diversity, urban funkiness, dynamic commerce and great blue skies.

Dining and Entertainment: A visit to Albuquerque is not complete without sampling authentic New Mexican cuisine. Looking for variety? You'll find international fare from every corner of the globe. You can have breakfast in an abuela's kitchen, lunch in a New York-style deli and dinner in "Thailand."

In Albuquerque's newly revitalized downtown, you can learn how to two-step or just listen to live music in one of the city's many nightspots. Other entertainment options include theater, dance, classical and rock concerts, and films.

Arts and Culture: You'll be amazed at the diversity of our performing arts. See a show at the historic Kimo Theatre, American Indian dances at the Indian Pueblo Cultural Center, Hispanic arts at the National Hispanic Cultural Center, or popular music at the outdoor Journal Pavilion. Popejoy Hall hosts world-class concerts and performances year-round.

For visual arts, browse the galleries of Old Town or the permanent and changing exhibits at the Albuquerque Museum. Try hands-on exhibits at !Explora! Science Center and Children's Museum of New Mexico, and see the stars at Lode Star Astronomy Center, part of the New Mexico Museum of Natural History and Science.

Shopping: Shop around in Albuquerque and you'll find a little bit of everything: from bargains, one-of-a-kinds, and secondhand to art, antiques, and even tepees. Albuquerque's three malls feature national chain stores, but it's the unique neighborhood specialty shops where you'll find treasures like American Indian and traditional Hispanic jewelry, pottery, weavings, paintings, carvings, clothes and furniture.

Recreation: With mild year-round weather, an average altitude of more than a mile, and mountains, rivers and lakes nearby, it's hard not to be active in Albuquerque. Try hang-gilding off the Sandias, snowboarding at Sandia Peak, rollerblading along the Rio Grande, or mountain biking through the West Mesa. Professional sports fans can enjoy Scorpions Hockey or horse racing at the Downs.

We invite you to join us in this dynamic modern city that embodies the Spirit of the West. Albuquerque – it's the place to be for SITE 2003!

Attractons:

Albuquerque is a city full of exciting attractions and events, from Historic Old Town, where the Villa of Albuquerque was founded in 1706, to the Kodak Albuquerque International Balloon Fiesta, the most popular ballooning event in the world. Be sure to check out these and other local attractions during your visit:

- Historic Old Town Discover the location of the original Spanish villa, famous for its restaurants, shops and galleries.
- Petroglyph National Monument Find over 17,000 lava-rock etchings carved by hunting parties over thousands of years.
- Sandia Peak Tramway Ride the world's longest continuous single-span tramway to Sandia's 10,378-foot peak.
- Albuquerque Biological Park Tour the Albuquerque Aquarium/Rio Grande Botanic Garden and Rio Grande Zoo in search of flora, fauna and fun!
- Indian Pueblo Cultural Center Discover the art, history and culture of the region's 19 American Indian Pueblos.
- Kodak Albuquerque International Balloon Fiesta Marvel as nearly 1,000 balloons take part in Mass Ascensions, Balloon Glows and Special Shapes Rodeos.
- National Hispanic Cultural Center Celebrate Hispanic arts and culture through compelling exhibits and performances.

Countless treasures await you beyond the city limits. Explore these attractions on your day off:

- Turquoise Trail Travel this beautiful, scenic route from Albuquerque to Santa Fe.
- Santa Fe Wander through the charming and sophisticated City Different, renowned for its first-class galleries and restaurants.
- Acoma Sky City Visit the oldest continuously inhabited community in the United States, situated on a 356-foot sandstone mesa.
- Bandelier National Monument Explore part of a 50-square-mile wilderness area, including miles of trails that lead to spectacular Ancestral Pueblo cliff dwellings.
